Summary

Port Chester (FP No. 1) was one of seven waterways that the U.S. Army Corps of Engineers-New York District (USACE-NYD) requested the Battelle Marine Sciences Laboratory (MSL) to sample and evaluate for dredging and disposal in March 1994. Sediment samples were collected from Port Chester, as well as from the Hudson River, Gravesend Bay Anchorage, South Brother Island, Buttermilk, Eastchester, and Brown's Creek, during a survey conducted from March 7 through 14, 1994. Combining sample collection and concurrent evaluation of multiple dredged material projects was more cost-effective for the USACE-NYD, because the expense of reference site testing and quality control analyses could be shared among project budgets.

Tests and analyses were conducted on Port Chester sediment core samples according to the manual developed by the USACE and the U.S. Environmental Protection Agency (EPA), *Evaluation of Dredged Material Proposed for Ocean Disposal (Testing Manual)*, commonly referred to as the "Green Book," and the regional manual developed by the USACE-NYD and EPA Region II, *Guidance for Performing Tests on Dredged Material to be Disposed of in Ocean Waters*. Because the Port Chester area is located on the border between New York and southeast Connecticut, its dredged material may also be considered for disposal at the Central Long Island Sound Disposal Site (CLIS). Therefore, Port Chester sediment was also tested for possible disposal at the CLIS according to the USACE-New England Division (NED) guidelines, *Guidance for Performing Tests on Dredged Material to be Disposed of in Open Waters (Draft)*.

The evaluation of proposed dredged material from Port Chester consisted of bulk sediment chemical analyses, chemical analyses of site water and dredged material elutriate preparations, water-column and benthic acute toxicity tests, and bioaccumulation studies. Individual sediment core samples collected from Port Chester were analyzed for grain size, moisture content, and total organic carbon (TOC). Additionally, a composite sediment sample, representing the entire area proposed for dredging, was analyzed for bulk density, specific gravity, metals, chlorinated pesticides, polychlorinated biphenyl (PCB) congeners, polynuclear aromatic hydrocarbons (PAHs), and 1,4-dichlorobenzene. Additional testing requirements specified by the USACE-NED consisted of an extended list of sediment chemical parameters of additional metals, chlorinated pesticides, and PAHs. Site water and elutriate water, prepared from the suspended-particulate phase (SPP) of Port Chester sediment, were analyzed for metals, pesticides, and PCBs. Water-column or SPP toxicity tests were performed with three species, the mysid *Mysidopsis bahia*, the juvenile silverside *Menidia beryllina*, and larvae of the mussel *Mytilus galloprovincialis*. Benthic acute toxicity tests were performed with two amphipods, *Ampelisca abdita* and *Rhepoxynius abronius*, as well as with the mysid *M. bahia*. The amphipod benthic toxicity test procedures followed EPA guidance for reduction of total ammonia concentrations in test systems prior to test

initiation. A similar procedure was followed for the mysid toxicity test. Bioaccumulation tests were conducted with the burrowing, polychaete worm *Nereis virens* and the surface-feeding, bent-nose clam, *Macoma nasuta*.

Port Chester sediment core samples were either a black, silt and clay material or a black, sand and gravel mixture. The Port Chester sediment composite sample contained elevated levels of metals, pesticides (particularly the DDD/DDE/DDT group of compounds), PCBs, PAHs, and 1,4-dichlorobenzene.

In water-column toxicity tests, 100% SPP treatments were acutely toxic to all three species tested. The LC_{50} values ranged from 75.1% SPP for *M. beryllina* to >100% SPP for *M. bahia* and *M. galloprovincialis* survival. The EC_{50} value for *M. galloprovincialis* normal development, a more sensitive measure than survival, was 53.7% SPP. In the static renewal test with *A. abdita* exposed to Port Chester sediment, test organism survival was statistically significant and >20% lower than the Mud Dump Reference and the CLIS Reference. In the static renewal test with *R. abronius*, survival was statistically significantly different when compared with both reference site sediments, but there was not a >20% reduction in survival. In the *M. bahia* static test, that was not manipulated to reduce porewater or overlying ammonia concentrations prior to test initiation, test organisms survival was 77% in the Port Chester sediment treatment, which was not statistically significant nor was there a 10% or greater difference in survival between the test and either of the two reference sediments.

Concentrations of some contaminants were elevated in tissues of *N. virens* and *M. nasuta* that were exposed to Port Chester sediment in 28-day bioaccumulation tests. Concentrations of metals, pesticides, PCBs, and PAHs were generally the same or slightly higher in *M. nasuta* than in *N. virens*. Tissues of both species exposed to Port Chester sediment had tissue body burdens that were lower than the U.S. Food and Drug Administration (FDA) action levels for poisonous or deleterious substances in fish and shellfish for human consumption for selected pesticides, and FDA levels of concern for chronic shellfish consumption for selected metals. Tissue burdens of organisms exposed to Port Chester sediment compared with those exposed to Mud Dump Reference Site and the Central Long Island Sound Reference Site sediment were significantly higher for selected metals, pesticides, PCBs, and PAHs. Therefore, Port Chester sediment requires further evaluation to determine limiting permissible concentration (LPC) and benthic effects compliance.

1.0 Introduction

1.1 Project Objectives

The objective of the Port Chester project (FP No. 1) was to evaluate proposed dredged material from Port Chester in the Byram River and Port Chester Harbor to determine its suitability for unconfined ocean disposal at the Mud Dump Site or at the Central Long Island Sound Disposal Site (CLIS). Tests and analyses for Mud Dump Site disposal were conducted on Port Chester sediment core samples according to the manual developed by the U.S. Army Corps of Engineers (USACE) and the U.S. Environmental Protection Agency (EPA), *Evaluation of Dredged Material Proposed for Ocean Disposal (Testing Manual)* (EPA/USACE 1991), commonly referred to as the "Green Book," and the regional manual developed by the USACE-New York District (NYD) and EPA Region II, *Guidance for Performing Tests on Dredged Material to be Disposed of in Ocean Waters* (USACE-NYD/EPA Region II 1992), hereinafter referred to as the "Regional Guidance Manual." The Regional Guidance Manual provides specifications for the use of local or appropriate test species in biological tests and identifies chemical contaminants of concern. Because the Port Chester area is located on the border between New York and southeast Connecticut, its dredged material may also be considered for disposal at the Central Long Island Sound Site. Therefore, Port Chester sediment was also tested for possible disposal at the Central Long Island Sound Site according to the USACE-New England Division (NED) guidelines (USACE-NED/EPA Region I 1989).

As required by the Regional Guidance Manual, the evaluation of proposed dredged material from Port Chester consisted of bulk sediment chemical analyses, chemical analyses of site water and dredged material elutriate preparations, water-column and benthic acute toxicity tests, and bioaccumulation studies. Individual sediment core samples collected from Port Chester were analyzed for grain size, moisture content, and total organic carbon (TOC). An additional composite sediment sample, representing the entire area proposed for dredging, was analyzed for bulk density, specific gravity, metals, chlorinated pesticides, polychlorinated biphenyl (PCB) congeners, polynuclear aromatic hydrocarbons (PAH), and 1,4-dichlorobenzene. Site water and elutriate water, prepared from the suspended-particulate phase (SPP) of Port Chester sediment, were analyzed for metals, pesticides, and PCBs. Water-column or SPP toxicity tests were performed with three species, the mysid *Mysidopsis bahia*, the juvenile silverside *Menidia beryllina*, and larvae of the mussel *Mytilus galloprovincialis.* Benthic acute toxicity tests were performed with two amphipods, *Ampelisca abdita*, and *Rhepoxynius abronius*, as well as with the mysid *M. bahia*. Bioaccumulation tests were conducted with the burrowing worm *Nereis virens* and the surface-feeding clam *Macoma nasuta*.

Additional testing requirements specified by the USACE-NED consisted of an extended list of sediment chemical parameters of additional metals, chlorinated pesticides, and PAHs.

1.2 Project Background

The proposed Port Chester project area is located on the border of southwest Connecticut and New York in the Byram River and Port Chester Harbor. The Byram River empties into Long Island Sound (Figure 1.1). The project requires dredging and disposal of an estimated 40,000 cu yd of sediment. Project depth of the channel is -10 ft mean low water (MLW) plus 2 ft of overdepth. Port Chester was one of seven waterways that the USACE-NYD requested the Battelle Marine Sciences Laboratory (MSL) to evaluate in a series of dredged material projects that became known as the New York/New Jersey Federal Projects 2 program. The projects evaluated under the Federal Projects 2 program were Port Chester, the Hudson River, South Brothers Island, Gravesend Bay Anchorage, Brown's Creek and Buttermilk Channel survey. Sediment samples from 12 reaches in these waterways were collected during a survey that took place from March 7 through March 14, 1994. Combining sample collection and concurrent evaluation of multiple dredged material projects was more cost-effective for the USACE-NYD, because the expense of reference site testing and quality control analyses could be shared among project budgets. The results of each project were reported separately.

1.3 Organization of This Report

Following this introduction, Section 2 presents the methods and materials used for sample collection, sample processing, sediment sample analysis of physical and chemical parameters, and quality assurance. Results of all physical/chemical analyses and bioassays are presented in Section 3. A discussion of the results and conclusions are provided in Section 4. Section 5 lists the literature cited in this report. Appendix A contains tabulated quality control data for all physical and chemical sediment analyses. Appendix B contains results of replicate sample analyses and quality control data for site water and elutriate chemical parameters. Appendix C contains raw data associated with water-column toxicity tests, such as water quality measurements, test animal survival data, and results of reference toxicant tests. Similar data for benthic acute toxicity tests are provided in Appendix D. Appendix E contains water quality measurements, test animal survival data, and results of reference toxicant tests for the bioaccumulation tests. Appendix F contains replicate sample results and quality control data for chemical analyses of *M. nasuta* tissue samples generated by the bioaccumulation tests, and Appendix G contains replicate sample results and quality control data for chemical analyses of *N. virens* tissue samples.

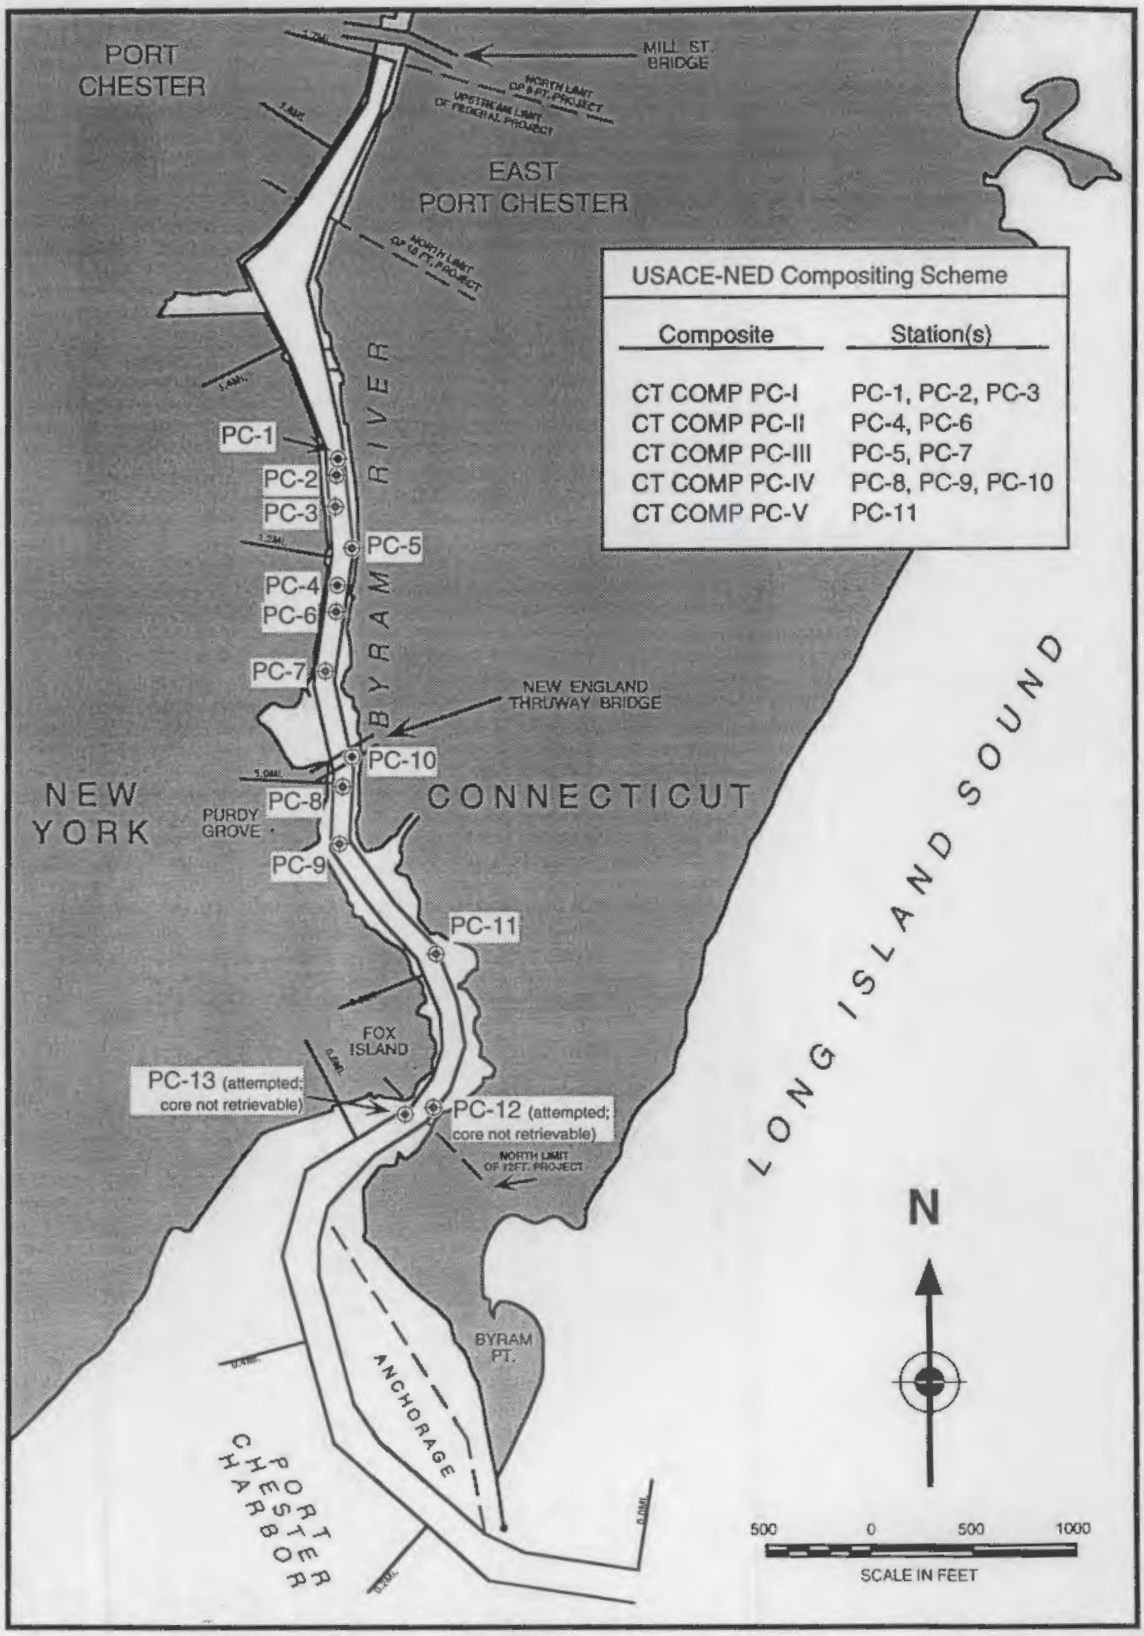

FIGURE 1.1. Location of Port Chester Project Area and Sample Collection Stations

2.0 Materials and Methods

2.1 Sediment and Water Collection

The sampling plan required collection of sediment from 13 stations, but samples from stations 12 and 13 were not collected because the depth (MLW) of those stations was greater than project depth. Numerous unsuccessful attempts were made to locate shoaled areas in the vicinity of stations 12 and 13 using the ship's fathometer. Samples were collected from 11 stations within Port Chester. Sampling locations were selected by the USACE-NYD based on recent bathymetric surveys. The locations, their coordinates, and water and core sampling depths are presented with the sampling results in Section 3.0. Water samples were collected at a representative location in Port Chester and the Mud Dump Site. Reference sediments were collected from the Mud Dump Reference Site and the Central Long Island Sound Reference Site. All samples were collected aboard the M/V *Gelberman*, a vessel owned and operated by USACE-NYD at Caven Point, New Jersey.

2.1.1 Test Sediment and Site Water Sampling

Test sediment core samples were collected using a vibracore sampler deployed from the *Gelberman*. The approximate sampling locations were first determined with the aid of reference to landmarks, such as shoreline features or buoys, as well as by water depth. Then, a hand-held Magellan Global Positioning System (GPS) was used to identify and record (within 30 m) each sampling station. The vessel's LORAN was available as a backup system. Water depth at the time of sampling was measured by a fathometer on the ship. The actual water depth was corrected to MLW depth by correcting to the tide height at the time the depth was recorded. The difference between the MLW depth and the project depth, plus 2 ft overdepth, yields the amount of core required. Sediment from stations representative of the upper west shore sites was difficult to collect with the vibracore sampler and caused damage to the core cutter head. To evaluate the problem, van Veen grab samples were taken at those sites. The sediment was characterized as gravel and stone, which is similar to material present on the shore at various commercial facilities. At the stations where this problem occurred, sediment was collected using a van Veen grab sampler.

Core samples were collected aboard the *Gelberman* using the MSL's vibracore sampler. The vibracore sampler consisted of a 4-in. outer diameter, steel core barrel attached to an electric vibratory hammer. The vibratory hammer could be fitted to steel core barrels of various lengths, depending on the length of core needed. To collect a core sample, the core barrel was fitted with a 3.125-in. interior diameter, steam-cleaned, Lexan polycarbonate tube. The vibracore was then

suspended by the ship's crane. Once the coring apparatus was directly above the sampling station, the core was lowered through the water to the sediment surface. At this point, the station coordinates were recorded from the Magellan GPS, and water depth was recorded from the ship's fathometer. The vibratory hammer was switched on until the corer penetrated through the sediment to the desired project depth. Adequate penetration was determined relative to marks on the outside of the core barrel and on the cable suspending the vibracore from the crane. The vibracore apparatus was then pulled out of the sediment and lowered onto the ship's deck. A cutter-head and core-catcher assembly prevented loss of the sediment through the bottom of the core liner. After each core was brought on board, the liner was pulled from the barrel and the length of cored sediment was measured from the mudline to determine whether the appropriate depth had been reached. If not, the liner was replaced and a second core sample was attempted. If the sediment core length achieved project depth plus 2 ft overdepth, it was capped, sealed with tape, and labeled. While on board the sampling vessel, cores were kept cool (~4°C) in a freezer on the deck of the ship. If necessary, cores were cut into shorter sections to fit in the freezer.

A surface-water sample for site water chemical analysis was collected at one station in Port Chester (PC-5). Site water was also collected from the Mud Dump Site for chemical analysis and used as dilution water in water-column toxicity tests. Water samples were collected using a clean, epoxy-coated bucket below the surface of the water. Water was then transferred to precleaned, 20-L polypropylene carboys. (Prior to the sampling survey, carboys were washed with hot water and detergent, acid-rinsed with dilute hydrochloric acid, then rinsed with distilled water, followed by acetone and methylene chloride). The carboys were rinsed with site water three times before filling. Water samples were labeled and stored at ambient temperature (in the shade) while on board the ship.

A log book was maintained containing records of each sample collected, including station designation, coordinates, replicate number, date, sampling time, water depth, core length, and number of core sections per core. At the end of each sampling day, all sediment cores and water samples were loaded into a refrigerated van, thermostatically controlled to maintain approximately 4°C. Sample identification numbers were logged on chain-of-custody forms daily.

At the conclusion of the sample collection survey, sediment cores and water samples were shipped by refrigerated van from Caven Point, New Jersey, to the MSL in Sequim, Washington. The shipment departed from Caven Point on March 14, 1994, and arrived at the MSL on March 18, 1994.

2.1.2 Reference and Control Sediment Sampling

Reference sediment for toxicity and bioaccumulation tests was collected from the Mud Dump and the Central Long Island Sound Reference Sites. Four 5-gal containers of surficial sediment were collected from each site using a van Veen grab sampler. After recovery, the sediments were transferred to epoxy-coated steel buckets. The buckets were covered, labeled, and stored in a freezer at 4°C on the deck of ship, and then were transferred to the refrigerated van at the end of the sampling day.

Records of the collected reference sediment included latitude/longitude, replicate number, date, sampling time, and water depth. Sample identification numbers were logged on chain-of-custody forms.

Control sediments were used in each toxicity and bioaccumulation test to validate test procedures. Control sediment used in *M. nasuta* and *M. bahia* tests was collected from Sequim Bay, Washington, using a van Veen sampler deployed from an MSL research vessel. *R. abronius* control sediment was collected from West Beach, at Whidbey Island, Washington, using a small anchor-dredge sampler specially designed for collecting the amphipods and their sediment. Locations of these control sites were determined by reference to known shoreline features. While in transit from the sampling site, all control sediments were placed in coolers maintained at ambient temperature which were then stored in a walk-in cold room at 4°C±2°C upon arrival at the MSL. Native sediment for *A. abdita and N. virens* were supplied with the test organisms by their respective suppliers.

2.2 Test Organism Collection

Seven species of test organisms were used to evaluate sediment samples from the Port Chester project area:

- *Ampelisca abdita*, a tube-dwelling, surface detrital-feeding amphipod
- *Rhepoxynius abronius*, a free-burrowing, subsurface detrital-feeding amphipod
- *Mysidopsis bahia*, a juvenile (1-to 5-day old) mysid shrimp
- *Menidia beryllina*, a juvenile (9-to 14-day old) silverside fish
- *Mytilus galloprovincialis*, the larval zooplankton stage of the mussel
- *Macoma nasuta*, the bent-nose clam, a burrowing, detrital-surface feeder
- *Nereis virens*, a burrowing, deposit-feeding polychaete.

All test organisms except mysids, silversides, and mussels were wild-captured animals, collected either by a commercial supplier or by MSL personnel. The amphipod *A. abdita* was supplied by East Coast Amphipod, Kingston, Rhode Island. *A. abdita* and its native sediment were collected from Narragansett Bay, Rhode Island, by dragging a large dipnet along the sediment surface. Test organisms were carefully removed from their tubes for counting, and then placed in clean, native sediment for overnight transport to the MSL. The amphipod *R. abronius*

was collected by MSL personnel from West Beach, at Whidbey Island, using the same anchor-dredge sampler that was used for collecting the amphipod's native sediment. The amphipods were transported to the MSL in clean coolers containing approximately 10 cm of sediment and 5 gal of clean seawater at a temperature approximating natural conditions. Mysids were purchased from Aquatic Biosystems, Fort Collins, Colorado. Mysids that were less than 24 h old were shipped via overnight delivery in plastic bags containing oxygen-supersaturated seawater maintained at approximately 15°C with "blue ice." Silversides were supplied by Aquatic Research Organisms in Hampton, New Hampshire, and were shipped via overnight delivery in plastic bags containing oxygen-supersaturated seawater maintained at approximately 22°C with blue ice. Mussels used for obtaining *M. galloprovincialis* larvae were purchased from the commercial supplier Johnson and Gunstone, Quilcene, Washington. Mussels were wrapped in moist paper towels and transported in a Styrofoam cooler packed with blue ice to maintain an ambient temperature of approximately 15°C. Clams (*M. nasuta*) were collected from intertidal zones in Discovery Bay, Washington, by Johnson and Gunstone. The clams were kept in large containers filled with sediment and seawater obtained from the collection site and transported to the MSL. Worms (*N. virens*) were purchased through Enviro Systems, Inc., Hampton, New Hampshire, and were collected from an intertidal region in Newcastle, Maine. The worms were packed in insulated boxes with mats of moist seaweed and shipped at ambient temperature to the MSL via overnight delivery.

All organisms were shipped or transported in native sediment or under conditions designed to ensure their viability. After arrival at the MSL, the test organisms were gradually acclimated to test conditions. Animals with abnormal behavior or appearance were not used in toxicological tests. All acclimation and animal care records are part of the raw data files for these projects.

2.3 Sediment Sample Preparation

Sediment sample preparation consists of all steps performed in the laboratory between receipt of the samples at the MSL and the preparation of samples for biological testing and physical/chemical analyses. Sediment samples for physical, chemical, and biological analysis were prepared from individual core samples, composites of a number of core samples, reference sediment, and control sediment. All sediment samples were assigned random, unique code numbers to ensure that samples are handled without bias by staff in the biology or chemistry laboratories.

Sediment for biological testing was used within the 6-week holding period specified in the Green Book. During this holding time, the sediment samples were received at the MSL;

inventoried against chain-of-custody forms; processed and used for benthic and water-column toxicity tests, elutriate analysis, and bioaccumulation tests; and subsampled for sediment physical/chemical analyses. This section describes procedures for equipment preparation, compositing strategy, and preparation of sediments for biological testing and chemical analyses.

2.3.1 Laboratory Preparation and Safety Considerations

All glassware, stainless-steel or titanium utensils, Nalgene, Teflon, and other laboratory containers and equipment underwent stringent cleaning procedures to avoid contamination of samples. Glassware (e.g., test containers, aquaria, sediment transfer dishes) was washed with hot water and detergent, rinsed with deionized water, then soaked in a 10% solution of reagent grade nitric acid for a minimum of 4 h and rinsed again with deionized water before it was allowed to air dry. Glassware was then rinsed with methylene chloride and allowed to dry under a fume hood. Polyvinyl chloride (PVC), Nalgene, and Teflon tools were treated in the same manner as glassware. Stainless-steel bowls, spoons, spatulas, and other utensils were washed with hot water and detergent, rinsed with deionized water, and allowed to air dry. They were then solvent-rinsed with methylene chloride and allowed to dry under a fume hood.

Neoprene stoppers and polyethylene sheets or other porous materials were washed with hot water and detergent and rinsed with deionized water. These items were then "seasoned" by continuous soaking in 0.45-μm filtered seawater for at least 2 days prior to use. Large pieces of laboratory equipment, such as the epoxy-coated sediment mixer, were washed with a dilute solution of detergent, and thoroughly rinsed with tap water followed by deionized water.

Equipment used for determining water quality, including the meters for pH, dissolved oxygen (DO), temperature, and salinity, were calibrated according to the manufacturers' specifications and internal MSL standard operating procedures (SOPs). Calibration records are part of the raw data files for this project.

Because the potential toxicity of the Port Chester sediment was unknown, sediment processing and testing were segregated from other laboratory activities. Specific areas at the MSL were established for sample storage and for core-cutting, sediment mixing, and sediment sieving. Work areas were covered with plastic sheeting to contain any waste sediment. Wastewater generated during all operations was retained in 55-gal barrels and periodically pumped through activated charcoal filters and into the MSL's wastewater treatment system. These procedures minimized any potential for cross-contamination of sediment samples.

Laboratory staff members were protected by personal safety equipment such as Tyvek suits, plastic aprons, and rubber gloves. Those who were likely to have the most exposure to the potential volatile compounds in the bulk sediment (i.e., those responsible for opening, homogenizing, and compositing core samples) were also provided with half-mask respirators.

2.3.2 Preparation of Sediment for Benthic Testing and Bulk Sediment Analyses

Each core was opened by scoring the Lexan core liner longitudinally with a circular saw and splitting the liner with a clean linoleum knife to expose the sediment. As each sediment core sample was opened, it was examined for physical characteristics (e.g., sediment type and consistency, color, odor). In particular, the presence of any strata in the cores was noted. All core observations were recorded in the sediment preparation log book. The sediment between the mudline and project depth was then transferred from the core liner to a clean, stainless-steel bowl by scooping the sediment from the core liner with a spoon or spatula. The sediment was mixed by hand with stainless-steel utensils until the color and consistency appeared homogenous, creating a sample representative of the individual sampling station. Sieving was not necessary because organisms that might interfere with the benthic toxicity tests were not present in the sediment samples.

Aliquots of the homogenized sediment were then transferred to the appropriate sample jar(s) for physical or chemical analyses required on individual core samples. A portion of each homogenized core sample was also retained as an archive sample. The remainder of the homogenized sediment from the individual core stations was combined to create a composite sample representing the entire Port Chester project area, designated COMP PC. The composite sediment was homogenized in an epoxy-coated mixer. Aliquots of homogenized composite sediment were transferred to the appropriate sample jar(s) for physical or chemical analyses required on the composite sample. Additional composites were created for chemical analysis as required for USACE-NED. The compositing scheme for these samples is provided in Section 3. A portion of the homogenized composited sediment was also retained as an archive sample. The remainder was stored in labeled epoxy-coated pails, tightly covered, at 4°C±2°C until used for SPP/elutriate preparation or benthic toxicity and bioaccumulation tests.

The Mud Dump Reference Site sediment, Central Long Island Reference Site sediment, *M. nasuta* native control sediment, and *N. virens* native control sediment were homogenized in the large, epoxy-coated mixer, but prior to mixing, these sediments were pressed through a 1-mm mesh to remove live organisms that might affect the outcome of toxicity tests. After mixing, aliquots for physical and chemical analyses were removed. Control sediments for *A. abdita*, *R. abronius*, and *M. bahia* were sieved through a 0.5-mm mesh to remove live organisms and mixed in stainless-steel bowls after sieving. All reference and control sediments were stored at 4°C±2°C until use in benthic toxicity and bioaccumulation tests.

2.3.3 Preparation of Suspended-Particulate Phase and Elutriate

Toxicological effects of dredged sediment contaminants dissolved and suspended in the water-column at an open-water disposal site were simulated in the laboratory by preparation of the SPP. To prepare the SPP, a sediment-water slurry was created and centrifuged at low speed. Low speed centrifugation provided a timely SPP preparation and maintained consistency between projects. The supernatant was decanted and reserved for testing with water-column organisms. The elutriate phase was prepared by centrifuging the SPP at a higher speed and collecting the supernatant. This liquid was analyzed for chemical constituents to identify water-soluble contaminants that could remain in the water-column after dredge and disposal operations.

The SPP was prepared by creating a 4:1 (volume:volume) water-to-sediment slurry in 1--L glass jars with Teflon-lined lids. The jars were marked at 200 mL and 400 mL and filled to the 200-mL mark with 0.45-µm-filtered Sequim Bay seawater. Sequim Bay seawater was substituted for dredging site water to maintain consistency in salinity among the dredging projects tested. Homogenized COMP PC sediment was added until the water was displaced to the 400-mL mark. Each jar was then filled to 1 L with filtered seawater, placed on a shaker table, and agitated for 30 min at 120 to 150 cycles/min. The slurry was then transferred to 500-mL Teflon jars, tightly sealed, and centrifuged at approximately 1750 rpm for 10 min, at a relative centrifugal force of approximately 1000 g. Following centrifugation, the supernatant was poured into 4-L glass jars. The Teflon jars were rinsed after each use and the above process continued until an adequate amount of SPP was produced from each composite. Between SPP preparations, all glass and Teflon containers were cleaned according to procedures described in Section 2.3.1. When all SPP for a treatment was prepared, portions were taken for elutriate preparation. The remaining SPP was either used immediately for biological tests or stored at 4°C±2°C and used within 24 h for testing. The 100% COMP PC SPP was mixed with Mud Dump Site water to yield three dilutions: 0%, 10%, and 50% SPP, for a total of four concentrations.

To prepare elutriate for chemistry analyses, a 1-L aliquot of the SPP was collected in an acid-washed Teflon bottle for trace metals analysis, and three 1-L aliquots were collected in EPA-certified amber glass bottles for analysis of organic compounds. The SPP for metals analysis was transferred to acid-washed polycarbonate centrifuge jars, and the SPP for analysis of organic compounds was transferred to Teflon centrifuge jars. Both were centrifuged at 2000 rpm for 30 min at a relative centrifugal force of approximately 1200 g. The decanted supernatant liquid was the elutriate phase. One liter of elutriate was submitted for triplicate trace metals analysis and three 1-L portions were submitted for analysis of organic compounds.

2.4 Physical and Chemical Analytical Procedures

Sediment cores, composited bulk sediment, water, elutriate, and tissue samples were analyzed for physical and chemical parameters. Table 2.1 lists the parameters measured in each sample type, the method used for each analysis, and the target analytical detection limits. The following sections briefly describe the procedures used for physical and chemical analyses. Procedures followed those required by the Regional Guidance Manual unless otherwise noted.

2.4.1 Grain Size and Percentage of Moisture

Grain size was measured following two methods described by Plumb (1981). The wet sieve method was used to determine the size distribution of sand or coarser-grained particles larger than a U.S. No. 230 standard sieve (62.5-µm mesh). The size distribution of particles smaller than a U.S. No. 230 sieve was determined using the pipet method. Grain size was reported as percentages within four general size classes:

gravel	>2000-µm diameter
sand	≥ 62.5-µm diameter and <2000-µm diameter
silt	≥ 3.9-µm diameter and < 62.5-µm diameter
clay	< 3.9-µm diameter.

Percentage of moisture was obtained using the Plumb (1981) method for determining total solids. The procedure involves drying a sediment sample at 100°C until a constant weight is obtained. Percentage of moisture was calculated by subtracting the percentage of total solids from 100%.

2.4.2 Bulk Density and Specific Gravity

Bulk density, or unit weight, was determined according to EM 111-2-1906 (USACE 1970). Specific gravity, the ratio of the mass of a given volume of material to an equal volume of water at the same temperature, was measured according to ASTM D-854.

2.4.3 TOC

Samples were analyzed for TOC according to the EPA Edison, New Jersey, Laboratory Procedure (EPA 1986). Inorganic carbon was removed from the sediment sample by acidification. The sample was combusted and the evolved carbon dioxide was quantitated using a carbon-hydrogen-nitrogen (CHN) analyzer. TOC was reported as a percentage of the dry weight of the unacidified sample.

TABLE 2.1. List of Analytes, Methods, and Target Detection Limits

Analyte	Methods	Sediment Detection Limit (a)	Tissue Detection Limit (b)	Water Detection Limit
PHYSICAL PARAMETERS				
Grain Size	Plumb (1981)	1.0%		
Specific Gravity	ASTM D-854			
Bulk Density	EM 1110-2-1906 (USACE 1970)			
Percent Moisture	Sediment: Plumb (1981) Tissue: Freeze-dry	1.0 %	1.0 %	
METALS				
Arsenic	EPA 200.2, -.3, -.8 (c)	0.1 mg/kg	1.0 mg/kg	---

(b) Detection limits are in wet weight for all organic and inorganic tissue parameters.
(c) Equivalent MSL standard operating procedures were substituted for the methods cited.

2.4.4 Metals

Preparation and analysis of water samples for Cd, Cr, Cu, Pb, Ni, Ag, and Zn were conducted according to MSL SOPs equivalent to EPA Methods 200.2 and 200.9 (EPA 1991). Samples were chelated with 2% ammonium pyrrolidinedithiocarbamate (APDC), precipitated out of solution, and filtered. The filter was digested in concentrated nitric acid and the digestate was analyzed by graphite furnace atomic absorption (GFAA) spectroscopy for Cr and Zn, or by inductively coupled plasma/mass spectrometry (ICP/MS) for Cd, Cu, Pb, Ni, and Ag. Water samples were analyzed for Hg directly by cold vapor atomic fluorescence (CVAF) according to the method of Bloom and Crecelius (1983). This CVAF technique is based on emission of 254-nm radiation by excited elemental Hg atoms in an inert gas stream. Mercuric ions in an oxidized sample were reduced to elemental Hg with tin chloride ($SnCl_2$), then purged onto gold-coated sand traps to preconcentrate the Hg and remove interferences. Mercury vapor was thermally desorbed to a second "analytical" gold trap, and from that into the fluorescence cell. The amount of fluorescence (indicated by peak area) is proportional to the quantity of Hg collected, and was quantified using a standard curve as a function of the quantity of the sample purged.

Sediment samples for analysis of USACE-NYD metals, As, Cd, Cr, Cu, Pb, Ni, and Zn and the USACE-NED metals, Tl, Be, Se, and Sb, were prepared according to an MSL SOP equivalent to EPA Method 200.2 (EPA 1991). Solid samples were first freeze-dried and blended

in a Spex mixer mill. A 0.2- to 0.5-g aliquot of dried homogeneous sample was then digested using peroxide and nitric acid. Samples were heated in sealed Teflon bombs overnight at approximately 130°C. Sediment samples were analyzed for As, Cd, Cr, Cu, Pb, Ni, Zn, Tl, Be, Se, and Sb using ICP/MS, following an MSL SOP based on EPA Method 200.8 (EPA 1991). Sediment samples were analyzed for Ag by GFAA according to an MSL SOP based on EPA Method 200.9 (EPA 1991). Sediments were analyzed for Hg by CVAA according to an MSL procedure for total Hg determination equivalent to EPA Method 245.5 (EPA 1991).

Sediment samples initially showed poor matrix spike recovery for Ag. (Refer to Appendix A, QA/QC Summary for analysis of metals in sediment.) EPA Method 200.2 was modified by the addition of aqua regia to the digestion procedure and all samples were reanalyzed for Ag. Matrix spike recoveries improved and concentrations of Ag in the dredging site sediments increased slightly. The low recovery of Ag appears to occur in analysis of marine sediment samples having high (in excess of approximately 5 µg/g) Ag concentrations. During the EPA Method 200.2 digestion procedure, a precipitate of AgCl can form with the Ag in the sediment and the Cl in the seawater. The sample reanalyses showed little change between the EPA Method 200.2 digestion and the aqua regia-modified digestion because the dredging site sediments tested had fairly low levels of Ag. (Most samples were approximately 0.1 µg/g to 3 µg/g, with a few as high as 9 µg/g.) However, the aqua regia modification resulted in improved recovery of Ag in the matrix spike samples that were spiked with higher concentrations of Ag (20 µg/g). The additional metals required by USACE-NED (Sb, Be, Se, and Tl) were also analyzed in the sample extracts obtained from the aqua regia-modified digestion procedure.

Tissue samples were prepared according to an MSL SOP based on EPA Method 200.3 (EPA 1991). Solid samples were freeze-dried and blended, and a 0.2- to 0.5-g aliquot of dried homogeneous sample was then digested in a microwave using nitric acid, hydrogen peroxide, and hydrochloric acid. Tissue samples were analyzed for As, Cd, Cr, Cu, Pb, Ni, Ag, and Zn using the ICP/MS method (EPA Method 200.8 [EPA 1991]). Tissue samples were analyzed for Hg by CVAA following an MSL procedure equivalent to EPA Method 245.6 (EPA 1991).

2.4.5 Chlorinated Pesticides and PCBs

Water samples were prepared and analyzed for chlorinated pesticides and PCBs according to an MSL procedure equivalent to EPA Method 8080 (EPA 1990), and incorporating techniques developed by the National Oceanic and Atmospheric Administration (NOAA) National Status and Trends "Mussel Watch" Program (NOAA 1993). Samples were extracted with methylene chloride. Extract volumes were reduced and solvent exchanged to hexane. The sample extracts underwent cleanup by alumina and silica column chromatography; further interferences were removed by an additional cleanup treatment using high-performance liquid

chromatography (HPLC). Sample extracts were concentrated and analyzed using gas chromatography with electron capture detection (GC-ECD) using the internal standard technique.

Sediment and tissue samples for analysis of pesticides and PCBs required by both the USACE-NYD and USACE-NED guidance manuals were extracted and analyzed according to an MSL procedure similar to EPA Method 8080 for pesticides and the New York State Department of Environmental Conservation (NYSDEC) Congener-Specific Method 91-11 (NYSDEC 1992). The method also uses techniques from the NOAA Mussel Watch procedure. A 20- to 50-g sample of homogenized sediment or macerated tissue was first combined with sodium sulfate in a sample jar to remove water. Samples were extracted by adding successive portions of methylene chloride and agitating sample jars at ambient temperature using a roller technique. Extract volumes were reduced and solvent-exchanged to hexane, followed by Florisil column chromatography cleanup. Interferences were removed using HPLC cleanup; tissue sample extracts underwent an additional cleanup by gel permeation chromatography (GPC). Sample extracts were concentrated and analyzed using GC-ECD by the internal standard technique.

The concentration of total PCB in each matrix was estimated by taking the sum of the 22 congeners (x) and multiplying by two. The procedure for calculation of total PCBs was established in 1996 (Mario Del Vicario, Chief of the Marine and Wetlands Protection Branch, U.S. Environmental Protection Agency Region 2, Feb 14, 1996, letter to John F. Tavolaro, Chief Operations Support Branch, U.S. Army Corps of Engineers, New York District). One-half of the detection limit was used in summation when an analyte was undetected.

2.4.6 PAHs and 1,4-Dichlorobenzene

Sediment samples were prepared for the analysis of 16 PAHs and 1,4-dichlorobenzene, and an additional seven PAHs required by the USACE-NED guidance manual according to an MSL method based on the NOAA Mussel Watch procedure (NOAA 1993). A 20- to 50-g sample of homogenized sediment or macerated tissue was first combined with sodium sulfate in a sample jar to remove water. Samples were extracted by adding successive portions of methylene chloride and agitating sample jars at ambient temperature using an ambient shaker technique. Extract volumes were reduced and solvent-exchanged to hexane, followed by column chromatography cleanup. Interferences were removed using HPLC cleanup; tissue sample extracts underwent an additional cleanup by GPC. Sample extracts were concentrated and analyzed using gas chromatography with mass spectrometry (GC/MS) in the selective ion monitoring (SIM) mode.

2.4.7 Lipids

The lipid content of *M. nasuta* and *N. virens* was determined by the analysis of unexposed background tissue samples of each species. The lipid analysis procedure is a

modification of the Bligh and Dyer (1959) methods, which involves a chloroform extraction followed by gravimetric measurement of lipids. Randall (1988) modified the original Bligh and Dyer method to accommodate a smaller tissue sample size. Lipid analysis was performed in triplicate, once for each species. Lipid concentration was reported as a percentage on both a wet and dry weight basis.

2.5 Biological Testing Procedures

2.5.1 Water-Column Toxicity Tests

Water-column effects of open-water dredged-material disposal were evaluated by exposing three species of water-column organisms to the SPP of the Port Chester sediment composite. The three test species were juvenile *M. beryllina* (silverside) and *M. bahia* (mysid), and larval *M. galloprovincialis* (mussel). Total ammonia monitoring was not performed during water-column toxicity tests, but prior to test initiation total ammonia concentrations were measured for the 100% SPP concentration and is presented in Section 3.4.

2.5.1.1 Water-Column Toxicity Test with *Menidia beryllina*

Upon receipt, the *M. beryllina* were placed in a 10-gal glass aquarium and gradually acclimated from 27.5‰ seawater to 30.0‰ Sequim Bay seawater over a 24-h period. *M. beryllina* were received and held at 20°C±2°C prior to testing and were fed concentrated brine shrimp nauplii daily. During acclimation and holding, 2% to 3% mortality of the silversides was observed.

Test containers for the water-column toxicity test with silversides were 500-mL glass jars, labeled with sediment treatment code, concentration, position number, and replicate number. Five replicates of each concentration (0%, 10%, 50%, and 100%) were tested. The 300-mL test volume of SPP was placed in each of the five replicate test chambers. Each test chamber was then placed in a randomly assigned position on a water table at 20°C±2°C and allowed to equilibrate to test temperature for several hours. After the concentrations were prepared and placed on the water table, water quality parameters were measured and recorded for all replicates of all concentrations for each sediment treatment.

To initiate the test, *M. beryllina* were transferred from the holding tank to test chambers using a wide-bore pipet and small transfer cups. Ten individuals were introduced to each test chamber, creating a test population of 50 silversides per concentration for each treatment. Ten animals per test chamber were used, rather than the 20 animals per chamber as described in the Regional Guidance Manual, because it is not possible to make accurate daily observations of *M. beryllina* behavior when using 20 animals. Test initiation time and date were recorded.

Following test initiation, water quality parameters were recorded in one replicate of each concentration daily. Because several treatments had DO levels lower than 40% saturation prior to test initiation, all test chambers were aerated to maintain consistency in handling DO concentration among test containers. Acceptable parameters for this test were as follows:

Temperature	20°C±2°C
DO	>40% saturation (>3.04 mg/L at 20°C, 30‰)
pH	7.8±0.5
Salinity	30.0‰±2.0‰.

The test was run under a 16-h light/8-h dark photoperiod, and silversides were fed brine shrimp nauplii daily during the test. Observations of the animals were performed at 2 h, 24 h, 48 h, and 72 h, and the number of live, dead, and missing organisms was recorded. At the end of the 96-h test period, water quality parameters were measured for all test chambers, and the number of live, dead, and missing silversides was recorded on termination forms. As a quality control check, a second observer confirmed surviving test organisms on at least 10% of the termination counts.

A 96-h, water-only, reference toxicant test was performed concurrently with the toxicity test with each population of *M. beryllina* to establish the health and expected response of the test organisms. The reference toxicant test was conducted in the same manner as the water-column toxicity test. *M. beryllina* were exposed to a seawater control plus four concentrations of copper sulfate: 16, 64, 160, and 400 µg/L copper, using three replicates of each concentration.

2.5.1.2 Water-Column Toxicity Test with *Mysidopsis bahia*

Upon receipt, the *M. bahia* were placed in a 10-gal aquarium and gradually acclimated from 28.0‰ seawater to 30‰ Sequim Bay seawater over a 24-h period. Mysids were received and held at 20°C±2°C until testing and were fed concentrated brine shrimp nauplii twice daily prior to testing. Mortality of the *M. bahia* during holding was less than 1%.

The water-column toxicity test with the mysid was performed in 200 mL of test solution in 400-mL jars, labeled with sediment treatment code, concentration, position number, and replicate number. Five replicates of each concentration were tested. Each of the test chambers received 200 mL of test solution, then was placed randomly in a recirculating water bath and allowed to equilibrate to test temperature for several hours. Prior to test initiation, water quality parameters were measured in each replicate of each sediment treatment concentration. Acceptable water quality parameters for this test were as follows:

Temperature	20°C±2°C
DO	>40% saturation (>3.04 mg/L at 20°C, 30‰)
pH	7.8±0.5
Salinity	30.0‰±2.0‰.

To initiate the test, *M. bahia* were transferred from the holding tank to test chambers using a wide-bore pipet via small transfer cups. Ten individuals were introduced to each test chamber, creating a test population of 50 mysids per concentration (200 mysids per treatment). Ten animals per test chamber were used, rather than the 20 animals per chamber as described in the Regional Guidance Manual, because it is not possible to make accurate daily observations of *M. bahia* behavior when using 20 animals. Test initiation time and date were documented on data forms. Observations of test organisms were performed at 4 h, 24 h, 48 h, and 72 h, using a fluorescent light table to enhance visibility of the *M. bahia*. After test initiation, water quality parameters were measured daily in one replicate concentration of all concentrations for each sediment treatment. During the 96-h exposure, *M. bahia* were fed <24-h-old brine shrimp twice daily. Excess food was removed daily with a small pipet, taking care not to disturb test animals. Molted exoskeletons and any particles from the SPP solutions were also removed.

Prior to test termination, water quality parameters were measured in all replicates. At 96 h, the number of live versus dead animals was recorded for each test container. An animal was considered dead if it did not respond to gentle probing. As a quality control check, a second observer confirmed surviving test organisms on at least 10% of the termination counts.

A 96-h, water-only, reference toxicant test was performed concurrently with the SPP toxicity test, to establish the health and expected response of the test organisms. Water quality conditions were the same as for the SPP test, and animals were fed daily over the 96-h exposure. *M. bahia* were exposed to a seawater control plus four concentrations of copper sulfate: 50, 100, 150, and 200 µg/L copper, using three replicates of each concentration.

2.5.1.3 Water-Column Toxicity Test with *Mytilus galloprovincialis* Larvae

Prior to testing, adult *M. galloprovincialis* were held in flowing, unfiltered Sequim Bay seawater at ambient temperatures for approximately 5 days.

Chambers for the bivalve larvae test were 500-mL glass jars labeled with sediment treatment code, concentration, position number, and replicate number. Dilutions of SPP from the sediment composites (0%, 10%, 50%, and 100%) were prepared with Mud Dump Site water in a 2000-mL graduated cylinder, then 300 mL of test solution was transferred into each test chamber. Test chambers were placed in random positions on a water table and allowed to equilibrate to test temperature for several hours. Initial water quality parameters were measured in all replicates once test chambers reached testing temperatures (16°C±2°C).

Spawning was induced by placing *M. galloprovincialis* into 15°C, filtered Sequim Bay seawater and rapidly raising the holding water temperature to 20°C. Spawning generally occurs within 1 h of temperature elevation; however, on the first day of spawning, gametes were shed after 3 h to 4 h. For this group of mussels, the water bath was changed when DO levels fell

below 3.0 mg/L. When spawning began, males and females were identified and isolated in individual jars containing filtered Sequim Bay seawater and allowed to shed gametes for approximately 45 min. Eggs from each female were filtered through a 75-µm Nytex screen into separate jars to remove feces, detritus, and byssal fibers. Sperm from at least three males was pooled and 10 mL of sperm solution was then added to each of the egg stocks. Egg-sperm solutions were gently mixed every 10 min with a perforated plunger. Fertilization proceeded for 1 h, then fertilization rate (percentage of fertilized eggs) was determined by removing a subsample and observing the number of multicell-stage embryos. Fertilization was considered successful if greater than 90% of the embryos were in the multicell stage. Egg stocks with greater than 90% fertilization were combined and rinsed on a 20-µm Nytex screen to remove excess sperm. Stock embryo solution density was estimated by removing a 0.1-mL subsample and counting all multicell embryos, then multiplying by 10 to yield embryo density (embryos/mL). Stock solution was diluted or concentrated to yield 7500 to 9000 embryos/mL. The test was initiated by introducing 1 mL of stock solution into each test chamber, to produce embryo densities of 25 to 30 embryos/mL. Test initiation date and time were recorded on data sheets. Following initiation, 10-mL stocking-density subsamples were removed from each container and preserved in 5% formaldehyde to determine actual stocking density later.

Water quality parameters were measured in one replicate of each concentration per treatment daily throughout the test. Acceptable ranges for water quality parameters were as follows:

Temperature	16°C±2°C
DO	>60% saturation (>4.93 mg/L at 16°C, 30‰)
pH	7.8±0.
Salinity	30.0‰±2.0‰.

Each chamber was provided with gentle aeration to maintain consistency in handling DO concentration among test containers. The bivalve test was terminated after 72 h when greater than 80% of the larvae in the controls had reached the D-cell stage. Final water quality parameters were recorded for all replicates. The contents of each chamber were then homogenized with a perforated plunger, and a 10-mL subsample was removed and placed into a 20-mL scintillation vial. The subsample was then fixed with 1 mL of 50% solution of formaldehyde in seawater. Samples were scored for the appearance of normal and abnormal D-shaped larvae, blastula larvae, and total number of larvae. At least 10% of the counts were confirmed by a second observer.

A 72-h reference toxicant test was conducted to establish the health and expected response of the test organisms. The reference toxicant test was set up and conducted in the same manner as the liquid-phase tests. *M. galloprovincialis* larvae were exposed to a filtered

Sequim Bay seawater control plus copper sulfate concentrations of 1, 4, 16, and 64 µg/L copper, with three replicates per concentration.

2.5.2 Benthic Acute Toxicity Tests

Deposited sediment effects of open-water dredged material disposal were evaluated by benthic acute toxicity tests with three marine amphipod species, *A. abdita* and *R. abronius*, and the mysid *M. bahia*.

2.5.2.1 Static Renewal Tests with *Ampelisca abdita* and *Rhepoxynius abronius*

Upon receipt, the *A. abdita* were placed in a tub of clean sand from their collection area and gradually acclimated with flowing Sequim Bay seawater from 28‰ to 30.5‰, over a period of 2 days. *A. abdita* were received at approximately 11°C and acclimated to 20°C±2°C over 4 days. They were held at 20°C±2°C for one day and were not fed prior to testing. The *R. abronius* were also placed in a tub of clean sand from their collection area and held under flowing seawater upon arrival at the laboratory. They were received and held at a salinity of 30‰±2‰ and a temperature of 15°C±2°C until testing. *R. abronius* were not fed during the 11-day holding period.

All amphipod static renewal tests were performed in 1-L glass jars modified for use as flow-through test chambers. The test chambers were fitted with funneled lids and screened outflow and overflow ports (Figure 2.1). The static-renewal system was turned on long enough to deliver the seawater at a rate of two chamber exchanges per day. Five replicates of COMP PC, Mud Dump Reference Site, Central Long Island Sound Reference Site, and native test animal control treatments were tested.

Concentrations of ammonia have been encountered in the porewater of sediment core samples from New York/New Jersey waterways at concentrations high enough to affect survival of amphipods in benthic toxicity tests (Barrows et al. 1996). Therefore, the amphipod tests were conducted according to the ammonia protocols issued by EPA and the USACE (EPA/USACE 1993). This guidance requires postponing test initiation (exposure of test animals) until pore-water total ammonia concentrations are <30 mg/L for *A. abdita* and *R. abronius*. During this "purging" period, test chambers were set up and maintained under test conditions, and the overlying water was exchanged twice daily until the porewater ammonia concentrations reached the level appropriate for the particular amphipod. Porewater ammonia measurements were made on "dummy" containers that were set up and maintained in the same manner as the actual test containers but without animals added to them. The porewater was obtained by siphoning off the overlying water in the dummy jar and centrifuging the sediment in a Teflon jar for at least 20 min at approximately 3000 rpm. Salinity, temperature, and pH were also determined in the porewater samples.

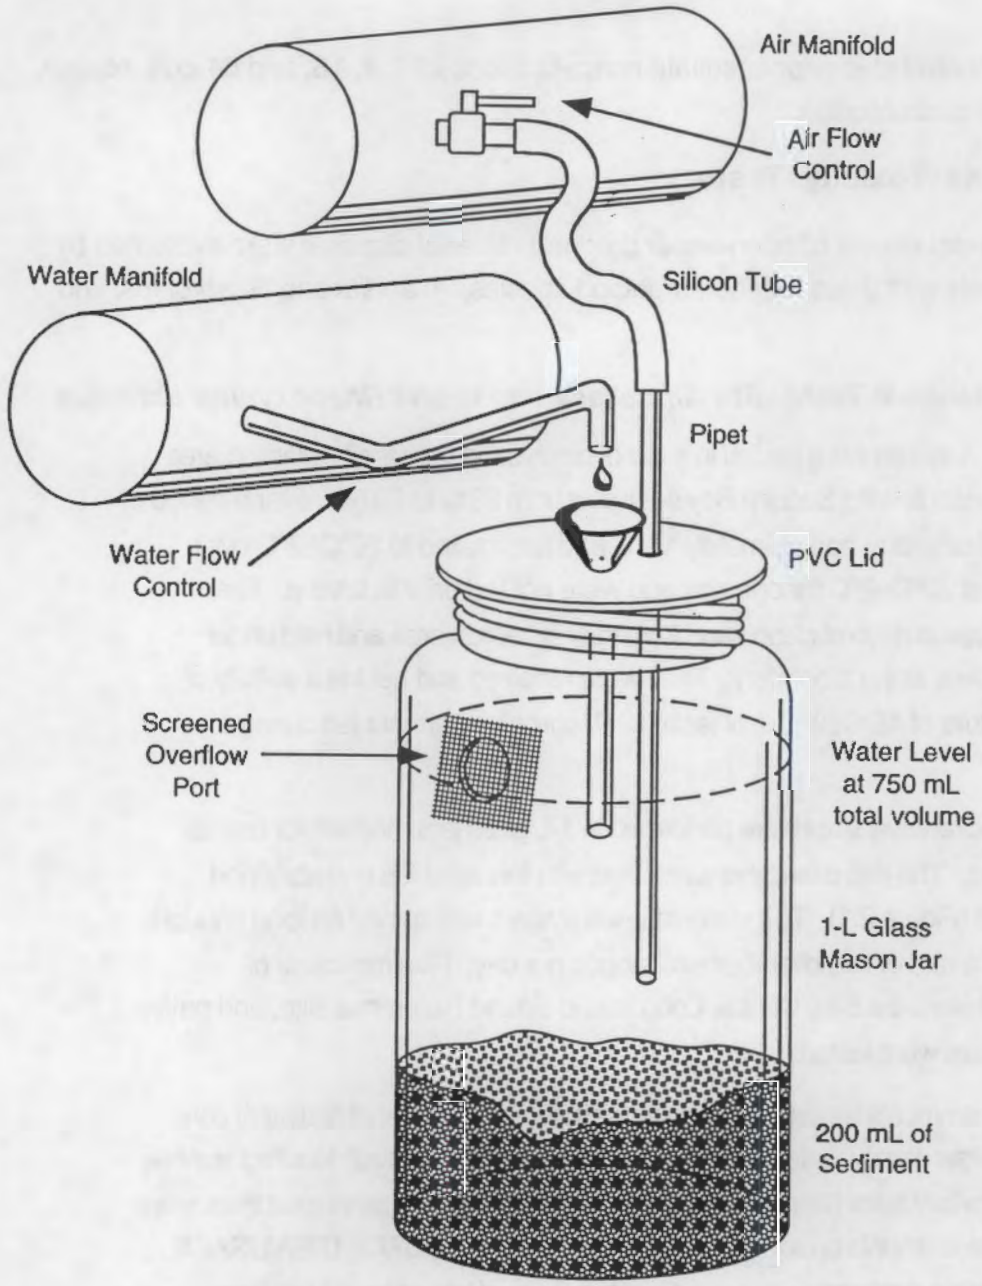

FIGURE 2.1. Testing Containers for Amphipod Static Renewal Toxicity Tests

The amphipod benthic toxicity tests were initiated by the addition of 20 organisms to each test chamber for a test population of 100 amphipods per sediment treatment. Amphipods were gently sieved from their native sediment in holding tanks and transferred to shallow baking dishes. For each test chamber, five animals were counted and transferred by pipet into each of four small, plastic cups. The organisms in each transfer cup were recounted by a second analyst and then placed in the test chamber by dipping the cup below the water surface of release the amphipods.

Salinity, temperature, DO, and pH were measured in all replicates prior to test initiation, in at least one replicate per treatment daily, and in all replicates at test termination. Measurements of total ammonia levels in the overlying water and porewater also continued during testing. Overlying water ammonia was measured in all replicates prior to test initiation (Day 0), in at least one replicate per treatment daily, and in all replicates at test termination (Day 10). Porewater ammonia was measured on Day 0 and Day 10. Flow rates to each test chamber were calibrated once at the start on the renewal process. The water-system was turned on for 15 min twice a day. Test chambers were renewed for 9 days before testing and continued daily throughout the 10-day test. The following were the acceptable ranges for water quality parameters during the amphipod tests:

	A. abdita	*R. abronius*
Temperature	20°C±2°C	14°C±2°C
D O	>60% saturation	>60% saturation
pH	7.8±0.5	7.8±0.5
Salinity	30‰±2‰	30‰±2‰
Ammonia	<30 mg/L	<30 mg/L
Renewal Rate	2 exchanges/day	2 exchanges/day.

Gentle aeration was provided throughout the test, and the amphipods were not fed during testing. At the end of the 10-day period, the contents of each chamber were gently sieved through 0.5-mm mesh, and the number of live, dead, and missing amphipods was recorded on termination forms. An animal was considered dead if it did not respond to gentle probing. As a quality control check, a second observer confirmed surviving organisms on at least 10% of the termination counts.

Reference toxicant tests with cadmium chloride were performed concurrently with each species. The reference toxicant tests were 96-h, water-only exposures that were otherwise conducted following the same procedures as for the static tests with sediment. *A. abdita* were exposed to nominal concentrations of 0, 0.25, 0.5, 1, and 2 mg/L cadmium. *R. abronius* were exposed to nominal concentrations of 0, 0.5, 1, 2, and 4 mg/L cadmium.

2.5.2.2 Static Test with *Mysidopsis bahia*

Upon receipt at the laboratory, *M. bahia* were placed in 10-gal aquaria and acclimated from 28‰ seawater to 30‰ with Sequim Bay seawater over a 24-h period. Mysids were received

and held for 4 days at 20°C±2°C until testing and were fed concentrated brine shrimp nauplii twice daily prior to testing. Mortality of the *M. bahia* during holding was less than 1%.

The 10-day static benthic acute toxicity test with *M. bahia* was performed in 1-L glass jars. To prepare each test container, 200 mL of clean seawater was placed in each jar. Sediment was added until water was displaced up to the 400-mL mark, then seawater was added up to the 750-mL mark. Five replicates of each Port Chester composite, Mud Dump Reference Site sediment, Central Long Island Sound Reference Site, and control sediment (Sequim Bay sediment) were tested. Static jars were renewed twice daily for 8 days. At the start of the test the overlying water ammonia concentrations were all less than 14.5 mg/L.

The mysid benthic toxicity test was initiated by the addition of 20 organisms to each test chamber for a test population of 100 mysids per sediment treatment. Mysids were transferred from holding tanks to shallow glass dishes. For each test chamber, five animals were counted and transferred by pipet into each of four small, plastic cups. The animals in each transfer cup were recounted by a second analyst. The animals were placed in the test chamber by dipping the cup below the surface of the water to release the mysids.

Salinity, temperature, DO, pH, and total ammonia in overlying water were measured in all replicates prior to test initiation, in at least one replicate per treatment daily, and in all replicates at test termination. The total ammonia concentrations in the overlying water were <20 mg/L in each test chamber. The following were the acceptable ranges for water quality parameters during the *M. bahia* benthic test:

Temperature	20°C±2°C
DO	>40% saturation
pH	7.8±0.5
Salinity	30‰ ± 2‰.

Gentle aeration was provided to all test chambers during the test to maintain consistency in handling DO concentration among test containers. Animals were fed 1-2 mL of brine shrimp nauplii (<24-h old) in suspension daily. At the end of the 10-day period, the contents of each chamber were gently sieved through 0.5-mm mesh, and the number of live and dead or missing mysids was recorded on termination forms. An animal was considered dead if it did not respond to gentle prodding. As a quality control check, a second observer confirmed surviving test organisms on at least 10% of the termination counts.

A 96-h, water-only, reference toxicant test was performed concurrently with the benthic test to establish the health and expected response of the test organisms. Water quality conditions were the same as for the SPP test, and animals were fed daily over the 96-h exposure. *M. bahia* were exposed to a seawater control plus four concentrations of copper sulfate: 50, 100, 150, and 200 µg/L copper, using three replicates of each concentration.

2.5.3 Bioaccumulation Testing

The bivalve *M. nasuta* and the polychaete *N. virens* were used to evaluate the potential bioaccumulation of contaminants from dredged material. The bioaccumulation tests were 28-day flow-through exposures to sediment followed by a 24-h depuration period that allowed the organisms to void their digestive tracts of sediment. *M. nasuta* and *N. virens* were tested in separate 10-gal flow-through aquaria. Animals were exposed to five replicates of COMP PC, Mud Dump Reference Site sediment, Central Long Island Reference Site sediment, and native control sediment. Each chamber contained 25 *M. nasuta* or 20 *N. virens*. Water quality parameters (temperature, DO, pH, and salinity) were measured in all replicates at test initiation, in at least one replicate per treatment daily, and in all replicates at test termination. Flow rates were measured daily in all chambers.

Upon receipt at the laboratory, *M. nasuta* were received damp and held in control sediment with flowing Sequim Bay seawater at 15°C±2°C until testing and were not fed. *N. virens* were placed in holding trays of control sediment with heated Sequim Bay seawater flowing into the trays. *N. virens* were received at 17°C and gradually acclimated to 20°C±2°C. *N. virens* were not fed prior to testing. Mortality of *M. nasuta* and N. *virens* during holding was less than 1%.

The Regional Guidance Manual provides an acceptable temperature range of 13°C±1°C for *M. nasuta*; however, laboratory logistics required that *M. nasuta* share a 15°C flow-through water supply with *R. abronius*. This alteration of test temperature was not expected to affect the outcome of the test; bioaccumulation tests with *M. nasuta* have been conducted at 15°C±2°C successfully. After discussion with the USACE-NYD project manager, the following ranges for water quality parameters were established as acceptable for the *M. nasuta* and *N. virens* tests:

	M. nasuta	*N. virens*
Temperature	14°C±2°C	20°C±2°C
DO	> 60% saturation	> 60% saturation
pH	7.8±0.5	7.8±0.5
Salinity	30‰±2‰	30‰±2‰
Flow Rate	125±10 mL/min	125±10 mL/min.

Aeration was provided to all test chambers to maintain consistency in handling DO concentrations among test chambers. Water quality, organism behavior (e.g., burrowing activity, feeding) and organism mortality were recorded daily. Dead organisms were removed daily and at the end of the 28-day testing period, *M. nasuta* and *N. virens* were placed in clean, flowing seawater for 24 h, after which the tissues were transferred into the appropriate chemistry jars for metals, and organic compound analyses. All tissue samples were frozen immediately and stored at less than -20°C until analysis.

Water-only reference toxicant tests (96-h) were also performed using copper sulfate in six geometrically increasing concentrations. The exposures were conducted using a test volume of 5 L in static 9.5-L (2.5-gal) aquaria. Three replicates of each concentration were tested, each containing 10 organisms. Water quality parameters were monitored at the same frequency and maintained within the same limits as the 28-day test, except that there were no flow rates. The *M. nasuta* reference toxicant test was conducted with treatments of 0, 0.25, 0.50, 0.75, 1.0, 1.5 and 2.5 mg/L copper; the *N. virens* test was conducted with treatments of 0, 0.05, 0.075, 0.15,0.20, 0.25, and 0.30 mg/L copper.

2.6 Data Analysis and Interpretation Procedures

Statistical analyses were conducted to determine the magnitude and significance of toxicity and bioaccumulation in test treatments relative to the reference treatment. Each statistical test was based on a completely random design that allowed unbiased comparison between treatments.

2.6.1 Randomization

All water-column and benthic toxicity tests were designed as completely random tests. Organisms were randomly allocated to treatments, and treatments were randomly positioned on water tables. To determine randomization, a random-number table was generated for each test using the discrete random-number generator in Microsoft *Excel* spreadsheet software.

2.6.2 Statistical Analysis of Water-Column Tests

Two statistical analyses are presented in the Green Book for the interpretation of SPP (water-column) tests. The first is a one-sided t-test between survival in control test replicates and survival in the 100% SPP test replicates. A significant difference indicates acute toxicity in the 100% SPP treatment. This analyses was performed only when survival in the 100% SPP is less than the control (0% SPP) survival, and when control survival is >90% for nonlarval tests and >70% for larval tests. Prior to conducting the t-test, angular transformation (arcsine of the square root) of the proportion surviving in test replicates was performed to reduce possible heterogeneity of variance between mean survival of test organisms in the control and in the 100% SPP. The second analysis required by the Green Book is estimation of the medium lethal concentration (LC_{50}) or median effective concentration (EC_{50}). The LC_{50} or EC_{50} values for these tests were estimated using the trimmed Spearman-Karber method (Finney 1971) and are expressed in percentage of SPP. The Spearman-Karber estimator is appropriate only if there was increasing mortality (or effect) with increasing concentration, and if ≥50% mortality (or effect) was observed in at least one test concentration when normalized to control survival. If 50%

mortality (or effect) did not occur in the 100% SPP concentrations for any treatments, then LC_{50} or EC_{50} values were reported as >100% SPP.

2.6.3 Statistical Analysis of Benthic Toxicity Tests

Benthic toxicity of all sediment treatments was compared to a single reference treatment using Dunnett's test (Dunnett 1964). The arcsine square root of the proportion of organisms surviving the test was used to stabilize the within-class variances. As recommended by the Green Book an experiment-wise error α=0.05 was used. Acute toxicity for the amphipod test indicates that the test treatment was statistically significant relative to the reference treatment and had a greater than 20% difference in survival from the reference treatment. Acute toxicity for the mysid test indicates that the test treatment was statistically significant relative to the reference treatment and had a greater than 10% difference in survival from the reference treatment.

2.6.4 Statistical Analysis of Bioaccumulation

The results of the chemical analyses of test organism tissues exposed to the dredged sediment treatments was statistically compared with those of tissues similarly exposed to the Mud Dump Reference Site treatment using Dunnett's test with an experiment-wise error of α=0.05. The Dunnett's tests determined whether or not the concentrations of contaminants of concern in the organisms exposed to the dredged sediments statistically exceeded those of organisms exposed to the reference sediment.

Statistical analyses were performed on the dry weight concentrations. When a compound (metals, pesticides, PCBs, and PAHs) was undetected (indicated by a "Q" flag in the report tables and a "U" flag in the appendix tables), one-half the detection limit of a compound was used in numerical calculations. If the compound was undetected in all five replicates of a test treatment, or if the mean concentration of a compound was greater in tissue samples from the reference treatment than in tissue samples from the test treatments, no further analysis was necessary. If a compound was undetected in all five replicates of the reference treatment, a one-sided, one-sample t-test (α=0.05) was used to determine if the tissue concentrations from organisms exposed to dredged sediment treatments were statistically greater than the mean detection limit for that compound from the reference tissue. Results of background and control tissues were not statistically compared with the reference.

Magnification factors were calculated for each compound as the dry weight ratio of the mean tissue concentration from organisms exposed to dredged sediment treatments to the mean tissue concentration from organisms exposed to the Mud Dump Reference Site sediment. Whole detection limits were used for non-detects in this calculation.

2.7 Quality Assurance/Quality Control Procedures

The quality assurance/quality control (QA/QC) procedures for the Port Chester project were consistent with the Regional Guidance Manual and the Green Book, and were documented in the Work/Quality Assurance Project Plan, *Evaluation of Dredged Material Proposed for Ocean Disposal from Federal Projects in New York*, prepared by the MSL and submitted to the USACE-NYD for this program. This document describes all QA/QC procedures that were followed for sample collection, sample tracking and storage, and physical/chemical analyses. A member of Pacific Northwest National Laboratory's quality engineering staff was present throughout all phases of this program to observe procedures, review and audit data, and ensure that accepted protocols were followed. Data accumulation notebooks were assigned to each portion of these studies and served as records of day-to-day project activities.

3.0 Results

This section presents results of sample collection and processing, and physical and chemical analyses conducted on sediment samples collected from the proposed Port Chester dredging area.

3.1 Sample Collection and Processing

Sediment core and grab samples were collected from the Port Chester project area on March 8, 1994. The western shore of the project area is in New York and the eastern shore is in Connecticut. The sediment collected on the eastern shore was generally muddy and contained leaves and twigs. The sediment collected on the western shore was difficult to collect with the vibracore sampler. Several core cutters were damaged trying to collect sediment from this area. A van Veen grab was used to collect sediment representative of the western shore and was approved by the USACE project manager. Sediment collected with the van Veen grab was characterized by gravel and stones. This material was also present on the shore at the commercial facilities; it could have fallen in the water during loading onto barges, or fallen off barges that may not have been properly secured in transit. During sampling, oil was noted in the sediment samples, and two samples taken from PC-4 and PC-6 smelled of pesticides. The field crew also noted the presence of an oil sheen on the water surface at the time that core or grab samples were collected. The presence of oil was reported to state agencies and the Coast Guard. A site water sample was collected from PC-10.

Table 3.1 lists each sampling station within the Port Chester project area, sampling coordinates, collection date, length of core required for testing, and length of core actually collected. All core and grab samples were collected aboard the *Gelberman* for the 11 Port Chester samples. Seven core samples were collected to a project depth of -10 ft MLW and overdepths ranging from 0.3 ft to 4 ft. Four stations were collected with a van Veen grab sampler. Two of these stations were collected to project depth and varying overdepth lengths whereas the two remaining stations were not.

Upon receipt of the sediment samples at the MSL on March 18, 1994, samples were prepared for the physical and chemical analyses according to the procedures described in Section 2. Individual sediment samples were analyzed for grain size, moisture content, and TOC. One composited sediment sample representing the entire Port Chester project area (COMP PC) was analyzed for bulk density, specific gravity, metals, chlorinated pesticides, PCBs, PAHs, and 1,4-dichlorobenzene. Prior to sample analysis, the USACE-NED and State

of Connecticut requested the USACE-NYD to analyze the Port Chester sediment samples according to a different compositing scheme. Table 3.2 lists the stations or samples included in each of the five USACE-NED chemistry composites (CT COMP). The CT COMP samples were also analyzed for an extended list of metals, chlorinated pesticides, PCBs, PAHs, and 1,4-dichlorobenzene.

3.2 Physical and Chemical Analyses

3.2.1 Sediment Core Sample Description

Table 3.3 lists physical characteristics of each sediment core sample. Port Chester sediment samples were generally black or gray-black, silty-clayey material.

TABLE 3.1. Summary of Sediment Sample Data for Port Chester

Station	Collection Date	Station Coordinates		Core Length Required (ft)	Core Length Collected (ft)	Mudline Depth (-MLW ft)
		Latitude N	Longitude W			
Core Samples

3.2.2 Grain Size, Percentage of Moisture, Bulk Density, and Specific Gravity

Table 3.4 shows the results of the analysis of Port Chester sediment samples for grain size percentage of moisture, and TOC. A quality control sample summary and associated quality control data for grain size and TOC measurements are provided in Appendix A. The upriver Port Chester samples PC-1, PC-2, PC-3, PC-4, PC-6 and PC-7, sediments were predominantly coarse-grained. Port Chester samples PC-5, PC-8, PC-9, PC-10, and PC-11, were predominately fine-grained: percentages of sand ranged from 21% to 34%; silt ranged from 34% to 48%; and clay ranged from 20% to 33%. The Mud Dump Reference Site sediment was composed of 98% sand and the Central Long Island Sound Reference Site sediment was 60% silt and 34% clay. The total percentage of solids ranged from 30% to 96%. Bulk density was analyzed on COMP PC. The results were reported in wet weight and dry weight with values of 100 lb/cu ft and 58 lb/cu ft respectively. The specific gravity value for COMP PC was 2.49.

3.2.3 Total Organic Carbon

The upriver Port Chester sediments PC-1 through PC-4 had ≤1.51% TOC (Table 3.4) in Stations PC-5 through PC-11 had percentages of TOC ranging from 5.34% to 6.99%, which are higher than both that of the Mud Dump Reference sediment (0.01%) and of the Central Long Island Sound Reference sediment (1.64%).

TABLE 3.3. Port Chester Sediment Core Descriptions

Station	Depth Below Mudline (-ft MLW) Core Top	Core Bottom	Project Depth[a]	Description of Observations
PC-1	8.5	10.3	12.0	Black sand and gravel at top of core; remaining core black silty sand.
PC-2	8.7	10.2	12.0	Black, slippery, silty material at top of core; black sandy gravel in middle section of core; remaining core had a layer of gray silty clay followed by a layer of slippery, black silty/clayey material.
PC-3	8.7	9.95	12.0	All black pea-size gravel.
PC-4	9.1	10.8	12.0	All black gravel and stone.
PC-5	9.0	11.75	12.0	All uniform black silty material.
PC-6	9.5	11.3	12.0	All black gravel bound together with black sand. Some rocks, mussels, and shells interspersed through the core.
PC-7	7.0	8.75	12.0	All rocks, leaves, shells bound together with black silty material.
PC-8	11.0	12.0	12.0	All uniform black silty material; high water content, almost liquid.
PC-9	8.7	11.3	12.0	All uniform black silty material.
PC-10	7.5	12.0	12.0	All uniform slippery, black, silty/clayey material with a band at -8.5 ft to -10.0 ft MLW where rocks and shells were mixed in with black material.
PC-11	8.0	4.0	12.0	Few rocks and mussel shells on top surface of core. From mudline to -11 ft MLW all uniform slippery, black, silty/clayey material; remaining of core was a band of grayish silty clay followed by band of black slippery material.

(a) Project depth of 10 ft plus 2 ft overdepth.

TABLE 3.4. Results of Analysis of Port Chester Sediment Samples for Grain Size and Percentage of Moisture

Sediment Treatment	Total Percent (dry weight) Gravel >2000 µm	Sand 62.4-2000 µm	Silt 3.9-62.4 µm	Clay <3.9 µm	Percent Moisture	Percent Total Organic Carbon

(a) ND No data.

3.2.4 Metals

Table 3.5 shows the results of the analysis of COMP PC, the five CT COMPs, the Mud Dump Reference Site, and the Central Long Island Sound Reference Site sediment samples for metals. The initial analysis of metals in sediment resulted in low spike recoveries for Ag. It was determined that sodium chloride in marine sediments caused an interference during ICP-MS analysis. The sediment digestion was repeated on the Port Chester samples with the addition of aqua regia to the procedure. This step alleviated the sodium chloride interference problem and improved spike recovery. The results of the Ag reanalysis are presented in Table 3.5. A quality control summary and quality control data associated with the metals, including the reanalysis of sediment samples for Ag, are provided in Appendix A.

Levels of all nine metals in COMP PC exceeded those found in the Mud Dump Reference Site sediment. Concentrations of Ag, As, Cr, Cu, Ni, Pb, and Zn were an order of magnitude higher in COMP PC than in the reference sediment. Mercury levels were two orders of magnitude greater in COMP PC than in the reference site sediment; Cd levels were eight orders of magnitude greater in COMP PC than in the reference site sediment.

Concentrations of eight metals in CT COMPs PC-III, PC-IV, and PC-V exceeded those found in the Central Long Island Sound Reference Site sediment. Levels of seven metals in CT COMPs PC-I and PC-II were lower than those found in the Central Long Island Sound Reference Site sediment.

TABLE 3.5. Results of Analysis of Port Chester Sediment Samples for Metals

Sediment Treatment	Metals (mg/kg dry weight)

3.2.5 Chlorinated Pesticides

Table 3.6 shows the results of the analysis of COMP PC, the five CT COMPs, the Mud Dump Reference Site, and the Central Long Island Sound Reference Site sediments for chlorinated pesticides. A quality control sample summary and associated quality control data are provided in Appendix A.

The COMP PC sediment contained concentrations of pesticides at concentrations elevated over those found in the Mud Dump Reference site sediment. The dominant pesticides found in COMP PC were the DDT family of compounds (167 µg/kg total DDTs), followed by dieldrin, α-chlordane, and *trans*-nonachlor. Endosulfan I and 2,4-DDE coeluted in the primary GC analysis of these samples, but examination of the confirmatory analysis using a second GC column revealed that neither compound was detected. The value shown is the detection limit for 2,4-DDE. Pesticides were undetected or detected at concentrations near or below the target detection limit (1.0 µg/kg) in sediment from the Mud Dump Reference Site.

Concentrations of pesticides were generally higher in the sediments from CT COMPs PC-III, PC-IV, and PC-V relative to those found in the Central Long Island Sound Reference Site sediment. The dominant pesticides found in the five CT COMPs were generally the same as found in COMP PC sediment. Pesticides were either undetected or detected at concentrations near or below the target detection limit (1.0 µg/kg) in sediment from the Central Long Island Sound Reference Site.

3.2.6 PCBs

Table 3.7 shows the results of the analysis of COMP PC, the five CT COMPs, the Mud Dump Reference Site, and the Central Long Island Sound Reference Site sediment for PCBs. A quality control sample summary and associated quality control data are provided in Appendix A.

All of the 22 PCB congeners analyzed were detected in COMP PC sediment, with only two congeners (PCB 8 and PCB 18) found at a concentration below the detection limit. The total PCB concentration calculated for COMP PC was 1060 µg/kg, about two orders of magnitude higher than in reference site sediment. PCBs were either undetected or detected at concentrations near or below the target detection limit (1.0 µg/kg) in Mud Dump Reference Site sediment.

Concentrations of the 22 PCB congeners in CT COMPs PC-I and PC-II were generally undetected or detected at concentrations near or below the target detection limit. All of the 22 PCB congeners analyzed were detected in CT COMPs PC-III, PC-IV, and PC-V sediment and at concentrations higher than those in the Central Long Island Sound Reference

Total PCB[d]	**1060**	**35.1**	**20.7**	**277**	**1110**	**1260**	**13.4**	**36.3**

(a) J Concentration estimated; analyte detected below method detection limit.
(b) D Dilution required; results in higher detection limit.
(c) U Undetected at or above given concentration.
(d) Total PCB = 2.0 (x), where x = sum of all PCB congeners detected; one-half of the detection limit used in summation when analyte was undetected.

All 16 PAHs analyzed were detected in COMP PC sediment. Low-molecular-weight PAH (LPAH) made up approximately 20% of the total PAH concentration, whereas high-molecular-weight PAH (HPAH) made up 80% of the total. The COMP PC PAH levels ranged from 1 to 3 orders of magnitude higher than those found in the reference site sediments. Concentrations of PAH compounds in Mud Dump Reference Site sediment were either undetected or detected at concentrations below the target detection limit (0.01 µg/kg). The COMP PC concentration of 1,4-dichlorobenzene was two orders of magnitude higher than that in the Mud Dump Reference Site sediment samples.

All 23 PAHs analyzed were detected in the five CT COMPs. CT COMPs PC-I, PC-II, PC-III, and PC-IV had concentrations of LPAH compounds that made up approximately 20% of the total PAH concentration and HPAH compounds that made up approximately 80% of the total PAH concentration. CT COMP PC-V had 43% LPAH compounds and 57% HPAH compounds. The concentrations of PAH compounds in the CT COMPs PC-I, PC-II, and PC-III were ≤ six times higher than those found in the Central Long Island Sound Reference Site sediment. Concentrations of PAH compounds in Central Long Island Sound Reference Site sediment ranged from 214 µg/kg (LPAH) to 1310 µg/kg (HPAH). All five CT COMPs had detected concentrations of 1,4-dichlorobenzene that were higher than those found in the Central Long Island Sound Reference Site sediment.

In addition to the list of PAH analytes required for analysis in the Regional Guidance Manual, hydrocarbon fingerprint characterization of the Port Chester sediment composite was accomplished using a tiered analytical approach. This fingerprinting characterization was done because of the visible oil sheen present on the water and in the sediment at the time of collection. As the first tier analysis, COMP PC was evaluated by gas chromatography with flame ionization detection (FID) to determine total petroleum hydrocarbon levels and to obtain a qualitative chromatographic representation of potential product type(s) present in the samples. As a second tier analysis, individual petroleum-specific PAH were measured using GC/MS for more detailed information used for petroleum source identification.

High resolution GC/FID analysis is a useful means for measuring total petroleum hydrocarbon (TPH), for making preliminary determinations about product type, and for evaluating weathering state of products in environmental samples. Figure 3.1 is the GC chromatogram for COMP PC. Based on a comparison of this chromatogram with those of petroleum product standards, the GC trace suggests that the Port Chester sediment sample appears to be contaminated with a petroleum product in the lubricating oil/fuel oil range. The product in the sample appears to be heavily degraded.

GC/MS analysis of PAH can confirm product identification and source allocation, because the PAH compounds are substantially more resistant to weathering and degradation and therefore retain the characteristic chemical pattern of the product in the samples than the aliphatic compounds measured by GC/FID. In this analysis, samples are monitored for the parent (unsubstituted) PAH compounds as well as for their alkylated homologs. This extended list of PAH compounds and concentrations in µg/kg dry weight is shown in Table 3.9. The distribution of parent PAH compounds and their alkyl homologs in COMP PC are presented graphically in Figure 3.2. This PAH distribution was matched against distribution graphs from Battelle's Standard Oil Library to identify the source of the PAH input to the

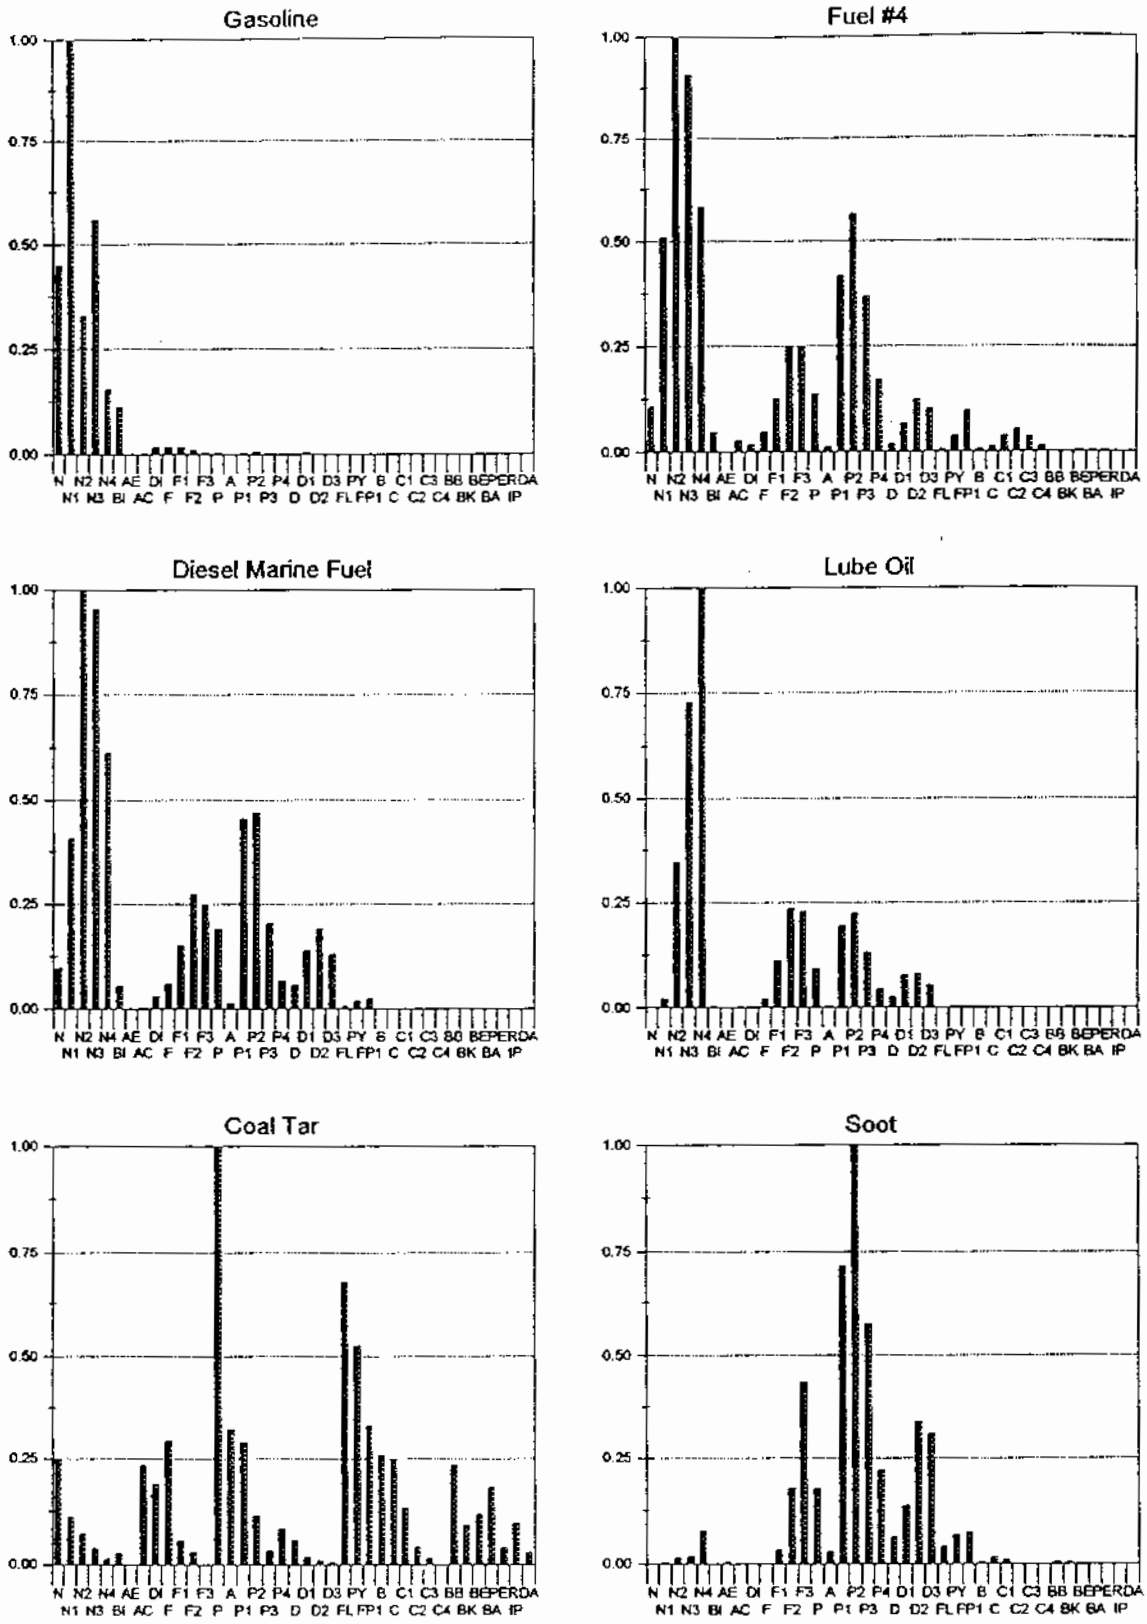

FIGURE 3.3. Typical PAH Distributions for Oil Products

Qualitatively, the distribution of PAHs suggests that COMP PC contains a mixture of hydrocarbons. The PAH distribution between naphthalene and dibenzothiophene resembles that of marine diesel fuel or a lubricating oil where the alkylated homologs of parent PAHs increase in concentration with level of alkylation (C1 thru C4). The presence of 4- and 5-ring PAHs also suggest inputs of coal tar or creosote material to the Port Chester sediment.

3.3 Site Water and Elutriate Analyses

Metals, chlorinated pesticides, and PCBs were analyzed in dredging site water collected from Port Chester and in elutriate samples prepared from clean seawater (Sequim Bay) and the Port Chester sediment composite. Sequim Bay seawater was used in place of dredging site water to maintain consistency in salinity among the dredging projects. Mud Dump Site water and Sequim Bay control water were also analyzed. All water and elutriate samples were analyzed in triplicate. Mean results of the triplicate analyses are presented and discussed in the following sections. Complete results of site water and elutriate samples, and quality control summary and associated quality control data are provided in Appendix B.

3.3.1 Metals

Results of analysis of Sequim Bay control water, Mud Dump Site water, Port Chester site water, and Port Chester sediment elutriates are shown in Table 3.10. Concentrations of Cd, Cr, and Zn were similar between the control water and Mud Dump Site water, whereas concentrations of Ag, Cu, Hg, Ni, and Pb were at least twice as high in the Mud Dump Site water than in the control. In particular, Hg and Pb were about an order of magnitude higher in the Mud Dump Site than in the control water.

Port Chester Site water had elevated levels of all metals measured when compared with Mud Dump Site Water. Concentrations of Hg, Ni, and Zn were only slightly elevated, whereas concentrations of Ag, Cd, Cr, Cu, and Pb were at least twice as high in Port Chester site water than in Mud Dump Site water. Port Chester elutriate concentrations for metals were generally more similar to those found in the Mud Dump Site water than to those in the Port Chester site water. Concentrations of all metals, with the exception of Cd and Ni, were lower in the Port Chester elutriate than in the Port Chester site water.

3.3.2 Chlorinated Pesticides and PCBs

Results of analysis of Sequim Bay control water, Mud Dump Site water, Port Chester site water, and Port Chester elutriate are shown in Table 3.11. With few exceptions, pesticides and PCB congeners were not detected in any of the samples. Traces of 4,4'-DDD,

Zn	9.20	10.3	23.8	6.94

(a) Value shown is the mean of triplicate analyses; one-half the detection limit used when analyte was undetected.
(b) Q undetected at or above twice the given concentration.

4,4'-DDE, 4,4'-DDT, α-chlordane, and dieldrin were found in Port Chester site water samples above the detection limits for these compounds. Concentrations of pesticides in the Port Chester elutriate samples were elevated by a factor of 50 for 4,4'-DDD, and by a factor of 10 to 15 times for 4,4'-DDE, dieldrin and α-chlordane. Only PCB 28 was detected above the detection limit in Port Chester site water samples. Nineteen PCB congeners were detected in the Port Chester elutriate samples at concentrations ranging from 1.3 to 84.6 times above those found in the Port Chester site water and the control and Mud Dump site water.

3.4 Water-Column Toxicity Testing

Water-column tests were performed on four concentrations of an SPP preparation made from the Port Chester composite. SPP tests were conducted with the silverside, *M. beryllina*, the mysid, *M. bahia*, and larvae of the bivalve *M. galloprovincialis*. This section discusses the results of all water-column and reference toxicant testing. Complete test results, water quality measurements, and the results of the reference toxicant tests are presented in Appendix C. Throughout this section, the term "significant difference" is used to express *statistically* significant differences only. Tests for statistical significance between test and reference treatments were performed following methods outlined in Section 2.6.

TABLE 3.11. Results of Analysis of Port Chester Site Water and Elutriate for Chlorinated Pesticides and PCBs

Analyte	Concentration in ng/L[a] Control Water		Mud Dump Site Water		Port Chester Site Water		Port Chester Elutriate	
2,4'-DDD	0.39	Q[b]	0.38	Q	0.38	Q	0.40	Q

Total PCB[d]	**23.4**		**23.7**		**29.8**		**1020**	

(a) Value shown is the mean of triplicate analyses; one-half the detection limit used when analyte was undetected.

(b) Q undetected at or above twice the given concentration.

(c) Total DDT is the sum of 4,4'-DDT, 4,4'-DDE, 4,4'-DDD, 2,4'-DDT, 2,4'-DDE, and 2,4'-DDD; one-half of the detection limit was used in summation when analyte was not detected.

(d) Total PCBs = 2(x), where x is the sum of all PCB congeners detected; one-half of the detection limit used in summation when an analyte was undetected.

3.4.1 *Menidia beryllina* Water-Column Toxicity Test

Results of the *M. beryllina* water-column toxicity test are summarized in Table 3.12. Complete test results as well as water quality data are presented in Appendix C, Tables C.1 through C.4. Control survival was 100%, validating this test. Survival in the 100% SPP preparation was 26% and was significantly lower than in the controls. The *M. beryllina* LC_{50} of the Port Chester composite was 75.1% SPP.

Water quality parameters were within acceptable ranges throughout testing, except for one pH measurement above the acceptable range. Ammonia concentrations in the 100% SPP preparation reached 15.6 mg/L. The copper reference toxicant test produced an LC_{50} of 98.1 µg/L Cu, which is within the control limits established at the MSL (71µg/L to 136 µg/L Cu).

3.4.2 *Mysidopsis bahia* Water-Column Toxicity Test

Results of the *M. bahia* water-column toxicity test are summarized in Table 3.12. Complete test results, as well as water quality data are presented in Appendix C, Tables C.5 through C.8. This test was validated by a control survival of 98%. Survival in the 100% SPP preparation was 58% and was significantly lower than the controls. The LC_{50} was greater than 100% SPP.

All water quality parameters were within acceptable ranges throughout the test, with the exception of pH, which rose to 8.33 and 8.39 in the 50% and 100% treatments,

TABLE 3.12. Summary of Water-Column Toxicity Tests Performed with Port Chester Sediment

Test Organism	Percentage of Survival in 0% SPP	Percentage of Survival in 100% SPP	0% and 100% Significantly Different	LC_{50} (%SPP)
Menidia beryllina	100	26	Yes	75.1
Mysidopsis bahia	98	58	Yes	>100
Mytilus galloprovincialis (Survival)	99	84	Yes	>100
Mytilus galloprovincialis (Normal development)	99	0	Yes	53.7[a]

(a) Median effective concentration (EC_{50}) based on normal development to the D-cell, prodissoconch stage.

respectively. The ammonia concentration at test termination in the 100% SPP preparation was 15.6 mg/L. An LC_{50} could not be calculated for the copper reference toxicant test, because there was not a greater than 50% reduction in mortality.

3.4.3 *Mytilus galloprovincialis* Water-Column Toxicity Test

Results of the *M. galloprovincialis* water-column toxicity test are summarized in Table 3.12. Complete test results and water quality data are presented in Appendix C, Tables C.9 through C.12. This test was validated by 99% survival and 99% normal development in the controls. Survival was 84% in the 100% SPP preparation and was significantly lower than the controls. The LC_{50} was >100% SPP. Normal development, considered a more sensitive indicator of toxicity, was also significantly reduced in the 100% SPP, with 0% normal prodissoconch in this treatment. The EC_{50} was 53.7% SPP.

All water quality parameters were within acceptable ranges throughout the test. The ammonia concentration in the 100% SPP preparation was 7.9 mg/L. The copper reference toxicant test revealed an LC_{50} of 45.6 µg/L Cu and an EC_{50} of 6.5 µg/L Cu, which were within the control limits (LC_{50}: 5.8 µg/L to 35 µg/L copper; EC_{50}: 5.7 µg/L to 21µg/L copper) established at the MSL.

3.5 Benthic Acute Toxicity Testing

Benthic acute toxicity tests were performed on the Port Chester composite, Mud Dump Reference Site, and Central Long Island Sound Reference Site sediment. Benthic toxicity tests were conducted with the amphipods *A. abdita* and *R. abronius*, and the mysid, *M. bahia*. This section discusses the results of all benthic and reference toxicant testing. Complete test results, water quality measurements, and the results of the reference toxicant tests are presented in Appendix D. Throughout this section the term "significant difference" is used to express *statistically* significant differences only. In addition to statistical significance, a sediment is considered acutely toxic if a greater than 20% difference in amphipod (10% for mysids) survival is demonstrated between a test and reference sediment. Tests for statistical significance between the treatment and reference treatment were performed following methods outlined in Section 2.6.

3.5.1 *Ampelisca abdita* Benthic Acute Toxicity Test

Results of the benthic acute toxicity test with *A. abdita* are summarized in Table 3.13. Complete test results and water quality data are presented in Appendix D, Tables D.1 through D.5. Prior to test setup, total ammonia concentrations measured in the Port Chester

TABLE 3.13. Summary of Benthic-Acute Toxicity Tests Performed with Port Chester Sediment

Test Organism	Mean % Survival	Significantly Different Than MDRS Reference	≥ 20% Difference (Amphipod) ≥ 10% Difference (Mysid)	Significantly Different Than CLIS Reference	≥ 20% Difference (Amphipod) ≥ 10% Difference (Mysid)
A. abdita	0%	Yes	Yes	Yes	Yes
R. abronius	78%	Yes	Yes	Yes	No
M. bahia	77%	No	No	No	No

bulk sediment composite was about 156 mg/L. Test chambers containing sediment and overlying water were set up (March 25, 1994) and maintained under test temperatures with aeration during the ammonia purging period. Overlying water was exchanged twice daily, delivered via a flow-through system (i.e., two times each day, the seawater flow into the test chambers was turned on long enough to displace the volume of the water in the test chamber once). Porewater ammonia was measured in "dummy" jars every few days until concentrations were 30 mg/L or less. The test was initiated after 10 days (April 4, 1994) when the porewater ammonia concentration was 10.7 mg/L.

Survival in the *A. abdita* control sediment was 97%, validating this test. Survival in the Port Chester composite was 0%, which was statistically significant and represented a > 20% reduction in survival compared with that in the Mud Dump (93%) and Central Long Island Sound (97%) reference sediments.

Temperature, pH, and DO were outside of acceptable water quality ranges in two test treatments during testing. However, test organism survival in the reference and control treatments were acceptable, thus these exceedences do not appear to have affected test interpretation. Ammonia concentrations were less than 1.0 mg/L in the overlying water during the 10-day test, and were 10.7 mg/L in the porewater at test termination. The cadmium reference toxicant test produced an LC_{50} of 0.66 mg/L Cd, which was within the control limits established at the MSL (0.5 mg/L to 1.4 mg/L Cd).

3.5.2 *Rhepoxynius abronius* Benthic Acute Toxicity Test

Results of the benthic toxicity test with *R. abronius* are summarized in Table 3.13. Complete test results and water-quality data are presented in Appendix D, Tables D.6 through D.10. The same procedure that was followed to reduce the bulk sediment porewater

ammonia concentration from 156 mg/L to 30 mg/L or less in the *A. abdita* test was used in the *R. abronius* test. Test chambers containing sediment and overlying water were set up (March 25, 1994) and maintained under test temperatures with aeration during the ammonia purging period. Overlying water was exchanged twice daily. The test was initiated after 11 days (April 5, 1994) when the porewater ammonia concentration was 11.0 mg/L.

Survival in the West Beach control sediment was 97%, validating this test. Survival in the Port Chester composite was 78% which was statistically significant and represented a ≥ 20% reduction in survival relative to that in both the Mud Dump (98% survival) and the Central Long Island Sound (91% survival) reference sediments.

All water quality parameters were within acceptable ranges throughout the test, with the exception of pH, which rose to 8.48 and 8.40 in COMP PC and C-WB sediments, respectively. Ammonia concentrations were less than 1.0 mg/L in the overlying water during the 10-day test, and were 11.0 mg/L in the porewater at test termination. The cadmium reference toxicant test produced an LC_{50} of 1.14 mg/L Cd, which was within the control limits established at the MSL (0.48 mg/L to 1.70 mg/L Cd).

3.5.3 *Mysidopsis bahia* Benthic Acute Toxicity Test

Results of the static benthic toxicity test with *M. bahia* are summarized in Table 3.13. Complete test results and water-quality data are presented in Appendix D, Tables D.11 through D.14. The mysid static test was not manipulated in any way to reduce porewater or overlying water ammonia concentrations prior to test initiation. Survival in the Port Chester composite was 77% and was not statistically significant, nor was the survival greater than 10% different from that in the Mud Dump Reference (76% survival) and the Central Long Island Sound Reference (74% survival) sediments. A control sediment treatment was not run concurrently with the Port Chester sediment treatments. However, the mysid benthic test was rerun 2 weeks later using other New York Federal Project-2 sediments. Mysid survival in the control treatment of that test was 93%.

All water quality parameters were within acceptable ranges throughout the test, with the exception of pH, which rose to 8.53 in COMP PC sediments. Ammonia concentrations were less than 1.0 mg/L in the overlying water during the 10-day static test; therefore, the *M. bahia* static renewal benthic acute toxicity test was not performed using Port Chester sediments. The copper reference toxicant test produced an LC_{50} of 151 µg/L Cu, which is within the control limits of 116 µg/L to 229 µg/L Cu, established at the MSL.

3.6 Bioaccumulation Tests with *Macoma nasuta* and *Nereis virens*

Bioaccumulation tests with *M. nasuta* and *N. virens* were conducted using the Port Chester composite, Mud Dump Reference Site, Central Long Island Sound Reference Site, and control sediments. Both *M. nasuta* and *N. virens* were exposed for 28 days under flow-through conditions. Survival was greater than 90% in the *M. nasuta* control sediment, and 89% in the *N. virens* control sediment. Statistical analysis of the survival data was not conducted, since the purpose of the 28-day solid-phase test was to provide results as to the bioaccumulation potential in *M. nasuta* and *N. virens* tissues. Complete test results and water quality data are presented in Appendix E.

The tissues of the exposed organisms were analyzed for metals and selected organic contaminants (pesticides, PCBs, and PAHs), the results of which are summarized in this section. Complete test results and water quality data are tabulated in Appendix E for both species. Analytical results, including a quality control summary and associated quality control data, are presented in Appendix F for *M. nasuta* and in Appendix G for *N. virens.* The statistical analysis of tissue data was performed using sample dry weight concentrations to remove any variance associated with water content in each sample. Statistical difference between reference site and test sediment exposures is shown in the following tables with the results of sample analysis on a wet weight basis. Reporting data in this manner allows for comparison of wet weight concentrations obtained from this study with regulatory levels such as the FDA action levels reported in section 4.0 of this report. Lipids were analyzed on the background samples of the *M. nasuta* and *N. virens* tissues. These samples were triplicated and the average dry weight lipid content in wet weight of tissues for *M. nasuta* and *N. virens* were 0.59% and 2.10%, respectively. At the end of this section magnification tables are presented that show a comparison of Port Chester tissue concentrations with the reference tissue concentrations. Whole detection limit and dry weight of samples were used to create the magnification tables.

3.6.1 Bioaccumulation of Metals in *Macoma nasuta*

All nine metals were detected in tissues exposed to the Port Chester composite and to the Mud Dump and CLIS Reference sediments, except Pb, which was undetected in the tissues exposed to Mud Dump Reference sediment (Table 3.14). Of these, Cd, Cu, Ni, and Pd were statistically significant and elevated relative to tissues exposed to the Mud Dump Reference Site sediment, and Pb was at statistically significant and elevated relative to tissues exposed to the Central Long Island Sound Reference Site sediment. The magnification factor, the magnitude by which a contaminant concentration in the test composite

TABLE 3.14. Mean Concentrations of Metals in *M. nasuta* Tissues Exposed to Port Chester Sediment

Analyte	Concentration (mg/kg wet weight) [a]			SD[d] MDRS	SD CLIS
	MDRS[b]	CLIS[c]	COMP PC		
Silver	0.0372	0.0294	0.0368	No	No
Arsenic	3.16	2.78	3.03	No	No
Cadmium	0.0355	0.0236	0.208	Yes	Yes
Chromium	0.408	0.451	0.436	No	No

Mercury	0.0180	0.0153	0.0148	No	No
Nickel	0.402	0.576	0.559	Yes	No
Lead	0.157 Q[e]	0.848	0.721	Yes	No
Zinc	13.1	11.2	14.0	No	No

(a) Value shown is a mean of five replicate s; one-half the detection limit used when analyte was undetected.
(b) MDRS- Mud Dump Reference Site.
(c) CLIS-Central Long Island Sound Reference Site.
(d) SD Significantly different.
(e) Undetected at or above twice the given concentration.

tissues exceeds that of the reference-exposed tissues, was below three for all metals, except Cd, which was 6.77 (MDRS) and 9.22 (CLIS).

3.6.2 Bioaccumulation of Pesticides in *Macoma nasuta*

Of the 15 pesticides analyzed, seven were detected in tissues exposed to the Port Chester composite (Table 3.15). With respect to both the Mud Dump Reference and Central Long Island Sound Reference Site tissues, aldrin, dieldrin, α-chlordane, *trans*-nonachlor, 2,4'-DDD, 4,4'-DDD, and 4,4'-DDE were statistically significant and elevated in the Port Chester composite tissues. Concentrations of α-chlordane, 2,4'-DDD, 4,4'-DDE, and 4,4'-DDD concentrations in Port Chester composite tissues exceeded those in tissues exposed to the Mud Dump Reference sediment by a factor of greater than 10. Concentrations of α-chlordane, 2,4'-DDD, and 4,4'-DDD concentrations exceeded those in the Central Long Island Reference tissues by a factor of greater than 10. The total concentration of DDT in the tissues exposed to the Port Chester composite was 21.9 µg/kg.

3.6.3 Bioaccumulation of PCBs in *Macoma nasuta*

Eighteen of 22 PCBs analyzed were detected in *M. nasuta* tissues exposed to the Port Chester composite (Table 3.15). Twelve PCBs were observed at concentrations that were statistically significant and elevated relative to tissues exposed to the Mud Dump Reference composite. Nine PCBs were significantly elevated relative to the Central Long Island Sound Reference Site tissues. Port Chester tissue concentrations of six PCB congeners (87, 101, 105,

(f) Total DDT is the sum of 4,4'-DDT, 4,4'-DDE, 4,4'-DDD, 2,4'-DDT, 2,4'-DDE, and 2,4'-DDD; one-half of the detection limit was used in summation when analyte was not detected.
(g) Total PCB = 2(x), where x=sum of all PCB congeners; one-half of the detection limit used in summation when analyte was undetected.

118, 138, and 153) exceeded those of the Mud Dump Reference tissues by a factor of greater than 10. Port Chester tissue concentrations of PCBs 87 and 105 exceeded those of the Central Long Island Sound Reference Site tissues by a factor of greater than 10. The concentration of total PCBs in the tissues exposed to the Port Chester composite was 67.1 µg/kg.

3.6.4 Bioaccumulation of PAHs and 1,4 Dichlorobenzene in *Macoma nasuta*

All PAHs analyzed were detected in *M. nasuta* tissues exposed to the Port Chester composites at statistically significant and elevated concentrations, relative to tissues exposed to both reference sediments (Table 3.16) except for acenaphthylene and benzo[k]fluoranthene. Nine PAHs were elevated above the Mud Dump Reference tissues by factors ranging from 12.7 times to 126 times. Acenaphthene, anthracene, fluoranthene, pyrene, benzo(a)anthracene, and chrysene were elevated above the Central Long Island Sound

(a) Value shown is a mean of five replicates; one-half the detection limit used when analyte was undetected.
(b) MDRS- Mud Dump Reference Site.
(c) CLIS-Central Long Island Sound Reference Site.
(d) SD Significantly different.
(e) Undetected at or above twice the given concentration.

Reference Site tissues by a factor of greater than 10. The compound 1,4-dichlorobenzene was undetected in all replicates of the Port Chester composite tissues.

3.6.5 Bioaccumulation of Metals in *Nereis virens*

All metals analyzed except silver and chromium were detected in *N. virens* tissues exposed to the Port Chester composite (Table 3.17). Of these, only cadmium was measured at concentrations that were statistically significant and higher than those measured in tissues exposed to the Mud Dump Reference Site sediments. Magnification factors were ≤ 3.0 for all metals.

3.6.6 Bioaccumulation of Pesticides in *Nereis virens*

Of the 15 pesticides analyzed, 8 were detected in the Port Chester tissues (Table 3.18). Aldrin, dieldrin, α-chlordane, *trans*-nonachlor, 2,4'-DDD, 4,4'-DDE, and 4,4'-DDD were detected at concentrations that were statistically significant and higher than in tissues exposed to both reference sediments. Several pesticides were detected in Port Chester

(c) CLIS-Central Long Island Sound Reference Site.
(d) SD Significantly different.
(e) Undetected at or above twice the given concentration.

tissues at concentrations greater than 10 times those of the Mud Dump Reference tissues (dieldrin, α-chlordane, 2,4-DDD, 4,4'-DDE, and 4,4'-DDD) and Central Long Island Sound Reference Site tissues (α-chlordane and 4,4'-DDD).

3.6.7 Bioaccumulation of PCBs in *Nereis virens*

Nineteen of 22 PCBs analyzed were detected in *N. virens* tissues exposed to the Port Chester composite (Table 3.18). Of these, 16 were statistically significant and elevated relative to the Mud Dump Reference tissues, and 13 relative to the Central Long Island Sound Reference Site tissues. Six PCBs (52, 87, 101, 105, 118, and 138) were observed at concentrations greater than 10 times those of the tissues exposed to the Mud Dump Reference composite. The magnification factors, relative to the CLIS Reference were all below 10. The concentration of total estimated PCBs in *N. virens* tissues exposed to the Port Chester composite was 189 µg/kg wet weight.

3.6.8 Bioaccumulation of PAHs and 1,4-Dichlorobenzene in *Nereis virens*

All PAHs analyzed were detected in tissues exposed to the Port Chester composites (Table 3.19). Of these, eight were detected in statistically significant and elevated concentrations relative to tissues exposed to the Mud Dump Reference composite. Fluoranthene, pyrene, and chrysene were detected at concentrations over 10 times higher in *N. virens* exposed to Port Chester sediments than in the two reference composites. The compound 1,4-dichlorobenzene was undetected in the Port Chester and both reference composite tissues.

3.6.9 Magnification Factors of Compounds in *Macoma nasuta* and *Nereis virens* Tissues

Table 3.20 shows the calculated magnification factors of all compounds analyzed in tissues of *M. nasuta* and *N. virens*. Magnification factors were calculated with the dry weight concentrations of the compounds in the tissues of the test organism. These factors show the magnification of the Port Chester-exposed tissues over the Mud Dump Reference Site-exposed tissues and the Central Long Island Site-exposed tissues. When all replicate analysis of a compound showed that the compound was undetected, the magnification factor displays the magnification of the Port Chester-exposed tissues above the detection limit of either of the reference tissue values.

(a) Magnification factors are the number of times the test treatment concentration is greater than the reference treatment concentration. When the analyte is undetected in one or more replicates, the achieved detection limit value is used in the calculation. Calculations are based on dry weight concentrations. Underlined values are between 5 and <10 times reference site values, values shown in bold are ≥10 times reference site values.

4.0 Discussion and Conclusions

In this section, physical and chemical analyses, and bioassays performed on the Port Chester sediment composite are evaluated relative to the Mud Dump Reference Site and the Central Long Island Sound Reference Site sediment by the guidelines of the Green Book Tier III. Tier III evaluations include water-column toxicity tests, benthic toxicity tests, and whole-sediment bioaccumulation studies. Tier III evaluations assess the impact of contaminants in the dredged material on marine organisms to determine whether there is potential for the material to have an unacceptable environmental effect during ocean disposal. The Green Book provides the following guidance for determining whether the proposed dredged material is unacceptable for ocean disposal based on the Tier III test:

- Water-Column Toxicity. The limiting permissible concentration (LPC) of dissolved plus suspended contaminants cannot exceed 0.01 of the acutely toxic concentration at the boundaries of the disposal site within the first 4 h after disposal, or at any point in the marine environment after the first 4 h. The acutely toxic concentration in this case is taken to the LC_{50}; therefore, acute toxicity in SPP tests would require at least 50% mortality in an SPP treatment to be evaluated according to the Green Book. A numerical mixing model should be used to predict whether concentrations greater than 0.01 of the acutely toxic SPP concentrations are likely to occur beyond the boundaries of the disposal site within the first 4 h after disposal.
- Benthic Acute Toxicity. The proposed dredged material does not meet the LPC for benthic toxicity when organism survival in the test sediment and the reference site sediment is statistically significant, and the decrease in survival is at least 20% for *A. abdita* and *R. abronius* or at least 10% for *M. bahia.*
- Bioaccumulation. The proposed dredged material does not meet the LPC for bioaccumulation if tissue concentrations of one or more contaminants of concern are greater than the applicable FDA levels. Regional guidance (USACE 1981) for interpretation of bioaccumulation was also considered. When the bioaccumulation of contaminants in the dredged material exceeds that in the reference material exposures, further case-specific evaluation criteria listed in the Green Book should be consulted to determine LPC and benthic effects compliance.

Sections 4.1 through 4.4 discuss the proposed Port Chester dredged material in terms of sediment characterization and Tier III evaluations. The contribution of the Port Chester composite to water-column or benthic acute toxicity and potential for bioaccumulation relative to the Mud Dump Reference Site and the Central Long Island Sound Reference Site is also presented.

4.1 Sediment Physical and Chemical Characterization

Port Chester sediment core samples were either a black, silt and clay material or a black, sand and gravel mixture. The upriver Port Chester samples PC-1, PC-2, PC-3, PC-4, PC-6 and PC-7, sediments were predominantly coarse-grained. Port Chester samples PC-5, PC-8, PC-9,

PC-10, and PC-11, were predominately fine-grained, with percentages of sand ranging from 21% to 34%; silt ranging from 34% to 48%; and clay ranging from 20% to 33%. Sediment moisture contents varied from 4% to 70% in individual cores. Levels of metals (excluding As) in Port Chester sediment exceeded those found in the Mud Dump Reference Site sediment. The dominant pesticides found were those in the DDD/DDE/DDT group of compounds, α-chlordane, dieldrin, and *trans*-nonachlor. All of the 22 PCB congeners analyzed were detected in Port Chester sediment, with a total PCB concentration of 1060 µg/kg dry weight. All 17 PAHs analyzed were detected in Port Chester sediment. Total PAH was 15,800 µg/kg dry weight; 20% of the total was LPAH; 80% of the total was HPAH. The concentration of 1,4-dichlorobenzene was 76 µg/kg dry weight.

4.2 Site Water and Elutriate Chemical Characterization

Metals concentrations were consistently higher in the Port Chester site water than in Mud Dump site water. Port Chester elutriate concentrations of metals were generally lower than Mud Dump Site water, except for Cr, Hg, Ni, and Pb, which were elevated by a factor of two in the Port Chester elutriate. The dominant pesticides found in the Port Chester site water and elutriate samples were those in the DDD/DDE/DDT group of compounds, and α-chlordane. Measurable amounts of the PCB congener PCB (28) were found in Port Chester site water, and all the PCB congeners except PCB(08), PCB(18), and PCB(184) was found in the Port Chester elutriate.

4.3 Toxicity

The contribution of the Port Chester composite to water-column toxicity relative to the Mud Dump Reference Site and the Central Long Island Sound Reference Site are presented in Figures 4.1 and 4. In water-column toxicity tests, 100% SPP treatments were acutely toxic to all three species tested. The LC_{50} values ranged from 75.1% SPP for *M. beryllina* to >100% SPP for *M. bahia* and *M. galloprovincialis* survival. The EC_{50} value for *M. galloprovincialis* normal development, a more sensitive measure than survival, was 53.7% SPP. The LPC for water-column effects outside of the disposal site boundaries after 4 h is 0.75% SPP for Port Chester sediment. A projection of SPP concentrations exceeding 0.75% SPP after 4 h at the Mud Dump Site boundary would be unacceptable.

The contribution of the Port Chester composite to benthic acute toxicity relative to the Mud Dump Reference Site and the Central Long Island Sound Reference Site are also presented in Figures 4.1 and 4.2.

(d) Number of compounds bioaccumulating in tissues of test species.

FIGURE 4.2. Summary Matrix of Port Chester Sediment Toxicity and Bioaccumulation Potential Compared with the Central Long Island Sound Reference Site

In the static renewal test with *A. abdita* exposed to Port Chester sediment, test organism survival was statistically significant and ≥20% different from that in the Mud Dump Reference and the Central Long Island Sound Reference Sites.

In the static renewal test with *R. abronius*, survival was statistically significant when compared with both reference site sediments, but there was not a ≥20% difference in survival relative to the Central Long Island Sound Reference Site. In the *M. bahia* static test, which was not manipulated to reduce porewater or overlying ammonia concentrations prior to test initiation, test organisms survival was 77% in the Port Chester sediment treatment. The survival percentage statistically significant, nor was this difference ≥10% from that in either of the two references.

4.4 Bioaccumulation

Results of *N. virens* And *M. nasuta* tissue analyses from test sediment bioaccumulation studies were compared with action levels for poisonous or deleterious substances in fish and shellfish for human consumption published by the FDA and with USACE-NYD (1981) bioaccumulation matrix tables. Concentrations of As, Cd, Cr, Ni, and Pb were also compared with the FDA level of concern for chronic shellfish consumption (FDA 1993a, 1993b, 1993c, 1993d, 1993e) for each of these metals. Results of tissue analyses from test sediment bioaccumulation studies were also compared with contaminant concentrations in tissues of organisms similarly exposed to Mud Dump Reference Site and Central Long Island Sound Reference Site sediments.

When *N. virens* and *M. nasuta* were exposed to Port Chester sediment in 28-day bioaccumulation tests, concentrations of some contaminants were elevated in tissues of both species. Concentrations of metals were generally higher in *M. nasuta* than in *N. virens*. Pesticide and PCB concentrations were similar in the two species, with some analytes higher in the *N. virens*, and others higher in the *M. nasuta*. Concentrations of PAHs were higher in *M. nasuta*, many compounds by a factor of 4 to 10 times, than in *N. virens*.

When tissue burdens of organisms exposed to Port Chester sediment were compared with those exposed to Mud Dump Reference Site and Central Long Island Sound Reference Site sediment, the tissue burdens were statistically significant and elevated for metals, pesticides, PCBs, and PAHs in both *M. nasuta* and *N. virens* tissues. Figures 4.1 and 4.2 show bioaccumulation potential as the number of contaminants that were elevated in the tissues of

M. nasuta and *N. virens* at certain magnitudes (i.e. 2, 5, or 10 times) above tissues of each species exposed to each reference sediment. This format clearly indicates where and to what degree similar classes of contaminants were accumulated in both species.

Table 4.1 compares the FDA action levels for poisonous or deleterious substances in fish and shellfish for human consumption for selected pesticides, and FDA levels of concern for chronic shellfish consumption for selected metals with the mean concentration of these contaminants found in tissues of each test species. The *N. virens* and *M. nasuta* tissues exposed to Port Chester sediment had tissue body burdens that were lower than the FDA levels for each of these selected contaminants.

TABLE 4.1. Comparison of Contaminant Concentrations in *N. virens* and *M. nasuta* Tissues Exposed to Proposed Dredged Material from Port Chester with FDA Action Levels and Levels of Concern

Substance	FDA Level (mg/kg wet wt)	Concentrations[a] in *N. virens* Tissues (mg/kg wet wt) Port Chester Composite	Concentrations[b] in *M. nasuta* Tissues (mg/kg wet wt) Port Chester Composite
Chlordane[b]	0.3[c]	0.005	0.004
Total DDT[d]	5.0[c]	0.0489	0.0219
Dieldrin + Aldrin	0.3[c]	0.010	0.005
Heptachlor+ Heptachlor epoxide	0.3[c]	<0.0002	0.0004
Total PCBs[e]	2.0[c]	0.189	0.067
Arsenic	86[f]	1.85	3.03
Cadmium	3.7[f]	0.102	0.208
Chromium	13[f]	<0.218	0.436
Lead	1.7[f]	0.388	0.721
Nickel	80[f]	0.302	0.559
Methyl Mercury	1.0[f]	0.007[g]	0.015[g]
Total DDT[d]	0.04[h]	0.0489	0.0219
Total PCBs[e]	0.40[h]	0.189	NA [i]
Total PCBs[e]	0.10[h]	NA	0.067
Total Mercury	0.20[h]	0.007	0.015
Cadmium	0.30[h]	0.102	0.208

(a) Concentration shown is the mean of five replicate tissue analysis. If any constituents were undetected, one-half of the detection limit was used in calculation of the mean concentration.
(b) Sum of a-chlordane and *trans*-nonachlor only, whereas FDA action level is a sum of nine chlordane analytes.
(c) FDA action levels for poisonous and deleterious substances in fish and shellfish for human food.
(d) Sum of mean values for 2,4'-DDT, 4,4'-DDT, 2,4'-DDE, and 4,4'-DDE, 2,4'-DDD, and 4,4'-DDD. One-half of the detection limit was used in the summation when mean values were undetected in a replicate.
(e) Total PCBs= 2.0(x), where x equals the sum of the 22 congeners. One-half of the detection limit was used in summation when mean values were undetected in a replicate.
(f) FDA level of concern for chronic shellfish consumption.
(g) Value reported here is for total mercury.
(h) NYD bioaccumulation matrix value designated in 1981 (USACE 1981).
(i) NA Not applicable.

Appendix A

Quality Assurance/Quality Control Data for Sediment Physical/Chemical Analyses, Port Chester Project

QA/QC SUMMARY

PROGRAM: New York/New Jersey Federal Projects-2

PARAMETER: Grain Size, Bulk Density, Specific Gravity and Total Solids

LABORATORY: Soil Technology, Bainbridge Island, Washington

MATRIX: Sediment

QA/QC DATA QUALITY OBJECTIVES

	Reference Method	Range of Recovery	SRM Accuracy	Relative Precision	Detection Limit (dry wt)
Grain Size	ASTM D-2217 and D-422	N/A	N/A	≤20%	1.0%
Bulk Density	ASTM D-854	N/A	N/A	≤20%	N/A
Specific Gravity	EM 1110-2-1906	N/A	N/A	≤20%	N/A
Total Solids	Plumb 1981	N/A	N/A	N/A	1.0%

METHOD Grain size was measured for four fractions using a combination of sieve and pipet techniques, following ASTM method D-2217 and D-422 for wet sieving. Bulk density was measured in accordance with ASTM method D-854. Specific gravity was measured in accordance with USACE Method EM 1110-2-1906. Total solids were measured gravimetrically following Plumb (1981).

HOLDING TIMES Samples were analyzed within the 6 month holding time.

DETECTION LIMITS Target detection limits of 1.0% by weight for each fraction were met for all samples.

METHOD BLANKS Not applicable.

MATRIX SPIKES Not applicable.

REPLICATES Six samples were analyzed in triplicate for grain size for the entire set of NY/NJ Federal Projects-2 program. Precision was measured by calculating the relative standard deviation (RSD) among triplicate results. The RSD's ranged from 0% to 10%, indicating acceptable precision. Two samples were analyzed in duplicate for bulk density and specific gravity. Precision was measured by calculating the relative percent difference (RPD) between the replicate results. The RPDs for bulk density were 0% and 2% while the RPDs for specific gravity were both 1%, indicating acceptable precision of the methods.

For total solids, three samples were analyzed in duplicate and four samples were analyzed in triplicate. All RSDs and RPDs were 0%.

QA/QC SUMMARY/GRAIN SIZE, BULK DENSITY, SPECIFIC GRAVITY and TOTAL SOLIDS (continued)

SRMs Not applicable.

QA/QC SUMMARY

PROGRAM: New York/New Jersey Federal Projects-2

PARAMETER: Total Organic Carbon (TOC)

LABORATORY: Global Geochemistry, Canoga Park, California

MATRIX: Sediment

QA/QC DATA QUALITY OBJECTIVES

Reference Method	Range of Recovery	SRM Accuracy	Relative Precision	Detection Limit (dry wt)
EPA 1986	N/A	≤20%	≤10%	0.1%

METHOD TOC was analyzed in accordance with EPA (1986). Analysis was performed by combustion and quantitation of evolved carbon dioxide using a LECO analyzer.

HOLDING TIMES Samples were analyzed within the 6 month holding time.

DETECTION LIMITS Target detection limits of 0.1% was met for all samples.

METHOD BLANKS Thirty-four method blanks were analyzed with the entire set of NY/NJ Federal Projects-2 program sediment samples. TOC levels detected in blanks ranged from 0.001% to 0.008% which were less than the established detection limit.

MATRIX SPIKES Not applicable.

REPLICATES Four samples were analyzed in triplicate and three samples were analyzed in duplicate. Precision was measured by calculating the relative standard deviation (RSD) or relative percent difference (RPD) between the replicate results. All RSDs and RPDs were between 1% and 10% indicating acceptable precision of the method.

SRMs Standard reference material MESS-1, obtained from the National Research Council of Canada, was analyzed at least once per batch of sediment samples. Although MESS-1 is not certified for TOC, accuracy was measured by calculating the percent difference (PD) from the in-house consensus value. PD values reported ranged from 1% to 8%.

QA/QC SUMMARY

PROGRAM: New York/New Jersey Federal Projects-2

PARAMETER: Metals

LABORATORY: Battelle/Marine Sciences Laboratory, Sequim, Washington

MATRIX: Sediment

QA/QC DATA QUALITY OBJECTIVES

	Reference Method	Range of Recovery	SRM Accuracy	Relative Precision	Achieved Detection Limit (mg/kg dry wt)
Arsenic	ICP/MS	75-125%	≤20%	≤20%	0.572
Cadmium	ICP/MS	75-125%	≤20%	≤20%	0.020
Chromium	ICP/MS	75-125%	≤20%	≤20%	0.401
Copper	ICP/MS	75-125%	≤20%	≤20%	0.525
Lead	ICP/MS	75-125%	≤20%	≤20%	0.136
Mercury	CVAA	75-125%	≤20%	≤20%	0.001
Nickel	ICP/MS	75-125%	≤20%	≤20%	0.849
Silver	ICP/MS	75-125%	≤20%	≤20%	0.119
Zinc	ICP/MS	75-125%	≤20%	≤20%	2.55

METHOD

A total of nine metals was analyzed: silver (Ag), arsenic (As), cadmium (Cd), chromium (Cr), copper (Cu), mercury (Hg), nickel (Ni), lead (Pb) and zinc (Zn). Hg was analyzed using cold-vapor atomic absorption spectroscopy (CVAA) according to the method of Bloom and Crecelius (1983). The remaining metals were analyzed by inductively coupled plasma mass spectrometry (ICP/MS) following EPA Method 200.8 (EPA 1991)

To prepare sediment samples for analysis, samples were freeze-dried and blended in a Spex mixer-mill. Approximately 5 g of mixed sample was ground in a ceramic ball mill. For ICP/MS and CVAA analyses, 0.2- to 0.5-g aliquots of dried homogenous sample were digested using nitric acid following modified EPA Method 200.2 (EPA 1991). Sediment samples initially showed poor matrix spike recovery for Ag. (Refer to Matrix Spike section of this QA/QC Summary.) EPA Method 200.2 was modified by the addition of aqua regia to the digestion procedure and all samples were reanalyzed for Ag.

HOLDING TIMES

Samples were received on 3/30/94 and were logged into Battelle's log-in system. Samples were frozen to -80°C and subsequently freeze dried. Samples were all analyzed within 180 days of collection. The following list summarizes all analysis dates:

Task	Date Performed
Sample Digestion	5/5/94
ICP-MS	5/20/94
CVAA-Hg	5/9/94

QA/QC SUMMARY/METALS (continued)

DETECTION LIMITS Target detection limits were exceeded for some metals; however, metals were detected above the MDLs in all samples with the exception of Ag in one sample. MDLs were determined by multiplying the standard deviation of the mean of four replicate low level sediment spikes by 3.5.

METHOD BLANKS Two method blanks were analyzed. No metals were detected above the MDL in either blank with the exception of Pb in Blank-2. The value was less than three times the MDL and all sample values were detected at levels greater than five times the blank concentration, so no data were flagged. All data were blank corrected.

MATRIX SPIKES Two samples were spiked with all nine metals. In the original set of matrix spikes, recoveries of all metals, with the exception of Ag, were within the QC limits of 75% to 125%. Recoveries of Ag in the original spikes were low (3% and 10%). After reanalysis of the matrix spikes with the addition of aqua regia to the digestion procedure (see Methods section of this QA/QC Summary), matrix spike recoveries improved (93%) and concentrations of Ag in the dredging site sediments increased slightly. The low recovery of Ag appears to occur in analysis of marine sediment samples having high (in excess of approximately 5 µg/g) Ag concentrations. During the EPA Method 200.2 digestion procedure, a precipitate of AgCl can form with the Ag in the sediment and the Cl in the seawater.

REPLICATES Two samples were digested and analyzed in triplicate. Precision of triplicate analyses is reported by calculating the relative standard deviation (RSD) between the replicate results. RSD values ranged from 1% to 5%, within the QC limits of ±20%, indicating acceptable precision.

SRM Standard Reference Material (SRM) 1646 (estuarine sediment from the National Institute of Standards and Technology [NIST]), was analyzed for all metals. Only results for Cd, Cu and Hg were within ±20% of the certified value (Ag is not certified). Results for As, Ni, and Pb were between 20 and 30% of the certified values. The poorest result was with Cr, where the mean was 46% of the certified value. Values for the remaining metals were low because the digestion method used is not as strong as the method (perchloric acid) used to certify the SRM; thus, the results of this analysis should not be expected to match the SRM certified values. Therefore, no corrective actions were taken.

QA/QC SUMMARY

PROGRAM: New York/New Jersey Federal Projects-2

PARAMETER: Additional Metals

LABORATORY: Battelle/Marine Sciences Laboratory, Sequim, Washington

MATRIX: Sediment

QA/QC DATA QUALITY OBJECTIVES

	Reference Method	Range of Recovery	SRM Accuracy	Relative Precision	Achieved Detection Limit (mg/kg dry wt)
Antimony	ICP/MS	75-125%	≤20%	≤20%	0.03
Beryllium	ICP/MS	75-125%	≤20%	≤20%	0.5
Selenium	GFAA	75-125%	≤20%	≤20%	0.13
Thallium	ICP/MS	75-125%	≤20%	≤20%	0.024

METHOD

An additional four metals were analyzed for a subset of sediment samples: Antimony (Sb), Beryllium (Be), Selenium (Se) and Thallium (Tl).

To prepare sediment samples for analysis, samples were freeze-dried and blended in a Spex mixer-mill. Approximately 5 g of mixed sample was ground in a ceramic ball mill. For inductively coupled plasma mass spectrometry (ICP/MS) and graphite furnace atomic absorption (GFAA) analyses, 0.2- to 0.5-g aliquots of dried homogenous sample were digested according to EPA Method 200.2 (EPA 1991), modified by the addition of aqua regia to the digestion procedure. Se was analyzed using GFAA. The other three metals were analyzed by ICP/MS following EPA Method 200.8 (EPA 1991).

HOLDING TIMES

Samples were received on 3/30/94 and was logged into Battelle's log-in system. Samples were frozen to -80°C and subsequently freeze-dried. According to instructions from the program manager, 21 samples were composited into 8 samples. A subset of 17 samples (the Port Chester and Eastchester sediment composites) were analyzed for an additional four metals as requested in a memo from the program manager dated 1/11/95. The following list summarizes all analysis dates:

Task	Date Performed
Aqua Regia	2/1/95
ICP/MS - Sb, Be, Tl	3/7/95
GFAA - Se	2/7/95

DETECTION LIMITS

Target detection limits were met for Sb, Se, and Tl. The detection limit (DL) for Be exceeds the target detection limit. However, all but three values were greater than the estimated DL and these values were flagged with a J to indicate an estimation.

QA/QC SUMMARY/ADDITIONAL METALS (continued)

METHOD BLANKS Two method blanks were analyzed. Only Sb was detected in one of the blanks; however, the values were less than three times the MDL and all sample values were detected at levels greater than five times the blank concentration. Therefore, no data were flagged and all data were blank corrected.

MATRIX SPIKES One sample was spiked with all four metals. Recoveries of all metals except Sb (228%) were within the QC limits of 75% to 125%.

REPLICATES One sample was digested and analyzed in triplicate. Precision for triplicate analyses is reported by calculating the relative standard deviation (RSD) between replicate results. RSD values ranged from 2% to 12%, which is within the QC limits of ±20%, indicating acceptable precision.

SRM SRM 1646 (estuarine sediment from the National Institute of Standards and Technology [NIST]), was analyzed for all metals. None of the four additional metals are certified. However, non-certified values are reported and all four metals, with the exception of one replicate for Sb, are within 39% of the non-certified values.

EPA (U.S. Environmental Protection Agency). 1991. *Methods for the Determination of Metals in Environmental Samples.* EPA-600/4-91-010. Environmental Services Division, Monitoring Management Branch, Washington D.C.

QA/QC SUMMARY

PROGRAM: New York/New Jersey Federal Projects-2

PARAMETER: Chlorinated Pesticides, PCB Congeners, and 1,4-Dichlorobenzene

LABORATORY: Battelle Ocean Sciences, Duxbury, Massachusetts

MATRIX: Sediment

QA/QC DATA QUALITY OBJECTIVES

Reference Method	MS Recovery	Surrogate Recovery	SRM Accuracy	Relative Precision	Detection Limit (dry wt)
GC/ECD	50-120%	30-150%	≤30%	≤30%	1.0 - 20 ng/g

METHOD Sediment samples were extracted with methylene chloride according to a modified version of EPA Method 8080 and the National Oceanic and Atmospheric Administration (NOAA) Status and Trends cleanup procedure (Krahn et al. 1988). Extracts were analyzed using gas chromatography with electron capture detection (GC/ECD) following a modified version of EPA Method 8270. Pesticide detections were qualitatively confirmed on a secondary column.

HOLDING TIMES Samples were collected from 3/22/94 through 3/25/94, and after compositing, were held frozen at -20°C until shipment to the analytical laboratory. Sediment samples were received by Battelle Ocean Sciences on 4/22/94. Samples were held frozen at -20°C until extraction and analysis. Samples were extracted by 5/6/94 and analyzed from 6/2/94 to 6/29/94.

DETECTION LIMITS Target detection limits were exceeded for most of the analytes. Actual detection limits were determined by the Method Detection Limit (MDL) verification study. Four sediment samples with very low background concentrations of contaminants were spiked with target compounds. For each analyte, the standard deviation of the four spiked replicates was multiplied by 3.5.

METHOD BLANKS One method blank was extracted with batch of samples. No pesticides or PCB congeners were detected in the blank.

SURROGATES Two compounds, DBOFB and PCB congener 112, were added to all samples prior to extraction to assess the efficiency of the analysis. The mean recoveries of DBOFB and PCB 112 were 71% and 60%, respectively. Recoveries of these compounds were within the QC guidelines of 30% -150% for all samples analyzed.

MATRIX SPIKES One sample in each batch was spiked with pesticides and PCB congeners. Recoveries for PCB congener CL_2 (25% and 47%) fell below the acceptable criteria of 50% to 120%. The reason for this low recovery is probably that the PCB congener CL_2 coeluted with alpha-BHC. All other PCB congener recoveries ranged from 54% to 121%. Recoveries for all pesticides and 1,4-dichlorobenzene ranged from 57% to 115%. Since >80% of all analytes were between 50% and 120%, no corrective action was taken.

QA/QC SUMMARY/CHLORINATED PESTICIDES and PCB CONGENERS (continued)

REPLICATES

One sample from each batch was extracted in triplicate. Precision was measured by calculating the relative standard deviation (RSD) between the replicate results. RSDs were evaluated only when pesticides or PCB congeners were detected in all three replicates. RSDs ranged from 5% to 114%. Six of the RSDs were greater than 30% but of those six, only three were for analytes that were >10 times the MDL. These three were 31% for CL_3(18), 114% for CL_5(105) and 52% for CL_6(138).

SRMs

One SRM, 1941a, a marine sediment sample obtained from the National Institute of Science and Technology (NIST) was analyzed with each batch. Many of the values exceeded the acceptable criteria of ≤30%; however all were <10 times the MDL. Percent differences were calculated using SRM concentrations that were corrected for surrogate recovery.

QA/QC SUMMARY

PROGRAM: New York/New Jersey Federal Projects-2

PARAMETER: Polynuclear Aromatic Hydrocarbons (PAH)

LABORATORY: Battelle Ocean Sciences, Duxbury, Massachusetts

MATRIX: Sediment

QA/QC DATA QUALITY OBJECTIVES

Reference Method	MS/MSD Recovery	Surrogate Recovery	SRM Accuracy	Relative Precision	Detection Limit (dry wt)
GC/MS/SIM	50-120%	30-150%	≤30%	≤30%	10 ng/g

METHOD

Sediment samples were extracted according to a modified version of EPA Method 8080 and the NOAA Status and Trends cleanup procedure (Krahn et al. 1988). Extracts were analyzed using gas chromatography/mass spectrometry (GC/MS) in the selected ion mode (SIM) following a modified version of EPA Method 8270.

HOLDING TIMES

Samples were collected from 3/22/94 through 3/25/94, and after compositing, were held frozen at -20°C until shipment to the analytical laboratory. Sediment samples were received by Battelle Ocean Sciences, Duxbury, Massachusetts, on 4/22/94. Samples were held frozen at approximately -20°C until extraction and analysis. Samples were extracted by 5/6/94 and analyzed from 5/16/94 to 6/28/94.

DETECTION LIMITS

Target detection limits of 10 ng/g dry weight were met for most of the PAH compounds. Actual detection limits were determined by the Method Detection Limit (MDL) verification study. Four sediment samples with very low background concentrations of contaminants were spiked with target compounds. For each analyte, the standard deviation of the four spiked replicates was multiplied by 3.5. Actual detection limits ranged from 7.18 to 20.84 µg/kg.

METHOD BLANKS

One method blank was extracted with each batch of samples. No PAH compounds were detected above the MDL; however, 2 of the 17 compounds were detected below the MDL and are flagged with a "J" to indicate the values are estimates. They are pyrene in Batch 1 and naphthalene in Batch 2.

SURROGATES

Three isotopically labelled compounds were added prior to extraction to assess the efficiency of the method. These were naphthalene-d_8, acenaphthene-d_{10}, and chrysene-d_{12}. Recoveries of surrogates were within the quality control limits of 30% -150% with one exception. For Batch 1, mean recoveries of naphthalene-d_8, acenaphthene-d_{10}, and chrysene-d_{12} were 52%, 59%, and 48%, respectively. In one sample, recovery of chrysene-d_{12} was 28%. For Batch 2, mean recoveries of naphthalene-d_8, acenaphthene-d_{10}, and chrysene-d_{12} were 62%, 64%, and 57%, respectively.

QA/QC SUMMARY/PAHs (continued)

MATRIX SPIKES

One sample was spiked with all PAH compounds for each batch. Matrix spike recoveries for all analytes in Batch 2 ranged from 57% to 67%. Matrix spike recoveries for all analytes in Batch 1 ranged from 26% to 73%. Six of the analytes in Batch 1 fell outside the acceptable ranges of 50% to 120%. They are 48% for fluoranthene; 47% for pyrene; 44% for benzo[a]anthracene; 38% for chrysene; 26% for benzo[b]fluoranthene; and 32% for benzo[a]pyrene. These PAHs were present at naturally elevated levels in the background sample. A blank spike was prepared with this batch and had acceptable recoveries for all target PAHs. As a result, it appears that the failure of selected PAHs to meet the recovery criteria is related to the sediment sample. The recoveries of PAHs in the MS sample for Batch 2 met the acceptance criteria.

REPLICATES

One sample was extracted in triplicate for each batch. Precision was measured by calculating the relative standard deviation (RSD) between the replicate results. The RSDs ranged from 1% to 20%, within the target precision goal of ≤30%.

SRMs

One SRM,1941a, a marine sediment sample obtained from the National Institute of Standards and Technology, was analyzed with each batch of samples. Twelve of the 17 PAH compounds analyzed are certified at levels above the MDLs. Of these, all compounds were detected within 30% of the certified mean, with the exception of chrysene (58% and 73%), benzo[b]fluoranthene (32% and 45%), and dibenz[a,h]anthracene (63% and 40%) in both batches. Percent differences were calculated using SRM concentrations that were corrected for surrogate recovery.

TABLE A.6. (contd)

Qualifiers

(a) Sample concentration of the procedural blank adjusted for the average sample size of the batch.
(b) NA Not applicable.
(c) U Undetected at or above given concentration.
(d) NS Not spiked.
(e) J Concentration estimated; analyte detected below method detection limit (MDL), but above instrument detection limit (IDL).
(f) Analyte required only in samples designated for Central Long Island Disposal Testing Site.
(g) Outside quality control criteria (50-120%) for matrix spike recoveries.
(h) Percent Difference from certified
= absolute value [(certified value ,µg/kg - value detected corrected for surrogate recovery, µg/kg) / certified value, µg/kg].
(i) NC No certified value available.
(j) C Analyte not determined due to co-eluting peak.
(k) Outside quality control criteria (±30%) for replicates.

Site Water and Elutriate Chemical Analyses and Quality Assurance/Quality Control Data, Port Chester Project

QA/QC SUMMARY

PROGRAM: New York/New Jersey Federal Projects-2

PARAMETER: Metals

LABORATORY: Battelle/Marine Sciences Laboratory, Sequim, Washington

MATRIX: Site Water and Elutriate

QA/QC DATA QUALITY OBJECTIVES

	Reference Method	Range of Recovery	SRM Accuracy	Relative Precision	Target Detection Limit (µg/L)
Cadmium	ICP/MS	75-125%	≤20%	≤20%	0.025
Chromium	GFAA	75-125%	≤20%	≤20%	1.0
Copper	ICP/MS	75-125%	≤20%	≤20%	0.35
Lead	ICP/MS	75-125%	≤20%	≤20%	0.35
Mercury	CVAA	75-125%	≤20%	≤20%	0.002
Nickel	ICP/MS	75-125%	≤20%	≤20%	0.3
Silver	ICP/MS	75-125%	≤20%	≤20%	0.25
Zinc	GFAA	75-125%	≤20%	≤20%	0.15

METHOD

A total of eight metals was analyzed in water and elutriate samples: silver (Ag), cadmium (Cd), chromium (Cr), copper (Cu), mercury (Hg), nickel (Ni), lead (Pb) and zinc (Zn). Hg was analyzed using cold-vapor atomic absorption spectroscopy (CVAA) according to the method of Bloom and Crecelius (1983). Cr and Zn were analyzed by Graphite Furnace Atomic Absorption (GFAA) spectrometry following the EPA Method 200.9 (EPA 1991). The remaining metals were analyzed by inductively coupled plasma mass spectrometry (ICP/MS) following a procedure based on EPA Method 200.8 (EPA 1991).

All water and elutriate samples were acidified to pH <2 upon receipt in the laboratory. Five metals, Cd, Cu, Pb, Ni and Ag, were extracted from the water according to a procedure based on EPA Method 218.3 (EPA 1979). This preconcentration involves addition of a chelating agent which results in precipitation of the metals from solution, followed by filtration, and digestion of the filter in concentrated acid in order to achieve low detection limits. The digestates were then analyzed by ICP/MS as described above.

HOLDING TIMES

Twelve site water samples (for triplicate analysis) were received on 3/24/94. Five elutriate samples (for triplicate analysis) were received on 4/11/94, and another five elutriate samples (for triplicate analysis) were received on 4/16/94. All samples were received in good condition, assigned ID numbers according to Battelle's log-in system, acidified to pH<2 with concentrated nitric acid, and held at ambient temperature until analysis.

QA/QC SUMMARY/METALS (continued)

Mercury in water has a holding time of 28 days from collection to analysis. All samples were analyzed within this holding time. Samples were analyzed for the remaining metals within 180 days of collection. Samples were received, digested, and analyzed in two batches, Batch 1a/1b (site waters), and Batch 2 (elutriate). The following table summarizes analysis dates:

	Date	
Task	Batch 1a/1b	Batch 2
APDC Extraction	6/13/94	5/24/94
ICP-MS	7/14/94	7/14/94
CVAA-Hg	4/26-28/94	5/9/94
GFAA-Cr	1a: 5/5/94 1b: 5/6/94	5/9/94
GFAA-Zn	5/16/94	5/16/94

DETECTION LIMITS

Target detection limits were met for all metals except Zn. Detection limits for Zn exceeded the target limits; however, all sample values were well above the detection limits achieved. Method Detection Limits (MDLs) for Ag, Cd, Cu, Hg, Ni and Pb were determined by spiking eight replicates of laboratory deionized water and multiplying the standard deviation of the resulting analysis by the Student's t value for n=8. MDLs reported for Cr and Zn were determined by taking the standard deviation of three replicate analyses of the method blank and multiplying the standard deviation by 3. An MDL verification study was performed within the previous year by spiking four replicates of Sequim Bay seawater and multiplying the standard deviation of the resulting analysis by 4.451. All sample MDLs were lower than the MDL verification values.

METHOD BLANKS

Method blanks were generated during the APDC extraction step and analyzed for the metals that were preconcentrated (Ag, Cd, Cu, Ni and Pb.) The blanks reported for Hg, Cr and Zn (the metals analyzed by direct injection of water samples) consist of a dilute nitric acid solution used to dilute all samples for analysis. For Batch 1a/1b, two APDC procedural blanks were analyzed and no APDC metals were detected in the blanks. Cr and Zn were detected in the blank; Cr at levels less than three times the MD, and Zn at levels greater than three times the MDL. All data were corrected for the blank concentrations, and no data were flagged. For Batch 2, two APDC procedural blanks were analyzed and no APDC metals were detected in the blanks. Zn and Cr were detected in the blank at levels less than three times the MDL. All data were corrected for the blank concentrations.

MATRIX SPIKES

Two samples were spiked in duplicate with all metals except Hg, which was spiked on two single samples. The APDC metals (Ag, Cd, Cu, Ni and Pb) were spiked prior to sample processing and the other metals were spiked just prior to analysis. For Batch 1a/1b, all recoveries were within the QC limits of 75% -125%, with the exception of Ag, Cd, and Cu in some of the spikes. Spike recoveries for these metals ranged from 70% to 74%, just below the lower QC limit. No action was taken. For Batch 2, all recoveries were within the QC limits of 75% -125% with the exception of Pb and Ni in one direct spike. Because Pb and

Ni values for the other spikes were acceptable, no further action was taken.

REPLICATES

Each sample was analyzed in triplicate. Precision for triplicate analyses was reported by calculating the relative standard deviation (RSD) of the replicate results. For Batch 1a/1b, RSD values were within the QC limits of ±20%, with the exception of Hg, Pb, and Ni on one sample. For Batch 2, RSD values were all within the QC limits of ±20%, with the exception of Cd in one sample and Ag in two samples.

SRMs

Standard Reference Material (SRM), CASS-2, a certified seawater sample from the National Institute of Standards and Technology, (NIST), was analyzed for all metals with the exception of Ag and Hg, which are not certified in this SRM. Results for all metals were within ±20% of mean certified value. Cd and Pb are certified below the MDL and were not detected.

A second SRM, 1641b, a freshwater sample from NIST, was analyzed twice for Hg. Results were within ±20% of mean certified value. No salt water SRMs certified for Ag are available.

A third SRM, 1643c, a freshwater sample from NIST, was analyzed for all metals except Hg. All metals were recovered within ±20% of mean certified value.

QA/QC SUMMARY

PROGRAM: New York/New Jersey Federal Projects-2

PARAMETER: Chlorinated Pesticides and PCB Congeners

LABORATORY: Battelle Ocean Sciences

MATRIX: Site Water and Elutriate

QA/QC DATA QUALITY OBJECTIVES

Reference Method	Surrogate Recovery	MS Recovery	Relative Precision	Detection Limit
GC/ECD	30-150%	50-120%	≤30%	2-20 ng/L

SAMPLE CUSTODY Twelve site water samples (in triplicate) were received on 3/31/94. Five elutriate samples (in triplicate) were received on 4/15/94, and another six elutriate samples (in triplicate) were received on 4/19/94. All samples were received in good condition, assigned ID numbers according to Battelle's log-in system, and stored at approximately 4°C until extraction.

METHOD Water samples were extracted with methylene chloride in a separatory funnel under ambient conditions following a procedure based on the National Oceanic and Atmospheric Administration (NOAA) Status and Trends Program method (Krahn et al. 1988). Sample extracts were passed through a silica/alumina (5% deactivated) chromatography column followed by high performance liquid chromatography (HPLC) cleanup (Krahn et al. 1988). Extracts were analyzed for 15 chlorinated pesticides using gas chromatography with electron capture detection (GC/ECD) following a procedure based on EPA Method 8080 (EPA 1986). The GC column used was a J&W DB-17 capillary column (30-m x 0.25-mm I.D.) with confirmatory analysis on a DB-1701 column (also 30-m x 0.25-mm I.D.).

HOLDING TIMES Samples were extracted in four batches: Batches 1 and 2 consisted of site waters; Batches 3 and 4 were elutriate samples. The following table summarizes sample extraction and analysis dates for each batch:

Batch No.	Receipt	Extraction	Analysis
1	3/31/94	4/5/94	4/22-26/94
2	3/31/94	4/5/94	4/26-28/94
3	4/15/94	4/19/94	5/5-7/94
4	4/19/94	4/22/94	5/13-15/94

DETECTION LIMITS Target detection limits (DLs) were met for all pesticides except endosulfan II in some samples (target DL for endosulfan II was 4 ng/L; achieved DL was 11 ng/L).

QA/QC SUMMARY/PESTICIDES AND PCBS (continued)

METHOD BLANKS One method blank (Sequim Bay seawater) was extracted with each extraction batch for a total of four method blanks. No pesticides or PCBs were detected in any of the method blanks.

SURROGATES Two compounds, dibromooctafluorobiphenyl (DBOFB) and PCB congener 112, were added to all samples to assess the efficiency of the analysis. Sample surrogate recoveries were all within the QC guidelines of 30% -150%.

MATRIX SPIKES One water sample in each batch (for a total of four) was spiked with 11 pesticides and 19 PCB congeners. Matrix spike recoveries were within the control limit range of 50-120% with the following exceptions: In the Batch 1, 2, 3, and 4 spike, recovery of PCB 8 was unacceptable due to interference from coelution of the non-target pesticide, alpha-BHC. In the batch 2 matrix spike, recovery of PCB 18 was 48%. In the Batch 3 matrix spike, recovery of endosulfan I/2,4'DDE was 123% and recovery of heptachlor epoxide was 125%. No action was taken.

REPLICATES Each sample was extracted and analyzed in triplicate. Precision was measured by calculating the relative standard deviation (RSD) of the replicate results. The target precision goal was ≤30% RSD for analytes >10 times the Method Detection Limit (MDL). RSDs ranged from 6% to 79%, however, the majority of mean concentrations of all analytes (in each set of triplicate samples) were <10 times the detection limit. Twenty-five PCB/pesticides had a mean >10 times the detection limit and had an RSD of >30%. These RSDs ranged from 31% to 64%.

(a) Sample concentration of the method blank adjusted for the average sample size of the batch.
(b) U Undetected at or above concetntration shown.
(c) NS Not spiked.
(d) NA Not applicable.
(e) C PCB congener 08 coeluted with non-target pesticide a-BHC, resulting in unacceptable recovery in matrix spike samples.
(f) NC Percent recovery not calculated due to coeluting peak.
(g) J Concentration estimated; analyte detected below method detection limit (MDL) and above instrument detection limit (IDL).
(h) Outside quality control criteria (50-120%) for matrix spike recovery.

(a) % RSD Percent relative standard deviation.
(b) U Undetected at or above concentration shown.
(c) NA Not applicable.
(d) J Concentration estimated; analyte detected below method detection limit (MDL) and above instrument detection limit (IDL).
(e) Outside quality control criteria (≤ 30% for replicate analysis) for analytes >10 times the achieved MDL.

Mercury	CVAA	75-125%	≤20%	≤20%	0.02
Nickel	ICP/MS	75-125%	≤20%	≤20%	0.1
Silver	ICP/MS	75-125%	≤20%	≤20%	0.1
Zinc	ICP/MS	75-125%	≤20%	≤20%	1.0

METHOD

A total of nine (9) metals was analyzed for the New York Federal Projects-2 Program: silver (Ag), arsenic (As), cadmium (Cd), chromium (Cr), copper (Cu), mercury (Hg), nickel (Ni), lead (Pb) and zinc (Zn). Hg was analyzed using cold-vapor atomic absorption spectroscopy (CVAA) according to the method of Bloom and Crecelius (1983). The remaining metals were analyzed by inductively coupled plasma mass spectrometry (ICP/MS) following a procedure based on EPA Method 200.8 (EPA 1991).

To prepare tissue for analysis, samples were freeze-dried and blended in a Spex mixer-mill. Approximately 5 g of mixed sample was ground in a ceramic ball mill. For ICP/MS and CVAA analyses, 0.2- to 0.5-g aliquots of dried homogenous sample were digested using a mixture of nitric acid and hydrogen peroxide following EPA Method 200.3 (EPA 1991).

HOLDING TIMES

A total of 68 worm and 68 clam samples was received on 6/15/94 in good condition. Samples were logged into Battelle's log-in system, frozen to -80°C and subsequently freeze dried within approximately 7 days of sample receipt. Samples were analyzed within 180 days of collection. Worms and clams were digested in two separate batches. The following table summarizes the analysis dates:

Task	Clams	Worms
Sample Digestion	8/9/94	9/9/94
ICP-MS	9/15/94	10/6/94
CVAA-Hg	8/17-8/24/94	8/17-8/24/94

QA/QC SUMMARY METALS (continued)

DETECTION LIMITS Four aliquots of a background clam tissue were analyzed as four separate replicates. The standard deviation of these results were multiplied by 4.541 to determine a method detection limits (MDL). Target detection limits were exceeded for all metals except Ag, Cd and Hg.

METHOD BLANKS One procedural blank was analyzed per 20 samples. No metals were detected in the blanks above the MDLs.

MATRIX SPIKES One sample was spiked with all metals at a frequency of 1 per 20 samples. All recoveries were within the QC limits of 75% -125% with the exception of Ag in one spiked worm sample and Zn in three of the four spiked worm samples. Zn was spiked at a level near the level found in the native samples and, in one case, Zn was spiked at a level below that detected in the native sample and no recovery was calculated.

REPLICATES One sample was analyzed in triplicate at a frequency of 1 per 20 samples. Precision for triplicate analyses is reported by calculating the relative standard deviation (RSD) between the replicate results. Only the RSDs for Zn in one of the four replicated worm analyses exceeded the QC limits of ±20%. RSDs for the rest of the metals were within the QC limits.

SRMs Standard Reference Material (SRM), 1566a (Oyster tissue from the National Institute of Standards and Technology, NIST), was analyzed for all metals. Results for all metals were within ±20 % of mean certified value with the exception of Cr and Ni. Cr values were below the lower QC limit in two of the five SRMs analyzed with the clams and for three of the four SRMs analyzed with the worms. The SRM certified value for Cr (1.43 µg/g) is close to the detection limit (1.46 µg/g). Ni was also recovered below or above the control limits in some samples.

QA/QC SUMMARY

PROGRAM: New York/New Jersey Federal Projects-2

PARAMETER: Chlorinated Pesticides/PCB Congeners

LABORATORY: Battelle/Marine Sciences Laboratory, Sequim, Washington

MATRIX: Worm and Clam Tissue

QA/QC DATA QUALITY OBJECTIVES

Reference Method	Surrogate Recovery	Spike Recovery	Relative Precision	Detection Limit
GC/ECD	30-150%	50-120%	≤30%	0.4 ng/g wet wt.

SAMPLE CUSTODY A total of 68 worm and 68 clam samples was received on 6/15/94 in good condition. Samples were logged into Battelle's log-in system and stored frozen until extraction.

METHOD Tissues were homogenized wet using a stainless steel blade. An aliquot of tissue sample was extracted with methylene chloride using the roller technique under ambient conditions following a procedure which is based on methods used by the National Oceanic and Atmospheric Administration for its Status and Trends Program (Krahn et al. 1988). Samples were then cleaned using silica/alumina (5% deactivated) chromatography followed by HPLC cleanup (Krahn et al. 1988). Extracts were analyzed for 15 chlorinated pesticides and 22 PCB congeners using gas chromatography/electron capture detection (GC/ECD) following a procedure based on EPA Method 8080 (EPA 1986). The column used was a J&W DB-17 and the confirmatory column was a DB-1701, both capillary columns (30m x 0.25mm I.D.). All detections were quantitatively confirmed on the second column.

HOLDING TIMES Samples were extracted in seven batches. All extracts were analyzed by GC/ECD. The following summarizes the extraction and analysis dates:

Batch	Species	Extraction	Analysis
1	*M. nasuta*	7/28/94	9/9-9/12/94
2	*M. nasuta*	8/3/94	9/13-9/15/94
3	*M. nasuta*	8/17/94	9/23-9/25/94
4	*N. virens*	8/19/95	9/26-9/30/94
5	*N. virens*	8/26/94	9/8-9/11/94
6	*N. virens*	9/6/94	9/17-9/19/94
7	*M. nasuta/N. virens*	9/26/94	9/15-9/17-94
8	*M. nasuta* MDL study	10/10/94	10/25/94

DETECTION LIMITS Target detection limits of 0.4 ng/g wet weight were met for all pesticides and PCB congeners, with the exception of dieldrin, PCB 8 and PCB 18, and for the samples that were analyzed in triplicate. These elevated detection limits for the replicates were due to the limited amount of tissue available resulting in smaller aliquots used for extraction. Method detection limits (MDLs) reported were determined by multiplying the

standard deviation of seven spiked replicates of clam tissue by the Student's t value (99 percentile). Actual pesticide MDLs ranged from approximately 0.1 to 1.1 ng/g wet weight and PCB congener MDLs ranged from approximately 0.1 to 0.9 ng/g wet weight, depending on the compound and the sample weight extracted. MDLs were reported corrected for individual sample wet weight extracted.

Method detection limit verification was performed by analyzing four replicates of a spiked clam sample and multiplying the standard deviation of the results by 3.5. All detection limits calculated in this way were below the target detection limit of 0.4 ng/g wet weight with the exception of 4,4'-DDD which had a DL of 0.467 ng/g.

METHOD BLANKS

One method blank was extracted with each extraction batch. No pesticides or PCBs were detected in any of the method blanks.

SURROGATES

Two compounds, PCB congeners 103 and 198, were added to all samples prior to extraction to assess the efficiency of the analysis. Sample surrogate recoveries were all within the QC guidelines of 30% - 150%, with the exception of one sample in Batch 3 and two samples in Batch 4. All of these incidents involved a high recovery of PCB 198. This was most likely due to matrix interferences with the internal Standard octachloronaphthalene (OCN) which is used to quantify the recovery of surrogate PCB 198. Since no sample data are corrected for the OCN, sample results should not be affected. One sample had low surrogate recoveries for both PCB 103 and 198. This sample was re-extracted once due to surrogate recoveries. Since the recoveries in the reextraction also exceeded control limits, the problem was determined to be matrix interferences and no additional extractions were performed. Sample results were quantified using the surrogate internal standard method.

MATRIX SPIKES

Ten out of the 15 pesticides and 5 of the 22 PCB congeners analyzed were spiked into one sample per extraction batch. Matrix spike recoveries were within the control limit range of 50-120% for all Pesticides and PCBs in Batches 1, 2, 3, 6 and 7 with the exception of PCB 138 in Batch six and three pesticides and 2 PCBs in Batch seven. In all cases, the recoveries were high and are most likely due to matrix interferences. Recoveries for the majority of pesticides and PCBs in Batches four and five exceeded control limits due to high native levels compared with the levels spiked. In most cases, the spiked concentrations were 2 to 10 times lower than the concentrations detected in the samples.

REPLICATES

One sample from each extraction batch was analyzed in triplicate. Precision was measured by calculating the relative standard deviation (RSD) between the replicate results. RSDs for all detectable values were below the target precision goal of ≤30% in Batches 1, 2, 3, 4 and 7. The RSD for Endosulfan Sulfate in Batch 5 was high due to comparison of very low concentrations, less than 1 ng/g in the replicates. RSDs for two pesticides and for two PCB congeners in Batch 6 were high due to matrix interferences associated with the first replicate sample.

SRMs Not applicable.

MISCELLANEOUS All pesticide and PCB congener results are confirmed using a second dissimilar column. RPDs between the primary and confirmation values must be less than 75% to be considered a confirmed value.

QA/QC SUMMARY

PROGRAM: New York/New Jersey Federal Projects-2

PARAMETER: Polynuclear Aromatic Hydrocarbons (PAH) and 1,4-Dichlorobenzene

LABORATORY: Battelle/Marine Sciences Laboratory, Sequim, Washington

MATRIX: Clam and Worm Tissue

QA/QC DATA QUALITY OBJECTIVES

Reference Method	MS Recovery	Surrogate Recovery	SRM Accuracy	Relative Precision	Detection Limit (wet wt)
GC/MS/SIM	50-120%	30-150%	≤30%	≤30%	4 ng/g

SAMPLE CUSTODY A total of 68 worm and 68 clam samples was received on 6/15/94 in good condition. Samples were logged into Battelle's log-in system and stored frozen until extraction.

METHOD Tissue samples were extracted with methylene chloride using a roller under ambient conditions following a procedure which is based on methods used by the National Oceanic and Atmospheric Administration for its Status and Trends Program (Krahn et al. 1988). Samples were then cleaned using silica/alumina (5% deactivated) chromatography followed by HPLC cleanup.

Extracts were quantified using gas chromatography/mass spectrometry (GC/MS) in the selected ion mode (SIM) following a procedure based on EPA Method 8270 (EPA 1986).

HOLDING TIMES Samples were extracted in seven batches. All extracts were analyzed by GC/MS/SIM. The following summarizes the extraction and analysis dates:

Batch	Species	Extraction	Analysis
1	*M. nasuta*	7/28/94	9/9-9/12/94
2	*M. nasuta*	8/3/94	9/13-9/15/94
3	*M. nasuta*	8/17/94	9/23-9/25/94
4	*N. virens*	8/19/95	9/26-9/30/94
5	*N. virens*	8/26/94	9/8-9/11/94
6	*N. virens*	9/6/94	9/17-9/19/94
7	*M. nasuta/N. virens*	9/26/94	9/15-9/17-94
8	*M. nasuta* MDL study	10/10/94	10/25/94

DETECTION LIMITS Target detection limits of 4 ng/g wet weight were met for all PAH compounds except for fluoranthene and pyrene, which had method detection limits (MDL) between 4 and 6 ng/g wet weight. MDLs were determined by multiplying the standard deviation of seven spiked replicates of a background clam sample by the Student's t value (99 percentile). These MDLs were based on a wet weight of 20 g of tissue sample.

Aliquots of samples that were analyzed in triplicate, used for spiking, or were re-extracted, were generally less than 20 g due to limited quantities of tissue available. Because MDLs reported are corrected for sample weight, the MDLs reported for these samples appear elevated and in some cases may exceed the target detection limit.

In addition a method detection limit verification study was performed, which consisted of analyzing four spiked aliquots of a background clam sample received with this project. The standard deviation of the results of these replicate analyses was multiplied by 3.5. Detection limits calculated in this way were all less than the target detection limit of 4 ng/g wet wt.

METHOD BLANKS

One method blank was extracted with each extraction batch. Benz[a]anthracene was detected in blanks from all batches and benzo[b]fluoranthene was detected in the blank from Batch 3. Two method blanks were analyzed with Batch 7 and in addition to benz[a]anthracene, three other compounds were detected in at least one of the two blanks; naphthalene, benzo[a]pyrene and indeno(123-cd)pyrene. All blank levels were less than three times the target MDL of 4 ng/g wet wt. Sample values that were less than five times the value of the method blank associated with that sample were flagged with a "B."

SURROGATES

Five isotopically labeled compounds were added prior to extraction to assess the efficiency of the method. These were d8-naphthalene, d10-acenaphthene, d12-chrysene, d14-dibenz[a,h]anthracene and d4-1,4 dichlorobenzene. Recoveries of all surrogates were within the quality control limits of 30% -150% with the exception of low recoveries for d4-1,4 dichlorobenzene in one sample from Batch 1 and Batch 4 and two samples in Batch seven. In addition, d8-naphthalene recovery was low in two samples in Batch seven.

MATRIX SPIKES

One sample from each batch was spiked with all PAH compounds. Matrix spike recoveries were generally, within QC limits of 50% -120%, with some exceptions. The recoveries for benzo(b)- and benzo[k]fluoranthene were variable due to the poor resolution of these two compounds. Spike recoveries quantified as the sum of these two compounds were within QC limits. Spike recoveries for a number of PAH compounds in Batches 4 and 7 were out of control due to high native levels, relative to the levels spiked. Spike concentrations were from 2 to 20 times lower than native concentrations. Recoveries for a number of compounds in Batches 4 and 6 were slightly above the upper control limit. These recoveries were all between 120% and 140%.

REPLICATES

One sample from each batch was extracted and analyzed in triplicate. Precision was measured by calculating the relative standard deviation (RSD) between the replicate results. All RSDs were within ±30%.

SRMs

Not applicable.

MISCELLANEOUS

Some of the compounds are flagged to indicate that the ion ratio for that compound was outside of the QC range. This is due primarily to low levels of the compound of interest. Because the confirmation ion is present at only a fraction of the level of the parent ion, when the native level of the compound is low, the amount of error in the concentration measurement of the confirmation ion goes up. The compound is actually quantified from the parent ion only, so most likely this will not affect the quality of the data. For sample values that are relatively high (>5 times the MDL) it may be an indication of some sort of interference.

Silver	ICP/MS	75-125%	≤20%	≤20%	0.1
Zinc	ICP/MS	75-125%	≤20%	≤20%	1.0

METHOD

A total of nine (9) metals was analyzed for the New York Federal Projects-2 Program: silver (Ag), arsenic (As), cadmium (Cd), chromium (Cr), copper (Cu), mercury (Hg), nickel (Ni), lead (Pb) and zinc (Zn). Hg was analyzed using cold-vapor atomic absorption spectroscopy (CVAA) according to the method of Bloom and Crecelius (1983). The remaining metals were analyzed by inductively coupled plasma mass spectrometry (ICP/MS) following a procedure based on EPA Method 200.8 (EPA 1991).

To prepare tissue for analysis, samples were freeze-dried and blended in a Spex mixer-mill. Approximately 5 g of mixed sample was ground in a ceramic ball mill. For ICP/MS and CVAA analyses, 0.2- to 0.5-g aliquots of dried homogenous sample were digested using a mixture of nitric acid and hydrogen peroxide following EPA Method 200.3 (EPA 1991).

HOLDING TIMES

A total of 68 worm and 68 clam samples was received on 6/15/94 in good condition. Samples were logged into Battelle's log-in system, frozen to -80°C and subsequently freeze dried within approximately 7 days of sample receipt. Samples were analyzed within 180 days of collection. Worms and clams were digested in two separate batches. The following table summarizes the analysis dates:

Task	Clams	Worms
Sample Digestion	8/9/94	9/9/94
ICP-MS	9/15/94	10/6/94
CVAA-Hg	8/17-8/24/94	8/17-8/24/94

QA/QC SUMMARY METALS (continued)

DETECTION LIMITS Four aliquots of a background clam tissue were analyzed as four separate replicates. The standard deviation of these results were multiplied by 4.541 to determine a method detection limits (MDL). Target detection limits were exceeded for all metals except Ag, Cd and Hg.

METHOD BLANKS One procedural blank was analyzed per 20 samples. No metals were detected in the blanks above the MDLs.

MATRIX SPIKES One sample was spiked with all metals at a frequency of 1 per 20 samples. All recoveries were within the QC limits of 75% -125% with the exception of Ag in one spiked worm sample and Zn in three of the four spiked worm samples. Zn was spiked at a level near the level found in the native samples and, in one case, Zn was spiked at a level below that detected in the native sample and no recovery was calculated.

REPLICATES One sample was analyzed in triplicate at a frequency of 1 per 20 samples. Precision for triplicate analyses is reported by calculating the relative standard deviation (RSD) between the replicate results. Only the RSDs for Zn in one of the four replicated worm analyses exceeded the QC limits of ±20%. RSDs for the rest of the metals were within the QC limits.

SRMs Standard Reference Material (SRM), 1566a (Oyster tissue from the National Institute of Standards and Technology, NIST), was analyzed for all metals. Results for all metals were within ±20 % of mean certified value with the exception of Cr and Ni. Cr values were below the lower QC limit in two of the five SRMs analyzed with the clams and for three of the four SRMs analyzed with the worms. The SRM certified value for Cr (1.43 µg/g) is close to the detection limit (1.46 µg/g). Ni was also recovered below or above the control limits in some samples.

QA/QC SUMMARY

PROGRAM: New York/New Jersey Federal Projects-2

PARAMETER: Chlorinated Pesticides/PCB Congeners

LABORATORY: Battelle/Marine Sciences Laboratory, Sequim, Washington

MATRIX: Worm and Clam Tissue

QA/QC DATA QUALITY OBJECTIVES

Reference Method	Surrogate Recovery	Spike Recovery	Relative Precision	Detection Limit
GC/ECD	30-150%	50-120%	≤30%	0.4 ng/g wet wt.

SAMPLE CUSTODY A total of 68 worm and 68 clam samples was received on 6/15/94 in good condition. Samples were logged into Battelle's log-in system and stored frozen until extraction.

METHOD Tissues were homogenized wet using a stainless steel blade. An aliquot of tissue sample was extracted with methylene chloride using the roller technique under ambient conditions following a procedure which is based on methods used by the National Oceanic and Atmospheric Administration for its Status and Trends Program (Krahn et al. 1988). Samples were then cleaned using silica/alumina (5% deactivated) chromatography followed by HPLC cleanup (Krahn et al. 1988). Extracts were analyzed for 15 chlorinated pesticides and 22 PCB congeners using gas chromatography/electron capture detection (GC/ECD) following a procedure based on EPA Method 8080 (EPA 1986). The column used was a J&W DB-17 and the confirmatory column was a DB-1701, both capillary columns (30m x 0.25mm I.D.). All detections were quantitatively confirmed on the second column.

HOLDING TIMES Samples were extracted in seven batches. All extracts were analyzed by GC/ECD. The following summarizes the extraction and analysis dates:

Batch	Species	Extraction	Analysis
1	*M. nasuta*	7/28/94	9/9-9/12/94
2	*M. nasuta*	8/3/94	9/13-9/15/94
3	*M. nasuta*	8/17/94	9/23-9/25/94
4	*N. virens*	8/19/95	9/26-9/30/94
5	*N. virens*	8/26/94	9/8-9/11/94
6	*N. virens*	9/6/94	9/17-9/19/94
7	*M. nasuta/N. virens*	9/26/94	9/15-9/17-94
8	*M. nasuta* MDL study	10/10/94	10/25/94

DETECTION LIMITS Target detection limits of 0.4 ng/g wet weight were met for all pesticides and PCB congeners, with the exception of dieldrin, PCB 8 and PCB 18, and for the samples that were analyzed in triplicate. These elevated detection limits for the replicates were due to the limited amount of tissue available resulting in smaller aliquots used for extraction. Method detection limits (MDLs) reported were determined by multiplying the

standard deviation of seven spiked replicates of clam tissue by the Student's t value (99 percentile). Actual pesticide MDLs ranged from approximately 0.1 to 1.1 ng/g wet weight and PCB congener MDLs ranged from approximately 0.1 to 0.9 ng/g wet weight, depending on the compound and the sample weight extracted. MDLs were reported corrected for individual sample wet weight extracted.

Method detection limit verification was performed by analyzing four replicates of a spiked clam sample and multiplying the standard deviation of the results by 3.5. All detection limits calculated in this way were below the target detection limit of 0.4 ng/g wet weight with the exception of 4,4'-DDD which had a DL of 0.467 ng/g.

METHOD BLANKS

One method blank was extracted with each extraction batch. No pesticides or PCBs were detected in any of the method blanks.

SURROGATES

Two compounds, PCB congeners 103 and 198, were added to all samples prior to extraction to assess the efficiency of the analysis. Sample surrogate recoveries were all within the QC guidelines of 30% - 150%, with the exception of one sample in Batch 3 and two samples in Batch 4. All of these incidents involved a high recovery of PCB 198. This was most likely due to matrix interferences with the internal Standard octachloronaphthalene (OCN) which is used to quantify the recovery of surrogate PCB 198. Since no sample data are corrected for the OCN, sample results should not be affected. One sample had low surrogate recoveries for both PCB 103 and 198. This sample was re-extracted once due to surrogate recoveries. Since the recoveries in the reextraction also exceeded control limits, the problem was determined to be matrix interferences and no additional extractions were performed. Sample results were quantified using the surrogate internal standard method.

MATRIX SPIKES

Ten out of the 15 pesticides and 5 of the 22 PCB congeners analyzed were spiked into one sample per extraction batch. Matrix spike recoveries were within the control limit range of 50-120% for all Pesticides and PCBs in Batches 1, 2, 3, 6 and 7 with the exception of PCB 138 in Batch six and three pesticides and 2 PCBs in Batch seven. In all cases, the recoveries were high and are most likely due to matrix interferences. Recoveries for the majority of pesticides and PCBs in Batches four and five exceeded control limits due to high native levels compared with the levels spiked. In most cases, the spiked concentrations were 2 to 10 times lower than the concentrations detected in the samples.

REPLICATES

One sample from each extraction batch was analyzed in triplicate. Precision was measured by calculating the relative standard deviation (RSD) between the replicate results. RSDs for all detectable values were below the target precision goal of ≤30% in Batches 1, 2, 3, 4 and 7. The RSD for Endosulfan Sulfate in Batch 5 was high due to comparison of very low concentrations, less than 1 ng/g in the replicates. RSDs for two pesticides and for two PCB congeners in Batch 6 were high due to matrix interferences associated with the first replicate sample.

SRMs Not applicable.

MISCELLANEOUS All pesticide and PCB congener results are confirmed using a second dissimilar column. RPDs between the primary and confirmation values must be less than 75% to be considered a confirmed value.

QA/QC SUMMARY

PROGRAM: New York/New Jersey Federal Projects-2

PARAMETER: Polynuclear Aromatic Hydrocarbons (PAH) and 1,4-Dichlorobenzene

LABORATORY: Battelle/Marine Sciences Laboratory, Sequim, Washington

MATRIX: Clam and Worm Tissue

QA/QC DATA QUALITY OBJECTIVES

Reference Method	MS Recovery	Surrogate Recovery	SRM Accuracy	Relative Precision	Detection Limit (wet wt)
GC/MS/SIM	50-120%	30-150%	≤30%	≤30%	4 ng/g

SAMPLE CUSTODY A total of 68 worm and 68 clam samples was received on 6/15/94 in good condition. Samples were logged into Battelle's log-in system and stored frozen until extraction.

METHOD Tissue samples were extracted with methylene chloride using a roller under ambient conditions following a procedure which is based on methods used by the National Oceanic and Atmospheric Administration for its Status and Trends Program (Krahn et al. 1988). Samples were then cleaned using silica/alumina (5% deactivated) chromatography followed by HPLC cleanup.

Extracts were quantified using gas chromatography/mass spectrometry (GC/MS) in the selected ion mode (SIM) following a procedure based on EPA Method 8270 (EPA 1986).

HOLDING TIMES Samples were extracted in seven batches. All extracts were analyzed by GC/MS/SIM. The following summarizes the extraction and analysis dates:

Batch	Species	Extraction	Analysis
1	*M. nasuta*	7/28/94	9/9-9/12/94
2	*M. nasuta*	8/3/94	9/13-9/15/94

4	*N. virens*	8/19/95	9/26-9/30/94
5	*N. virens*	8/26/94	9/8-9/11/94
6	*N. virens*	9/6/94	9/17-9/19/94
7	*M. nasuta/N. virens*	9/26/94	9/15-9/17-94
8	*M. nasuta* MDL study	10/10/94	10/25/94

DETECTION LIMITS Target detection limits of 4 ng/g wet weight were met for all PAH compounds except for fluoranthene and pyrene, which had method detection limits (MDL) between 4 and 6 ng/g wet weight. MDLs were determined by multiplying the standard deviation of seven spiked replicates of a background clam sample by the Student's t value (99 percentile). These MDLs were based on a wet weight of 20 g of tissue sample.

Aliquots of samples that were analyzed in triplicate, used for spiking, or were re-extracted, were generally less than 20 g due to limited quantities of tissue available. Because MDLs reported are corrected for sample weight, the MDLs reported for these samples appear elevated and in some cases may exceed the target detection limit.

In addition a method detection limit verification study was performed, which consisted of analyzing four spiked aliquots of a background clam sample received with this project. The standard deviation of the results of these replicate analyses was multiplied by 3.5. Detection limits calculated in this way were all less than the target detection limit of 4 ng/g wet wt.

METHOD BLANKS

One method blank was extracted with each extraction batch. Benz[a]anthracene was detected in blanks from all batches and benzo[b]fluoranthene was detected in the blank from Batch 3. Two method blanks were analyzed with Batch 7 and in addition to benz[a]anthracene, three other compounds were detected in at least one of the two blanks; naphthalene, benzo[a]pyrene and indeno(123-cd)pyrene. All blank levels were less than three times the target MDL of 4 ng/g wet wt. Sample values that were less than five times the value of the method blank associated with that sample were flagged with a "B."

SURROGATES

Five isotopically labeled compounds were added prior to extraction to assess the efficiency of the method. These were d8-naphthalene, d10-acenaphthene, d12-chrysene, d14-dibenz[a,h]anthracene and d4-1,4 dichlorobenzene. Recoveries of all surrogates were within the quality control limits of 30% -150% with the exception of low recoveries for d4-1,4 dichlorobenzene in one sample from Batch 1 and Batch 4 and two samples in Batch seven. In addition, d8-naphthalene recovery was low in two samples in Batch seven.

MATRIX SPIKES

One sample from each batch was spiked with all PAH compounds. Matrix spike recoveries were generally, within QC limits of 50% -120%, with some exceptions. The recoveries for benzo(b)- and benzo[k]fluoranthene were variable due to the poor resolution of these two compounds. Spike recoveries quantified as the sum of these two compounds were within QC limits. Spike recoveries for a number of PAH compounds in Batches 4 and 7 were out of control due to high native levels, relative to the levels spiked. Spike concentrations were from 2 to 20 times lower than native concentrations. Recoveries for a number of compounds in Batches 4 and 6 were slightly above the upper control limit. These recoveries were all between 120% and 140%.

REPLICATES

One sample from each batch was extracted and analyzed in triplicate. Precision was measured by calculating the relative standard deviation (RSD) between the replicate results. All RSDs were within ±30%.

SRMs

Not applicable.

MISCELLANEOUS

Some of the compounds are flagged to indicate that the ion ratio for that compound was outside of the QC range. This is due primarily to low levels of the compound of interest. Because the confirmation ion is present at only a fraction of the level of the parent ion, when the native level of the compound is low, the amount of error in the concentration measurement of the confirmation ion goes up. The compound is actually quantified from the parent ion only, so most likely this will not affect the quality of the data. For sample values that are relatively high (>5 times the MDL) it may be an indication of some sort of interference.
