CONTENTS

More detailed tables of contents are to be found within the various parts of the compendium. The following provides merely an overview.

ACKNOWLEDGMENTS

The HIV Sequence Database and Analysis Project is funded by the Vaccine and Prevention Research Program of the AIDS Division of the National Institute of Allergy and Infectious Diseases (Dr. James Bradac, Project Officer) through an interagency agreement with the U.S. Department of Energy.

We thank the many researchers who have made their sequences available prior to publication.

We also thank last year's editors, Beatrice Hahn, Francine McCutchan, Lou Henderson and George Pavlakis, who were not a part of this year's publication but who may, at one time or another, return in this role.

INTRODUCTION

This compendium and the accompanying floppy diskettes are the result of an effort to compile and rapidly publish all relevant molecular data concerning the human immunodeficiency viruses (HIV) and related retroviruses. The scope of the compendium and database is best summarized by the five parts that it comprises: (I) Nucleic Acid Alignments and Sequences; (II) Amino Acid Alignments; (III) Analysis; (IV) Related Sequences; and (V) Database Communications. Information within all the parts is updated throughout the year on the Web site, *http://hiv-web.lanl.gov*.

While this publication could take the form of a review or sequence monograph, it is not so conceived. Instead, the literature from which the database is derived has simply been summarized and some elementary computational analyses have been performed upon the data. Interpretation and commentary have been avoided insofar as possible so that the reader can form his or her own judgments concerning the complex information. In addition to the general descriptions below of the parts of the compendium, the user should read the individual introductions for each part.

Part I. Nucleic Acid Alignments and Sequences. Annotated nucleic acid sequences of certain HIVs and SIVs are presented in a form close to that of the GenBank Sequence Library. Our few modifications of standard GenBank format were instituted to better serve the particular community for which this database is intended. Beginning in 1995, most sequences are not presented but rather are catalogued, in order to conserve space; the full formatted GenBank entries of these sequences are located on the Web site (*http://hiv-web.lanl.gov*) and the database FTP server.

The LOCUS name or identifier of an entry may differ slightly from that found in the GenBank or EMBL libraries, but the ACCESSION numbers are identical for entries in all (four) nucelotide sequence databases. Thus each entry is universally and uniquely traceable. Sequences may also be described by COMMON NAMES.The SOURCE line provides information, when available, about the infectivity or biological activity of the molecular clone from which a sequence has been derived. REFERENCES are limited to literature or personal communications having authority for the original sequence data; references that review sequence information, or that shed light upon the function or variation of coding and regulatory sequences, are listed in Part V.

Entries in Part I are annotated within the sequence, while their GenBank or EMBL-formatted versions on the floppy diskettes make use of FEATURES tables. The hard-copy annotation includes coding regions, regulatory structures, splice sites, and other features of functional significance. The authority for this annotation is largely invariance, the recurrence of patterns such as TATAA and AATAAA. Although our practice has been to conservatively annotate, we caution the user against docility: sequence information regarding transcripts, for example, is far from certain or complete at this time. Part I is sometimes divided into three subsections, A, B, and C, concerned with HIV-1s, HIV-2/SIVs, and SIVAGMs, SIVMND and SIVSYK.

Part II. Amino Acid Alignments. This section contains in alignment the amino acid sequences (mostly full-length) of all known coding regions and open reading frames of HIV-1, HIV-2, and SIVs. In 1996, large alignments are presented in terms of representative primate immunodeficiency viral types and subtypes. Consensus sequences for HIV-1 subtypes have also been aligned in this release. Other alignments are available on the Web site. Protein processing sites are annotated when known. The reader should consult the introduction to Part II for further explanation of the presentation and annotation of the amino acid sequences.

Part III. Analysis. This section is open-ended with the constraint that the sequence analyses and compilations be basic and of interest to the diversity of users. In 1996, analyses and curatorial contributions include tables of mutations relating to drug resistance, sections on Tat and VpU, analyses of sequence alignment and structure prediction, discussions of HIV-1 subtypes, etc.

Part IV. Related Sequences. Heretofore, this section of the compendium has featured HIV related viral sequences—of nonprimate lentiviruses and the human T-cell lymphotropic viruses. Beginning in 1993, Part IV entries include, with greater emphasis, coding sequences for cellular proteins involved with HIV pathogenesis. In 1996, there are articles summarizing cellular factors and viral mimicry.

Part V. Database Communications. This part contains a printed supplemental reference list for citations in 1995 and 1996. It also provides diskettes of sequences and information about accessing sequences through Internet. The floppy diskettes contain new nucleic acid sequences from Part I (especially those found in alignments) and Part IV and their translated amino acid sequences. For the most current information regarding database files, see the READ.ME file on each diskette. Nucleotide entries are presented in GenBank format for North American users and in EMBL format for European users (unless otherwise requested). Similarly, amino acid sequences are in either PIR or Swiss-Prot format. The diskettes themselves are either 3.5" IBM-DOS format or 3.5" Macintosh format, depending upon what has been requested. If there is any trouble using these files with software designed to work with the format we have sent, please let us know the name of the program you are using and the file that it could not handle.

A comprehensive compilation of the nucleic acid and protein sequences published in the Human Retroviruses and AIDS Database since 1987 is available through our Web site, *http://hiv-web.lanl.gov* and on our FTP Server, as described in Part V.

We are prepared to quickly enter both protein and nucleotide sequences into the Human Retroviruses and AIDS database, and in the case of nucleotide sequences, oversee their entry into the large gene libraries. Submission of unpublished sequences is invited and encouraged. Sequence data or inquiries regarding the database should be addressed to

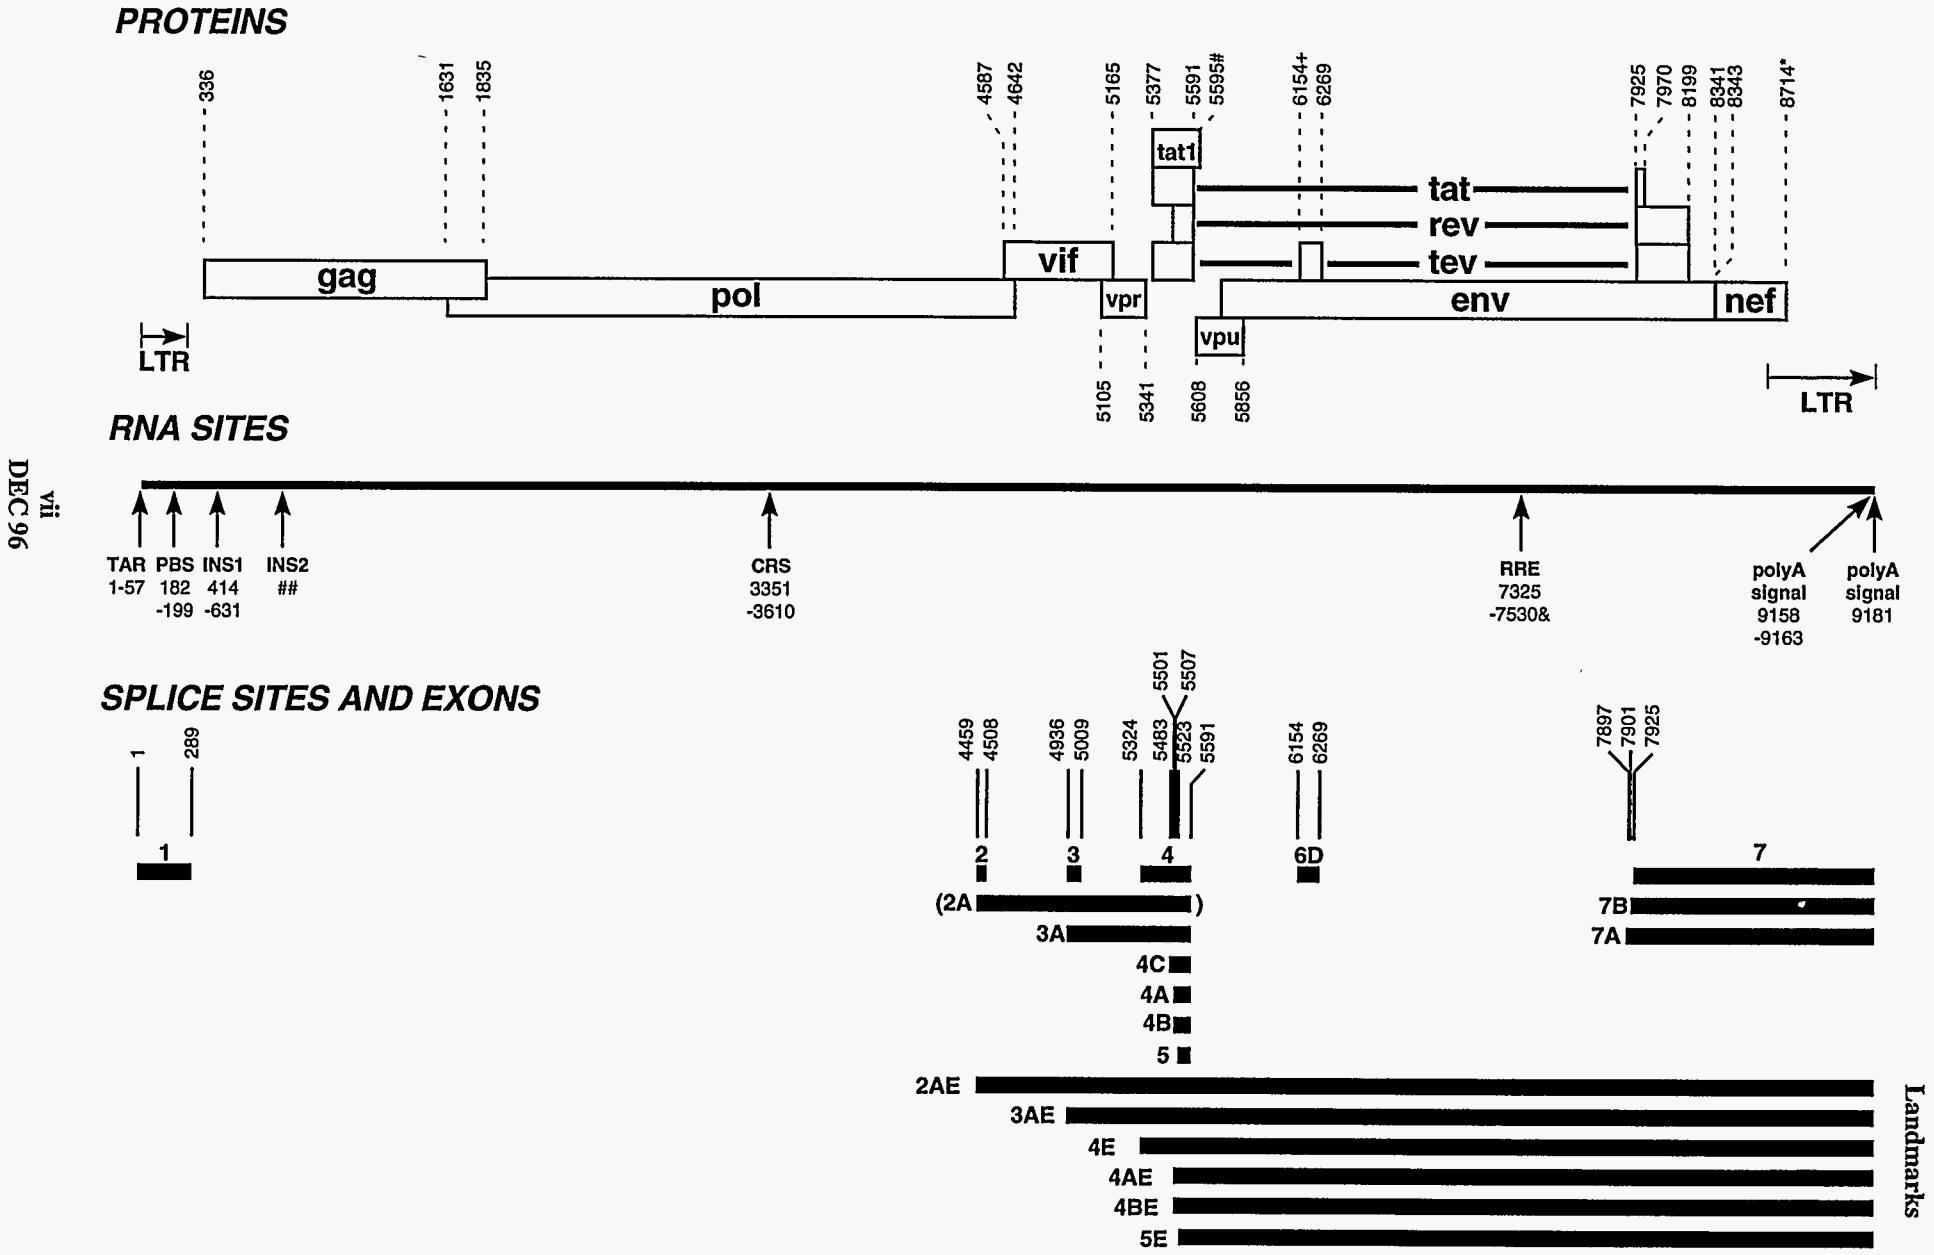
HIV/SIV PROTEINS

NAME	SIZE	FUNCTION	LOCALIZATION
Gag MA	p17	membrane anchoring; env interaction; nuclear transport of viral core. (myristylated protein)	virion
CA	p24	core capsid	virion
NC	p7	nucleocapsid, binds RNA	virion
	p6	binds Vpr	virion
Protease (PR)	p15	gag/pol cleavage and maturation	virion
Reverse transcriptase (RT), RNase H	p66 p51 (heterodimer)	reverse transcription, RNase H activity	virion
Integrase (IN)		DNA provirus integration	virion
Env	gp120/gp41	external viral glycoproteins bind to CD4 receptor	plasma membrane, virion envelope
Tat	p16/p14	viral trancriptional transactivator	primarily in nucleolus/nucleus
Rev	p19	RNA transport, stability and utilization factor (phosphoprotein)	primarily in nucleolus/nucleus shuttling between nucleolus and cytoplasm
Vif	p23	promotes virion maturation and infectivity	cytoplasm (cytosol, membranes) virion
Vpr	p10-15	promotes nuclear localization of preintegration complex, inhibits cell division, arrests infected cells at G2/M	virion, nucleus (nuclear membrane?)
Vpu	p16	promotes extracellular release of viral particles; degrades CD4 in the ER; (phosphoprotein only in HIV-1 and SIVcpz)	integral membrane protein
Nef	p27-p25	CD4 downregulation (myristylated protein)	plasma membrane, cytoplasm (virion?)
Vpx	p12-16	vpr homolog? (not in HIV-1, only in HIV-2 and SIV)	virion (nucleus?)
Tev	p28	tripartite tat-env-rev protein (also named Tnv)	primarily in nucleolus/nucleus

LANDMARKS ON THE HIV-1 GENOMIC RNA



DEC 96 vii

Landmarks

LANDMARKS:

HIV GENOMIC STRUCTURAL ELEMENTS

LTR Long terminal repeat, the DNA sequence flanking the genome of integrated proviruses. It contains important regulatory regions, especially those for transcription initiation and polyadenylation.

TAR Target sequence for viral transactivation, the binding site for Tat protein and for cellular proteins; consists of approximately the first 45 nucleotides of the viral mRNAs in HIV-1 (or the first 100 nucleotides in HIV-2 and SIV.) TAR RNA forms a hairpin stem-loop structure with a side bulge; the bulge is necessary for Tat binding and function.

RRE Rev responsive element, an RNA element encoded within the env region of HIV-1. It consists of approximately 200 nucleotides (positions 7327 to 7530 from the start of transcription in HIV-1.) The RRE is necessary for Rev function; it contains a high affinity site for Rev; in all, approximately seven binding sites for Rev exist within the RRE RNA. Other lentiviruses (HIV-2, SIV, visna, CAEV) have similar RRE elements in similar locations within env, while HTLVs have an analogous RNA element (RXRE) serving the same purpose within their LTR; RRE is the binding site for Rev protein, while RXRE is the binding site for Rex protein. RRE (and RXRE) form complex secondary structures, necessary for specific protein binding.

CRS cis-acting repressive sequences postulated to inhibit structural protein expression in the absence of Rev. One such site was mapped within the pol region of HIV-1. The exact function has not been defined; splice sites have been postulated to act as CRS sequences.

INS Inhibitory/Instability RNA sequences found within the structural genes of HIV-1 and of other complex retroviruses. Multiple INS elements exist within the genome and can act independently; one of the best characterized elements spans nucleotides 414 to 631 in the gag region of HIV-1. The INS elements have been defined by functional assays as elements that inhibit expression posttranscriptionally. Mutation of the RNA elements was shown to lead to INS inactivation and up regulation of gene expression.

GENES AND GENE PRODUCTS

GAG genomic region encoding the capsid proteins (group specific antigens). The precursor is the p55 myristylated protein, which is processed to p17 (MAtrix), p24 (CApsid), p7 (NucleoCapsid), and p6 proteins, by the viral protease. Gag associates with the plasma membrane where the virus assembly takes place. The 55 kDa Gag precursor is called assemblin to indicate its role in viral assembly.

POL the genomic region encoding the viral enzymes protease, reverse transcriptase and integrase. These enzymes are produced as a Gag-pol precursor polyprotein, which is processed by the viral protease; the Gag-pol precursor is produced by ribosome frameshifting at the C-terminus of gag.

ENV viral glycoproteins produced as a precursor (gp160) and processed to the external glycoprotein gp120 and the transmembrane glycoprotein gp41. The mature proteins are held together by non-covalent interactions; as a result, a substantial amount of gp120 is released in the medium. gp120 contains the binding site for the CD4 receptor.

TAT Transactivator of HIV gene expression. One of the two necessary viral regulatory factors (Tat and Rev) for HIV gene expression. Two forms are known, Tat-1exon (minor form) of 72 amino acids and Tat-2exon (major form) of 86 amino acids. The electrophoretic mobility of these two forms in SDS gels is anomalous, with apparent sizes of approximately 16 kD and 14 kD for Tat- 2exon and Tat-1exon, respectively. Low levels of both proteins are found in persistently infected cells. Tat has been localized primarily in the nucleolus/nucleus by immunofluorescence. It acts by binding to the TAR RNA element and activating transcription initiation and/or elongation from the LTR promoter. It is the first eukaryotic transcription factor known to interact with RNA rather

than DNA and may have similarities with prokaryotic anti- termination factors. Extracellular Tat can be found and can be taken up by cells in culture.

REV The second necessary regulatory factor for HIV expression. A 19 kD phosphoprotein, localized primarily in the nucleolus/nucleus, Rev acts by binding to RRE and promoting the nuclear export, stabilization and utilization of the viral mRNAs containing RRE. Rev is considered the most functionally conserved regulatory protein of lentiviruses. Rev cycles rapidly between the nucleus and the cytoplasm.

VIF Viral infectivity factor, typically 23 kD. Promotes the infectivity but not the production of viral particles. In the absence of Vif the produced viral particles are defective, while the cell-to-cell transmission of virus is not affected significantly. Found in almost all lentiviruses, Vif is a cytoplasmic protein, existing in both a soluble cytosolic form and a membrane-associated form. The latter form of Vif is a peripheral membrane protein that is tightly associated with the cytoplasmic side of cellular membranes. Some recent observations suggest that Vif is incorporated in the virion.

VPR Vpr (viral protein R) is a 96-amino acid (14 kd) protein, which is incorporated into the virion. It interacts with the p6gag part of the Pr55gag precursor. Vpr detected in the cell is localized to the nucleus. Proposed functions for Vpr include the nuclear import of preintegration complexes, cell growth arrest, transactivation of cellular genes, and induction of cellular differentiation. Found in HIV-1, HIV-2, SIVmac and SIVmnd. It is homologous to VPX of SIVagm.

VPU Vpu (viral protein U) is unique to HIV-1 and SIVcpz, a close relative of HIV-1. There is no similar gene in HIV-2 or SIV. Vpu is a 16-kd (81-amino acid) type I integral membrane protein with at least two different biological functions: (a) degradation of CD4 in the endoplasmic reticulum, and (b) enhancement of virion release from the plasma membrane of HIV-1-infected cells. Vpu probably possesses an N-terminal hydrophobic membrane anchor and a hydrophilic moiety. It is phosphorylated by casein kinase II at positions Ser52 and Ser56. Vpu is involved in env maturation; not found in the virion.

NEF (previously named 3′ ORF) is an approximately 27-kd myristylated protein produced by an ORF located at the 3′ end of the primate lentiviruses. Other forms of Nef are known, including nonmyristylated variants. Nef is predominantly cytoplasmic and associated with the plasma membrane via the myristyl residue linked to the conserved second amino acid (Gly). Nef has also been identified in the nucleus and found associated with the cytoskeleton in some experiments. Its association with the virion is suspected but not proven. One of the first HIV proteins to be produced in infected cells, it is the most immunogenic of the accessory proteins. Initially thought to be a negative factor, Nef was found to be important for viral replication in vivo. The nef genes of HIV and SIV are dispensable in vitro, but are essential for efficient viral spread and disease progression in vivo. Nef is necessary for the maintenance of high virus loads and for the development of AIDS in macaques. Nef downregulates CD4, the primary viral receptor, and is also proposed to increase viral infectivity. Nef contains PxxP motifs that bind to SH3 domains of a subset of Src kinases and are required for the enhanced growth of HIV but not for the downregulation of CD4.

VPX Virion protein of 12 kD found only in HIV-2/SIVagm and not in HIV-1 or SIVmnd. Vpx function in relation to Vpr is not fully elucidated. Vpx is necessary for efficient replication of SIV in PBMCs. Some studies indicate that Vpx and Vpr proteins may be functionally distinct. Progression to AIDS and death in SIV-infected animals can occur in the absence of Vpr or Vpx. Double mutant virus lacking both vpr and vpx was severely attenuated, whereas the single mutants were not, suggesting a redundancy in the function of Vpr and Vpx related to virus pathogenicity.

TEV (also named tnv) tripartite 28 kD viral phosphoprotein produced by some HIV-1 strains. Found primarily in the nucleolus/nucleus. Tev contains the first exon of Tat, a small part of Env and the second exon of Rev. It exhibits both Tat and Rev functions and can functionally replace both essential regulatory proteins of HIV-1. It is produced very early in infection.

STRUCTURAL PROTEINS/VIRAL ENZYMES The products of gag, pol and env genes, which are essential components of the retroviral particle.

REGULATORY PROTEINS Tat and Rev proteins of HIV/SIV and Tax and Rex proteins of HTLVs. They modulate transcriptional and posttranscriptional steps of virus gene expression and are essential for virus propagation.

ACCESSORY OR AUXILIARY PROTEINS additional virion and non-virion- associated proteins produced by HIV/SIV retroviruses: Vif, Vpr, Vpu, Vpx, Nef. Although the accessory proteins are in general not necessary for viral propagation in tissue culture, they have been conserved in the different isolates; this conservation and experimental observations suggest that their role in vivo is very important.

COMPLEX RETROVIRUSES Retroviruses regulating their expression via viral factors and expressing additional proteins (regulatory and accessory) essential for their life cycle.

I

Nucleic Acid Alignments and Sequences

Nucleotide sequence alignments were generated in the 1996 compendium by two different approaches: On the one hand, a Hidden Markov Method (HMM) was used as described in Part III (Myers and Farmer). For simplicity, only representative PIVs are shown; in some cases, hundreds of sequences contributed to the alignment. A simple consensus over just the representative sequences was deduced using MASE. On the other hand, new HIV-1 subtype sequences were added to previous alignments generated using the PIMA and MASE tools, as in earlier compendiums. Alignments of subtype consensus are presented. Mixed case consensus sequences are used as the reference sequences for each alignment. Upper case letters indicate 100% conservation of nucleotide bases in a given position of the alignment, and lower case letters represent bases conserved in at least 50% of the sequences. The symbol "?" indicates no consensus at a position.

With few exceptions, only full-length coding sequences were included in these alignments. Tables of information pertaining to each sequence in an alignment are provided. The common names given to sequences in alignment and in the accompanying tables were selected on several grounds: for sequences corresponding to samples provided by the NIAID repository, WHO and DAIDS conventions are employed for the names; for other sequences, the name given by the authors of the paper reporting the sequence are usually utilized. We wish to thank many sequencers for providing data prior to publication.

Prior to the 1992 database compendium, HIV-1 sequences had been roughly classified as 'U.S.' and 'African.' In light of many new HIV-1 *gag* and *env* sequences, it became more useful, starting with the 1992 compendium, to categorize HIV-1 sequences into five sequence subtypes, depending upon the coding sequence. HIV-1 subtypes now number ten (A through J). Collectively, these are called group M sequences, as they are significantly distinct from group O sequences. The bases for this classification, discussed at greater length in Part III of this compendium, are:

i) subtypes are approximately equidistant from one another in *env* (a "star phylogeny");

ii) the *env* phylogenetic tree is for the most part congruent with *gag* phylogenetic trees;

iii) two or more samples are required to define a sequence subtype.

Subtype naming problems have arisen for several reasons. A small but not insignificant number of viral sequences are hybrid, clustering with one sequence subtype in *gag* and another sequence subtype in *env*, for example; or, to take another example, clustering over different stretches with two or more subtypes in *env*. All subtype E sequences based on *env* have *gag* sequences that align with subtype A sequences; and, moreover, the 3′ half of the gp41 cds of E and subtype G *env* sequences align with subtype A sequences (Gao *et al, J. Virol.* **70**:1651,1996). Given the homogeneity of G and E subtype sequences, these are handled as subtypes and not as hybrids in the following alignments. It remains to be discovered whether these states have arisen from recombination or lack of divergence.

Several analyses of mosaic molecules were presented in Part III of the 1995 compendium. Naming also becomes problematic when highly divergent forms of a given subtype arise: such forms are sometimes designated A′, B′, F′ , etc. It is increasingly necessary to have sequence data from both *gag* and *env* coding sequences when a new form or subtype is being claimed.

The authority for some of the annotation is limited largely to invariance—the recurrence of patterns such as AATAAA, for example. The reader should be cautious in drawing upon this information. Due to space limitations, only certain sequences are reported as entries in this section. Beginning in 1995, most sequences are cataloged in Part I using just the headers of GenBank entries; to gain the full entry including the sequence itself, users should go to the HIV Sequence Database WWW site (*http://hiv-web.lanl.gov*),

the FTP site (also described in Part V of this compendium) or any of the large gene libraries. Sequences used in alignments are provided on the accompanying diskettes, and the alignments themselves are on the WWW site. Sequence entries from previous years are presented in the 1990–1994 compendiums.

The following alignment was generated using the HMMER program. For simplicity, only representative types and subtypes are shown. An ordinary consensus sequence (lowercase signifies majority, uppercase signifies 50% or greater) was created from these sequences using MASE; this is not a "most likely sequence" based on a HMMER model (Part II). Annotation is based on HIV-1s, therefore the user shouod be cautious about its applicability to other PI sequences. Cleavage sites are designated by '\/'.

The following alignment was generated using the HMMER program as described in the introduction to this Part and in Part III. For simplicity, only representative types and subtypes are shown. An ordinary consensus sequence (lowercase signifies majority, uppercase signifies 50% or greater) was constructed from these representatives using MASE; this is not a "most likely sequence" derived from the HMMER model (Part II). Annotation is based on HIV-1s, therefore the user should be cautious about its applicability to other PIV sequences.

The following alignment was generated using the HMMER program as described in the introduction to this Part and in Part III. For simplicity, only representative types and subtypes are shown. An ordinary consensus sequence (lowercase signifies majority, uppercase signifies 50% or greater) was created from these using MASE; this is not a "most likely sequence" based on an HMM model (Part II). Annotation is based on HIV-1s, therefore the useer should be cautious about its applicability to other PIV sequences.

The following alignment was generated using the HMMER program as described in the introduction to this Part and in Part III. For simplicity, only representative types and subtypes are shown. An ordinary consensus sequence (lowercase signifies majority, uppercase signifies 50% or greater) was created from these sequences using MASE; this is not a "most likely sequence" based on an HMM model (Part II). Annotation is not attempted for this alignment of paralogous sequences.

The following alignment was generated using the HMMER program as described in the introduction to this Part and in Part III. For simplicity, only representative types and subtypes are shown. An ordinary consensus sequence (lowercase signifies majority, uppercase signifies 50% or better) was created from these representative sequences using MASE; this is not a "most likely sequence" generated from a HMMER model (Part II). Annotation is based on HIV-1s, therefore the user should be cautious about its applicability to other PIV sequences. Putative splice sites are designated by '\/'.

The following alignment was generated using the HMMER program as described in the introduction to this Part and in Part III. For simplicity, only representative types and subtypes are shown. An ordinary consensus sequence (lowercase signifies majority, uppercase signifies 50% or greater) was created from these sequences using MASE; this is not a "most likely sequence" generated from the HMM model (Part II). Annotation is based on HIV-1s, therefore users should be cautious about its applicability to other PIV sequences.

The following alignment was generated using the HMMER program as described in the introduction to this Part and in Part III. For simplicity, only representative HIV-1 subtype sequences are shown. An ordinary consensus sequence (lowercase signifies mqjority, uppercase signifies 50% or greater) was created from these using MASE; this is not a "most likely sequence" based on an HMM model.

The following alignment was generated using the HMMER program as described in the Introduction to this Part and in Part III. For simplicity, only representative PIV types and subtypes are shown. An ordinary consensus sequence (majority for lowercase, 50 percent or higher for uppercase) was deduced using MASE; this consensus is not a "most likely sequence" derived from an HMM model(see Part II). Annotation is based upon HIV1s, therefore the user should be cautious about its applicability to other PIV sequences.

The following alignment was generatede using the HMMER program as described in the introduction to this Part and in Part III. For simplicity, only representative types and subtypes are shown. An ordinary consensus sequence (lowercase signifies majority, uppercase signifies 50% or greater) was created from these sequences using MASE; this is not a "most likely sequence" based on a HMMER model (Part II). Annotation is based on HIV-1s, therefore the user should be cautious about its applicability to other PIV sequences.

  TITLE     Direct Submission
  JOURNAL   Submitted (07-JUL-1996) HIV Database, LANL, Mail Stop K710, Los
            Alamos, NM 87545, USA
COMMENT     Subtype E.  93TH253 has been previously named as CMU010 or
            302053.  It is from a Thai patient with end-stage AIDS.  The
            isolate has been adapted to growth in H9 cells.
            There are two frameshifts in 93TH253.  There is a G insertion at
            position 5798 which shifts the vpr gene.  The second is in vpu,
            where an A deletion occurs right after the ATG start codon.

LOCUS       HIVCM240    9203 bp    DNA             VRL       13-SEP-1996
DEFINITION  Human immunodeficiency virus type 1, strain CM240, complete
            proviral genome.
ACCESSION   U54771
SOURCE      Human immunodeficiency virus type 1 (HIV-1), strain CM240; PBMCs
            extracted from male patient from Thailand; proviral DNA amplified;
            complete genomic sequence determined from three clones of viral genome.
  ORGANISM  Human immunodeficiency virus type 1
            Viridae; ss-RNA enveloped viruses; Positive strand RNA virus;
            Retroviridae; Lentivirinae.
REFERENCE   1  (bases 1 to 9203)

   TITLE    Direct Submission
 JOURNAL    Submitted (11-APR-1996) J.K. Carr, Molecular Epidemiology, Henry M.
            Jackson, 1600 E. Gude Dr., Rockville, MD 20850, USA
 COMMENT    Blood from an asymptomatic 21-year-old Thai man was transported
            from Chiang Mai to the USA where PBMCs were separated and
            co-cultivated with PHA-stimulated donor PBMCs.  DNA from p24
            antigen-positive culture was used to amplify the proviral DNA.
            The complete genomic sequence of the provirus was determined by the
            compilation of three clones containing different parts of the viral
            genome.  CM240 is an example of a Thai E virus, which is a mosaic of
            a clade A virus and a clade E virus.
FEATURES             Location/Qualifiers

LOCUS       HIVETH2220   9031 bp    DNA             VRL       19-JUN-1996
DEFINITION  HIV-1 isolate C2220 from Ethiopia, subtype C, complete genome.
ACCESSION   U46016
SOURCE      Human immunodeficiency virus type 1 (HIV-1), strain C2220 (ETH2220),
            clone pNOTA/C2220/C3.6.4; subtype C from Ethiopia; isolate by
            short-term co-culture on patient's PBMCs.
  ORGANISM  Human immunodeficiency virus type 1
            Viridae; ss-RNA enveloped viruses; Positive strand RNA virus;
            Retroviridae; Lentivirinae.
REFERENCE   1  (bases 1 to 9031)
  AUTHORS   Salminen,M.O., Johansson,B., Sonnerborg,A., Ayehunie,S., Gotte,D.,
            Leinikki,P., Burke,D.S. and McCutchan,F.E.
  TITLE     Full-length sequence of an Ethiopian human immunodeficiency virus
            type 1 (HIV-1) isolate of genetic subtype C
  JOURNAL   AIDS Research and Human Retroviruses 12 (14), 1329-1339 (1996)
REFERENCE   2  (bases 1 to 9031)
  AUTHORS   Salminen,M.O.
  TITLE     Direct Submission
  JOURNAL   Submitted (16-JAN-1996) Mika O. Salminen, Global Molecular
            Epidemiology, Henry M. Jackson Foundation, 1600 East Gude Drive,
            Rockville, MD 20850, USA
 COMMENT    U46016 is the first reported almost full length subtype C
            sequence from Ethiopia.  In its genomic organization, this clone
            closely resembles subtype A, B, and D isolates except that the core
            promoter contains three potential binding sites for the
            transcription factor NF-kB instead of containing two.
            See also GenBank accession number U15061.

LOCUS       HIVU51188    9843 bp    DNA             VRL       18-JUL-1996
DEFINITION  Human immunodeficiency virus type 1 (HIV-1), clone 90cr402 from the
            Central African Republic, complete genome.
ACCESSION   U51188
KEYWORDS    .
SOURCE      Human immunodeficiency virus type 1 (HIV-1), clone 90cr402; PBMCs
            extracted from symptomatic male patient from Central African
            Republic; expanded in chimpanzee cells and re-expanded in human
            PBMCs; complete genome lambda cloned and sequenced.
  ORGANISM  Human immunodeficiency virus type 1
            Viridae; ss-RNA enveloped viruses; Positive strand RNA virus;
            Retroviridae; Lentivirinae.
REFERENCE   1  (bases 1 to 9843)
  AUTHORS   Gao,F., Morrison,S.G., Robertson,D.L., Thornton,C.L., Craig,S.,
            Karlsson,G., Sodroski,J., Morgado,M., Galvao-Castro,B., von
            Briesen,H., Beddows,S., Weber,J., Sharp,P.M., Shaw,G.M. and
            Hahn,B.H.
  TITLE     Molecular cloning and analysis of functional envelope genes from
            human immunodeficiency virus type 1 sequence subtypes A through G.
            The WHO and NIAID Networks for HIV Isolation and Characterization

  TITLE     The heterosexual HIV-1 epidemic in Thailand is caused by an
            intersubtype (A/E) recombinant of African origin
  JOURNAL   J. Virology 70 (10), 7013-7029 (1996)
REFERENCE   3  (bases 1 to 9843)

  TITLE     Direct Submission
  JOURNAL   Submitted (12-MAR-1996) John Blouin, HIV Database, Los Alamos
            National Laboratory, Eniwetok Dr., Los Alamos, NM 87545, USA
  COMMENT   A set of three complete genomes from a study linking the HIV-1
            epidemic in the heterosexual population in Thailand to an A/E
            recombinant. 90cr402, previously named CAR-E 4002, was obtained
            from a man from Bangui, Central African Republic, who had
            lymphadeopathy, diarrhea, severe weight loss and recurrent
            respiratory infections. He was infected through heterosexual
            contact, but the year of infection is unknown. 90cr402 was first
            adapted to growth in chimpanzee cells, expanded in chimpanzee
            cells, and then re-expanded in human PBMCs before lamba cloning
            and sequencing. 90cr402 and another sequence in the study, 93th253,
            are subtype A/E recombinants, and comparison of the two strains
            shows that they were derived from a common A/E recombinant ancestor,
            presumably from Central Africa.

  TITLE     Direct Submission
  JOURNAL   Submitted (12-MAR-1996) John Blouin, HIV Database, Los Alamos
            National Laboratory, Enitwetok Dr., Los Alamos, NM 87545, USA
 COMMENT    A set of three complete genomes from a study linking the HIV-1
            epidemic in the heterosexual population in Thailand to an A/E
            recombinant. 92ug037 was obtained from WHO-NIAIDS and comes from
            an asymptomatic 31-year-old female from Entebbe, Uganda, early in
            infection. The year of infection is unknown and the mode of
            infection was heterosexual contact. 92ug037, U51190, was
            established and propagated by cocultivation with normal donor
            lymphocytes, and then PCR amplified and sequenced. 92ug037
            is subtype A.

HIVU53175 HIVCA9 U53175 422 bp gag Braaten, D. JVI 70, 4220 (1996)
Comment: This study compared the five lineages of primate immunodeficiency viruses and found that only HIV-1 group M requires cyclophilin A for replication. HIV-1 gag binds to cyclophilin A and incorporates it into virions. If this process is disrupted, virion infectivity is inhibited. Cloned isolates from clades A, B, and D of HIV-1 group M and two clones from group O were used. This first phenotypic difference between group M and group O is consistent with the idea that the two HIV-1 groups were introduced to humans by different zoonotic transmissions. This sequence was obtained by PCR from human PBMCs infected with HIVCA9, a group O virus from Cameroon. GenBank accession number U53175.

HIVU54771 CM240 U54771 9203 bp comp. gen. Carr, J.K. JVI 70, 5935 (1996)
Comment: Blood from an asymptomatic heterosexual 21-year-old Thai man was transported from Thailand to the USA where PBMCs were separated and co-cultivated with PHA-stimulated donor PBMCs. DNA from p24 antigen-positive culture was used to amplify the proviral DNA. The complete genomic sequence of the provirus was determined by the compilation of three clones containing different parts of the viral genome. CM240 is an example of a Thai subtype E virus, which is a mosaic of a clade A virus and a clade E virus. GenBank accession number U54771.

SIU17646 SIVsmSL92a U17646 825 bp gag Chen, Z. JVI 70, 3617 (1996)
Comment: Eight SIV gag and env sequences from sooty mangabeys. Six of them represent new viruses from West Africa. All belonged to the SIVsm/HIV-2 family. The characterization of these sequences supports the hypothesis that each HIV-2 subtype in West Africans originated from widely divergent SIVsm strains, transmitted by independent cross-species events in the same geographic locations. GenBank accession numbers U17646,U48810-U48824.

HIVU52194 U52194 325 bp gag Diaz, R.S. Unpublished (1996)
Comment: This work also includes ten envelope sequences. GenBank accession numbers U52194 and U51942,U52055-U52603.

HIVU56888 1C U56888 402 bp gag Fultz, P.N. Unpublished (1996)
Comment: A set of 12 gag sequences and 12 env sequences from a study on the diversification of two HIV-1 LAI Subtype B strains during the dual infection of a chimpanzee for nine years. GenBank accession numbers U56866-U56899.

HIVU51188 90CR402 U51188 9843 bp comp. gen. Gao, F. JVI 70, 7013 (1996)
Comment: One of a set of three complete genomes from a study linking the HIV-1 epidemic in the heterosexual population in Thailand to an A/E recombinant. 90CR402, previously named CAR-E 4002, was obtained from a man from Bangui, Central African Republic, who had lymphadeopathy, diarrhea, severe weight loss and recurrent respiratory infections. He was infected through heterosexual contact, but the year of infection is unknown. 90CR402 (U51188) was first adapted to growth in chimpanze cells, expanded in chimpanzee cells, and then re-expanded in human PBMCs before lamba cloning and sequencing. 93TH253 (U51189) is from a 21-year-old man from Chiang Mai, Thailand and was previously named CMU010 or 302053. The patient had end-stage AIDS. The mode and year of infection are unknown. 93TH253 was isolated and expanded in human PBMCs, then expanded in H9 cells followed by lambda cloning and sequencing. 92UG037 (U51190) was obtained from WHO-NIAIDS and comes from an asymptomatic 31-year-old female from Entebbe, Uganda, early in infection. The year of infection is unknown and the mode of infection was heterosexual contact. 92UG037 was established and propagated by cocultivation with normal donor lymphocytes, and then PCR amplified and sequenced. 93TH253 and 90CR402 are subtype E (A/E recombinant). Comparison of the two strains showed that they were derived from a common A/E recombinant ancestor, presumably from Central Africa. 92UG037 is subtype A. LTR sequences are available under accession numbers U51282-U51297.

SIVCPZANT CPZANT U42720 8182 bp comp. gen. Vanden Haesevelde, M. Virology 221, 346 (1996)
Comment: A simian immunodeficiency virus phylogenetically linked to HIV-1 which was isolated from a captured wild chimpanzee from Zaire. This is the third SIV strain linked to HIV-1 after SIVCPZ-GAB (X52154) and SIVCPZ-GAB2 (U11495) isolated from chimps in Gabon. While SIVCPZ-ANT and SIVCPZ-GAB share a common ancestor with HIV-1, they differ in that the SIVCPCZ strains have highly conserved V3 regions and HIV-1 has a highly variable V3 region. SIVCPZ-ANT is considered to be an outgroup of HIV-1 and is used to suggest the possibility of various introductions of HIV-1 into the human population.

HO74C12DG 074 Z76649 390 bp gag Kampinga, G.A. Unpublished (1996)
Comment: A set of 224 sequences from an extensive HIV-1 mother-to-child-transmission study in Rwanda. The study covers heterogeneity and coinfection with subtypes A and C. GenBank accession numbers Z75969-Z75978, Z75989-Z75997, Z76010-Z76019, Z76030-Z76038, Z76043, Z76045, Z76047, Z76058-Z76069, Z76071-Z76073, Z76084-Z76093, Z76104-Z76113, Z76123-176133, Z76144-Z76152, Z76154-Z76159, Z76162-Z76166, Z76177-Z76182, Z76184-Z76187, Z76208-Z76217, Z76232, Z76246, Z76249-Z76261, Z76274, Z76283, Z76294, Z76302, Z76312-Z76321, Z76343-Z76352, Z76363-Z76372, Z76383-Z76392, Z76413-Z76422, Z76433-Z76442, Z76453-Z76462, Z76649, Z76706, Z76707, Z76733.

HIVU70271 LIT9485 U70271 210 bp gag Liitsola, K. J. Infect. Dis. In press (1996)
Comment: One of thirty-four Baltic and Russian sequences derived from PCR amplified DNA from PBMCs. GenBank accession numbers U70271-U70304.

HIVMCK1 MCK1 D86068 9752 bp comp. gen. Iwatani, Y. Unpublished (1996)
Comment: This sequence is ~98% identical to HXB2 and other IIIB lab strains of HIV-1. PM213 is another complete genome also ~98% identical to HXB2. GenBank accession numbers D86068 and D86069.

HBABMNT BAB-MNT X99948 387 bp gag Narwa, R. JVI 70, 4474 (1996)
Comment: A set of 54 sequences from a mother-to-child-transmission study. The encoding regions of the matrix protein, p17, were sequenced from viral isolates from 22 nontransmitting mothers, 12 HIV-1 positive mother-and-child pairs, 4 infected children, and 4 transmitting mothers. All patients were attending urban hospitals in Paris. Blood samples taken during delivery for mothers and the first month of life for infants. Most of the European mothers were drug users or sexual partners of drug users. The main route of infection for African mothers was heterosexual intercourse. Sequences were classified among the A, B and G subtypes. GenBank accession numbers X99948-X99949, Z79527-Z79578.

HIVETH2220 ETH2220 U46016 9031 bp comp. gen. Salminen, M.O. ARHR 12, 1329 (1996)
Comment: U46016 is the first reported (almost full length) subtype C sequence from Ethiopia. In its genomic organization, this clone closely resembles subtype A, B, and D isolates except that the core promoter contains three potential binding sites for the transcription factor NF-kB instead of containing two.

HIVKUMM1C KUMM1 L42019 410 bp gag Voevodin, A. ARHR 12, 641 (1996)
Comment: Six sequences (I1-5, KUMM2) from Indian expatriates in Kuwait and one sequence from an Ethiopian expatriate in Kuwait used in a study of the diversity of subtypes found in India, Ethiopia, and Kuwait using gag nucleotide sequences. Voevodin et al. found that isolates KUMM1, KUMM2, I1, I3, I4, and I5 clustered with subtype C while the rest clustered with subtype B sequences. GenBank accession numbers U42013, L42014, L42016-L42019, L42022.

LOCUS	COMMON	ACCESSION	LENGTH	REGION	FIRST AUTHOR	REFERENCE
HIVU53606	MB.01	U53606	306 bp	pol (protease)	Barrie, K.A.	Virology 219, 407 (1996)

Comment: This study analyzed HIV-1 gag and pol sequences from PBMCs from HIV-1-infected mothers and their children. Sixty protease alleles from 12 individuals differed by from 3 to as many as 10 amino acids. Protease variants with a proline at position 63, a substitution associated with resistance to protease inhibitors, appeared in the absence of antiprotease therapy in 7 patients and were transmitted by 2 mothers to their infants. Gag p7 p6 regions were more variable than protease. GenBank accession numbers for the set of 61 sequences are U53606-U53666.

HIVU54771	CM240	U54771	9203 bp	comp. gen.	Carr, J.K.	JVI 70, 5935 (1996)

Comment: Blood from an asymptomatic heterosexual 21-year-old Thai man was transported from Thailand to the USA where PBMCs were separated and co-cultivated with PHA-stimulated donor PBMCs. DNA from p24 antigen-positive culture was used to amplify the proviral DNA. The complete genomic sequence of the provirus was determined by the compilation of three clones containing different parts of the viral genome. CM240 is an example of a Thai subtype E virus, which is a mosaic of a clade A virus and a clade E virus. GenBank accession number U54771.

HIVU50207	HIVZ321B	U50207	1497 bp	gag, pol	Choi, D.J.	Unpublished (1996)

Comment: The virus HIVZ321B is a later passage of HIVZ321 (GenBank accession number M15896), which was isolated from a 1976 Zairian serum sample. Z321 was grown to industrial scale in a chronically infected T-cell line to manufacture an inactivated, therapeutic HIV-1 immunogen. Z321B was established from this industrial scale stock.

HIV1U45026	74H9E1.2	U45026	117 bp	pol (rt)	Cleland, A.	JAIDS 12, 6 (1996)

Comment: Sequences of the RT domain of HIV1 from ten plasma and PBMCs samples of two hemophiliac patients. Samples were obtained before, during, and after long-term treatment with ZDV. The appearance of resistance-associated substitutions differed in both patients both in order and timing. The sequences were too short to subtype. GenBank accession numbers U45206-U45664.

HIVU51188	90CR402	U51188	9843 bp	comp. gen.	Gao, F.	JVI 70, 7013 (1996)

Comment: One of a set of three complete genomes from a study linking the HIV-1 epidemic in the heterosexual population in Thailand to an A/E recombinant. 90CR402, previously named CAR-E 4002, was obtained from a man from Bangui, Central African Republic, who had lymphadeopathy, diarrhea, severe weight loss and recurrent respiratory infections. HIVMCK1	MCK1	D86068	9752 bp	comp. gen.	Iwatani, Y.	Unpublished (1996)

Comment: This sequence is ~98% identical to HXB2 and other IIIB lab strains of HIV-1. PM213 is another complete genome also ~98% identical to HXB2. GenBank accession numbers D86068 and D86069.

HIV759RT01 V759 U14902 204 bp pol Quinones, M.E. ARHR 12, 1117 (1996)
Comment: This study looked at sequences from 81 patients from USA, Venezuela, and Spain who were divided into two groups: those with and those without AZT antiretroviral therapy. Several patients had blood drawn on sequential dates to observe change in sequence over time. Patients came from a variety of risk groups, ages, and health status, and a table of patient data is presented. Envelope gene sequences are also available from some of the patients. Not all 81 sequences reported in this paper were released to the database. GenBank accession numbers U14786-U14903, U16764-U16779 and U40533-U40552. The paper also reports on a new sequence analysis software tool for calculating an "evolutionary index" which is a measure of the evolutionary distance between sequences.

HIVETH2220 ETH2220 U46016 9031 bp comp. gen. Salminen, M.O. ARHR 12, 1329 (1996)
Comment: U46016 is the first reported (almost full length) subtype C sequence from Ethiopia. In its genomic organization, this clone closely resembles subtype A, B, and D isolates except that the core promoter contains three potential binding sites for the transcription factor NF-kB instead of containing two.

HIVU53869 PFA330AZT0.2p25 U53869 969 bp pol Tachedjian, G. Virology 212, 58 (1996)
Comment: This sequence was isolated by passing wild-type HIV1 strain PD in the presence of increasing concentrations of AZT and foscarnet in MT-2 cells. Following 25 passes this strain replicated in the presence of 330 micromolar foscarnet and 0.2 micromolar AZT. This protein has three nonpolymorphic substitutions, LYs70Arg, Val75Ile and Lys219Arg, which together give reduced susceptibility to PFA and wild type susceptibility to AZT. The two other sequences in this set also have mutations which give them similar susceptibilities to PFA and AZT. GenBank accession numbers U53669, U53870, and U53871.

SIU65787 SIVmac79A6.1 U65787 1317 bp pol (rt) VanRompay, K.K.A. Unpublished (1996)
Comment: This sequence was derived from an isolate from a rhesus macaque infected with uncloned SIVmac251 following prolonged zidovudine treatment.

HIVU68783 CFSR1 U68783 380 bp pol Wong, J.K. Unpublished (1996)
Comment: Set of 314 sequences of four patients (A, B, C, and D) from San Diego, USA. Samples obtained from the lymph node, spleen, brain, and cerebral spinal fluid of the patients. Sequences are likely from subtype B viruses. GenBank accession numbers for patient A, U68783-U68866; patient B, U68867-U68924; patient C, U68925-U69008; patient D, U69009-U69096.

HIV1AA201 AA201 U64106 738 bp pol (rt) Zheng, N.N. ARHR 12, 1731 (1996)
Comment: Sequences of 91 subtype B HIV-1 isolates obtained between 1990 and 1995 from 23 males from the Sydney region of New South Wales, Australia. These patients were symptomatic or had AIDS, were on long-term antiviral therapy (ZDV and ddI) and showed the development of resistance mutations. Proviral DNA was isolated from PBMCs and the RT region amplified by nested PCR. GenBank accession numbers U64106-U64196.

LOCUS	COMMON	ACCESSION	LENGTH	REGION	FIRST AUTHOR	REFERENCE

HIVMCK1 MCK1 D86068 9752 bp comp. gen. Iwatani, Y. Unpublished (1996)
Comment: This sequence is ~98% identical to HXB2 and other IIIB lab strains of HIV-1. PM213 is another complete genome also ~98% identical to HXB2. GenBank accession numbers D86068 and D86069.

HIVU57217 T01 U57217 216 bp tat Lorenzo, E. Unpublished (1996)
Comment: A set of 113 env sequences and 88 tat sequences from US patients derived during a study on the variability of tat and env genes in HIV-1. Sequences are subtype B. GenBank accession numbers U57217–U57304 and U57104–U57216 for the env sequences.

HIVETH2220 ETH2220 U46016 9031 bp comp. gen. Salminen, M.O. ARHR 12, 1329 (1996)
Comment: U46016 is the first reported (almost full length) subtype C sequence from Ethiopia. In its genomic organization, this clone closely resembles subtype A, B, and D isolates except that the core promoter contains three potential binding sites for the transcription factor NF-kB instead of containing two.

HIVCI17D1 CI17D1 U59559 326 bp env Audoly, G. ARHR In press (1996)
Comment: These sequences are from six different AIDS patients suffering from pulmonary tuberculosis at the Pneumology Hospital of Cocody, Abidjan, Ivory Coast. In this study sequences from viral RNA cocultured on donor PBMCs, proviral DNA sequences from each patients' PBMCs after coculture with donor PBMCs, and proviral DNA sequences directly from uncultured PBMCs were determined. For the cocultured samples viral RNA was harvested from the culture supernatant. PCR or RT-PCR was used to amplify the env V3 region, and 4-7 cloned PCR products were sequenced. A total of 66 sequences from the six patients were published. All 66 were subtype A, and intrapatient sequences were more similar than interpatient sequences. GenBank accession numbers U59559–U59624.

HIVU46206 BHGM5 U46206 290 bp env (C2V3) Barbosa, E.F. Unpublished (1996)
Comment: Set of three Brazilian sequences. Sequence U46206 was obtained by PCR amplification from DNA derived from PBMCs of a female blood donor of unknown health status. This sample was classified as subtype F by the HMA method. Sequence U46210 was obtained from a male individual of unknown health status and was also classified as subtype F by the HMA method. A third sequence, U46122, was classified as subtype B.

HIV1U08355 RU103A U08355 675 bp env (V3-V5) Bobkov, A.F. ARHR 12, 251 (1996)
Comment: One of a set of sequences derived from proviral DNA extracted from PBMCs of a Russian patient. V3-V5 region of env gene extended by nested PCR amplification. The patient belonged to a group of 22 seropositive patients infected nosocomially by HIV-1 originating from a single source. RU103A has a V3 sequence identical to 12 other patients in the group. GenBank accession numbers U08355-U08368.

HIV1BUK3A BUK3A U33095 1089 bp env (V1-V5) Bobkov, A.F. ARHR 12, 1385 (1996)
Comment: Sequences from a study on the genetic variability of HIV-1 in the former Soviet Union. U33095 and U33096 come from a blood sample taken November 1992 from a 39-year-old male Caucasian heterosexual (patient BUK) who lived in Uzbekistan. He reported living in Mozambique in 1984-85 where he was admitted to the hospital several times; however, he reported no sexual relationships with the African residents. Proviral DNA extracted from PBMCs; env gene extended by nested PCR amplification. BUK3A (U33095)and BUK4A (U33096) belong to subtype G, but diverge from the subtype G viruses previously reported from Russia. GenBank accession numbers U33095-U33096.

HIV1MLY10A MLY10A U33104 1218 bp env (V1-V5) Bobkov, A.F. ARHR 12, 1687 (1996)
Comment: One hundred and thirty subjects living in the Russian Federation were enrolled in this study between 1992 to 1996. Proviral DNA was extracted from PBMCs and the env gene was extended by nested PCR; amplified products were then cloned. The study showed that subtypes B and G are predominant in the Russian Federation, although subtypes A, C, D, and H are also present. In this article special attention is given to two epidemiologically linked patients SHL (U33106-U33108) and MLY (U33104-U33105) whose genetic subtypes could not be identified clearly by the HMA method. SHL became infected through sexual contact with an HIV-1 positive student from Zaire. MLY became infected by a blood transfusion from SHL after a cesarean section in 1987. MLY child is believed to have acquired the disease through breast feeding. The authors concluded that MLY and SHL belonged to the H subtype after phylogenetic tree analysis.

H92MY14093 92MY14093 U65538 345 bp env (V3) Brown, T.M. ARHR 12, 1655 (1996)
Comment: Blood samples were collected between 1992 and 1993 from 13 IV drug-using prisoners in Kuala Lumpur, Malaysia and one HIV-1 infected baby born in Thailand but adopted by Malaysian parents. PCR products amplified from uncultured PBMCs were directly sequenced. Eleven sequences clustered with the B subtype (U65538-U65548), two grouped in the C subtype (U65549-U65550) and the baby's sequence (U65551) was determined to be subtype E. Subtype C patients were Malaysian nationals who had visited India in 1989 and 1990 for medical treatment. GenBank accession numbers U65538-U65551.

HIV194UG003 94UG003 U44878 275 bp env (C2-V3) Buonaguro, L. JVI 69, 7971 (1995)
Comment: These 10 sequences are from Gulu, northern Uganda. They are direct sequences of PCR products amplified from uncultured PBMCs. Blood samples were drawn in March 1994 from 217 pregnant women attending a clinic in Gulu, northern Uganda. Ages ranged from 17 to 37 years. The 29 seropositive women (13.4% of the 217 tested) were all asymptomatic. Eight sequences were subtype A and two were D (U44881 U44884). Genbank accession numbers U44878–U44887.

HIV1U37030 AR06 U37030 331 bp env (V3) Campodonico, M. ARHR 12, 79 (1996)
Comment: Fourteen sequences from a study examining HIV-1 strains in Rosario, Agentina. The cohort included individuals infected through heterosexual and homosexual contact, blood transfusion, and intravenous drug use. The patients were enrolled in the study in April 1995. Two (U37032, U37033) clustered with subtype F sequences, ten (U37030, U37031, U37034-U37042) with subtype B, and one (U37043) appeared to be a B/F hybrid.

HIVU54771 CM240 U54771 9203 bp comp. gen. Carr, J.K. JVI 70, 5935 (1996)
Comment: Blood from an asymptomatic heterosexual 21-year-old Thai man was transported from Thailand to the USA where PBMCs were separated and co-cultivated with PHA-stimulated donor PBMCs. DNA from p24 antigen-positive culture was used to amplify the proviral DNA. The complete genomic sequence of the provirus was determined by the compilation of three clones containing different parts of the viral genome. CM240 is an example of a Thai subtype E virus, which is a mosaic of a clade A virus and a clade E virus. GenBank accession number U54771.

HIVU53278 CMCH1 U53278 287 bp env Cassol, S. ARHR 12, 1435 (1996)
Comment: A set of sequences from a study on the detection of HIV-1 subtypes A,B,C, and E in India, Myammar, Thailand, China, and Indonesia involving dried blood spots collected in 1992. Envelope gene extended by PCR amplification from DNA of dried blood spots. The patients belonged to a wide variety of risk categories. GenBank accession numbers UU53286, U53291 (subtype A); U53304-U53308, U53310, U53311, U53314-U53317(subtype B); U53278-U53285, U53287-U53290, U53292-U53303 (subtype C); U53309, U53312, U53313 (subtype E).

HIVTW644 TW64-4 U73045 214 bp env (V3) Chang, K.S.S. ARHR In press (1996).
Comment: These 16 sequences represent healthy HIV-1 carriers or AIDS patients from Taiwan. Three subtype B sequences in this set were greater than 97% identical to the HXB2/LAI lab strain of HIV-1 (TW83, U73049; TW271, U73059; and TW335, U73061). The manuscript reports that 123 of 143 sequences from Taiwan were subtype B, but only 27 of the 143 sequences were submitted to the sequence databases. Other subtypes found in Taiwan in this study were E (U73060, U73062 and U73070), C (U73055), F (U67765) and G (U73058). GenBank accession numbers for B subtype are U73045–U73054, U73056, U73057, U73059, U73061 and U73063–U73069.

HIVU50207 Z321B U50207 1497 bp env Choi, D.J. ARHR In press (1996)
Comment: The virus HIVZ321B is a later passage of HIVZ321, which was isolated from a 1976 Zairian serum sample (GenBank accession number M15896). Z321 was grown to industrial scale in a chronically infected T-cell line to manufacture an inactivated, therapeutic HIV-1 immunogen. Z321B contains a mutation in the termination codon of the tat gene and extends further downstream by 48 nucleotides. The authors present evidence for Z321 being an A/G recombinant. GenBank accession numbers U50207 and U50208.

HIV1GP41 BSMADGP41 X83215 372 bp gp41 Cohen, H.J.M. Lancet 345, 856 (1996)
Comment: One of two partial env group O sequences, one of gp41 and the other of gp120. GenBank accession numbers X83215 and X83216.

HIV1U56263 2BD20 U56263 656 bp env (C2-V5) Contag, C.H. Unpublished (1996)
Comment: These sequences come from a study of mother to child transmission of HIV1 in Sweden involving five subtypes. Subtype A: mother 4, and infant 4 (U56274-U56283, U56328); Subtype B: mother 2, infant 2, mother 6, and infant 6 (U56263-U56273, U56288-U56291, U56299, U56300, U56303, U56317-U56321, U56335); Subtype C, mother 5, infant 5, mother 7, and infant 7; Subtype D, mother 3, infant 3 (U56304-U56306, U56310-U56312, U56330); Subtype E, mother 1, infant 1 (U56309, U56329). Proviral DNA derived from PBMCs or plasma.

HIVG134 G134 X90912 873 bp env (V3-V5) Delaporte, E. AIDS 10, 903 (1996)
Comment: In this study, 17 partial HIV-1 env (V3-V5) gene sequences were determined from 17 different patients selected from a study involving serological screening of 7,082 patients in Libreville, Gabon, and 771 pregnant women and 886 asymptomatic adults in Franceville, Gabon. The study took place from 1986-1994 during which the prevalence of HIV infection in Gabon was low (0.7 - 1.6% in pregnant women, 2,1 - 2.6% in the general population) and remained stable. The 17 isolates sequenced represented five different subtypes (A, C, D, F, and G) and Group O. The high sequence diversity, and low prevalence rates are similar to Cameroon, but different from the rest of Africa. Of the 17 strains, 10 were isolated from Libreville. Of these, 4 were from asymptomatic seropositive persons in 1988 and 6 were collected from AIDS patients between 1989 and 1993. The remaining 7 were collected between 1988 and 1989 from AIDS patients in Franceville. GenBank accession numbers X90912 (G134), X90913 (LBV10-5), X90914 (LBV2-3), X90915 (G135), X90916 (G98), X90917 (G41), X90918 (LBV23-10), X90919 (G109), X90920 (G141), X90921 (VI1076), X90922 (VI526), X90923 (VI354), X90924 (VI685), X96526 (VI686), U09665 (LBV21-7), L22953 and U09665 (VI525). Isolate G139 is not available from GenBank.

HIVU43035 U43035 235 bp env (V3) Diaz, R. Unpublished (1996)
Comment: Set of 124 closely related sequences presumably belonging to subtype B. All 124 sequences came from patients from the United States who had been infected by a common source. GenBank accession numbers U29433-U29437, U29956-U30054, and U43035-U43054. Gag sequences from 12 clones are also available in GenBank entries U31573-U31584.

HIVU43986 D1-116 U42986 240 bp env (C2-V3-C3) Diaz, R. ARHR 12, 1291 (1996)
Comment: These sequences come from a study on the lack of dual HIV infection in a transfusion recipient who was exposed to two seropositive blood components. The patient was a 54-year-old male with oat cell carcinoma of the lung who was treated with prednisone at the time of index transfusion. He was transfused in November 1984. Samples of sera and leukocytes from both donors and from the dual recipient were analyzed. GenBank accession numbers U43986-U44023.

HIVU51942 U51942 325 bp env (C2V3-C3) Diaz, R. Unpublished (1996)
Comment: This work also includes a gag sequence. GenBank accession numbers U51942, U52055-U52063 and U52194.

HIV1V3NO1 NO1 X92902 252 bp env (V3) Engelstad, M. ARHR 12,1733 (1996)
Comment: Sequences of 40 individuals of Norwegian origin from four major risk groups. Eleven were homosexual or bisexual men, 11 were IVDUs, 4 were heterosexual partners of IVDUs, 6 were hemophiliacs who had received contaminated blood products, and 8 were heterosexual individuals infected through intercourse with persons from Zambia (3), USA (1), Grenada (1), Italy (2), and South Africa (1). The dates of seroconversion were unknown. Thirty-eight of the patients were asymptomatic and two of the hemophiliacs were classified as CDC IV at the time when the samples were obtained. Thirty-six of these sequences are subtype B (X92902–X92912, X92915, X92916, X92919–X92941) and four are subtype C (X92913, X92914, X92917, X92918). GenBank accession numbers X92902–X92941.

HIVU56866 C499env1 U56866 573 bp env Fultz, P.N. Unpublished (1996)
Comment: A set of 12 env sequences from a study on the diversification of two HIV-1 LAI Subtype B strains during the dual infection of a chimpanzee for 9 years. GenBank accession numbers U56866-U56887. Also, see GenBank accession numbers U56888-U56899 for gag sequences from the same study.

HIVU51188 90CR402 U51188 9843 bp comp. gen. Gao, F. JVI 70, 7013 (1996)
Comment: One of a set of three complete genomes from a study linking the HIV-1 epidemic in the heterosexual population in Thailand to an A/E recombinant. 90CR402, previously named CAR-E 4002, was obtained from a man from Bangui, Central African Republic, who had lymphadeopathy, diarrhea, severe weight loss and recurrent respiratory infections. He was infected through heterosexual contact, but the year of infection is unknown. 90CR402 (U51188) was first adapted to growth in chimpanze cells, expanded in chimpanzee cells, and then re-expanded in human PBMCs before lamba cloning and sequencing. 93TH253 (U51189) is from a 21-year-old man from Chiang Mai, Thailand and was previously named CMU010 or 302053. The patient had end-stage AIDS. The mode and year of infection are unknown. 93TH253 was isolated and expanded in human PBMCs, then expanded in H9 cells followed by lambda cloning and sequencing. 92UG037 (U51190) was obtained from WHO-NIAIDS and comes from an asymptomatic 31-year-old female from Entebbe, Uganda, early in infection. The year of infection is unknown and the mode of infection was heterosexual contact. 92UG037 was established and propagated by cocultivation with normal donor lymphocytes, and then PCR amplified and sequenced. 93TH253 and 90CR402 are subtype E (A/E recombinant). Comparison of the two strains showed that they were derived from a common A/E recombinant ancestor, presumably from Central Africa. 92UG037 is subtype A. LTR sequences are available under accession numbers U51282-U51297.

HIVUGO2116 UGO2116 U27426 2928 bp env Gao, F.J. JVI 70, 1651 (1996)
Comment: The complete gp160 coding region of this isolate was sequenced along with those of others collected at major epicenters of the AIDS epidemic during a study by Gao et al. The 35 members of this representative panel include members of all major sequence subtypes of HIV-1 group M (clades A-G) as well as an inter-subtype recombinant (F/B) from an infected individual in Brazil. In this panel, all subtype E and three subtype G viruses initially classified on the basis of partial env sequences were found to cluster in subtype A in the 3' half of their gp41 coding region, suggesting that they are also recombinant. The biological activity of PCR derived envelope genes was examined in a single round virus infectivity assay. This analysis identified 20 clones, including one from each subtype or recombinant, that expressed fully functional envelope glycoproteins. GenBank accession numbers U27443-U27445, U27434, U27426, U27419, U27413, U27408, U27401, U27399, U04900-U04929, U30312, U43386, L34667, U08797, U08794, U09131, U08801, U08441–U08447, U09127, U09126.

HIVU48855 94CU053 U48855 1416 bp env (V3) Gomez, C.E. ARHR 12, 553 (1996)
Comment: DNA sequence of the gp120 cds of a HIV-1 isolate from a bisexual male, most probably infected in Cuba in 1992 by heterosexual contact. The virus was isolated two years after seroconversion by cocultivation of patient PBMCs with seronegative donor PBMCs. Nested PCR was used to amplify the gp120 gene and the C2-V3 region. Five clones from the C2-V3 region were isolated and studied. The amino acid sequence GRGR in the tip of the V3 loop is reported here for the first time. This atypical sequence suggests that this virus can escape from antibodies directed against the V3 region of other HIV-1 isolates more frequently found in America. The sequence clustered with subtype B sequences SF2 and LAI. GenBank accession number U48855.

SIVCPZANT CPZANT U42720 8182 bp comp. gen. Vanden Haesevelde, M. Virology 221, 346 (1996)
Comment: A simian immunodeficiency virus phylogenetically linked to HIV-1 which was isolated from a captured wild chimpanzee from Zaire. This is the third SIV strain linked to HIV-1 after SIVCPZ-GAB (X52154) and SIVCPZ-GAB2 (U11495) isolated from chimps in Gabon. While SIVCPZ-ANT and SIVCPZ-GAB share a common ancestor with HIV-1, they differ in that the SIVCPCZ strains have highly conserved V3 regions and HIV-1 has a highly variable V3 region. SIVCPZ-ANT is considered to be an outgroup of HIV-1 and is used to suggest the possibility of various introductions of HIV-1 into the human population.

HIVBJ1 BJ1 U61854 255 bp env (V3) Heyndrickx, L. ARHR 12, 1495 (1996)
Comment: These 18 sequences are from female prostitutes, born in either Ghana or Togo, who live in Benin. Fifteen are from directly sequenced PCR products, derived via RT-PCR from patient serum RNA. Three (233, 251 and 253) are from cloned PCR products, also by RT-PCR from serum RNA. Another subtype A sequence (366, U61870) is not included here, because it was nearly identical (254 of 255 bases identical) to the SF170 sequence from 1988, and thus it likely represents a lab artifact. GenBank accession numbers U61854–U61869, U61871 and U61873.

HIVU63314 HIV-1MN U63314 275 bp env Hua, J. Virology In press (1996)
Comment: HIV-1 MN env and rev gene sequences from a study on the changes of function resulting from a natural sequence variation in the activation domain of HIV-1 rev. MN is from the USA. GenBank accession number U63314.

HIVU47562 A1-E1 U47562 608 bp env Hutto, C.J. JVI 70, 3589 (1996)
Comment: These sequences come from a study on twins with different disease courses. Envelope gene was extended by nested PCR amplification from proviral DNA derived from patients PBMCs. Heterozygotic twins who had been perinatally infected were observed during their first 2 years of life. Twin A (U47562-U47572), the first born, remained asymptomatic while twin B (U47573-U47588) developed AIDS when he was 6 months old and died when he was 22 months old. The absence of neutralizing antibodies may correlate with disease progression since twin A developed neutralizing antibodies and twin B did not. The samples were determined to be nonsyncytium inducing and subtype B. Also see GenBank accession numbers U47589-U47613 for tat sequences from the same patient.

HIVMCK1 MCK1 D86068 9752 bp comp. gen. Iwatani, Y. Unpublished (1996)
Comment: This sequence is ~98% identical to HXB2 and other IIIB lab strains of HIV-1. PM213 is another complete genome also ~98% identical to HXB2. GenBank accession numbers D86068 and D86069.

HIV1686EN VI686 X96526 2640 bp env Janssens, W. AIDS 10, 903 (1996)
Comment: A group O sequence from a study on the charactarization of HIV-1 group O viruses. This sequence is from a 1992 sample taken from a Gabonese woman with AIDS (Libreville). The Method of DNA isolation was not described. DNA was PCR amplified and cloned. See also GenBank accession numbers X90912-X90924.

HIVV3REO1 1A-2 D78614 105 bp env (V3) Kakizawa, J. ARHR 12, 561 (1996)
Comment: These sequences come from a study of the diversity of the HIV1 env V3 region in saliva. Eight saliva samples were collected from seven patients. Two were asymptomatic carriers (isolates 7 and 8), three had AIDS-related complex (isolates 2, 4, 5, and 6, 5 and 6 being from the same patient), and two were patients with AIDS (isolates 1 and 3). Saliva samples corresponding to isolates 1 through 5 were collected between April and June, and isolates 6 through 8 were collected in January 1995. Five cases were children with hemophilia (isolates 1-4, 6 and 7) and two patients were homosexual adults (isolates 5 and 8). Proviral DNA was extracted by glass powder method. DNA was then PCR amplified and sequences. GenBank accession numbers: Isolate 1, D78614-D78616; Isolate 2, D78617; Isolate 3, D78618-D78621; Isolate 4, D78622-D78623; Isolate 5, D78624-D78626; Isolate 6, D78627-D78630; Isolate 7, D78631-D78633; Isolate 8, D78634-D78637. These sequences belong to subtype B and, of the previously-reported Japanese strains, are more closely related to SF162 than to MN.

Comment: A set of 73 env sequences from a Scottish study on the variability of env and pol genes in HIV-1 LAI during zidovudine therapy. PCR amplified PBMC DNA were sequenced and are most probably sybtype B. GenBank accession numbers U58393–U58465.

HIVU68496 sample 136 p1 U68496 276 bp env (V3) Leitner, T. PNAS 93, 10864 (1996)
Comment: This set of 26 sequences from 13 samples contains sequences from env V3 and gag p17. The set is derived from an exactly known Swedish transmission history and includes serial samples from some patients. The index case (patient 1) was a Swedish male who is believed to have contracted HIV while visiting Haiti in 1980. Six Swedish females (patients p2, p4, p5, p7, p8, and p11) were infected by patient 1. Two males (patients p6 and p10) were then infected by these females, and two HIV-infected children (patients p3 and p9) were born to the women. The phylogeny of this data set spans the time 1980 to 1994. GenBank accession numbers p1, U68496, U68497, U68509; p2, U68498, U68511; p3, U68499, U68500, U68512, U68513; p5, U68501, U68514; p6, U68502, U68515; p7, U68503, U68516; p8, U68504, U68505, U68517, U68518; p9, U68506, U68519; p11, U68507, U68508, U68520, U68521. Sequences are unavailable for p4 and p10.

HIVU69646 RU3 U69646 258 bp env (V3) Leitner, T. ARHR 12, 1595 (1996)
Comment: This set contains 22 env V3 sequences from Russian infected patients. The set contains both epidemiologically linked and unlinked patient sequences. Subtypes A, B, F, and G were found from hetero-, homo-, and bisexual as well as nosocomially infected patients. All sequences are direct population estimates from uncultured patient PBMCs and were characterized on MT-2, CEM, and Jurkat-tat cells. GenBank accession numbers U69646-U69667.

HIV1U56146 14Pb1-16 U56146 629 bp env (V3-V5) Liu, S-L. Unpublished (1996)
Comment: Set of sequences from a study on different patterns of progression to AIDS from the same source of infection. GenBank accession numbers U56146-U56235.

HIVU54646 3BC01V2 U54646 174 bp env (V1/V2) Lockey, T.D. ARHR 12, 1297 (1996)
Comment: These sequences represent 22 clones from 2 descendant HTLV-IIIB cultures. The HTLV-IIIB stocks were propagated on H9 cells. DNA was isolated and PCR used to amplify the envelope gene. The sequences were then compared to each other, and to other previously isolated clones, to determine the degree of heterogeneity. The heterogeneity found poses questions about the validity of comparing results from different labs. GenBank accession numbers U54646-U54689.

HIVU57104 e01 U57104 360 bp env (C2-V3) Lorenzo, E. Unpublished (1996)
Comment: A set of 113 env sequences and 88 tat sequences from U.S. patients derived from a study on the variability of tat and env genes in HIV-1. Sequences are subtype B. GenBank accession numbers U57104–U57216 and U57217–U57304 for the tat sequences.

HRW890388 RR890388 L76870 270 bp env (V3) Lukashov, V.V. ARHR 12, 951 (1996)
Comment: These sequences are from recent immigrants to the Netherlands from various countries where AIDS is endemic. Unconventional country codes were used in the common names. Viral RNA was prepared from patient serum and RT-PCR was used to amplify the V3 region of the env gene. The PCR products were directly sequenced. Individuals originating from African countries belonged to subtypes A, C, and D. Individuals originally from Zaire showed subtypes F and G. GenBank accession numbers L76870-L76913 and L86887.

HIV1ENVAA 131871 L76842 270 bp env (V3) Lukashov, V.V. ARHR 12, 1179 (1996)
Comment: This set of sequences comes from a study that links the origin of the AIDS epidemic in Northern Europe to the United States. HIV1 RNA coding for the V3 envelope region was derived from serum samples taken at seroconversion from 31 homosexual men who seroconverted in 1985-1988 and 12 IVDUs who seroconverted in 1986-1990 in Amsterdam, and 11 IVDUs from Baltimore who seroconverted in 1988-1990. In addition, V3 sequences from 8 IVDUs in Scotland and Germany and 10 homosexual men in Scotland, Germany, the United States, and Russia were used to conclude the existence of a link to the US in the origin of the northern European AIDS epidemic. GenBank accession numbers L76842-L76863.

HIVU48274 1018 U48274 644 bp env (C2-V5) McCutchan, F.E. JVI 70, 3331 (1996)
Comment: Four of these sequences are from Uruguayan servicemen who acquired HIV-1 infections while deployed as United Nations peacekeepers in Cambodia in 1993. Two sequences are from samples collected in 1993 in Thailand. One sequence is from a U.S. serviceman who acquired an HIV-1 infection while deployed in Thailand. All of these patients were asymptomatic when samples were collected. Six sequences were from patients hospitalized with AIDS-related illnesses in northern Thailand. Viral DNA was PCR amplified from patient PBMCs. All sequences are HIV-1 clade E. GenBank accession numbers U48272-U48278 and U48264–U48269.

HIVU57788 KI4803 U57788 1610 bp env McKeating, J.A. Virology 220, 450 (1996)
Comment: HXB2 viruses chimeric for gp120 were constructed from a primary isolate. The primary isolate was KI4803 which comes from Sweden and whose subtype is uncertain. Primary and chimeric viruses were compared to ascertain differences in functionality. XHB2 chimeras showed same patterns of cell tropism and cytopathicity. Both primary and chimeric viruses were sensitive to neutralization by sCD4 and had the same gp120 conformation. GenBank accession numbers U57788-U57794.

HAR20016 AR20016 U68522 258 bp env (V3) Marquina, S. ARHR 12, 1651 (1996)
Comment: Blood samples from four unrelated patients in Buenos Aires, Argentina, were collected in 1993. Two patients had AIDS: one was an intravenous drug user, 21280 (U68524), and the other a promiscuous heterosexual, 21281 (U68525). Two samples came from asymptomatic patients, 20021(U68523) and 20016 (U68522). Direct sequencing of PCR products was done from uncultured PBMCs. Two sequences were of subtype F (21280 and 20016) and one of subtype B (21281). The last sequence (20021) was a B/F recombinant.

HESP11158 ESP1-1158 U62618 402 bp env Mas, A. ARHR 12, 1647 (1996)
Comment: These sequences come from blood samples taken from a 35-year-old man from Spain collected in April and September 1995. The V3 region was PCR amplified from uncultured PBMCs, cloned into PGEM-SZF, and an individual clone sequenced. The sequences belong to group O. The April sequence has GenBank accession number U62618 and the September sequence has number U62617.

HIVU66414 UY726 U66414 313 bp env Medina, R.D. ARHR 12, 1491 (1996)
Comment: These nine subtype B sequences were derived from blood samples obtained in March-April 1995 from nine HIV-1 infected patients in Montevideo, Uruguay. Uncultured PBMCs were lysed and viral DNA was amplified by nested PCR. These sequences show a high degree of heterogeneity in the apex motif of V3. GenBank accession numbers U66414-U66422.

HIV1U29209 HCM9 U29209 219 bp env Menu, E. Unpublished (1995).
Comment: This subtype B sequence is from Ho Chi Minh city, from a woman infected by her HIV seropositive sexual partner who was thought to have been infected while traveling in Europe, Genbank accession number U29209. Three other sequences in this Vietnamese study from IV drug users in Ho Chi Minh city and Dong Nai, and a female prostitute in Can Tho were found to be subtype E. Genbank accession numbers U29206-U29209

HIV1HWCL1 HWCL1 U34049 487 bp env (V3) Montpetit, M. ARHR 11, 1421 (1995)
Comment: This sequence is the first published sequence of subtype A HIV-1 in Canada. The patient had moved from Uganda in 1983, and was diagnosed as HIV+ in 1989. Viral RNA was recovered from archived, stored patient serum by binding viral particles to CD4-coated wells of an ELISA plate. After RT-PCR, products were cloned and 10 clones were sequenced. This sequence is from a single clone, L1.

HIVU48719 HIV1VN4 U48719 322 bp env (V3) Nerurkar, V.R. ARHR 12, 841 (1996)
Comment: A genotypic analysis from IDUs and CSWs in Vietnam to determine if concurrent epidemics with different HIV-1 subtypes are occurring among the high risk-behavior groups. Blood samples were collected from two HIV-1 CSWs and three IDUs in southern Vietnam during April and May 1995. VN1 (U45239) and VN2 (U45240) were from healthy 17 and 25 year-old female prostitutes from Can Tho and An Giang. VN3 (U48720) and VN4 (U48719) were a 43 year-old male IV drug user with pruritus and splenomegaly from Nha Thang and a 31 year-old healthy IV drug user male from Nha Thang respectively. Genomic DNA was extracted. The V3 loop region was then amplified through PCR and sequenced. It was determined that the Vietnam HIV-1 strains belong to subtype E and that the patients had been infected with indigenous strains circulating within Vietnam.

HIVU67348 VI1011 U67348 453 bp env Nyambi, P.N. ARHR In press (1996)
Comment: Five HIV-2 sequences derived for use in an examination of the cross-neutralization characteristics between HIV-1 and SIVcpz and those between HIV-1 and HIV-2. Nyambi et al. found that the cross-neutralization between HIV-1 and HIV-2 was less extensive than between the HIV-1 and SIVcpz. In addition they saw that, though their binding capacity did not readily reflect their neutralizing capacity, a majority of HIV-1 and SIVcpz sera bound to the V3 peptides while the HIV-2 sera lacked the neutralizing antibodies to the homologous isolate and did not have any reactivity to the V3 peptide. GenBank U67348-U67352.

HIV1U52247 P1T1A1 U52247 243 bp env (V1-V2) Palmer, C. Virology 220, 436 (1996)
Comment: Variations in the V1V2 region were followed over time in six HIV1 infected individuals. Peripheral blood samples were obtained from six seropositive males (CDC II) attending an STD clinic. The V1V2 sequences were cloned into HXB2 to produce chimeras. The chimeras showed that the V1V2 region of gp120 can determine both tropism and cytopathicity independently from the V3 region. GenBank accession numbers for patient 1, U52247-U52264; patient 2, U52265-U52285; patient 3, U52286-U52303; patient 4, U52304-U52315; patient 5, U52316-U52333; patient 6, U52334-U52339.

HIV1ES106 ES106 U40533 402 bp env (C2-V3) Quinones, M.E. ARHR 12, 955 (1996)
Comment: These subtype B sequences are from 41 patients sampled in Madrid, Spain between 1985 and 1991. Proviral DNA was extracted from uncultured patient PBMCs and the C2V3 region was PCR amplified. The PCR products were directly sequenced. Two of the sequences reported in this set (D22-28 and D22-48) were 99.5% identical to the LAI strain of HIV-1. Three other groups of sequences had members that were greater than 98% identical to each other (R1, R2 and R3; THF13-2, THF12-24; S1, S4). GenBank accession numbers U40533–U40552 and U45286–U45307.

HIVENVB HIV1BB L78831 1546 bp env Ray, S.C. Unpublished (1996)
Comment: These subtype B sequences come from a study on the cytolytic T lymphocyte strain-specific responses that are directed against the HIV-1 env. Virus was isolated from PBMCs. GenBank accession numbers L78831 and L78832.

HIVKZ21 KZ21 U43097 945 bp partial env Reitz, M. Unpublished (1990)
Comment: These subtype A sequences are from Zaire. GenBank accession numbers U43097–U43100.

HIV1U61875 94TZ1574 U61875 342 bp env (C2V3) Robbins, K.E. ARHR 12, 1389 (1996)
Comment: These sequences come from a study on the genetic variability of HIV1 in rural Northwest Tanzania. Sequences were obtained by PCR amplification of patient PBMCs. Seven of the Tanzanians lived in the Mara region and their samples were collected in 1994. The other patient, 87TZ4622, was originally from the Mara region, but had lived in Kigoma for several years. The specimen used was collected in 1987. Sequences 94TZ1627, 87TZ4622, 94TZ1585, and 94TZ1604 are subtype D. Sequences 94TZ1577, 94TZ1576, 94TZ1574, and 94TZ1584 are subytpe A. GenBank accession numbers U61875-U61881 and U65075.

HIV1U31585 SP203 U31585 648 bp env (V3) Sabino, E.C. AIDS 10, 1579 (1996)
Comment: This is a set of 11 sequences from a study on the prevalence of HIV-1 subtypes in Sao Paulo, Brazil. Five sequences are subtype B (U31586, U31587, U31589-U31591), one sequence is subtype C (U31585), and four sequences are subtype F (U31588, U31592-U31595).

HIVETH2220 ETH2220 U46016 9031 bp comp. gen. Salminen, M.O. ARHR 12, 1329 (1996)
Comment: U46016 is the first reported (almost full length) subtype C sequence from Ethiopia. In its genomic organization, this clone closely resembles subtype A, B, and D isolates except that the core promoter contains three potential binding sites for the transcription factor NF-kB instead of containing two.

HIV1G1X11 G1-11 Z50841 105 bp env (V3) Schreiber, M.G. Unpublished (1996)
Comment: Sequences from a study of the loss of antibodies specific for the V3 domain over time in certain HIV-1 variants. Proviral DNA extracted from patients PBMCs. Probably subtype B. GenBank accession numbers Z50841-Z50847.

HIVU45860 1018674A U45860 280 bp env (C2V3) Schwartz, D.H. Unpublished (1996)
Comment: These subtype B sequences are from a study of the envelope glycoprotein C2-V3 region on isolates obtained from PBMCs of four HIV-1 infected patients. GenBank accession numbers for patient 101867 are U45860-U45876, U49624-U49640; patient 10188B, U51311-U51326; patient 10185W, U49600-U49623; patient 10187Y, U49518-U49553.

HIVU45330 U45330 363 bp env (V3) Sheehy, N. J.Gen.Virol 77, 1071 (1996)
Comment: Set of subtype B sequences from an AIDS patient from the United Kingdom who had received treatment with zidovudine for 9 months. Proviral DNA obtained from PBMCs drawn 13 months and 10 months prior to death and from autopsy samples of cardiac blood, lymph node, spleen, bone marrow and brain was PCR amplified and sequenced. A reduction in genetic heterogeneity of the envelope region of viruses present in the proviral blood population occured during treatment coinciding with increased pol heterogeneity. GenBank accession numbers U45330-U45421.

HIV1U29179 UIND1 U29179 1488 bp env Tripathy, S.P. ARHR 12, 1199 (1996)
Comment: Part of a set of nine sequences from New Delhi and Pune, India, eight of which were subtype C (U29179,U29694-U29698, U31362-U31363) and one of which was subtype B (U31364). All 8 subtype C sequences were from heterosexually infected patients. DNA was isolated from cocultured PBMCs after one week of culture. PCR product was cloned and a single clone was sequenced.

SIVmac251 SIU62333 U62333 1114 bp env Trivedi, P. JVI 70, 6875 (1996)
Comment: Fifty-one env sequences from a study of intrarectal transmission of SIV in rhesus macaque monkeys. Trivedi et al. found that a condition now called transient viremia sometimes occurs after mucosal inoculation of monkeys with low doses of SIV as opposed to the more prevalent persistent infection with evident disease progression. Also, after a 1000 infective dose, they found that transiently viremic monkeys were resistant to an intrarectal SIVmac challenge but not to an intravenous SIVmac challenge. GenBank U62333-U62383.

HIVFF1 FF1 Z76463 303 bp env (V3) van der Hoek, L. J. Gen. Virol. In press (1996)
Comment: These subtype B sequences are of 81 clones (patient N) and 105 clones (patient F) from serum, sigmoid tissue and fecal matter from each patient. All sequences from patient N were more similar to other sequences from patient N than to any other sequence in the database. Likewise all sequences from patient F were most similar to other patient F sequences. Both patients are from the Netherlands. GenBank accession numbers Z76463–Z76648.

HIVIU60152 ID4-77c7 U60152 939 bp env Wang, W.K. ARHR 12, 1195 (1996)
Comment: This study concentrates on the change of cysteine residues in region 1 of gp120 HIV-1 Subtype B. Sequential isolates from eight subjects were used though these 11 sequences account for only one of the subjects. Subjects came from a group of 315 homosexual and bisexual men who have been followed at the Fenway Community Health Center in Boston and were enrolled between January 1985 and June 1986. Viruses were isolated from PBMCs of the subjects by co-cultivation with PBMCs of HIV-1 seronegative donors. GenBank accession numbers U60152-U60162.

HIVBJP23A BJP23 D67089 264 bp env (C2V3) Xin, K. Lancet 346, 1372 (1996)
Comment: This pair of sequences is from a study of a dual infection with HIV1 Thai subtype B and E. D67089 is Subtype E and D67090 is Subtype B or a B/E recombinant. GenBank accession numbers D67089 and D67090.

HIV1U32658 NA111 U32658 285 bp env (V3) Zachar, V. ARHR 12, 75 (1996)
Comment: This was a May-June 1992 study of pregnant women from the Pumwani Maternity Hospital in Nairobi, Kenya. Viral RNA was concentrated from patient serum just prior to delivery, and the envelope C2-V3 region was amplified by RT-PCR. The PCR product was cloned and 20 clones from each patient were sequenced. Patients from this study had viral subtypes A (U32658, U33763, U33764, U33766, U33767, and U34905), C (U33762), and D (U33765).

HIVU53192 BTS11 U53192 285 bp env (V3) Zachar, V. ARHR 12, 1069 (1996)
Comment: Genetic analysis of the V3 env region of virus isolates obtained in 1993 from 11 homosexual men living in the inner city of Bratislava. A 32-year-old homosexual man from Prague was also included in the study. Viruses were cultivated in PBMCs. The C2V3 region of HIV-1 LAI was amplified by nested PCR. PCR product was cloned and eight clones from each patient were sequenced. These strains cluster in the B clade together with the majority of North American and western European strains. GenBank accession numbers U53192-U53203.

HIVU50780 AD39PB1 U50780 1047 bp env (V1-V5) Zhu, T. JVI 70, 3098 (1996)
Comment: DNA extracted from PBMCs of an acute seroconvertor male patient, AD39, who was infected with HIV-1 through homosexual transmission by his partner AD38. Sequences spanned by primers PE1 and P2 from the gp120 gene were expanded by PCR amplification. A second round of PCR amplification expanded V1-V2 sequences (using inner primers P1 and P10) and V3 (using inner primers P5 and PV3). AD39PB1 has been characterized as non-syncytium inducing (NSI). GenBank accession numbers U50780-U50815.

LOCUS	COMMON	ACCESSION	LENGTH	REGION	FIRST AUTHOR	REFERENCE
HIVU48901	122-16	U48901	615 bp	nef	Artenstein, A.W.	ARHR 12, 557 (1996)

Comment: Sequences derived from PCR amplified PBMC DNA from nineteen Thai individuals. Only two clones (28-19, 28-2) from one subject clustered with subtype B sequences while the rest clustered with subtype E sequences. The lack of subtype E nef sequences led Artenstein et al. to begin this study. GenBank accession numbers U48897-U48934.

HIVU54771 CM240 U54771 9203 bp comp. gen. Carr, J.K. JVI 70, 5935 (1996)
Comment: Blood from an asymptomatic heterosexual 21-year-old Thai man was transported from Thailand to the USA where PBMCs were separated and co-cultivated with PHA-stimulated donor PBMCs. DNA from p24 antigen-positive culture was used to amplify the proviral DNA. The complete genomic sequence of the provirus was determined by the compilation of three clones containing different parts of the viral genome. CM240 is an example of a Thai subtype E virus, which is a mosaic of a clade A virus and a clade E virus. GenBank accession number U54771.

HIVU51188 90CR402 U51188 9843 bp comp. gen. Gao, F. JVI 70, 7013 (1996)
Comment: One of a set of three complete genomes from a study linking the HIV-1 epidemic in the heterosexual population in Thailand to an A/E recombinant. 90CR402, previously named CAR-E 4002, was obtained from a man from Bangui, Central African Republic, who had lymphadeopathy, diarrhea, severe weight loss and recurrent respiratory infections. He was infected through heterosexual contact, but the year of infection is unknown. 90CR402 (U51188) was first adapted to growth in chimpanze cells, expanded in chimpanzee cells, and then re-expanded in human PBMCs before lamba cloning and sequencing. 93TH253 (U51189) is from a 21-year-old man from Chiang Mai, Thailand and was previously named CMU010 or 302053. The patient had end-stage AIDS. The mode and year of infection are unknown. 93TH253 was isolated and expanded in human PBMCs, then expanded in H9 cells followed by lambda cloning and sequencing. 92UG037 (U51190) was obtained from WHO-NIAIDS and comes from an asymptomatic 31-year-old female from Entebbe, Uganda, early in infection. The year of infection is unknown and the mode of infection was heterosexual contact. 92UG037 was established and propagated by cocultivation with normal donor lymphocytes, and then PCR amplified and sequenced. 93TH253 and 90CR402 are subtype E (A/E recombinant). Comparison of the two strains showed that they were derived from a common A/E recombinant ancestor, presumably from Central Africa. 92UG037 is subtype A. LTR sequences are available under accession numbers U51282-U51297.

SIVCPZANT CPZANT U42720 8182 bp comp. gen. Vanden Haesevelde, M. Virology 221, 346 (1996)
Comment: A simian immunodeficiency virus phylogenetically linked to HIV-1 which was isolated from a captured wild chimpanzee from Zaire. This is the third SIV strain linked to HIV-1 after SIVCPZ-GAB (X52154) and SIVCPZ-GAB2 (U11495) isolated from chimps in Gabon. While SIVCPZ-ANT and SIVCPZ-GAB share a common ancestor with HIV-1, they differ in that the SIVCPCZ strains have highly conserved V3 regions and HIV-1 has a highly variable V3 region. SIVCPZ-ANT is considered to be an outgroup of HIV-1 and is used to suggest the possibility of various introductions of HIV-1 into the human population.

HIVMCK1 MCK1 D86068 9752 bp comp. gen. Iwatani, Y. Unpublished (1996)
Comment: This sequence is ~98% identical to HXB2 and other IIIB lab strains of HIV-1. PM213 is another complete genome also ~98% identical to HXB2. GenBank accession numbers D86068 and D86069.

HIVU61773 And1.dat U61773 618 bp nef Mariani, R. Unpublished (1996)
Comment: Set of 62 sequences from a German study on the frequency of defective nef alleles in an HIV-1 long term survivor. GenBank accession numbers U61773-U61834.

HIVETH2220 ETH2220 U46016 9031 bp comp. gen. Salminen, M.O. ARHR 12, 1329 (1996)
Comment: U46016 is the first reported (almost full length) subtype C sequence from Ethiopia. In its genomic organization, this clone closely resembles subtype A, B, and D isolates except that the core promoter contains three potential binding sites for the transcription factor NF-kB instead of containing two.

II

Amino Acid Alignments

Alignments in this section of the 1996 compendium were generated in one of two ways: On the one hand, a Hidden Markov Method (HMM) was employed as described in Part III of this compendium (Myers and Farmer). In some instances, hundreds of sequences contributed to the alignment and the generation of a consensus-like (model) sequence. The latter is not an ordinary consensus sequence but rather a "most-likely" sequence, with some bias towards HIV-1 sequences. The BLOCKMAKER program (Henikoff and Henikoff, *Meth. Enzymol.* **266**:88, 1996) was utilized to critique the HMM alignments; the blocks found (usually by the Motif option rather than the Gibbs sampler option) are shown by shading. Also, the "Cobbler" sequence inferred from the blocks is appended to each alignment; this sequence serves as another consensus-like sequence. Because the Cobbler sequence was derived from just the twenty or so representative PIVs, it is not so biased towards HIV-1s. On the other hand, new HIV-1 sequences were added to previous HIV-1 alignments that had been created using the PIMA and MASE tools, as in earlier compendiums. The new subtype consensus sequences were then aligned to one another using MASE.

With few exceptions (most notably with HIV-1 Env), only full-length protein sequences have been included in this compilation. Tables giving the basic information about each sequence contained in these alignments precede the amino acid alignments; these tables also appear in Part I.

Ten sequence subtypes have been identified for HIV-1s (see Part I and Part III) and five sequence subtypes exist for HIV-2s. Sequence subtypes have been defined by "cladistic" criteria applied to nucleotide sequences; it remains to be seen whether the amino acid sequence subtypes inferred from that classification are valid, or whether a "phenetic" classification would be preferable.

The reference sequences for the ordinary alignments are mixed case consensus sequences in which upper case letters refer to amino acid residues which are conserved 100% and lower case letters represent amino acid residues conserved in at least 50% of the sequences. The symbol "?" indicates no consensus at a position. Consensus sequences have been generated for each of the defined subtypes (see Parts I and III), and these are presented both with the grand alignments and in alignment to one another. The user should keep in mind that these subtypes have been "cladistically" defined, not "phenetically" defined (the number of phenotypes remains to be discovered).

Within the sequences, "-" is used to indicate residues conserved with respect to the reference sequence and "." represents actual gaps. The symbol "$" indicates a stop codon and the symbol "#" indicates a frameshift or untranslatable situation. Blank spaces within the alignment indicate lack of sequence information over that region. Annotation of the *env* amino acid sequences utilizes "*" for conserved cysteine residues and "^^^" for potential N-linked glycosylation sites.

At the risk of relaxing standards of annotation, we have elected to annotate features for which some evidence supports a particular role for a motif—nls for nuclear localization signal, for example. The authority for these additions can be found for the most part in section III curatorial comments (see the Gag entry from 1994 or the Vpr entry from 1995, for example).

PART II Amino Acid Alignments

HMMER Sequences in the Gag Alignment

The following alignment and most-likely sequence were generated using the HMMER program as described in Part III. For simplicity, only representative type and subtype sequences are shown. The annotation is based on HIV1s, therefore the user should be cautious about its applicability to other PIV sequences. Nuclear localization signal is indicated by nls. MHR is the major homology region. Cleavage sites are indicated by '\/'. Four conserved, gapless blocks were generated using the BLOCKMAKER and Motif programs; these are shown by shading (The Gibbs program identified five blocks that overlap the four Motif blocks). The Motif "Cobbler" sequence follows this alignment.

The following alignment and most likely sequence were generated using the HMMER program as described in Part III. For simplicity, only representative types and subtypes are shown. Annotation is based on HIV1s, therefore the user should be cautious about its applicability to other PIV sequences. Five key sites for drug resistance are indicated; for further information regarding drug resistance, see the section by J. Mellors and colleagues in Part III. Cleavage sites are indicated by '\/'. Ten conserved, gapless blocks were identified using the BLOCKMAKER and Motif programs; these are shown by shading. The Motif "Cobbler" sequence follows this alignment.

The following alignment and most likely sequence were generated using the HMMER program as described in Part III. For simplicity, only representative PIV types and subtypes are shown. The BLOCKMAKER and Gibbs programs were employed to identify four conserved, gapless blocks (shown by shading); the Motif program did not give satisfactory results in this case. The Gibbs' "Cobbler" sequence follows this alignment.

The following alignment and most likely sequence were generated using the HMMER program as described in Part III. For simplicity, only representative PIV type and subtype sequences are shown. Because annotation cannot simultaneously apply to VpR and to VpX, see the accompanying HIV-1 consensus alignments for this. Two conserved, gapless blocks were found using the BLOCKMAKER and Motif (or Gibbs) programs; these are shown by shading. The Motif "Cobbler" sequence follows the alignment.

The following alignment and most likely sequence were generated by the HMMER program as described in Part III. For simplicity, only representative types and subtypes are shown. The annotation is based on HIV1s, therefore the user should be cautious about its applicability to other PIV sequences. The BLOCKMAKER program was employed to identify one conserved, gapless block (using either the Motif or Gibbs approach); the block has been indicated with shading. A putative nuclear localization signal (nls) is shown. The Motif "Cobbler" sequence follows this alignment. For further information regarding the Tat protein, see the section by K.-T. Jeang in Part III of this compendium.

The following alignment and most-likely sequence were generated using the HMMER program as described in Part III. For simplicity, only representative types and subtypes are shown. The annotation is based on HIV1s, therefore the user should be cautious about its applicability to other PIV sequences. The high affinity binding site to RRE, which also contains a nuclear localization signal (nls) and the leucine effector domain are shown. The BLOCKMAKER program (using the Motif or Gibbs approach) produced one conserved, gapless block, which is shown by shading. The Motif "Cobbler" sequence follows this alignment.

HIV1 VPU

The following alignment and most likely sequence were generated using the HMMER program as described in Part III. For simplicity, only representative HIV1s are shown. Two sites of phosphorylation are indicated. One conserved, gapless block was found using the BLOCKMAKER and Motif (or Gibbs) program, which is shown by shading. The "Cobbler" sequence from the Motif analysis follows this alignment. For further information about the VpU protein, see the section by K. Strebel in Part III of this compendium.

The following alignment and most-likely sequence were generated by the HMMER program as described in Part III. Approximately 400 HIV and SIV sequences contributed to the output; for simplicity, only representative subtypes and types are shown. Hybrid (i.e. recombinant) viral sequences will not affect the profile. The annotation was based upon information for HIV-1s and therefore the user should be cautious about its applicability to other PIV sequences. Cysteines are indicated by '*'. Potential N-linked glycosylation sites are indicated by '^^^'. Four highly conserved residues involved in CD4 interaction have been annotated. Eight conserved, gapless blocks (shaded) were independently derived from the representative sequences below (excluding the most-likely sequence) using the BLOCKMAKER and Motif programs; in most instances, the boundaries of these blocks are consistent with the HMM alignment. Block sizes are limited to 55 residues, hence contiguous blocks may occur. Five additional blocks over the C-terminal region of gp41 were separately determined, as variability and the existence of prematurely truncated (or unsequenced) representatives necessitated a separate determination. These five blocks should be given less weight. The Motif "Cobbler" sequence (involving just the first eight blocks) follows this alignment.

The following alignment and most-likely sequence were generated using the HMMER program as described in Part III. For simplicity, only representative types and subtypes are shown. The annotation is based on HIV1s, therefore the user should be cautious about its applicability to other PIVs. Cysteines are indicated by '*'. Two conserved gapless blocks were found using the BLOCKMAKER/Motif program; these are shown with shading. The Motif "Cobbler" sequence follows this alignment. For further information about Nef, see the section by S. Wain-Hobson in Part II of this compendium.

HIV-1 Tat: Structure and Function

Kuan-Teh Jeang

Molecular Virology Section, LMM, NIAID, National Institutes of Health
Bethesda, MD 20892-0460, USA

Introduction

Most viruses encode functions for regulating genome transcription. Examples include the SV40 T-antigen, the adenovirus E1a protein, and the herpes virus immediate-early proteins. For the human immunodeficiency viruses (HIV), Tat functions similarly, though not identically, to those other activators. Over the past decade, we have learned much about Tat, both in structure and in function. The intent of this brief accompanying overview is to "add flavor" to raw data, it is written for the purpose of apprising, in a short format, the readers on some of the current thoughts about Tat. For more in-depth discussions, extensive subject reviews can be found elsewhere (e.g. Jones and Peterlin, 1994; Chang et al., 1995; Gatignol et al., 1996). This overview was revised from an earlier version appearing in the 1994 compendium.

Tat function

Tat is a small nuclear protein of 86 to 101 amino acids (depending on the viral strain) which is encoded from two separate exons (see Section I). Analyses of "full-length" Tat have been performed commonly using the 86 amino acid version. However, it should be noted that while a few laboratory strains (e.g. HXB2 and NL4–3) have the truncated Tat (86 aa) most HIV-1s have the 101 aa protein (see compendium part II).

A. LTR Transcription. Despite intensive efforts, the mechanism of Tat action remains incompletely understood. It is accepted that Tat is required for optimal HIV viability (Fisher et al., 1986; Dayton et al., 1986). The role of Tat in critically directing transcription (Peterlin et al., 1986; Rice and Mathews, 1988; Laspia and Mathews, 1989) from the HIV LTR is one necessary function suggested for this protein. However, increasingly there is evidence that Tat has other significant effects on the virus and on the host cell (Huang et al., 1994; Chang et al., 1995; Neuveut and Jeang, 1996; Goldstein, 1996). In the setting of viral pathogenesis, both aspects need to be considered.

In activating transcription from the LTR, Tat differs from other prototypic viral trans-activators in requiring a bipartite responsive element consisting of DNA and RNA. To our knowledge, Tat is the first characterized eukaryotic transcription factor that binds to a nascent leader RNA, TAR (Berkhout et al., 1989; Dingwall et al., 1989; Cordingley et al., 1990; Roy et al., 1990; Calnan et al., 1991); and then influences events at the TATAA-enhancer-promoter (Berkhout et al., 1990; Selby and Peterlin, 1990; Southgate et al., 1990; Jeang et al., 1993b; Gatignol et al., 1996; see fig. 1A). TAR RNA has an extensive secondary structure including a stem, a bulge, and a loop (Muesing et al.,1987; Berkhout and Jeang, 1989; Roy et al., 1990c; Wang and Rana, 1996; see fig. 1B). Early studies indicated that the UCU sequence of the bulge is critical for binding by Tat (Dingwall et al. 1989,; Roy et al. 1990a, Calnan et al., 1991; Cordingley et al., 1990). By contrast, the structure of the stem, but not its specific sequence, was proposed to be important for function. The loop of TAR RNA serves as binding site(s) for cellular factor(s) that cooperate with Tat in the activation of the LTR (Sheline et al., 1991; Wu et al., 1991). A more extensive discussion of the role of cellular factors that bind TAR RNA (Gatignol et al., 1989; Gaynor et al., 1989; Gatignol et al., 1991; Gatignol et al., 1996) is presented in Section IV.

Both for Tat binding and for transcription, there are sequence specific requirements for the immediate stem nucleotide pairs that flank the bulge (Weeks and Crothers, 1991; Berkhout and Jeang, 1991; Churcher et al., 1993; Wang et al., 1996). In a recent series of studies, Rana and colleagues have provided physical insights on how Tat interacts with TAR RNA. Using photo-activated cross-linkers, they were able to elucidate the orientation of Tat as it intercalates into TAR RNA. They found that

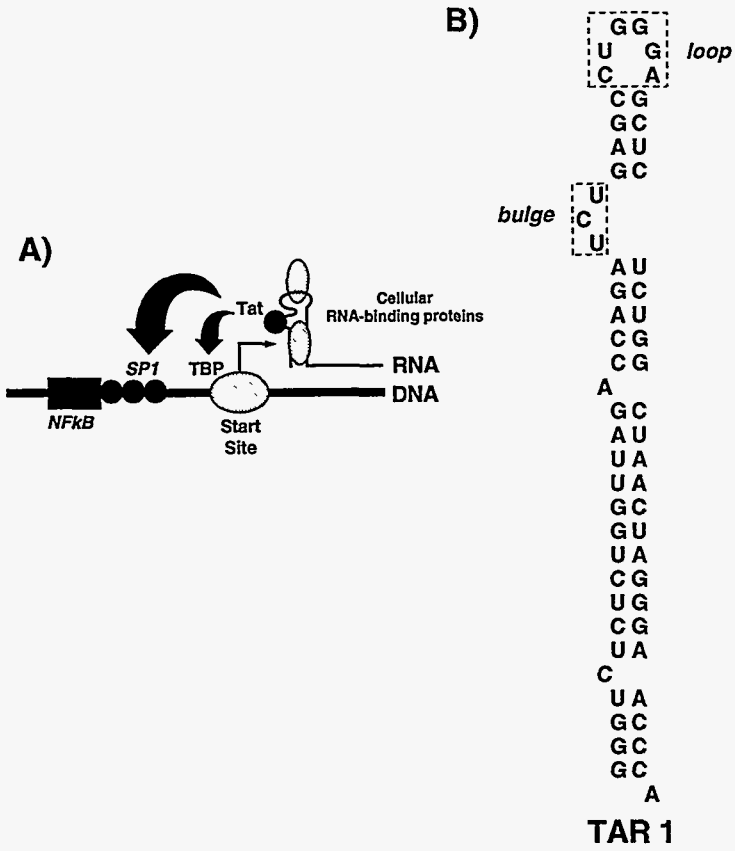

Fig. 1. Interaction of Tat with DNA and RNA targets in the HIV-1 LTR. A) A schematic representation of the functional interactions between Tat, TAR-RNA-binding proteins and promoter elements. Biochemical evidence exists that Tat contacts directly SP1 (Jeang et al., 1993b) and TATAA-binding protein (TBP; Kashanchi et al., 1994). B) Secondary structure of TAR RNA. The crucial trinucleotide bulge and hexanucleotide loop elements are boxed.

amino acid 41 of Tat lies in close proximity to U42 in the lower TAR stem, that amino acid 47 of Tat is proximal to the G26 nucleotide positioned immediately above the TAR bulge, and that amino acid 57 of Tat is close to U31 in the TAR loop (Wang and Rana, 1995; Liu et al., 1996; Wang et al., 1996). At the same time, the basic domain of Tat was shown to interact with RNA residues U23, U38, and U40 and to distort/widen the major groove of TAR RNA (Wang and Rana, 1996; Metzger et al., 1996).

While it is clear that Tat binds TAR RNA and interacts with enhancer-promoter-binding factors (Berkhout and Jeang, 1992; Jeang et al., 1993a; Southgate and Green, 1995), the direct mechanism through which these physical events influence transcription is not wholly evident. A number of models that attempt to explain the transcription function of Tat have been proposed. These include i) anti-terminating (Kao et al., 1987) stalled RNA polymerase II (RNAP II), ii) increasing processivity/elongation of transcribing RNAPII complex (Laspia et al., 1989; Marciniak et al., 1990; Hermann and Rice, 1995; Zhou and Sharp, 1996), and iii) facilitating formation of RNAPII complexes at the promoter (Laspia et al., 1989, Jeang and Berkhout, 1992; Jeang et al., 1993a; reviewed in Cullen, 1993). Currently, there are findings consistent with each of these models. Possibly, Tat, like basal transcription factor TFIIF (Buratowski, 1994), acts simultaneously as an initiation and elongation factor. Alternatively, because transcription from a given promoter is a dynamic multi-cycled process, efficient

disassembly (i.e. processive promoter-clearance) of a previous round is necessary to permit initiation of the next round (reviewed in Zawel and Reinberg, 1995). Thus, initiation and elongation/clearance events at the promoter may be mechanistically linked and, in some cases, inseparable processes. Recent findings indicate that Tat plays a mechanistic role not at the stage of recruiting TBP to the promoter (Kashanchi et al., 1994), but at the step of clearing RNA polymerase II from the promoter (Chun and Jeang, 1996; Xiao and Jeang, unpublished observations).

Lastly, one must exercise care in not assuming that different look-alike experimental systems would share the same the rate-limiting step (Jeang et al., 1993a). Two examples suggest caution. First, results from Pomerantz and co-workers have recently shown that short LTR-transcripts are not found in cells that are fully functional for Tat-transactivation (Niikura et al., 1996). Second, some of the analogies drawn between EIAV Tat and HIV-1 Tat bear re-visiting. One recent report has raised the consideration that EIAV Tat is a DNA-binding and not an RNA-binding protein (Rosch and Willbold; 1996).

B. Translation. There are suggestions that Tat also functions in regulating translation (Rosen et al., 1986; Cullen, 1987). TAR RNA can inhibit translation (Parkin et al., 1988; SenGupta and Silverman, 1989) of HIV-1 mRNAs, most likely through activation of double-stranded RNA-dependent protein kinase (PKR) and 2–5A synthetase (SenGupta and Silverman, 1989; Edery et al., 1989). Addition of Tat was found to reverse this translational inhibition (SenGupta et al., 1990; Braddock et al., 1990). It is possible that one part of Tat's translational effect stems from its ability to form physically a functional complex with PKR (McMillan et al., 1995).

C. Effects on cellular function. There is increasing evidence that Tat has pleiotropic effects on cellular genes and host cell metabolism (reviewed in Chang et al., 1995). This would not be surprising, since it clearly serves the advantage of the virus to be able to modify optimally the cellular environment for replication. In this regard, Tat has been reported to function as a secreted growth factor in stimulating the growth of Kaposi-like cells (Ensoli et al., 1990; Ensoli et al., 1993; Barillari et al., 1993) and in promoting angiogenesis (Albini et al., 1996). Tat is further described to affect the organization of neurons and astrocytes (Kolson et al., 1993); it is neurotoxic at low concentrations (Sabatier et al., 1991).

Expression of many cytokines is modulated by Tat (Rautonen and Rautonen, 1992). These include TNFa,b (Buonogaro et al., 1992; 1994), TGFa,b (Lotz et al., 1994; Nabell et al., 1994), IL-2 (Purvis et al., 1992; Westerndorf et al., 1994), and IL-6 (Scala et al., 1994) among others. Tat has also been reported to activate cellular signal transduction pathways that involve phosphatidylinositol-3-kinase (Milani et al., 1996) and NF-kB (Biswa et al., 1995). It has been further suggested that Tat can affect programmed cell death by protecting lymphocytes against apoptosis (Gibellini et al., 1995). However, the validity of this last point point has been contested by conflicting findings that Tat promotes apoptotic death of lymphocytes (Li et al., 1995).

Domains in Tat

Tat is synthesized from an mRNA joined from two coding exons. The first exon encodes amino acids 1–72 and (in most strains of HIV-1) the second exon encodes amino acids 73–101 (see fig. 2). In reporter plasmid co-transfection assays, the first 72 amino acids of Tat fully trans-activates transcription from the LTR. In fact, a truncated 58 amino acid form of Tat is virtually wild type in this type of co-transfection assay (Seigel et al., 1986; Garcia et al., 1988; Kuppusway et al., 1989). Whether data from plasmid co-transfections reflect accurately the normal physiological function of Tat during replication of HIV-1 in lymphocytes has been a poorly studied issue. Recent investigations suggest that reporter plasmid co-transfection results cannot be interpreted literally for their relevance towards viral replication (Neuveut and Jeang, 1996).

A. First coding exon. The combined results from many laboratories have permitted an arbitrary demarcation of "domains" in Tat (Kuppuswamy et al., 1989). For instance, the N-terminus of Tat

(domain 1; .fig. 2) has 13 amino acids with amphipathic characteristics. Mutations that alter the acidic composition of this region were felt originally to affect trans-activation (Rappaport et al., 1989); however, results from a later study conflicted with this interpretation (Tiley et al., 1990).

Amino acids 22 to 37 (domain 2, fig. 2) contain seven cysteines and are highly conserved between different isolates of HIV-1s. Individual mutation in six of the seven cysteines abolish Tat function (see Table I). Although originally proposed as a metal-chelating dimerization domain (Frankel et al., 1988), this region was recently shown to be used for intra-molecular disulfide bond formation in monomeric molecules of Tat protein found inside cells (Koken et al., 1994). Currently, it is believed that Tat is active functionally as a monomer rather than a dimer (Rice and Chan, 1991; Koken et al., 1994).

Domain 3 (amino acids 40 to 48) contains a RKGLGI motif that is conserved between HIV-1, HIV-2 and SIV Tat. This region, in conjunction with the amino terminus and the cysteine domain, has been suggested to circumscribe the minimal activation domain of HIV-1 Tat (Carroll et al., 1991; Derse et al., 1991). Domain 4 (amino acids 49–72) contains a basic RKKRRQRRR motif. These amino acids confer TAR RNA-binding properties to Tat (Dingwall et al., 1989; Roy et al., 1990; Weeks et al., 1990; Chang and Jeang, 1992) and are important for nuclear localization of the protein (Ruben et al., 1989; Hauber et al., 1989). However, recent studies suggest that this short basic stretch is insufficient in determining the entire specificity of Tat-TAR binding since amino acids outside of the basic domain also contribute to this interaction (Churcher et al., 1993; Luo et al., 1993).

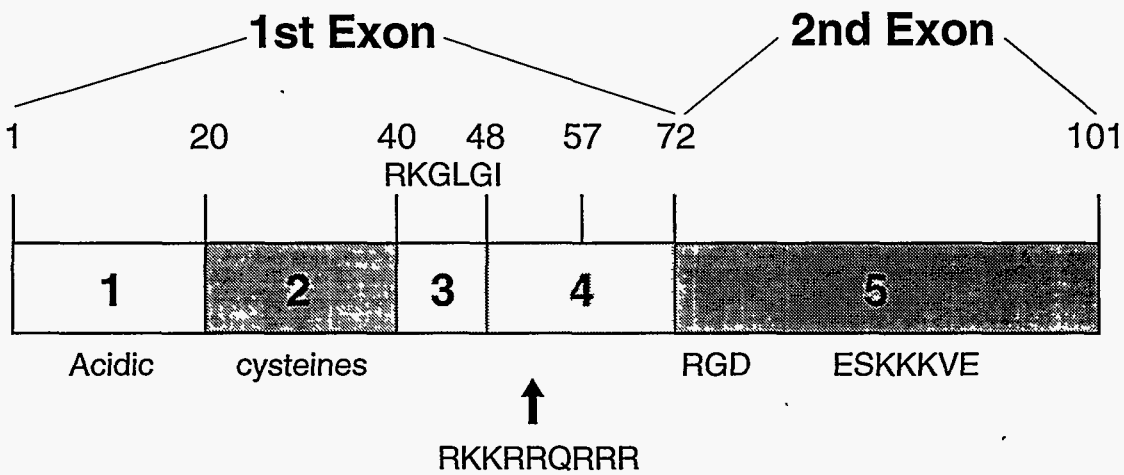

Fig. 2. Domain classifications of Tat protein. The demarcation of domains is somewhat arbitrary. The first exon includes amino acids 1–72, while the second exon includes 73–101. Motifs and characteristics of each "domain" are indicated above or below each region.

Table I summarizes 77 point mutations in Tat collated from the work of nine laboratories (Garcia et al., 1988; Sadaie et al., 1989; Kuppuswamy et al., 1989; Ruben et al., 1989; Hauber et al., 1989; Meyerhans et al., 1989; Rice and Carlotti, 1990a; Rice and Carlotti, 1990b; Siderovski et al., 1992; Neuveut and Jeang, 1996). As alluded to above, most studies were performed based on measurements from reporter-plasmids. Because the first 58 amino acids of Tat recapitulate well the trans-activation function in this type of assay, it is not surprising that the great majority of engineered mutations is concentrated within amino acids 1 to 58. In many cases, individual amino acids have been changed to more than one counterpart, heightening the validity of the resulting phenotype. In rare instances, mutational analysis of the second coding exon of Tat has been studied. Two recent point mutants of the second exon of Tat (P81fs and K90R) showed unexpectedly that changes in this exon perturb not measurements of plasmid trans-activation but do affect virus replication (Neuveut and Jeang, 1996).

Column 1: First letter indicates original amino acid. Number indicates position of amino acid in Tat.

Column 2: Letter(s) indicate the resulting amino acid.

Column 3: ++ > 50% wild type activity; + > 10% wild type activity; +/− or − indicate < 10% wild type activity.

Column 4: Because not all isolates of HIV-1 have the same amino acids for Tat, a consensus sequence is listed also.

Notes: * Different results reported for the same mutation from Kuppuswamy et al., 1989; and Meyerhans et al., 1989. [1]Amino acids beyond position 59 completely changed. [2]fs = frame shift of amino acids beyond position 81. [3]Measurement is based not upon trans-activation of a reporter plasmid but on delayed replication of an HIV-1 molecular clone in T-cell lines (Neuveut and Jeang, 1996).

Examination of the mutants (Table 1) reveals that the region spanning amino acids 1–21 is remarkably tolerant of changes. In contrast, changes in amino acids 22 through 40 were generally deleterious for trans-activation. Finally, although the basic domain (amino acids 49–57) as a unit is necessary for Tat function, individual amino acid changes do not significantly affect activity.

B. Second coding exon. The second coding exon of Tat has been less studied. In routine transfection of reporter plasmids, absence of the second exon does not alter greatly measurements of Tat activity in this type of assay. However, findings from HIV-2 and SIV Tat are quite clear in demonstrating that this exon contributes towards optimal trans-activation (Viglianti and Mullin, 1988; Tong-Starksen et al., 1993). There are emerging findings that the second exon of HIV-1 Tat, in other assays, is important for trans-activation (Jeang et al., 1993b), trans-repression (Howcroft et al., 1993), and virus replication (Neuveut and Jeang, 1996).

Two short motifs in the second exon of HIV-1 Tat could have functional importance (see fig. 2). The first is an RGD sequence that is used as a cell adhesion signal for binding to cellular integrins (Brake et al., 1990). This RGD motif , however, is not found in HIV-2 or SIV Tat proteins. Recently, it has been suggested that the basic domain of Tat (rather than the RGD sequence) is the important protein portion for cellular uptake (Albini et al., 1996). The second exon also has an ESKKKVE motif which is conserved in most HIV-1 Tat proteins and is partially preserved in HIV-2 and SIV Tats. The functional significance of this motif has not been examined in detail.

C. Immunological epitopes in Tat. Evidence suggests that Tat has a role in viral infectivity and can contribute to pathogenesis (Huang et al., 1994; Neuveut and Jeang, 1996). Indeed, in tissue culture experiments, findings suggest that the addition of antibody against Tat to the culture supernatant can halt the spread of HIV-1 infection in T-lymphocytes (Steinaa et al., 1994; Re et al., 1995). Complementary observations in patients indicate that immune response to Tat correlates with better prognosis for disease progression (Reiss et al., 1991). These results have led to the suggestion that Tat should be considered as a candidate prophylactic vaccine (Goldstein, 1996) for HIV-1.

Although the immunological epitopes within Tat have not been studied in detail, some information is available. Figure 3 summarizes findings from 4 studies. Two regions of Tat (amino acids 1–9 and 70–83) have been found to be potent in eliciting humoral responses. Three other regions have been described to elicit CTLs. Interestingly, it has been observed that uninfected individuals have natural IgM antibodies directed against two portions of Tat, suggesting that this might be one basis for natural immunity against the virus.

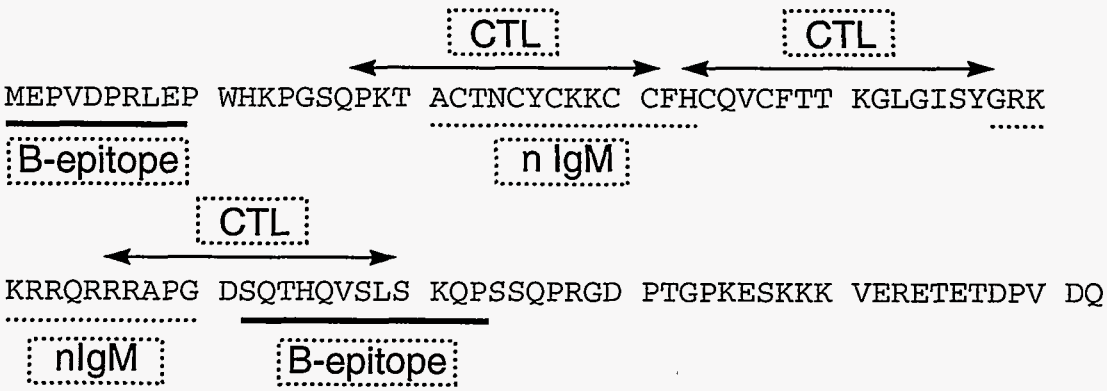

Fig. 3. Immunological epitopes in the HIV-1 Tat protein. B-cell immunodominant epitopes were determined by Krone et al. (1988) and McPhee et al. (1988); CTL-epitopes were mapped by Blazevic et al. (1993); and naturally occurring IgM epitopes in Tat were as reported by Rodman et al. (1993).

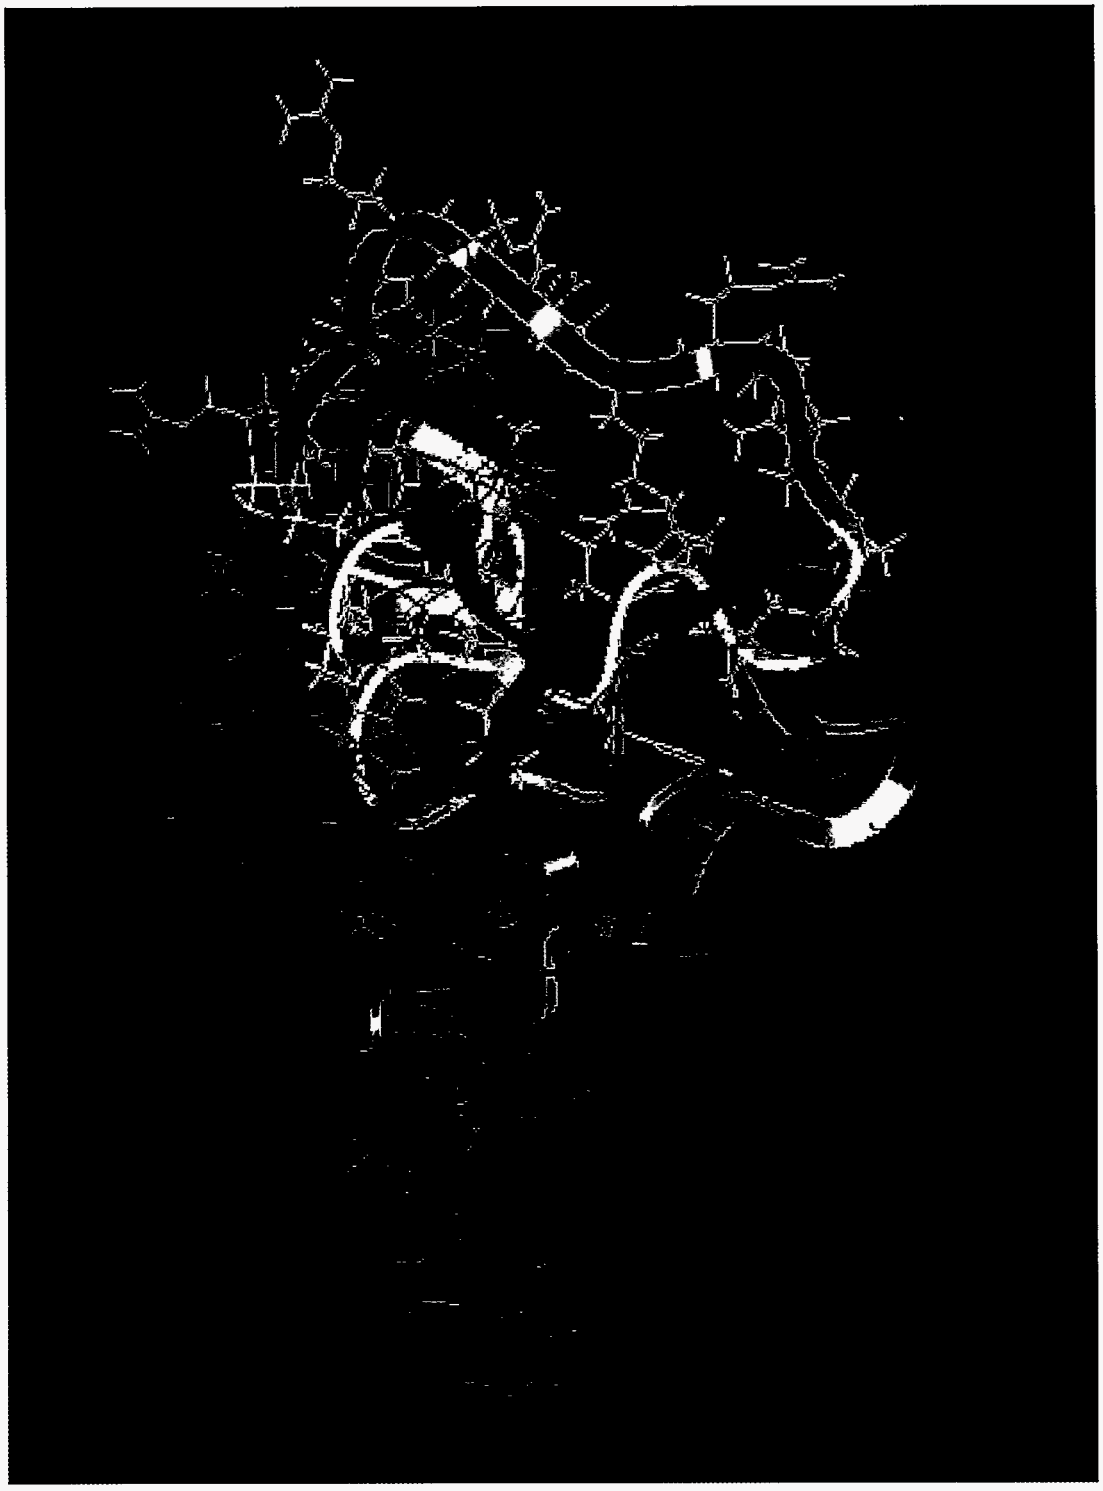
Concluding Remarks

For a relatively small protein, much effort has been expended on studying Tat. A recent search of Medline (conducted Nov. 1996) using the word Tat yielded more than 1400 papers in the last three year period. Obviously, one can't cover all these new findings in this brief summary on this intriguing protein. It is hoped that this synopsis highlights some of the currently important issues on Tat, albeit considered in a rather subjective manner. I hope to update periodically the contents in this text in coming years and in coming editions of the database.

I conclude this writeup with a figure (figure 4, provided by Dr. E. P. Loret) showing recently derived computer models of Tat structure (Gregoire and Loret, 1996). As yet, a crystal structure for Tat is not available. However, analyses of multiple sequences do yield informative findings. For instance, these analyses reveal that the regions circumscribed by amino acids 38–47 and 59–72 have the widest degree of three-dimensional structural variability between different HIV-1 Tat proteins. The structure of other portions of Tat seems to be well-conserved. At the level of our current understanding of Tat function, it is difficult to establish a clear one-for-one correlation between the physical model (figure 4) and the functional phenotypes revealed by point mutants (Table 1). In coming years, I hope that this will change.



Tat BRU structure obtained from molecular modeling (Gregoire and Loret, 1996) using the atomic coordinates of the Tat Z2 2D-NMR structure (Bayer et al., *J. Mol. Biol.* 247:529–535, 1995). Region I is colored in red, region II in orange, Region III in yellow, region IV in green, region V in light blue and region VI in blue. Molecular modeling was made with Insight II, Discover and Homology from MSI Technologies, Inc. (San Diego, CA) running on a R4600 Silicon Graphics Workstation. The CVFF force field was used to minimize the structure. Hydrogens were generated at pH 7. Steepest descent and conjugate gradient were the algorithms used for the minimization. Dynamic was performed at 300 K and 110 different structures were analyzed in the trajectory.

Backbone superimposition of Tat Bru (green) and Tat Oy (pink). The C-terminal extremity of Tat Oy (yellow) goes through the loop made by the cysteine rich region (region II) and ends up in a groove made by a part of region I and region III.

Structure and Function of HIV-1 Vpu

Klaus Strebel

LMM, NIAID, National Institutes of Health, Bethesda, MD 20892–0460

Introduction

Aside from the typical retroviral *gag*, *pol*, and *env* genes, HIV encodes a series of accessory genes, *vif*, *vpr*, *vpx*, *vpu*, and *nef*. The *vpu* gene is found exclusively in HIV-1 (Strebel et al., 1988; Cohen et al, 1988; Matsuda, 1988). In tissue culture systems, defects in accessory genes are frequently not correlated with a detectable impairment of virus replication and, as a result, these genes are often referred to as "non-essential". However, as more and more information on the function of the accessory proteins becomes available it also becomes increasingly clear that *in vivo*, these proteins indeed exert important functions. With respect to Vpu, Li et al found that macaques infected with Vpu-negative simian-human immunodeficiency virus chimeras (SHIV) had lower virus loads than Vpu-positive virus (Li et al., 1995). Also, using a SCID-hu model, Aldrovandi & Zack demonstrated that deletion of Vpu significantly affects virus infectivity and, to a somewhat lesser extend, pathogenicity of HIV (Aldrovandi & Zack, 1996). Thus, while there is currently only limited information available on the importance of Vpu *in vivo*, such model systems might be useful in investigating the *in vivo* relevance of Vpu. This article attempts to provide a brief overview on our current understanding of this viral accessory factor. More exhaustive reviews on Vpu can be found elsewhere (Jabbar, 1995; Bour et al., 1995a; Trono, 1995).

Structural Considerations

Vpu is a small integral transmembrane protein which is cotranslationally inserted into membranes of infected cells (Strebel et al., 1989). The protein consists of an N-terminal hydrophobic domain, which functions both as signal peptide and membrane anchor, and a hydrophilic C-terminal domain which protrudes into the cytoplasm. Vpu contains two highly conserved seryl residues, located in the cytoplasmic domain, which are phosphorylated by the ubiquitous protein kinase CK-2 (Schubert, et al., 1992; Schubert et al., 1994; Friborg et al., 1995). Phosphorylation is essential for at least one of the biological functions of Vpu as discussed below. Vpu forms homo-oligomeric structures (Maldarelli et al., 1993), a feature that may be critical for a proposed ion channel function of Vpu (see below). Based on 2D 1H NMR spectroscopy of a peptide corresponding to the cytoplasmic domain of Vpu (Wray et al., 1995; Federau et al., 1996), it was proposed that the cytoplasmic domain of Vpu contains two α-helical domains, helix-1 and helix-2 (Figure 1), which are connected by an unstructured region containing the two conserved phosphoseryl residues. In addition, computer models predict a third α-helical domain in the transmembrane domain of Vpu, which could play an important role in the formation of ion channels (Schubert et al., 1996b).

The *vpu* gene overlaps at its 3′-end with the *env* gene (Figure 2). Indeed, Vpu and Env are expressed from the same bicistronic mRNA in a Rev-dependent manner (Schwartz et al., 1990), presumably by leaky scanning of ribosomes through the *vpu* initiation codon. In tissue culture, this arrangement results in the synthesis of roughly equimolar levels of Vpu and Env proteins and it is possible that this unusual utilization of viral transcripts might reflect a requirement for the coordinate action of the two viral gene products. Several HIV-1 isolates were found to carry point mutations in the Vpu translation initiation codon but have otherwise intact *vpu* genes. Since removal of the Vpu initiation codon results in increased expression of the downstream *env* gene, it is possible that HIV-1 actually uses this mechanism as a molecular switch to regulate the relative expression of Vpu or Env in infected cells. The possible benefits of such a regulation are unclear; however, it is conceivable that, under certain circumstances, *vpu*-defective isolates expressing increased levels of Env protein have a selective advantage over "wild-type" viruses expressing Vpu.

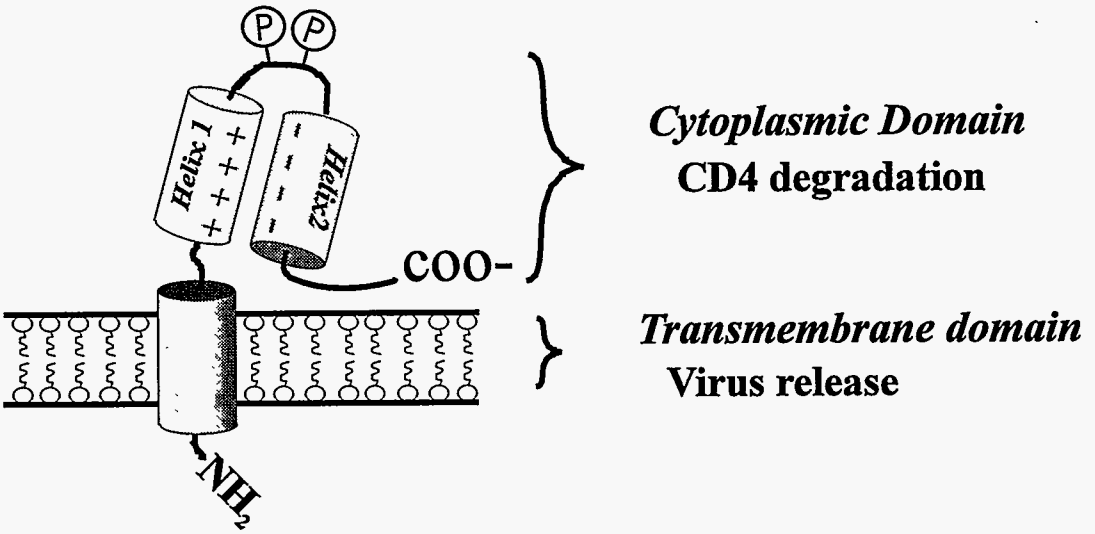

Figure 1. Structural domains of Vpu. Vpu consists of an N-terminal hydrophobic domain, that functions as membrane anchor, and a hydrophilic cytoplasmic domain. The cytoplasmic domain contains two amphipathic α-helical domains of opposite polarity. They are separated by an unstructured region containing two conserved seryl residues which are phosphorylated by protein kinase CK-2. The cytoplasmic domain contains seqences critical for CD4 degradation while the membrane anchor domain has a critical function in regulating virus release and plays an important role in the formation of cation selective ion channels. Vpu forms homo-oligomeric complexes. Only the monomeric form is shown. A putative interaction between helix 1 and helix-2 as shown in the cartoon suggests only one of many possible conformations of Vpu.

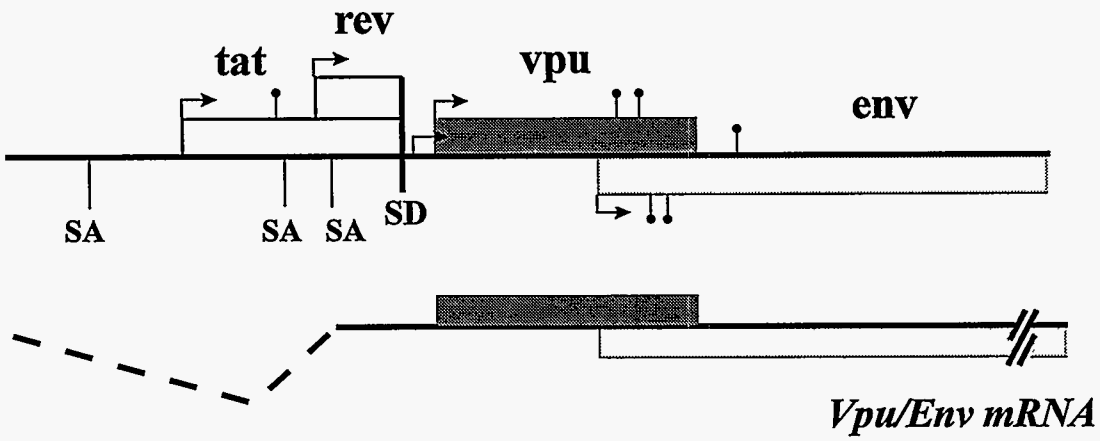

Figure 2. Structure of the *in vpu* gene. The *vpu* gene overlaps at its 3′-end with the *env* gene. Both Vpu and Env are expressed from the same bicistronic mRNA at roughly equimolar levels. The positions of AUG codons at the beginning of open reading frames are marked by arrows. Internal AUG codons are denoted by filled circles. SA = splice acceptor sites; SD = splice donor site.

Vpu has two primary biological activities which are discussed in detail below and are summarized in Figure 3. These include the degradation of CD4 in the endoplasmic reticulum and the augmentation of virus secretion from the plasma membrane. In addition, expression of Vpu has been associated with a reduction in syncytia formation of infected cells (Strebel et al., 1989; Terwilliger et al., 1989; Klimkait et al., 1990; Yao et al., 1993; Schubert et al., 1994). This latter phenomenon may be a consequence of the reduced presence of viral Env protein at the cell surface (Yao et al., 1993) due to the more efficient shedding of viral particles in the presence of Vpu. Aside from that, several other, less well defined functions have been associated with Vpu activity. These include the regulation of ER-to-Golgi transport of proteins (Vincent & Jabbar, 1995), or the modulation of MHC I antigen complexes (Kerkau, 1995).

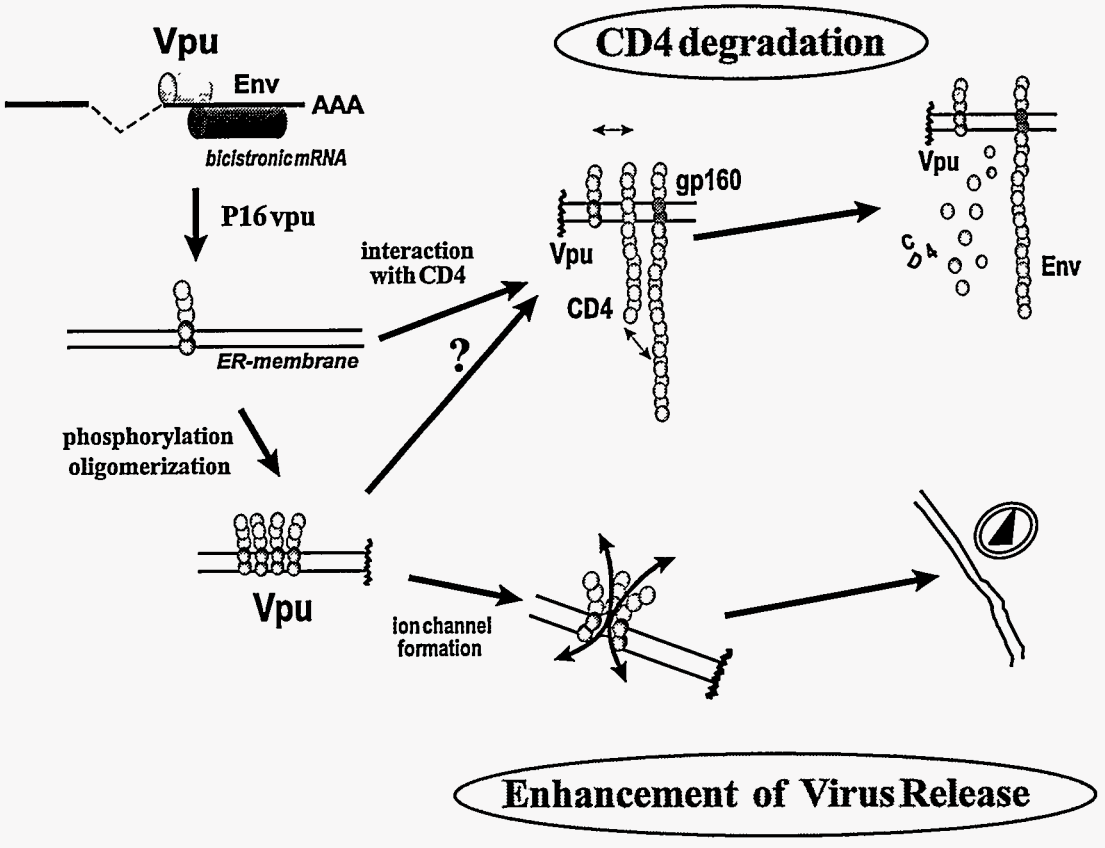

Figure 3. Vpu enhances virus particle secretion and induces degradation of CD4. The 81 amino acid Vpu protein (P16vpu) is synthesized from a bicistronic mRNA and cotranslationally inserted into membranes of the endoplasmic reticulum. Vpu is phosphorylated by CK-2 and forms homo- oligomeric structures. Newly synthesized CD4 is retained in the ER due to the formation of stable complexes with Env protein. Vpu physically associates with CD4 thereby triggering a mechanism that results in the destruction of CD4 and in the release of Env protein from the ER blockage. It is unclear whether this function of Vpu involves monomeric or oligomeric Vpu (? in the cartoon). Vpu exits the ER and accumulates at or near the Golgi. In cells overexpressing Vpu, small amounts of Vpu reach the plasma membrane. Oligomeric forms of Vpu have the capacity to form ion channels which presumably are involved in the regulation of virus particle release.

Vpu Facilitates the Release of Virus Particles

The original biological phenotype associated with viruses lacking a functional *vpu* gene was the impairment of virus particle secretion from infected cells (Strebel et al., 1988; Terwilliger et al.,

1989). This defect is manifested by the increased budding of viruses from internal membranes and the accumulation of budding particles at the cell surface where they remain loosely attached to the plasma membrane (Klimkait et al., 1990). Such particles can be released however, by vigorously shaking the cultures, and they are fully infectious (Klimkait et al., 1990). This suggests that Vpu regulates one of the final steps in virus production that is required for the efficient detachment of virions from the plasma membrane. Although it has been generally accepted that Vpu augments virus secretion from a variety of human cells, including PBMC, macrophages or CD4+ T cell lines, as well as non-T cell lines such as epithelial HeLa cells or SW480 cells (Strebel et al., 1988; Terwilliger et al., 1989; Klimkait et al., 1990; Westervelt et al., 1992; Yao et al., 1992; Göttlinger et al., 1993; Balliet et al., 1994; Kawamura et al., 1994; Schubert et al., 1994; Schubert et al., 1995; Sakai et al., 1995; Theodore et al., 1996), the enhancing effect of Vpu varies between different cell types and has been reported to range from a mere 2-to 3-fold in PBLs to up to 1000 fold in primary macrophages. Despite these cell type specific variations, the principal function of Vpu is not restricted to certain human cell types. In contrast, Geraghty et al. and Göttlinger et al. who analyzed the function of Vpu in Cos-1, Cos-7, or CV1 cells, were unable to detect any Vpu-mediated enhancement of virus secretion in simian cell lines (Geraghty et al., 1994; Göttlinger et al., 1991). It is possible that the efficient and Vpu-independent release of viruses from Cos cells is due to the expression of a cellular eqivalent to Vpu in simian cells.

The mechanistic details of Vpu activity are not well understood; however, several models can be proposed that are consistent with existing experimental data. First, Vpu could actively facilitate detachment of progeny virions from the cell surface, for example by altering the characteristics of the plasma membrane or by actively facilitating membrane fusion similar to the function exerted by annexin VI, which is required for budding of clathrin-coated pits during endocytosis (Lin et al., 1992). At least in the latter case, Vpu would be required in significant amounts at the cell surface. However, while Vpu was indeed observed at the plasma membrane of cells when overexpressed, the bulk of the protein is clearly sequestered on internal membranes (Maldarelli, personal communication; Schubert et al., 1996a). In addition, attempts to demonstrate the presence of Vpu in virions have thus far failed, also arguing against the presence of significant amounts of Vpu at the cell surface. Alternatively, Vpu could regulate virus release from internal membranes either by passively preventing budding on internal membranes, thus redirecting or restricting virus assembly to the cell surface, or by indirectly affecting particle release through the modulation of so far unidentified cellular factors.

Recent evidence suggests that Vpu has the ability to form cation selective ion channels (Ewart et al., 1996; Schubert et al., 1996b); there is some evidence that this activity of Vpu correlates with its ability to regulate virus release. The ability of Vpu to form ion channels requires the integrity of the TM domain, and alterations in the primary structure of the TM domain not only abolish the ability of Vpu to form ion conductive pores but also negate the capacity to regulate virus release (Schubert, 1996a/b). While these findings imply that regulation of virus release is mediated through an ion channel activity of Vpu, it remains to be shown how an ion channel activty of Vpu could affect the detachment of budding particles from the plasma membrane or how it could redirect virus budding from internal membranes to the plasma membrane.

Vpu Induces CD4 Degradation

A second function which has been extensively investigated is the ability of Vpu to induce degradation of CD4 at the endoplasmic reticulum (ER). One of the complications that HIV faces when replicating in CD4+ cells is the formation of stable complexes between cellular CD4 and the HIV Env protein. Such complexes are trapped in the ER (Bour et al., 1991; Crise et al., 1990; Kawamura et al., 1989; Jabbar & Nayak, 1990; Willey et al., 1992a/b) thereby preventing transport of both CD4 and Env to the cell surface. In the presence of Vpu, however, Env was found to be liberated from CD4/Env complexes (Willey et al., 1992a; Kimura et al., 1994) concomitant with a significant reduction in the detectable steady state levels of CD4. The reduction of CD4 was caused by Vpu-induced degradation which reduced the half-life of CD4 in Hela cells from normally 4–6 hours to approximately 10 minutes (Willey et al., 1992b). Efficient degradation of CD4 requires its retention in the ER. This is normally accomplished by the formation of stable complexes with HIV Env. However, Env protein per se is

not involved in CD4 degradation since it is not required when CD4 is artificially retained in the ER (Willey, 1992b). Also, CD4 degradation can be observed in an *in vitro* translation system where no viral proteins other than Vpu are required (Chen et al., 1993). Unlike Nef, Vpu is unable to target cell surface CD4, or, for that matter, CD4 that has exited the ER. Nevertheless, the rapid degradation of de novo synthesized CD4 in the presence of Vpu ultimately leads to a depletion of cell surface CD4 due to the reduction of the overall cellular CD4 pool.

Based on mutational analysis of CD4, it is known that deletion of the cytoplasmic domain of CD4 renders the protein insensitive to Vpu, suggesting that this domain of CD4 contains Vpu-responsive sequences (Chen et al., 1993; Lenburg & Landau, 1993; Vincent et al., 1993). This is supported by the fact that transfer of CD4 cytoplasmic sequences to CD8, a cellular receptor molecule that is not normally targeted by Vpu, resulted in Vpu-dependent degradation of the chimeric molecules (Willey et al., 1994). In fact, transfer of a 18 amino acid membrane proximal fragment of the CD4 cytoplasmic domain (amino acids 403 to 420) into the CD8 cytoplasmic tail was sufficient to confer Vpu sensitivity. While these results suggest that cytoplasmic sequences of CD4 are sufficient to confer Vpu sensitivity to heterologous membrane proteins, other studies suggest that sequences located in the TM domain of CD4 may also be required (Raja et al., 1994; Buonocore et al., 1994). It is possible that structural constraints imposed by the extracellular or TM domains of the model proteins employed in the different studies explain the apparently differing results. While the importance of the CD4 TM domain for this process thus remains unclear, the importance of the CD4 cytoplasmic domain is undisputed. It is now clear that this domain of CD4, which is predicted to form an α-helical structure (Yao et al., 1995), is involved in the physical interaction with the cytoplasmic domain of Vpu (Bour et al., 1995b; Schubert et al., 1996a; Margottin et al., 1996). Such interaction between CD4 and Vpu appears to be a prerequisite for CD4 degradation but is in itself not sufficient to trigger CD4 degradation. This is evidenced by the fact that mutants of Vpu that are unable to induce CD4 degradation are still able to bind to CD4 (Bour et al., 1995b).

Mutational analysis of Vpu demonstrated that phosphorylation of Vpu at two conserved seryl residues, Ser52 and Ser56, in its cytoplasmic domain is essential for its ability to induce CD4 degradation (Schubert, 1994; Friborg et al., 1995) but not for its ability to bind to CD4 (Bour et al., 1995b). The Vpu TM domain is not required for the interaction with CD4 (Margottin et al., 1996) and alterations in the Vpu TM domain have no apparent effect on CD4 degradation, provided the protein retains its ability to properly associate with membranes (Schubert et al., 1996a; Friborg et al., 1994). These results suggest that sequences critical for the induction of CD4 degradation are located in the Vpu cytoplasmic domain while the TM domain merely serves as a membrane anchor. How Vpu triggers degradation of CD4 is still unclear. It is conceivable that binding of Vpu to CD4 induces a conformational change in CD4 which in turn activates a cellular pathway designed to eliminate aberrantly folded proteins. However, the fact that CD4-Vpu interaction is necessary but not sufficient to induce CD4 degradation indicates that Vpu performs a catalytic function beyond the binding step.

Functional domains of Vpu and Vpu-like activities in HIV-2

In light of the multiple biological activities provided by the Vpu protein during the HIV-1 life cycle, it is intriguing that, except for the chimpanzee isolate SIVcpz (Huet, et al, 1990), no functional equivalent to Vpu is found in related viruses such as HIV-2 and SIV. This fact seems especially paradoxical since Vpu was shown to augment the release of chimeric viruses bearing the gag-pol regions of retroviruses that naturally lack a *vpu* ORF, such as HIV-2, visna virus and Moloney murine leukemia virus (Göttlinger et al., 1993). By examining the efficiency of particle release and Vpu-responsiveness of the ROD10 full-length molecular clone of HIV-2, we recently showed that mutations that disrupt the pROD10 env ORF, but not the *vif*, *vpr*, *vpx* or *nef* ORFs, have a profound negative effect on virus particle release (Bour et al., 1996a). Concomitantly, the pROD10 envelope glycoprotein provided in *trans* could rescue the envelope mutants and restore wild-type levels of particle release (Bour et al., 1996a). Similar results were independently reported by Ritter et al. who used a different HIV-2 isolate, HIV-2/ST (Ritter et al., 1996). The efficiency with which the ROD10 Env protein enhanced HIV-2 particle release was very similar to that of Vpu. Both activities could be provided in *trans* and were sensitive to treatment

of cells with Brefeldin A, suggesting that they both operate in a post-ER compartment (Bour et al., 1996a). Like Vpu, HIV-2 Env can regulate release not only of HIV-2 but of HIV-1 or SIV particles as well (Bour et al, 1996b). When compared in parallel, the effects of Vpu or ROD10 Env on HIV-1 or SIV virus release were identical. These findings suggest that the HIV-2 Env protein has a true Vpu-like activity with respect to virus particle release. However, in contrast to Vpu, there is no evidence that HIV-2 Env can induce degradation of CD4 (Bour et al., 1996b). This suggests that the activity of Vpu on CD4 is HIV-1-specific, a notion that may shed some light on the evolutionary relationship between the HIV-2 *env* and *vpu* genes. The selection pressure that promoted the appearance of the *vpu* gene in HIV-1 as well as the unique activity of Vpu on CD4 degradation may have been the increased affinity of the HIV-1 envelope for the CD4 receptor (Hoxie et al., 1991; Ivey-Hoyle et al., 1991; Mulligan et al., 1992), leading to more stable intracellular complexes and trapping of the envelope glycoprotein in the endoplasmic reticulum. The fact that the HIV-2 Env has a Vpu-like activity on particle release but not on CD4 degradation suggests that the ancestral activity of Vpu is particle release while the activity on CD4 was developed specifically by HIV-1 to counteract increased affinity of HIV-1 Env with the CD4 receptor.

The domain in HIV-2 Env which is responsible for the regulation of virus release has yet to be determined. Ritter et al. reported that an isolate containing a full-length 164 amino acid cytoplasmic tail is capable of performing this function while a variant, carrying a truncated, 17 amino acid cytoplasmic domain was inactive. It is tempting to speculate that the length of the cytoplasmic tail regulates this function of the HIV-2 Env protein. However, the ROD10 isolate used in our own studies carries only a short, 18 amino acid cytoplasmic tail yet efficiently activates virus release (Bour et al., 1996b). Thus it is likely that sequences other than the cytoplasmic domain of HIV-2 Env play a crucial role.

Genetic Subtypes of HIV-1

Thomas Leitner

Theoretical Biology and Biophysics, Group T-10, MS K710,
Los Alamos National Laboratory, Los Alamos NM 87545

Current Subtypes

HIV-1's are currently divided into two genetic groups, based on phylogenetic reconstruction using DNA sequences. The majority of these sequences fall into the M (major) group, while a smaller, but growing, number of sequences are classified as O (outlier). The M group has been further subdivided into several subtypes formed by more or less distinct clades in the M group phylogeny. These clades have been given subtype classification names from A to J (Figure 1).

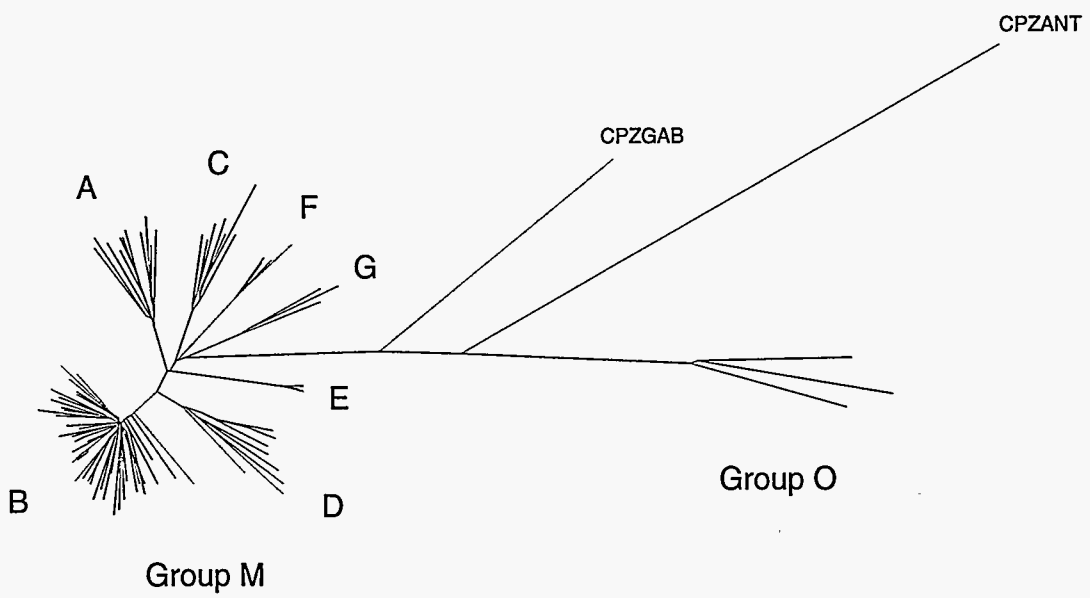

Figure 1. Unrooted neighbor-joining tree showing the HIV-1 group M and O relation with the chimpanzee SIV. The group M subtypes A–G are also indicated at the respective cluster, while for subtypes H and J full length sequences do not yet exist and therefore they are not included in this tree. The tree was based on all nucleotide sequences corresponding to the full length gp120 coding region of *env* in the data base, using a distance matrix calculated with the F84 ($\kappa = 2.0$) substitution model [19].

In phylogenetic trees the chimpanzee sequences usually have a branch point located between Group M and O (Figure 1), suggesting distinct origins of the Group M and O viruses. The branching order of the two chimpanzee sequences (CPZGAB and CPZANT) may change when different sequence fragments are investigated. The explanation for this inconsistency may be recombination between chimpanzee sequences.

Definition of a Subtype

The bases for what should be called a genetic subtype were originally proposed by Myers in *Human Retroviruses and AIDS 1994* [47].

i) subtypes are approximately equidistant from one another in *env* (a "star phylogeny");

ii) the *env* phylogenetic tree is for the most part congruent with the *gag* phylogenetic tree;

iii) two or more samples are required to define a sequence subtype.

These are both logical and reasonable practical criteria for the subdivision of sequences based on phylogenetic trees. However, many sequences were found to be unclassified because they clustered differently using different phylogenetic reconstruction methods or in different reference data sets. Furthermore, as discussed below, some sequences were either too short or were actually just one representative of a potential subtype. With recent knowledge and methods of detecting intersubtype recombinants, many of these unclassified sequences have been explained. In fact, many of these problems are typical for chimeric sequences. Salminen et al., therefore, in the 1995 issue of the *Human Retroviruses and AIDS* [55] suggested that the criteria for new subtypes should include:

i) the appearance of at least two epidemiologically unrelated isolates that cluster together and are separated from established genotypes;

ii) the availability of at least 1.5 kilobases of contiguous sequence from each;

iii) the absence of any subsegment that can join established genotypes.

The sum of all these criteria form a reasonable sound basis for establishing a new subtype. However, when attempting to classify a sequence as an established subtype, less strict criteria may be used, as long as this is made clear. For instance, if only the *env* V3 region (typically 300 bp) was used to classify a virus one might propose that the virus is *env* V3 subtype X (where X = A, B, C, etc.). It would be better, of course, if more of the above criteria were fulfilled. Should the sequence fall outside any of the established clusters, it is desired that further sequence be generated and that additional analyses be performed, as described below.

The M Group

Table 1 lists typical genotypes from each of the group M HIV-1 subtypes. The sequences in this table were chosen accordingly to these criteria: (1) The sequence from the sample should exist in *env*, *gag*, and *pol*; (2) The sequence should be a full length gene sequence; (3) The sequences should representthe variation within each subtype; (4) The sequences should not show any signs of recombination in any of the three genes *env*, *gag*, or *pol*; and (5) A maximum of four sequences should represent each subtype. These criteria were chosen in order to facilitate the subtyping effort. For instance, criterion 1 makes it easier to compare results from different genomic fragments, and criterion 2 makes it possible to use the same references even though studies are based on different subfragments. Criteria 3 and 4 allow a researcher to detect odd sequences for further analysis (see below), and finally, criterion 5 lessens the computational effort required. However, these criteria were not possible to follow in every case: in the more uncommon subtypes (G, H, and J) complete genes have not always been sequenced. Subtype I has not been included in the list, because it is only determined in the *env* V3 region [30], and has also preliminary been proposed to be a recombinant [53]. In *pol*, less sequencing has been done; therefore, the criteria were followed less strictly for this gene. Subtype E is also an exception from criterion 1 [23].

Table 1 also gives a brief description of the principal geographical locales of each subtype. All subtypes have been found in Central Africa, while only one or a few subtypes dominate in other parts of the world. However, in some European countries several subtypes have been reported [4, 21, 30, 54], and in one case nearly all subtypes have been found [1].

Subtype A is the most genetically diverged subtype, and in many tree analyses the more rare subtypes G and H are close to subtype A. Furthermore, all subtype E and at least three subtype G viruses have been found to cluster in subtype A in the 3' half of their gp41 coding region, suggesting that they are recombinants [23]. The Thai envelope subtype E sequences all appear to be mosaic, with

[1] These sequences have been found to be partly recombinant in *env* or *gag*.

[2] Full length gene sequences do not yet exist.

the *gag* gene from subtype A and the *env* from subtype E. The parental subtype E virus has yet not been found, but recently an extensive analysis of one such mosaic isolate showed multiple breakpoints between the two parental genotypes [9]. Subtype A is mostly prevalent in Central Africa, but has also been found in other parts of the world, including Europe [1, 4], Russia [41], East Asia [65], and America [7, 43]. It is possible that this subtype represents a contemporary pool of the original cross-species transmission(s) from monkey to human, from which all the other subtypes have been drawn [34].

Subtype B is by far the most studied subtype, mainly because viruses from this subtype represent the vast majority circulating in the western world, but also because many original laboratory isolates are of this type. However, subtype B has also established successful epidemics in Asia and South America, and is the dominant type in Australia. Most likely has this subtype spread to these parts of the world from contacts with America and Europe. In Thailand a separate type of subtype B has been referred to as B' [26], and more recently B_B , which has been found to further spread into China, Malaysia, and Japan [10]. Subtype B and subtype E transmissions in Thailand have been compared, and some authors have proposed that in this community subtype E was found to be more transmissible [26, 32, 62]. This observation alarmed some European countries, where it was shown that subtype E had recently entered [2]. Subtype E has also entered the American continent, including the USA [5, 7], and subtype E variants have been found in Central Africa [44, 48].

Subtype C seems to have its major center in East and South Africa, but has been reported to occur in many other parts of the world, including Europe, Russia, China, India, and Brazil. As an effect of communication, geographical patterns are becoming more and more blurred for essentially all subtypes. This in turn will increase the possibility of superinfections of different subtypes, and thereby the virus will have greater opportunities to explore new genetic variants by recombination [46].

The O Group

Virus and sequences from the O group have been investigated less thoroughly, mainly because this type of virus is less common. Currently, 3 full length *env* gp120 sequences have been published and are available in the database, but several groups are investigating these viruses. Most of these viruses originate from individuals who have been infected in West Africa, or from encounters with someone infected in West Africa [27]. Analysis of data suggest that the O group sequences do not form subtype clusters in the same way as the M group sequences [39].

Methods of Investigation

Strategy. In any attempt to do a sequence study a good strategy is required. Depending on what the goal is, different approaches will apply. In many cases several areas of interest may have been pursued simultaneously, and in other cases the sequences may have been determined for a goal other than the present one. For instance, samples may have been collected from a restricted area or disease group, or may have gone through different in vitro manipulations; and sequences may have been derived from either proviral DNA or genomic RNA. All these factors should be considered before going further, since they may bias the conclusions.

Sequencing. After an investigation strategy has been decided and samples have been collected, a study often starts with determining the primary DNA sequence. As mentioned above, the sequence template may be either proviral DNA or reverse transcribed RNA. It is important to remember that any HIV sample contains a population of related but genetically diverse variants, or quasispecies [42] (see also [15, 16, 25]). Any sequencing strategy must take this fact into account, i.e. it must be certain that a representative number of viral molecules are investigated. If this is not done, the chance of making erroneous conclusions arises: for instance, one could detect a "homogeneous" population, or a special sequence, derived from a single odd molecule. Thus, the number of molecules that goes into the sequencing effort should be determined, for example by a limiting dilution procedure [60].

The easiest way to determine a virus sequence is by direct PCR sequencing. This procedure suffers the least from methodological artifacts by introducing the least amount of undesired selection steps. Because a population is sequenced, some nucleotide positions may be populated by more than

one state (a multistate position); for instance, a position can harbor both an A and a G. There are different ways to handle this information. Some authors simply choose the dominant form at each such site (e.g., [49]), while others choose to report both nucleotides to a certain threshold [37]. It has also been shown that the different nucleotides at such positions can be accurately quantified [37]. The main drawback of the direct population sequencing strategy is that the linkage between nucleotides in multistate positions will remain unknown in most cases.

The other way to determine a population is by cloning prior to sequencing. There are several ways to do this, but the two most common ways are vector cloning or limited dilution of PCR fragments. Vector cloning involves many steps in which the population structure may be skewed, including transformation, growth, and clone picking. The limited dilution procedure [60] avoids these steps, but instead requires many PCR reactions. Both procedures also suffer from the fact that PCR-induced mutations may be amplified and accidentally analyzed as true information. Another seldom addressed problem with clones is that they generate a much larger dataset. This may be cumbersome in the stage of phylogenetic inference, because the number of possible tree topologies quickly reaches astronomical numbers, thereby making more advanced methods out of the question. However, some studies require exact knowledge of individual molecules, and a cloning procedure becomes the method of choice.

In addition to sequencing, a number of other procedures exist to determine genotypes. These include restriction enzyme analysis, SSCP, and different probe protocols such as the heteroduplex mobility assay (HMA) [12]. The advantage of such methods is that they can screen large sample sets in short time; efforts have been made to produce reference sets for standardization of the HMA method [6]. The resolution of this method is, however, lower than that of a sequencing study. Methods for rapid screening of subtypes based on V3 peptide serotyping have also been developed [58].

An important factor to consider is the amount of information fed to the subsequent analysis, usually a tree reconstruction. Although the discussion of phylogenetic information is difficult, in principle, two components decide whether it will be a good reconstruction or not. The first is sequence length. It is evident that the ideal procedure would be to use the complete HIV genome. However, to sequence such a fragment is difficult, and therefore the sequences of subfragments are usually determined. The second component is information density. The env gene is known to display a much higher degree of variability than the *pol* gene. Thus, a 300 bp fragment covering a hypervariable region in *env* contains far more information than the same length of sequence in pol. Several other factors, such as convergent changes as a result of influence of the immune system and/or drug treatment will affect the quality of the information, but normally, if the length of the sequence is reasonably long, this will only yield a slight background noise. However, it may be wise to choose a region that does not contain extensive length variations, such as V1-V2 of *env*, because much information will be lost in alignment columns where these occur as a result of gapstripping procedures [33] that many phylogenetic inference methods include. Leitner et al. recently showed that a 285 bp fragment covering the *env* V3 region was sufficient to reconstruct a known intrasubtype transmission chain covering 13 years of viral evolution [35]. For classifying subtypes, less would be required because of the larger sequence differences. Figure 2 shows the genetic distance correlation of common subfragments to their complete gene sequences. As is evident from the figure, shorter sequences are essentially giving the same answer as longer ones. This was true for both intra and inter subtype relations. Interestingly, some of the subfragments carry a higher information density than the complete genes: the V3 fragment of *env* and the p17 fragment of *gag* both display longer genetic distances than the complete genes (Figures 2B and 2C). Note, however, that the shorter a fragment gets, the more it will be affected by mutational noise and the lower the significance will be. Yet another problem with too-short sequences is that there may not be enough information there to estimate some parameters for more advanced distance estimates.

Phylogenetic inference. When a DNA sequence has been determined for a sample, the next step is to align it to the set of reference sequences describing established subtypes. Alignments of sequences covering the complete *env*, *gag*, and *pol* genes as well as subfragments gp120 and V3 of *env*, p17 (MA) of *gag*, and p51 (RT) of *pol* of the suggested reference sequences (Table 1) are available at the HIV database (http://hiv-web.lanl.gov). For the complete gene sequences, sets containing the subtypes shown in Figure 3 are included, while for the subfragments also more uncommon subtypes are represented when such sequences were available (according to Table 1).

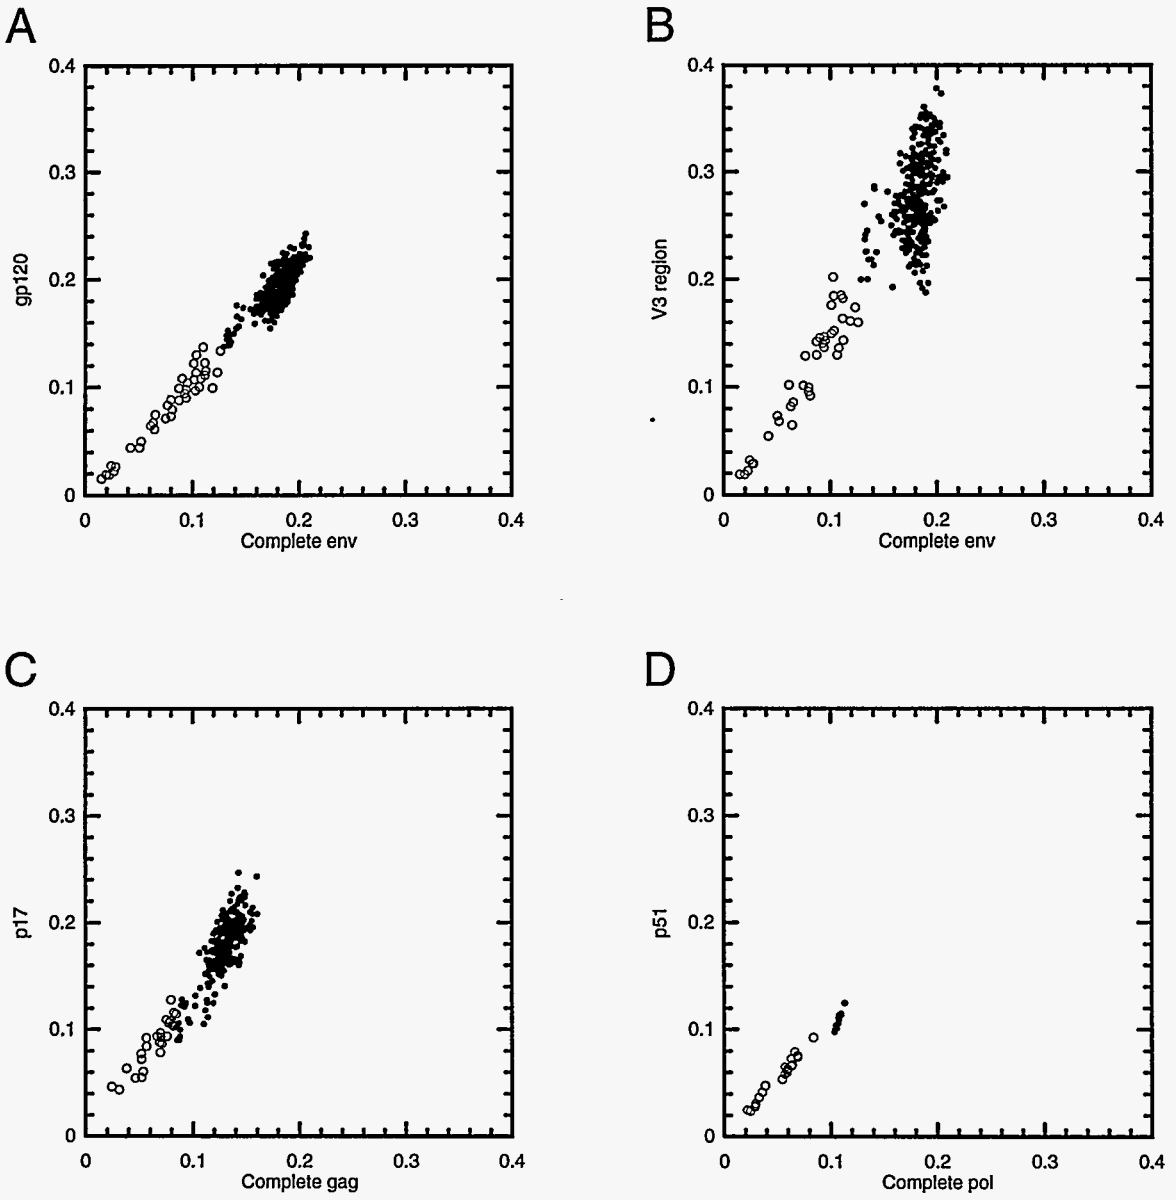

Figure 2. Comparison of distance estimates of nucleotide sequences from complete gene fragments to common gene subfragments. Open circles indicate within-subtype distances, and solid circles between-subtype distances. (A) The gp120 coding region (1251 bp) compared to the complete *env* gene (2301 bp); (B) The V3 region of gp120 (324 bp) compared to the complete *env* gene; (C) The p17 fragment of *gag* (381 bp including 24 bp into p24) compared to the complete *gag* gene (1380 bp); (D) The p51 fragment of *pol* (1320 bp) compared to the complete pol gene (3000 bp). All distance estimates were calculated using the F84 ($\kappa = 2.0$) nucleotide substitution model [19]. Note that sequence lengths are given for globally gapstripped datasets.

Figure 3 shows how maximum-likelihood, maximum-parsimony, and minimum-evolution based phylogenetic methods perform in reconstructing the established subtypes by use of *env*, *gag*, or *pol* sequences. All these methods and fragments can reconstruct the established subtypes. These trees were all calculated using the full length gene sequences, but essentially the same result would have been

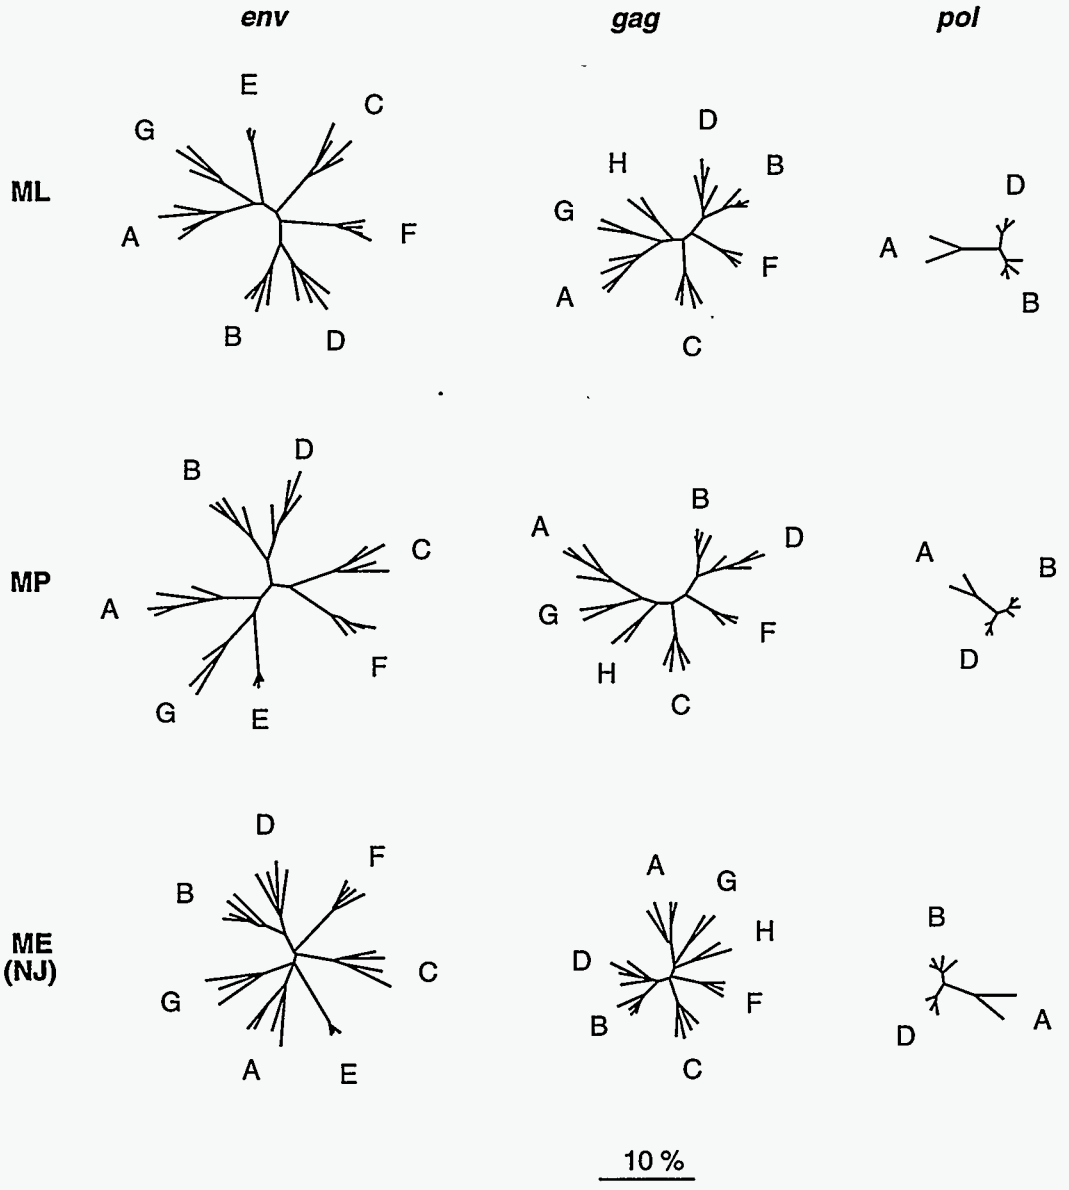

Figure 3. Unrooted trees calculated according to the maximum likelihood (ML) criteria, the maximum parsimony (MP) criteria, and the minimum evolution (ME) criteria. The ML search was conducted using the PHYLIP package [19] with the F84 substitution model, the MP search was conducted with a heuristic search using the PAUP program [63] under uniform weighting, and the ME search was conducted with the neighbor joining approximation using the PHYLIP package [19] with the F84 substitution model. Each method was applied to the complete *env*, *gag*, and *pol* gene alignments, gapstripped to 2301, 1380, and 3000 nucleotide sites, respectively. Branch lengths in ML and ME trees were adjusted to the indicated scale bar, and MP trees were drawn arbitrarily to reflect the information content in a comparable scale.

derived using the suggested subfragments (Figure 2). Thus, for subtyping purposes methods based on these criteria (maximum-likelihood, maximum-parsimony, and minimum-evolution) will give an acceptable answer. In other situations the method may influence the result. However, it has recently been shown in detailed analyses of transmission cases that the amount of information is more important

than the choice of phylogenetic inference method [35]. The opposite is true for calculating genetic distances [38]. Although this is not a primary goal when attempting to determine the subtype of a sequence, it may provide useful information regarding relatedness. When a p-distance (proportion of differences) reaches above 0.1, the choice of substitution model is already making a major impact on the distance estimates. From here, the effect of superimposed events is then rapidly increasing by increased distance. By using an oversimplified model of nucleotide substitution, longer distances will be less and less accurate. With increased distance, saturation effects also start to appear, especially on synonymous positions. If the sequence is long enough, one may consider using only nonsynonymous positions, only second codon positions, or translated amino acid sequences. Again, however, for simple subtyping purposes the substitution model is unlikely to influence the results.

Figure 3 also indicates the information density of the three investigated genes. As is evident from all trees, independent of phylogenetic method, the branch lengths of the tree are not reflected by the sequence length, but rather by the density of nucleotide variation of each gene. In other words, the faster a gene evolves the longer the branch lengths will be, as compared to the more slowly evolving gene over the same time interval. The speed at which the genes are evolving is dictated by several factors, most notably mutation and selection.

Rooting or using a specific sequence as an outgroup in a tree analysis, makes no difference when determining the subtype of a sequence. Depending on which type of tree plot one chooses to present the results, however, the choice of outgroup may influence the aesthetics of the tree. A root should only be assessed when its location in the phylogeny is known, while an outgroup can be chosen arbitrarily [64].

When a sequence falls outside an established subtype, more analyses are needed. The first thing to do would be to check if the used sequence fragment includes any sign of recombination. This can be done by several methods, including signature analysis by VESPA [17, 28] or RIP [59], tree analysis by the bootscanning method [56], or even by simply eyeballing an alignment against representative subtype sequences or subtype consensus sequences. A more extensive tree analysis should also be done, including all available sequences from the two subtypes surrounding the odd sequence as well as earlier reported unclassified sequences. The next step would be to sequence another part of the HIV genome, to see if the classification there indicates an odd location as well. Congruence of trees from two separate coding regions is a strong indication of a new genotype. Also, one should check that the sequence analyzed is not odd because of hypermutation events [66]. If the sequence falls outside established subtypes in two regions, and no signs of recombination are seen, it would be desirable to sequence the complete genome to allow for extensive recombination analysis and/or to establish a new subtype (or potential subtype, if only one sample was found).

Bootstrapping is a resampling technique used to test the robustness of an inferred tree topology [13, 18]. The method resamples data points from the original dataset, and for each resampled dataset a tree is inferred. Finally a consensus tree is constructed and each cluster in this tree is assigned a "bootstrap value" corresponding to the number of times it occurred in the resampled trees. The interpretation of such values varies among authors, since the values provide unbiased but highly imprecise estimates of repeatability. Some authors have claimed that the probability that the result represents the true phylogeny is a biased, but usually conservative, estimate of accuracy [24]. Recently, however, other authors showed that the method is not biased, but that it can be corrected to better agree with standard ideas of confidence levels and hypothesis testing [14]. The degree of "bias" varies from node to node, as well as from study to study, so bootstrap values are not directly comparable to each other. Additionally, bootstrap values for a given cluster in any tree will be highly affected by the control sequences chosen. However, many subtype studies include this analysis, and at best it gives a measure of how stable the inference is. In general, all the established subtypes should present high bootstrap values, but congruence of trees from two coding regions are preferable to bootstrap analysis over just one region.

Implications and Epidemiology

Genetic subtypes were originally defined on *env* and *gag* sequences. The main goal was to identify the major genetic lineages [40, 45]. Since then many studies have included or even concentrated on efforts of subtype classifications. The presence of distant genotypes also made it possible to investigate and realize that recombination events (and thereby, superinfections) are common, or at least not uncommon, in HIV evolution [36, 50, 52]. However, the key question that has been raised among researchers in this field is: What does a genetic subtype mean?

There are three main reasons for why genetic subtypes have been considered to be important to investigate, where the first two are based on the belief that the viral genetic factor is important in virus to host interactions. First, in the context of vaccine development it was realized that the different subtypes express different envelope proteins, and that this likely would effect vaccine treatments. For instance, the tip of the principal neutralization domain of the V3 loop is GPGR in subtype B viruses, while in most other subtypes the consensus is GPGQ. Together with the knowledge that genetic variants can escape the immune system, information on genetic subtypes becomes important [8, 26]. Another similar problem, resulting from genetic variation among subtypes is that some methods can fail in detecting virus [3].

Second, several studies have tried to correlate genetic factors to biological properties. For instance, specific amino acids in the *env* V3 loop have been found to be markers for the viral phenotype [11, 20]. However, such a correlation have been found to be subtype independent, or in other words, different phenotypes exist in all genetic subtypes [36, 51, 68]. Kostrikis et al. recently showed that no direct correlation between neutralization serotypes and genetic subtypes could be established [31]. It has been suggested that the Thai subtype E may be more transmissible than subtype B in Thailand [32, 62], but it is difficult to discriminate between the viral genetic factor and the epidemiological situation in such a comparison. Recently, viral phenotype was found to be dominant over genotype also in the context of chemokine receptors as being the long-sought second receptor of HIV-1 [67]. Genotypic studies have often concentrated to regions of special interest, and it is therefore not clear if genetic factors elsewhere in the HIV genome may play an important biological role. However, mutational trends have been observed within the V3 loop among different subtypes, which may reflect the acquisition of specific biological properties during the evolution of HIV-1 [29].

Finally, more informative are the subtypes for the understanding of the HIV-1 epidemic. It was early realized that subtype B represented the vast majority of virus circulating in North America and Europe, while it was almost absent in Africa. Instead, all other subtypes were found in Africa (more recently, subtype B has been reported several times from different African countries). Together with the fact that many species of African monkeys carry similar viruses, it was concluded that the origin of HIV was somewhere in Africa. The question of when the cross-species transmission from monkeys to humans occurred has been investigated by several groups, and the answers have been astonishingly different: ranging from 40 to millions of years ago [22, 57, 61]. The main reason for the different interpretations is that the true evolutionary pattern of the virus is not known, creating problems of interpreting the shape of the tree and correlating time to branch lengths. However, the current subtypes do tell us that very different viral genotypes can rapidly establish successful epidemics in naive human populations. This suggests that each subtype is well-adapted to its environment, but also that any existing variant could have established a successful clade. In this context, it is interesting to look a bit closer to the actual shape of the subtype tree (Figures 1 and 3). We can see that the star-like shape actually has structure: subtype B and D are always closer to each other; subtype A is usually more divergent than other subtypes and normally close to G and H; and that more recent subtypes form more distinct clusters away from clusters that mainly are derived from Central African sequences. It seems like there are two components in the tree: an early phase in which the virus spread more slowly between host groups in Africa, forming its network of variants; and a recent phase, which we are still in, in which the virus reaches a naive human population and uses its standing network to spread rapidly. Perhaps can this teach us about epidemic spreads, and how to prevent them in the future.

A Comparison of HIV-1 Group M and Group O Functional and Immunogenic Domains in the Gag p24 Protein and the C2V3 Region of the Envelope Protein

Bette Korber,[1] Ibtissam Loussert-Ajakai,[2] John Blouin,[1] and Sentob Saragosti[3]

[1] *T10 Los Alamos National Lab, Los Alamos, NM 87545, USA*
[2] *Laboratoire de Virologie, Hôpital Bichat-Claude Bernard, 75877 Paris cedex 18, France*
[3] *I.C.G.M. Cochin Hospital 75014 Paris, France*

The major focus of the sequencing effort of group O viruses to date has been on the p24 Gag and C2V3 gp120 env regions. A total of 42 p24 sequences and 45 C2V3 sequences derived from group O isolates have either been published or provided to the Los Alamos database prior to publication. The primary goals of this review are: i) to provide a brief summary of the accumulating knowledge concerning HIV-1 group O serology and epidemiology; ii) to outline differences and similarities group M and O HIV-1 viruses in the the heavily sequenced 24 Gag and C2V3 gp120 regions, with an emphasis on well-defined functional domains; and iii) to provide an alignment of the region of gp41 that harbors an immunodominant domain important for diagnostics. Only published sequences will be shown in alignments (Table 1), but complete sets of unpublished and published sequences currently in the database were used to generate the consensus sequences for group O sequences shown in the accompanying alignment figures.

Introduction

Group O characterization: After the discovery of the virus ANT70 by a group in Belgium [de Leys (1990)], and the further characterization of this isolate, as well as the MVP5180 and VAU isolates (VAU was isolated from a French woman with no ties to Africa) in 1994 [vanden Haesevelde (1994), Gurtler (1994), Charneau (1994)], it became clear that a new group of viruses, distinct from the HIV-1 Major (M) group, was present in the human population. This group was named the HIV-1 group O for "Outlier" group. The group O, group M, and chimpanzee viruses are genetically quite distant from one another, but these three groups share a distinct lineage relative to other primate lentiviurses (Figure 1). It is notable that four years separated the publications concerning the first and second of these outlier viruses.

Since the isolation of these first highly unusual HIV-1 strains, a second Caucasian patient was found in France [Cohen (1995)], and a quite large number of viruses of this group have been isolated, especially from Cameroonian patients [Loussert-Ajaka (1995)]. The main method for identifying group O viral infections is obtaining a paradoxical pattern of positive and negative serological reactivity using a set of HIV-1 enzyme-linked immunosorbent assay detection kits [Simon (1994)]. A variety of Western blot reactivity patterns can occur with group O serum. Phenotypic differences between group O and M have also been detected. HIV-1 group O isolates exhibited a high level of resistance to non-nucleoside inhibitors ([Descamps (1995)], and Descamps et al., manuscript in preparation), and group M, but not group O viruses, require the incorporation of cyclophilin A for the production of infectious virions [Braaten (1996)].

Sequence analysis of env and gag regions of the first ten group O isolates revealed a peculiar feature of this group relative to group M isolates – limited phylogenetic clustering patterns with only a few sequences grouping into clades in both the p24 and C2V3 regions [Loussert-Ajaka (1995)]. This is in marked contrast to the clear phylogenetic subtypes that emerge in phylogenetic analysis of the group M sequences. The original ten group O isolates are a subset of the 40-plus sequences currently stored in the Los Alamos database, and the observation of limited subtype structure among O group sequences [Loussert-Ajaka (1995)] is consistent with the additional data now available. The nucleotide

Table 1. List of public HIV-1 O group sequences included in this paper. The first two characters preceding the period indicate the country of residence of the individual who was the source of the isolate, followed by the sequence name.

Sequence	Accesion	Reference	Note
O_DE.HAM112		Hampl et al.	The protein sequences were entered by hand at the Los Alamos Database, from the paper by Hampl et al. The source was a 27 year old Cameroonian who had moved to Germany, and was tested for HIV infection because of eczematous skin lesions. This was the first group O infection to be found in Germany.
O_CM.ANT70	L20587	De Leys et al and vanden Haesevelde et al.	This was the first O subtype isolate discovered. The complete viral genome has been sequenced. The virus was derived from a symptomatic Cameroonian, CDC stage III.
O_FR.VAU	X80020	Charneau et al.	This sequence was from an isolate from a French woman who died of AIDS in 1992, who had no known ties to West Africa. DNA was extracted from VAU infected PBMCs, PCR amplified, cloned, and gp160 env was sequenced. The viral isolate was highly cytopathic.
O_CM.MVP5180	L20571	Gurtler et al.	The complete viral genome has been sequenced from the MVP5180 isolate derived from a Cameroonian woman, sampled in 1991; the donor died of AIDS in 1992. The viral isolate MVP5180 was grown in several human T-cell lines and the monocytic U937 line.
O_FR.BCF 01, 02, 03, 06, 06, 08, 11	C2V3 region U24562-U24568, p24 U24706-U24712	Loussert-Ajaka et al.	These seven sequences are from Cameroonian patients who were living in France. PBMC proviral DNA was PCR amplified and 3-6 clones from each patient were sequenced. The consensus of the 3-6 clones was presented. 07, 08 and 11 were CDC stage II; 01 was CDC IV; and 02, 03 and 06 were CDC IVC1.
O_CM.CA9	X78476 U53175	Janssens et al, Braaten et al.	The env sequence was kindly released for publication in the 1995 Human Retroviruses and AIDS database by Dr. Wouter Janssens. The Pol region was published by Janssens et al, 1994, and the p24 region by Braaten et al., 1996.
O_GA.VI686	X78476 X96526	Janssens et al. Delaporte et al.	The VI686 viral sequence spanning the pol region was published by Janssens et al., and the complete Env gp160 was published in a diversity study of HIV isolates from Gabon by Delaporte et al.
O_CM.YBF 22,26,28,32,35, and 37		(F. Simon, P. Mauclere, and S. Saragosti, submitted)	These sequences are derived from a set of individuals from Yaounde and have been submitted for publication. 22 and 26 were CDC stage II, the other four had AIDS. They were isolated in 1996.

Table 1 cont.

Sequence	Accesion	Reference	Note
O_FR.DUR or RUD	X84327		This group O viral sequence was derived from a French woman who had a Cameroonian sexual contact. It was made available in GenBank prior to publication by J. Cohen.
O_CM.MVP2171		(Lutz Gurtler, personal communication)	The complete genome of this sequence has been finished, but it is not yet available at the database. The immunodominant region of gp41 was available, and is included here.

GenBank accession numbers of additional sequences shown in the alignments.

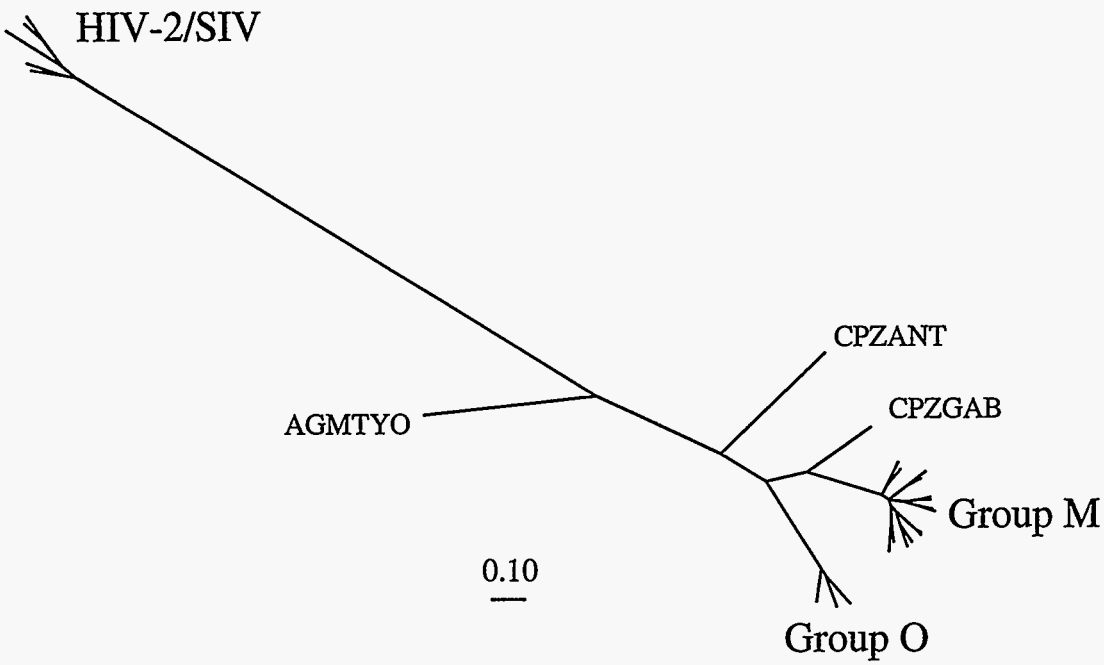

Figure 1. A maximum likelihood tree illustrating the phylogenetic relationship between HIV-1 Group M, HIV-1 Group O, and chimpanzee viral sequences relative to other primate lentiviral sequences. This tree was created using PHYLIP DNAML 4.0 (J. Felsenstein, `http://evolution.genetics.washington.edu/phylip`), with a series of optimization tests performed to select the parameters of three rate categories (1 3 and 9 with frequencies of 0.25, 0.50 and 0.25, respectively) and a transition/transversion ratio of 1.3. The sequences used were the group M isolates subtypes A–G from the alignments in Figure 1 and 2; the full length envelope group O sequences (MVP50, ANT70, VAU); AGMTYO; HIV-2/SIV sequences BEN, D205, ROD, and SIVMNE and SIVSTM; and the chimpanzee viral sequences CPZGAB and CPZANT70. There were 1866 positions spanning gp160 included in the alignment after gapstripping. The taxa included in this comparison were aligned using a Hidden Markov Model (HMMER version 1.8 `http://genome.wustl.edu/eddy/HMMER/main.html`) [Myers & Farmer(1996), Eddy (1995)]. The clade including the HIV-1 and chimpanzee viral sequences is also seen in 100/100 PHYLIP Neighbor Joining bootstrap replicates using a p24 region alignment. The chimpanzee sequences are sometimes linked in phylogenetic reconstructions, and other times are separated as is seen is this tree, with CPZGAB branching with the Group M isolates. The associations of the CPZ sequences depend upon the region of HIV-1 used to construct the tree (data not shown), and may reflect an early recombination event.

sequences of the envelope gene fragments spanning the C2V3 region have been shown to be particularly phylogenetically informative [Leitner (1996)] and to give accurate phylogenetic reconstructions of the M group clades using a variety of phylogenetic tree reconstruction methods [Korber (1994), Leitner(1996)]. Despite this, very little clear phylogenetic structure can be resolved among the group O sequences, in either the region encoding C2V3 of envelope or p24 (analysis was conducted on all sequences available, data not shown). This lack of clearly defined phylogenetic branching patterns in group O could be due to one or a combination of the following three possibilities.

i) An artifact of sample size; accumulation of sequences from new isolates should help us to evaluate this hypothesis.

ii) The length of the sequences in the regions studied not being adequate to reveal phylogenetic associations in group O, although the subtypes are clearly distinguishable using these regions for group M.

iii) A distinct evolutionary history of the two groups, such that the epidemiological history and biology of group M virus yields geographically and phylogenetically distinct subtypes, whereas the group O isolates had a different natural history and simply radiated out from an original ancestral virus [Loussert-Ajaka (1995)]. Interestingly, the first case of AIDS documented in Europe was a Norwegian sailor infected with a group O virus [Jonassen (1997)]. He developed clinical manifestations of HIV infection in 1966, his wife in 1967, and daughter in 1969. All of them died in the 1970s [Froland (1988)].

Geographical distribution: Group O isolates can be identified genetically or serologically. Group O isolates that have been genetically characterized originated in Norway [Jonassen (1997)], Belgium [de Leys (1990)], France [Loussert-Ajaka (1995)], Germany [Hampl (1995)], Spain [Soriano (1996)], the United States [Rayfield (1996)], and, of course, Cameroon [Mauclere (1997)]. Group O infections have been serologically characterized using sera originating in Cameroon and Gabon [Nkengasong (1994)], Equatorial Guinea [Hunt (1996)], Benin [Heyndrickx (1996)], and Kenya [Songok (1996)]. In Cameroon, 7 group O infections were found among 332 sera tested (7/332), Gabon (2/213), Niger (5/1459), Nigeria (2/183), Senegal (1/1283), Chad (2/619), and Togo (1/670) [Peeters (1997)].

It is clear that Cameroon has the highest known prevalence of group O infections. Epidemiology studies conducted in Cameroon indicate a prevalence of HIV-1 group O infection of 2% [Zekeng (1994)], and more recently, Mauclere et al. found prevalence of group O infections ranging from 1% in the northern part of the country, to 6.3% in the capitol; overall, 82 group O infections were found among 2458 HIV-1 samples [Mauclere (1997)]. Among the 19 cases found in France, 17 were from patients originally from Cameroon, and of the two French Caucasian patients, one acknowledged having a Cameroonian sexual partner.

The algorithm developed to characterize group O viruses [Gurtler(1996), Mauclere (1997)] has proven to be very effective. The development of new tools (for example, new peptides used in combination, LIA (Innogenetics)) has allowed the easy serological characterization of group O isolates and the screening of large numbers of samples.

The gag capsid (p24) protein

Background: The gag precursor poly-protein is initially incorporated into the budding viral particle, and is cleaved into the structural proteins of the mature virion by viral protease. The Gag precursor self-assembles into virion like proteins even in the absence of other viral proteins; it binds and packages viral RNA, and interacts with other viral proteins and envelope lipid to assemble the viral particles (for a review of Gag proteins, see [Gorelick & Henderson(1994)]). The capsid antigen (CA) is the p24 protein of HIV-1, and forms the viral core.

The major homology region: The major homology region (MHR) is a part of the capsid protein which is well conserved among lentiviruses of primates, cats, and ungulates [Otteken (1996), Matsuo (1992), Grund (1994), Gorelick & Henderson(1994)]. This region plays a role in viral particle formation and is critical for viral replication. Four highly conserved positions among all retroviruses (human, simian, caprine, bovine, equine, and feline) [Mammano (1994)] are indicated by asterisks in the alignment shown in Figure 2, on the following two pages, and in the consensus MHR alignment (Figure 3). The first three of these positions are critical for HIV-1 particle production, and mutations in forth residue result in aberrant particle size and inappropriate viral cores [Mammano (1994)].

The MHR is conserved among group O viral sequences, as expected, although slightly greater variation is apparent in the group O viruses than the M group viruses. The conserved arginine (R) is present in most retroviral sequences, but it is substituted with a serine (S) in two of the group O viral sequences (data not shown).

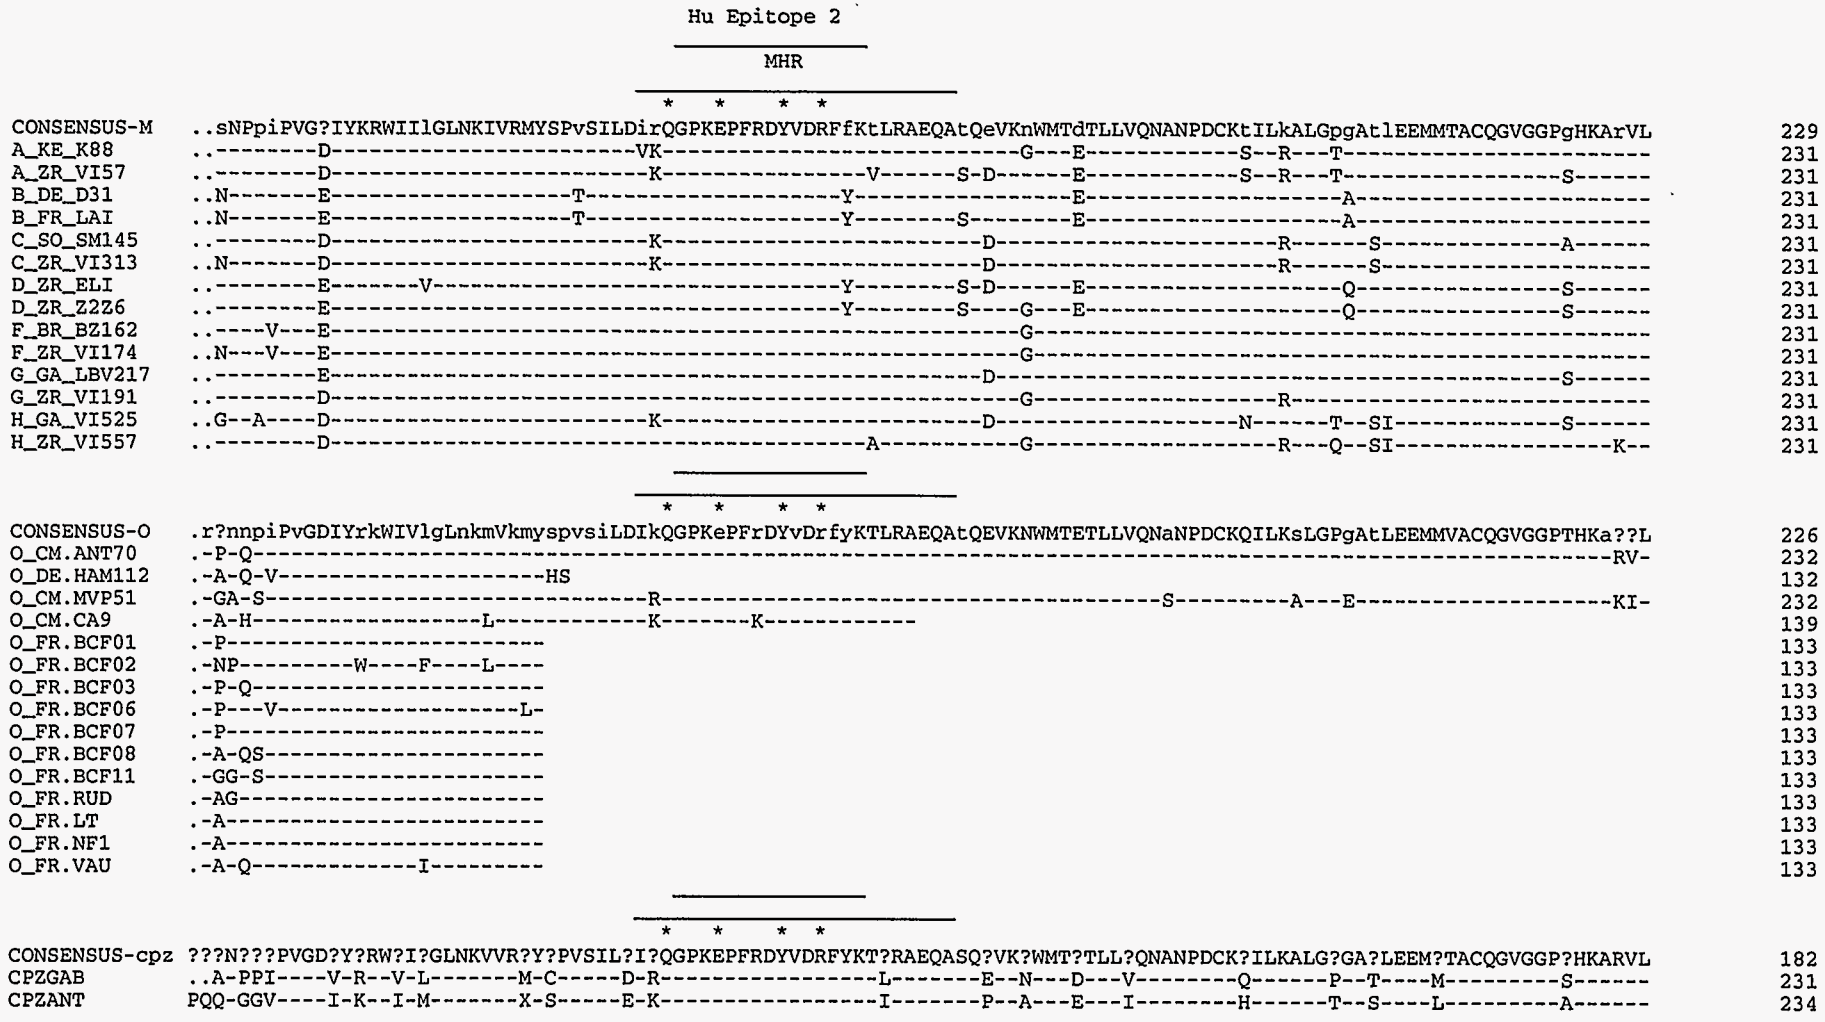

Figure 2. Alignment of the p24 protein. The group M consensus is based on the sequences shown, so each M subtype is equally represented, by two sequences. Upper case letters signify invariant amino acids, and lower case indicate the most common amino acid in a position with some variation. The group O consensus was constructed from all 42 sequences available, but only those published or released are shown. A dash indicates identity with the consensus, a period indicates a insertion made to maintain the alignment. Hu Epitope 1 and 2 are immunodominant linear B cell epitopes that have been identified in group M [Janvier (1996)], and are highly conserved between groups M and O. The MHR is the major homology region and the CyPa region is the cyclophilin A binding domain. Asterisks in the MHR mark highly conserved, functionally important residues, and in the CyPa region mark prolines critical for group M viral replication. The plus signs over the O group consensus indicate prolines that are common among O group sequences, but not perfectly conserved.

Figure 3. A comparison of the consensus sequences across the MHR of gag p24. Highly conserved amino acids essential for group viral particle formation are marked with asterisks.

There is an immunodominant region within the MHR that can stimulate both human and murine antibodies (see [Korber (1996)] for a summary). One of the immunodominant linear epitopes defined for HIV-1 M group viruses is located within this region, defined as: GPKEPFRDYVDRFYK, (called Hu Epitope 2 in Figure 2) [Janvier (1996)]. Only a single amino acid differs in this epitope between the group O consensus the M group consensuses. The tyrosine (Y) in the second to last position of the epitope matches the consensus of group O sequences, and is found in all B and D clade sequences, as well as among the Thai A subtypes. But in all other clades in the M group, this position is most commonly occupied by a phenylalanine (F). It is not clear whether this substitution would influence the antigenic specificity of the peptide, though it is very likely that the antigenic peptide studied by Janvier et al. would react with sera from individuals infected with group O strains of HIV-1, because the group M subtype B derived peptide perfectly matches the group O consensus. 9/20 sera from HIV-1 infected individuals reacted with this peptide [Janvier (1996)]. Among HIV-2 and SIV sequences, the immunogenic region is conserved except for two substitutions: the central RD in positions six and seven become QS (see the Gag protein alignments in this compendium). These substitutions may not be critical for binding, as murine monoclonal antibodies that bind to this region have been shown to be cross-reactive with HIV-1, HIV-2, and SIVmac and SIVagm strains [Matsuo (1992), Robert-Hebmann (1992), Niedrig (1989)]. Therefore, this immunodominant domain could potentially be useful for serological identification of all primate lentiviral infections, by sequence analogy, including those of group O.

Cyclophilin A binding region: Cyclophilin A (CyPa) is a human protein that binds to a proline rich region in the HIV-1 p55 Gag precursor protein, and is incorporated into group M HIV-1 viral particles, (). Group M HIV-1 viral particles that lack cyclophilin A are not infectious, in contrast to other retroviruses [Luban (1994), Thali (1994), Franke (1994)]. Cyclophilins are a family of proteins that catalyze protein folding and are protective against heat shock [Fisher & Schmid(1990), Gething & Sambrook(1992), Sykes (1993)]. In contrast to HIV M group virus and the SIVcpz GAB strain, and the group O viruses do not have to bind and incorporate CyPa to produce infectious virions; this is one of the first major biological differences between group M and group O to be documented [Braaten (1996)].

Three of the prolines in the highly conserved CyPa binding region of p24 are required for the production of infectious virions in M group strains. These prolines are marked with an asterisk in Figures 2 and 4. The proline at position 222 (AGP) was required for CyPa binding and incorporation into virions, and was required for replication. The proline at position 225 (PGQ) was not essential for replication, and so is not marked. Mutations in prolines 217 (lHP) and 231 (PRG) decreased particle yield and the mutant virus did not replicate [Franke (1994)]. Proline 222 was highly, but not perfectly, conserved among group O viruses, in spite of the lack of a requirement for cyclophilin A binding. Proline 231 was perfectly preserved among group M, group O, and SIVcpz. Proline 217 is perfectly preserved among group M and SIVcpz viruses, but varies somewhat in group O viruses. Two additional prolines are present in group O viruses proximal to position 217 (Figure 2).

There are many murine monoclonal antibodies that bind to the CyPa binding domain [Korber (1996)]. One particular epitope that has been defined by peptide reactivity (ETINEEAAEWDRVHP) was cross-reactive with sera from HIV-1, HIV-2 and SIV infections [Niedrig (1988)]. While there are frequent substitutions among group O isolates in this region, most are conservative aspartic acid (D) to glutamic acid (E) substitutions, and there are some O strains that are identical to the M consensus sequence in this region. Thus it is likely that group O sera would react with this peptide.

```

Figure 4. A comparison of the consensus sequences across the Cyclophilin A binding region in gag p24. Highly conserved prolines essential for group M viral replication are marked with asterisks.

Additional immunogenic domains in p24: A peptide covering positions 178-192 (HIV-1 IIIB) was recognized by sera from 8/20 HIV-1 positive people (Hu Epitope 1 in Figure 2) [Janvier (1996)]. The linear immunodominant antigenic regions (Hu Epitope 1 and 2) in p24 group M viruses are conserved in group O as well, particularly human epitope 2, suggesting that they may provide broadly cross-reactive antigenic peptides recognized by sera of individuals with O and M group infections.

Through studies involving M group strains, HIV-1 epitopes have been defined for both helper and cytotoxic T cells across the p24 protein. The p24 T-cell epitopes that have been defined in M group tend to cluster, some near the C-terminal region, and some crossing the CyPa binding site and the MHR [Korber (1996)]. Because of the conservation of p24, it is highly probably that some cross-reactivity between M and group O would be observed. For example, there is an HLA-A25 restricted CTL epitope, (ETINEEAAEW) that has been defined using CTL clones from long term survivors [van Baalen (1996)]. This epitope is conserved in viruses of the B and D subtypes, but the form DTINEEAAEW is commonly in other clades, and this variant was not recognized by CTL specific for the index peptide. While group O sequences show some variation in this epitope, some are very similar to the reactive M group epitope, and may be cross-reactive: (*e.g.* MVP51: EVINEEAAEW).

The C2V3 Region

Variation and immunogenicity of the V3 loop: The variation in the V3 loop has been the focus of extensive international research efforts, originally because it was noted in the late 1980s that antibodies directed against the tip of V3 loop could potently neutralize laboratory strains of HIV-1 in a type-specific manner [Javaherian (1989), Palker (1988), Rusche (1988)]. More recently, anti-V3 monoclonal antibodies have been shown in general to be potent neutralizing agents when directed against HIV-1 laboratory-adapted strains, but far less so when directed against primary isolates. This presumably is due to distinct conformations of envelope, such that the V3 loop of primary isolates is inaccessible (see [Moore & Ho(1995), Poignard (1996)] for review). Most anti-V3 monoclonal antibodies are type-specific, and monoclonals directed against one strain can be completely unreactive even with closely related viral strains, due to the hypervariable nature and high rate of amino acid substitution in the immunogenic tip of the V3 loop [Korber (1996)]. Other neutralizing epitopes, both continuous and discontinuous, have been identified in envelope [Poignard (1996), Moore & Ho(1995)]. Many neutralizing antibodies (but not all, *e. g.* [Trkola (1995)]) share the property of reduced neutralization of primary isolates relative to laboratory adapted strains [Moore & Ho(1995)].

The turn at the tip of the loop is the focus of most anti-V3 neutralizing antibodies, and is most often found to be GPGR or GPGQ among M group viruses [Foley (1996)]. These two motifs are not found among group O strains. With the exception of some common amino acids flanking the cysteines at the base of the V3 loop, group O and group M V3 loops are very different from each other. Helper and cytotoxic T cell epitopes, as well as antibody binding sites, have been identified within the V3 loop of M group viruses. Because group O and M viruses are highly variable in the C2V3 region within a group, and because the extent of the substitutions found between group O and M is so great, it is highly unlikely that there would be antigenic O and M cross-reactivity for either B or T cell epitopes in the V3 loop.

Phenotypic determinants in the V3 loop: The V3 loop has been shown to have a critical functional role in determining the phenotype of the virus [Hwang (1991), Chesebro (1992), de Jong (1992)]. Positively charged amino acids in certain positions in the V3 loop are correlated with a syncytium-inducing (SI), T-cell-tropic viral phenotype among group M subtype B viruses [Fouchier (1992)] (the two most critical positions are indicated in Figure 5). The observations concerning these two positions, and a correlation between net positive charge on the loop and rapid high and slow low

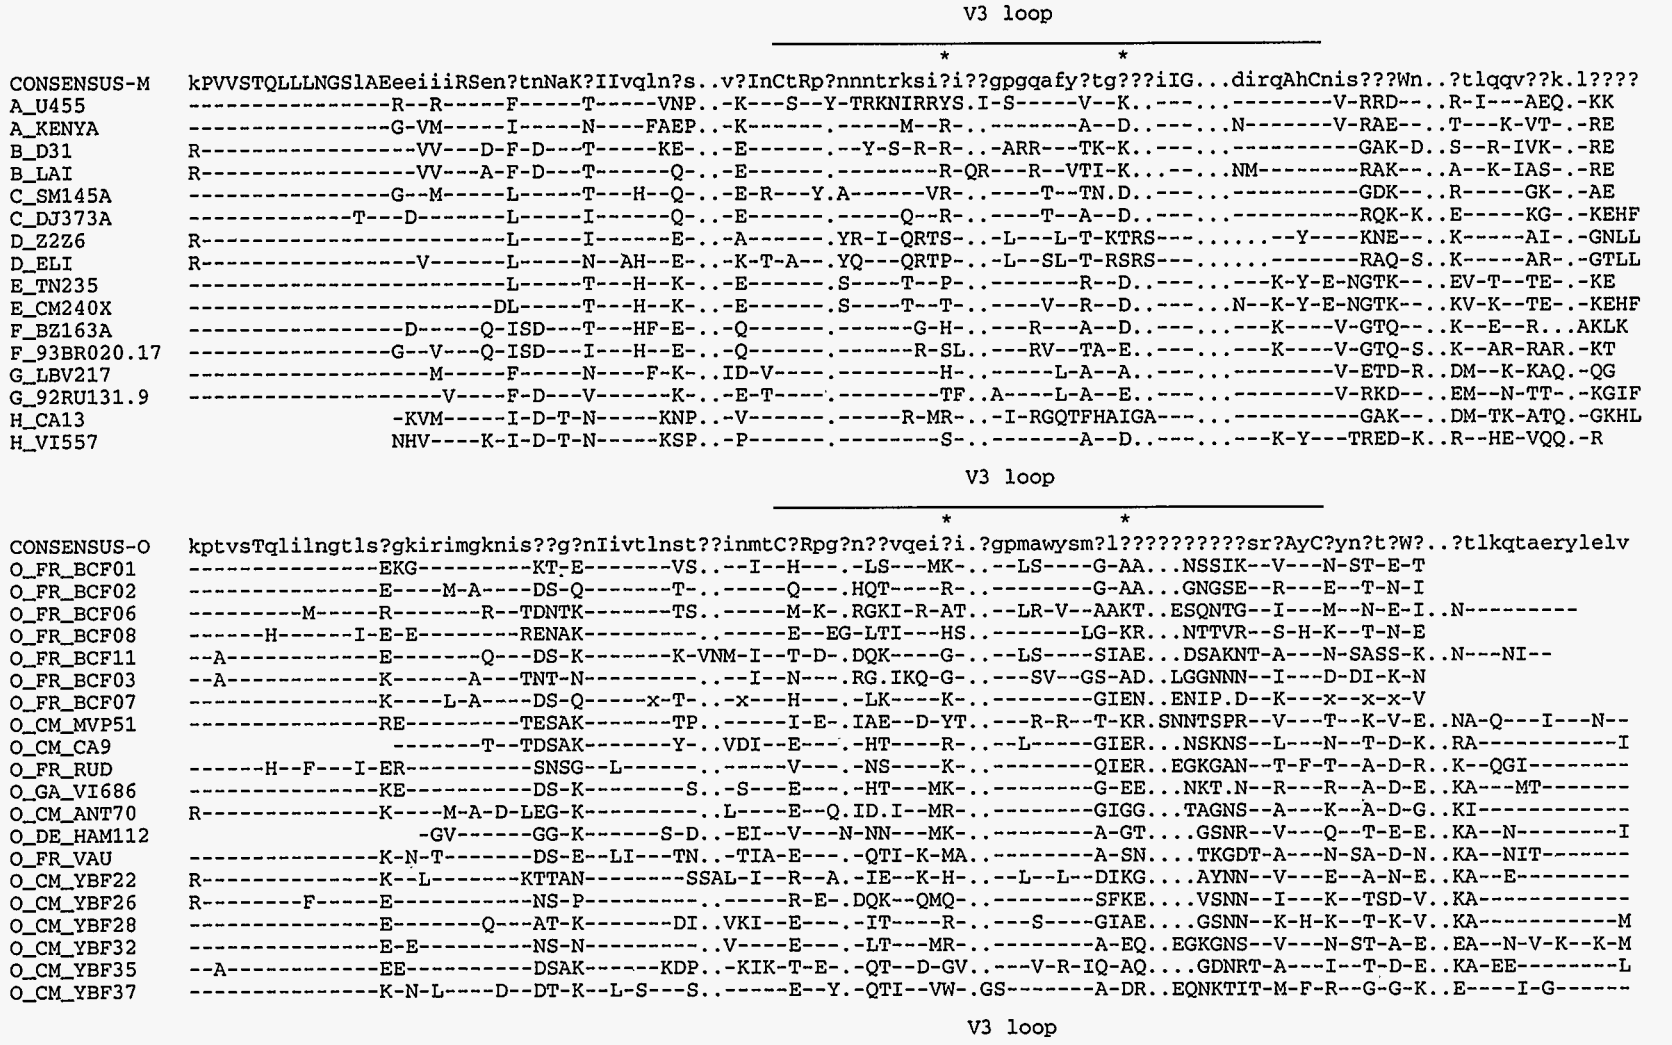

Figure 5. Alignment of the C2V3 region of gp120. The boundaries of the V3 loop are shown, and the positions that are associated with viral phenotype (SI phenotype and positive charge) are marked with asterisks. 45 group O sequences were used to generate the consensus, but only those published or released are shown.

phenotypes, were extended beyond subtype B to other group M subtypes [de Wolf (1994), Rubsamen-Waigmann (1994)]. Recently, a correlation between positive charge and phenotype was shown for the group O viruses [de Jong (1996)]. Because of the length variation between different strains and the diversity found in this region, it is difficult to be certain the alignment of V3 loop shown in Figure 5 is biologically appropriate. Despite this, in a best estimate the two critical sites in the V3 loop associated with group M SI/NSI phenotype switching display a similar pattern of variation among group O strains and group M sequences. Both are highly variable positions, and the first position alternates between neutral and positively charged amino acids, and the second position alternates between negative, neutral and positively charged amino acids.

Recently it has been shown that chemokine second receptor usage for HIV entry into CD4-positive immune cells is associated with the phenotype of the virus, and not with the genetically defined HIV-1 group or subtype [Zhang (1996), Choe (1996)]. CXCR4 (fusin) usage is associated with viruses of with T-cell tropic, SI phenotypes; CCR5 usage is associated with a macrophage tropic, non-SI (NSI) phenotype; and some SI viruses are able to use both CXCR4 and CCR5 [Zhang (1996)]. The group O viruses, similar to the M group, have both patterns of second receptor usage [Zhang (1996)]. The two group O isolates for which second receptor usage has been determined are CA9, with an NSI phenotype and second receptor usage restricted to CCR5; and MVP5180, with an SI phenotype and the ability to use both CCR5 and CXCR4. The pattern of positive charge substitutions in the V3 loop, at least in these two group O isolates, is consistent with what has been observed in the M group. The SI isolate MVP5180 has greater positive charge overall, and in particular, in the second of the two sites associated with the SI phenotype in the M group is positively charged in O_CM_MVP51 and negatively charged in O_CM_CA9 (Figure 6). The C-C chemokines RANTES, MIP-1α, and MIP-1β produced by CD8+ cells, can inhibit HIV-1 infection of primary and macrophage-tropic group M HIV-1 isolates, whereas T-cell tropic isolates tend to be resistant to the C-C chemokine suppressive effects [Cocchi (1995)]. The V3 loop was shown to be a critical region for determining the susceptibility to chemokine-mediated supression using chimeric gp120 proteins [Cocchi (1996)]. It will be interesting to see if SI group O viruses, like MVP5180, will have a similar pattern of resistance.

Figure 6) The V3 loop sequences of SI strain MVP51 and NSI strain CA9. The positions that have been associated with viral phenotype are marked with asterisks. The positively charged amino acids arginine (R) and lysine (K) near the tip of the loop V3 found in SI isolate MVP51 are marked with a plus (+). The dashes (-) indicated insertions made to maintain the alignment.

Immunodominant domain in gp41

The immunodominant region in gp41 is conserved between different group M strains, and is reactive with sera from individuals infected with a variety of group M subtypes [Engelbrecht (1994), Petrov (1990), Shafferman (1989), Gnann (1987)]. Although only a limited number of sequences are avalailable in the database across this region, because of its importance for diagnostics, a comparison of the and group M and O consensus sequences in this region is shown in Figure 7.

Acknowledgments

With thanks to Lutz Gurtler, Sushil Devare, Francois Simon, Philippe Mauclere, J. Cohen, Marie Laure Chaix, Guido Van der Groen and Wouter Janssens for their history of graciously providing sequences to the Los Alamos Database prior to publication of the primary articles introducing the sequences, for sharing their knowledge concerning group O viruses, and for contributions of sequences used to build the consensuses provided in this manuscript.

Figure 7. Alignment of amino acids from gp41 spanning the immunodominant domain of gp41. This alignment starts at 50 amino acids from the start of gp41 and continues for the next 100 amino acids. The M consensus is based on the set of sequences shown. The group O consensus is based on the 9 sequences currently available at the Los Alamos database covering this region; the five that have been published or made public are shown in the alignment.

Retroviral G → A Hypermutation

Simon Wain-Hobson

Institut Pasteur, 28 rue du Dr. Roux, 75724 Paris, Cedex 15, France

A G → A hypermutant is a term given to retroviral proviruses bearing an inordinate number of G → A transitions, typical examples being given in Figure 1. Although two cases were unwittingly described for HIV-1 (Goodenow et al., 1989), the phenomenon was first described for spleen necrosis virus (SNV) (Pathak and Temin, 1990). More examples followed for HIV-1 (Vartanian et al., 1991; Vartanian et al., 1994), SIV (Johnson et al., 1991; Pelletier et al., 1995), HIV-2 (Gao et al., 1992), EIAV (Perry et al., 1992) and CAEV (Wain-Hobson et al., 1995). As the previous sentence shows, most have been described for members of the lentiviral group and much less frequently for other retroviruses. To some extent this undoubtedly reflects the current passion with anything lentiviral, meaning that there are huge data bases for the lentiviruses with respect to other retroviruses, particularly collections of PCR amplified material. However, it probably reflects a penchant of the lentiviral reverse transcriptase (Martinez et al., 1995). Note for the time being the absence of published examples for BIV, FIV and visna virus. For the record it is not an artefact confined to viral cultures as G → A hypermutants have been identified in uncultured PCR amplified material (Gao et al., 1992; Li et al., 1991; Pelletier et al., 1995).

Figure 1. Some examples of hypermutated HIV gp120 env sequences.

Simple Criteria for Identifying G → A hypermutants

Nucleic acid sequence:

1) Monotony of G → A transitions with respect to the viral plus strand (Pathak and Temin, 1990; Vartanian et al., 1991). Only one recorded case of the phenomenon occurring during minus strand synthesis C → T hypermutation with respect to plus strand, (Pathak and Temin, 1990; Vartanian et al., 1991). Hypermutants may be occasionally accompanied by a few (<5%) other substitutions (Martinez et al., 1994).
2) All parts of the retroviral genome are vulnerable. There is one example of a provirus hypermutated throughout all 10 kb (Borman et al., 1995; Pelletier and Wain-Hobson, unpublished data).
3) Given that purine-purine transitions are the most frequent of all substitutions for lentiviruses, overall the number of G → A transitions per sequence should be ≥5 while the transition frequency should be >5% of the number of Gs. Up to 60% of Gs may be substituted (Wain-Hobson et al., 1995).
4) The distribution of substitutions may be confined to a very small region, say 50 bp (Delassus et al., 1991). Equally, they may be distributed in an erratic manner throughout the genome (Wain-Hobson et al., 1995). Finally hypermutation may be sustained throughout minus strand synthesis resulting in approximately 30% G substitution over a 10 kb proviral sequence (Borman et al., 1995; Pelletier and Wain-Hobson, unpublished data).

5) G → A transitions are associated with dinucleotide context declining in the order GpA > GpG > GpT ≥ GpC (Vartanian et al., 1991). Occasionally a few examples have GpG>GpA (Fitzgibbon et al., 1993; Vartanian et al., 1994). More complex sequence context rules have been proposed (Borman et al., 1995). This author is not convinced the latter will hold up.
6) Hypermutants may be accompanied by small deletions of 1–5 bases. Large deletions and small insertions (1–3 bases) are rarer (Pezo et al., 1996; Vartanian et al., 1991; Vartanian et al., 1994).

Protein sequence:

7) In phase stop codons resulting from tryptophan (TGG) to stop codons (TAA, TAG and TGA); see Figure 2.
8) Unusual proportions of certain amino acid substitutions, e.g., depletion of glycine (G → R, S, D, E and sometimes N or K), arginine (R → K, and less R → H or Q), serine (S → N), aspartic and glutamic acids (D → N and E → K respectively), valine (V → I), alanine (A → T), methionine (M → I) and cysteine (C → Y); see Figure 2.

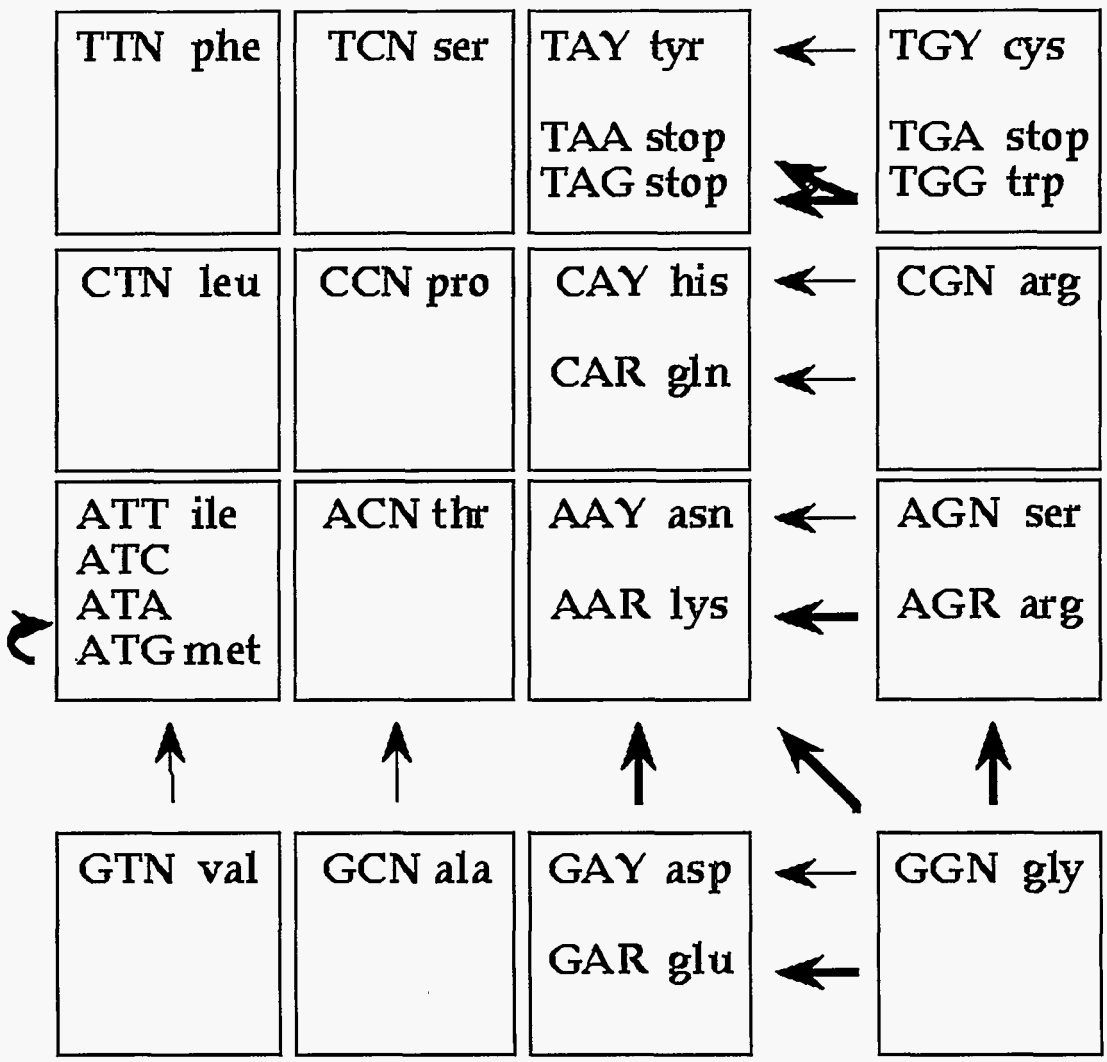

Figure 2. Amino acid substitutions resulting from G → A hypermutation. The intensity of the arrows indicates the relative frequency based generally on dinucleotide context.

Mechanism

G → A hypermutation results when minus strand DNA synthesis coincides with an increase in the intracellular [dTTP]/[dCTP] ratio.

Evidence

1) The two or so bases preceding the site of a misincorporation strongly influence the kinetics of misincorporation. Thus the strong dinucleotide context (Vartanian et al., 1991) indicates that it occurs during reverse transcription of plus stranded RNA into complementary DNA.
2) A sequence with a number of C → T transitions (with respect to the plus strand, which are but G → A transitions with respect to the minus strand) was identified along with many more G → A hypermutants (Vartanian et al., 1991). This indicated that the phenomenon could occur during both minus and plus DNA strand synthesis. The properties of RNA:DNA hybrids in vitro are more conducive to generation of rG:dT mismatches with respect to dG:dT mismatches in DNA:DNA duplexes (Sala et al., 1995).
3) G → A hypermutants may be produced in vivo by addition of deoxythymidine (dThd) to the culture supernatant (Vartanian et al., unpublished data). dThd is scavenged, and kinased up to dTTP which has a negative effect on ribonucleotide reductase reduction of CDP to dCDP. The net effect is to increase the [dTTP]/[dCTP] ratio.
4) G → A hypermutants may be simply reproduced in an in vitro reaction using RNA, purified RT and strongly biased [dTTP]/[dCTP] ratios (Martinez et al., 1994). They may also be made during endogenous strong stop synthesis (Martinez et al., 1994; Vartanian et al., unpublished data).
5) Many types of hypermutants can be produced in vitro by manipulation of the dNTP pools (Martinez et al., 1994; Vartanian et al., unpublished data). Thus the mutant spectrum is restricted by the intracellular milieu and much less the HIV-1 RT.
6) The extent of in vitro hypermutation was positively correlated to the magnitude of the [dTTP]/[dCTP] ratio (Martinez et al., 1994). The dinucleotide preference was reproduced at relatively low [dTTP]/[dCTP] ratio in the endogenous RT reaction (Vartanian et al., unpublished data).
7) HIV-1 RT is more sensitive in vitro to [dTTP]/[dCTP] imbalances than the Moloney murine leukemia virus (MoMLV) (Martinez et al., 1995). This helps explain the greater frequency of G → A hypermutants in lentiviral sequence data sets.
8) The clustering of rG:dT mismatches is partly explained by the observation that prior rG:dT mismatches increase the frequency of subsequent mismatches (Sala et al., 1995).

Additional negative arguments

1) Not associated with NTP imbalances during transcription. Given the pattern of reverse transcription the distribution of G → A transitions through contiguous U3 and R of the LTR proscribes a transcriptional origin (Vartanian et al., 1994).
2) Not related to excessive dUTP incorporation. Firstly hypermutants have been described for lentiviruses encoding a dUTPase (EIAV and CAEV, (Perry et al., 1992; Wain-Hobson et al., 1995)). Secondly for those without a dUTPase, such as HIV, the RT shows much greater discrimination against rG(template):dUTP as opposed to rGt:dTTP in vitro (Martinez et al., 1995). Finally, a dUTPase minus FIV mutant failed to generate G → A hypermutants (Lerner et al., 1995).
3) Not associated with a mutant polymerase. Hypermutants have been identified in a single cycle of reverse transcription with a "wild type" RT (Mansky, 1996; Pathak and Temin, 1990). Hypermutants can be produced in vitro using E. coli expressed RT derived from infectious molecular clones (Martinez et al., 1994).

Literature and Data Base

Overall hypermutants are rare, probably reflecting the rigours of purifying selection. There are probably fewer than 100 examples, many having been alluded to above. Some researchers relegate them

to the drawer as they are frequently defective. Others submit them to the data base without commenting on them in the conventional literature. Some examples go unperceived (Table 1).

*HIV-1 unless otherwise stated. The table includes those sequences which passed into the literature with little or no comment. Other G → A hypermutants have been found for SNV (Pathak and Temin, 1990), HIV-1 (Fitzgibbon et al., 1993; Mansky, 1996; Vartanian et al., 1991; Vartanian et al., 1994), SIV (Johnson et al., 1991; Pelletier et al., 1995), HIV-2 (Gao et al., 1992), EIAV (Perry et al., 1992) and CAEV (Wain-Hobson et al., 1995). This list is probably not exhaustive, representing all those recognized by the author.

When hypermutation is not very intense or confined to a small region the molecular products cannot be assumed to be defective (Martinez et al., 1996). Thus, hypermutants should not be incorporated in phylogenetic trees, for they are generated in a single cycle of replication. There never were intermediates as is implied when constructing phylogeny. Doing so can lead to spurious conclusions or groupings (Mariani et al., 1996).

As mentioned above, one example was noted for SNV (murine C type retrovirus group) (Pathak and Temin, 1990). One case has been described for HTLV-1 being limited to 5 G → A transitions (4 GpA, 1 GpG) within a 110 bp stretch (i.e. 4.2% substitution frequency). In this context it is worth noting that during the endogenous cDNA reaction HTLV-1 hypermutants may be produced by using biased [dNTP]s (Vartanian et al., unpublished data).

And the Pararetroviruses?

This term covers the hepadnaviruses of mammals, reptiles and birds as well as the plant badnaviruses. Perhaps the most celebrated viruses of each group are human hepatitis B virus (HBV) and cauliflower mosaic virus (CaMV) respectively. Although the infectious form harbours a DNA genome, intracellular replication passes through reverse transcription of a plus strand RNA pre-genome. Are there any hypermutants? None have been published, although two such HBV genomes have been sequenced (Günther et al., unpublished data). Hypermutation was noted in the viral plus strand, while substitutions were erratically distributed throughout the genome. The overall substitution frequencies were 12% and 26%. Both genomes encoded in phase stop codons. The dinucleotide preference for transitions was GpA>GpG>GpC GpT. Such characteristics are typical of retroviral hypermutation, indicating that HBV replication is also vulnerable to intracellular [dTTP]/[dCTP] imbalances.

A → G Hypermutation

This represents an even rarer form of retroviral hypermutation, only a few examples being published to date. The initial example was identified within the U3 region of an avian leukosis virus (ALV) provirus (Felder et al., 1994), while more recent examples come from ALV (Hajjar and Linial, 1995) and SNV (Kim et al., 1996). They most certainly arose via post transcriptional deamination of adenine moieties in the RNA genome by double stranded adenosine deaminase. Such a phenomenon was first noted for measles virus genomes in cases of subacute sclerosing panencephalitis, leading to intervention in the post transcriptional modification of some cellular mRNAs. Deamination of adenine leaves inosine, which preferentially base pairs with cytosine, leading to A → G transitions. For review see Bass, 1995. Given the high A content of HIV, the extensive secondary structure in the region 1–600 and RRE, as well as the size of the HIV sequence data, it is perhaps surprising that no good example of A → G hypermutation exists. There has been discussion of an A/I change at position 27 of TAR (Blanchard et al., 1992; Klaver and Berkhout, 1994; Sharmeen et al., 1991).

HIV Alignments, Database Searches, and Structure Predictions

Gerald Myers and Andrew Farmer

MS K710, Los Alamos National Laboratory, Los Alamos, New Mexico 87545

Analyses of more distantly related HIV and SIV sequences that take as their point of departure an alignment, either of the nucleic acid or amino acid sequences, will only be as sound as the alignment, which is itself an hypothesis. For this reason, many sequence analyses are conducted over only "unambiguously alignable" stretches of sequence, typically stretches for which the similarities are 50% or greater, and the information in the more varied regions (similarities less than 30%) is lost to the analysis. This is unfortunate insofar as structural information is typically derived from distantly related, not closely related, sequences. Given the diversity of primate immunodeficiency viral (PIV) sequences, alignments in the database publications up to this year were constrained of necessity to highly related subgroups of viral types, which were then "apposed" by eye. These safe, but restricted, alignments could not support some analyses based upon the entire set of PIV sequences. This year, in Parts I, II and III, we have brought into play a new alignment strategy that holds some promise for simultaneously and objectively aligning all members of the primate immunodeficiency virus family.

An additional reason for exploring new approaches to HIV and SIV sequence alignment concerns computational time: multiple alignment, viewed as an extension of pairwise alignment, requires time proportional to the average length of the sequences raised to power k, where k is the number of sequences being aligned. In the approach described below, sequences are aligned in time linearly proportional to k, the number of sequences. There are further advantages to the method. Most alignment strategies are "progressive", which is to say that the alignment unfolds from the pairs of most similar sequences to the pairs of most dissimilar sequences; the essence of this approach is captured by Doolittle's dictum—"once a gap always a gap" [1]. McClure and coworkers critique twelve different alignment methods, most of which are progressive, according to their abilities to correctly identify ordered series of motifs in highly divergent proteins that have been experimentally studied [2]. They find that no single approach is superior to all others, and most are time-consuming. Some of the newer multiple alignment programs are intentionally not progressive, partly for the reason that progressive alignments may be trapped by local optima, partly because phylogenetic inferences are implicitly assumed. The Hidden Markov Method (HMM) approach, which we utilize and describe herein, is not progressive; instead, it emphasizes position-specific probability distributions of character states, hence a gap in one portion of the alignment may be scored differently than a gap in another portion of the aligment. Most alignment programs have position-independent scoring schemes, which are unrealistic in the case of most proteins since they are composed of both conserved regions and indel-rich variable regions. As HMM is centered upon the columns of information, this approach, referred to as a "generalized profile", is indifferent to the relatedness of pairs of sequences [3,4]. On the other hand, because a probability distribution over the 20 amino acids must be constructed at each position in the sequence, HMM is employed with large sets (40 or more taxa) of highly divergent sequences such as is seen with HIVs and SIVs. Furthermore, an assumption of independence between sites is made. The latter assumption is not universally defensible, however neither is it new to sequence analyses.

At this point in the discussion, it will be helpful to briefly recall what a Markov chain is and in what sense the sequence alignment problem is said to be "hidden." A first order Markov process is one in which the state at time t is a probabilistic function of the state at time $t-1$. We *think* that this is a reasonable assumption for viral sequence evolution. Many phenomena describable by a Markov process are observable, *e.g.*, changes in weather where a complete history of weather is on record [5]; when the changes of state are themselves not observable, the process is said to be hidden. In the case of HIV sequences, we do not possess a history of the intermediate states through which sequences have evolved. Fitch's notion of a *covarion*, the set of concomitantly variable codons, can illustrate the hiddeness: we imagine that evolutionary changes shift the makeup of the covarion, at

one time a position be invariant, at another time being variable; one state representing one covarion, another state representing another covarion. These states are not observed. The overall problem is to formally arrive at a probabilitistic model that will satisfactorily account for the sequences that are known. Specific aspects of the problem, in addition to facilitating alignments, are to derive a suitable "consensus" sequence, to classify a sequence (is it distantly related or totally unrelated?), to support structural analysis, and to gain insight into the "hidden" evolutionary process.

Hence the HMM approach leads to a model for the sequence set that has been analyzed. An example of an HMM-generated model, or so-called architecture, is shown on the cover of this year's compendium. With subsequent database searches, this model—in the form of a "most likely" sequence, or *discriminator*—embodies all of the information contained in the data set, not merely one particular sequence. As we shall see, this consensus-like sequence is useful for database searching (below and accompanying Part IV section concerned with Molecular Mimicry). We have also coupled the HMM-generated model to prediction analyses of protein structure using an array of contemporary algorithms. Eventually, the sequence alignment and the structure prediction will become intertwined in an effort to optimize the alignment.

Be forewarned that the method is still in its infancy and that our utilization is at the most elementary level: refinement of the approach, especially to extend the analysis to nonprimate lentiviruses and other retroviruses, entails extensive parameterization studies such as those being undertaken by McClure and coworkers [6]. Issues such as optimum model length, size of training set, etc. are not taken up in this analysis, which was restricted to just primate lentiviral sequences.

In the following text, we first describe in some detail the HMM approach to alignment as we have applied it in this compendium, especially in Parts I and II, then we turn to discussions of database searching and protein structure prediction.

A. MULTIPLE SEQUENCE ALIGNMENT OF HIVS and SIVS USING HMM

The Hidden Markov Model (HMM), as it has been applied to sequence analysis, has many similarities to what is called a "profile" [7,8] in terms of the information that it captures concerning a set of related sequences. In a sense, each can be thought of as an extended consensus sequence in which the information retained at each position includes the frequency with which each possible base or amino acid residue is seen in the sequence set at that position. The HMM is constructed from a number of successive nodes generally corresponding to the columns of positional homology of an alignment; each of these nodes contains a match state, an insert state and a delete state (see figure on the cover of this compendium). Match states correspond to simple amino acid (or base) substitutions; insert and delete states are self-explanatory. Associated with each of the states in the model are vectors of probabilities that specify the likelihood with which the system might pass to each member of the set of next possible states; these are referred to as transition probabilities. Also associated with match states and insert states are vectors of probability specifying the likelihood that the system will generate or "emit" each possible amino acid or nucleotide when in that state; delete states allow for the possibility that a sequence not have a character in a certain column. Altogether, there will be three probability matrices to describe the model—the transition matrix, the emission matrix, and the initial state matrix.

The resultant architecture of the HMM allows one to establish a correspondence between the characters of a given sequence and the states of the model. The succession of the characters in the sequence will thus determine a path through the states of the model, and associated with this path will be a likelihood determined both by the probabilities of transition between successive states and the probability that each state has for generating the character that has been assigned to it. Provided that all the probabilities in the model, including both transition and emission probabilities, are non-zero, then each path through the model that is permissible according to the rules governing transitions from one node of the model to the next will have a non-zero probability of generating the given sequence. The task of finding the optimal path through the model for a given sequence, i.e. the path with the highest likelihood, can be thought of as aligning the sequence to the model, and may be solved using dynamic programming techniques.

The most important differences between the profile and the HMM lie not in the resultant information structures, but in the means by which these structures are generated from the sequence data. As with an ordinary consensus sequence, the profile is generated from a set of sequences whose alignment has been determined by some independent means. The parameters for describing an HMM can also be derived from a given alignment in this manner. More importantly, however, there exists an algorithm for HMMs that allows one to determine the parameters of the model having the highest likelihood (at least within the neighborhood of the initial model) given a set of unaligned sequences. This approach is quite similar to certain techniques used in connection with artificial intelligence applications, and is known as "training" the model. The general procedure for training makes use of an Expectation-Maximization algorithm, of which there are several [3,4,6].

Speaking generally, the algorithm used in training the parameters of an HMM involves an iterative approach that uses an initial model to estimate an alignment of the given set of sequences, then uses this alignment to re-estimate the model, and so on until the estimates converge to an optimum. For example, if we are given a set of protein sequences that are thought to be related, a good estimate for an initial model can be made by using the frequency distribution of amino acids in the unaligned set as a vector of probabilities assigned to all the match states and insert states of the model; transition probabilities between the states of the initial model can be assigned arbitrarily, or using a prior assessment of the relative frequencies of indel events. All of the sequences in the given set will now be aligned in turn to the model, finding the path through the model that maximizes the likelihood for the given sequence; by aligning all the sequences in the set to the model in this pairwise fashion, one transitively defines a multiple sequence alignment of the sequences to one another. The multiple sequence alignment thus created can be used for an estimate of the parameters of the HMM, by counting the frequency of occurrence of each amino acid at each position of the alignment and the frequency of indel events across the alignment. This adjusted HMM then serves as a model for another round of alignment, and so on. It can be shown that this process is guaranteed to converge to a local maximum of the likelihood function.

To address the problem of guaranteeing convergence to a global maximum for this function, a variation of the simulated annealing algorithm can be applied at each step of the iterative algorithm; this basically allows a stochastically generated sub-optimal alignment to be chosen for the re-estimation of the model's parameters, where the sub-optimality of the alignment decreases to zero with successive iterations of the re-estimation procedure.

As should be clear from the preceding discussion, the model can be used to generate a multiple sequence alignment of sequences, including sequences not belonging to the set used to train the parameters of the model. A distinct advantage to using the HMM over the standard dynamic programming algorithm for multiple sequence alignments is that since one is really performing a set of pairwise comparisons of the sequences to the model, the time and memory requirements increase only linearly with the number of sequences, as opposed to exponentially with dynamic programming. It follows that it is relatively easy to add a new sequence to the alignment and rebuild the model; experimentally-derived information can also be added to the model (known as *priors*) with relative ease.

A good general introduction to the basic ideas of HMMs (not oriented, however, toward sequence analysis) is reference 5 below. We have employed the HMMER implementation that is publicly available [9–10](*eddy@genetics.wustl.edu*). Another HMM suite that can be obtained is SAM (*http://www.cse.ucsc.edu/research/compbio/sam.html*). The SAM Web site contains a number of links to papers concerned with HMMs and sequence analysis. These programs were originally applied to highly studied data sets, "validation" sets [3,4,6] (globins, EF-hand proteins, kinases, and proteases), for which extensive experimentally-based data were available to help assess the alignment results. With HIV and SIV sequences, the results of the approach must be critiqued by scutinizing motifs—do cysteines, cleavage sites, and potential glycosylation sites in envelope align, for example? This can be problematic as it is not preordained, for instance, that all sequons need align [11]. Another approach to critiquing the HMM-generated alignment involves construction of blocks using representative PIV sequences (described below). Finally, it is necessary to compare scores from matching individual HIV

and SIV sequences to the "most likely", or *discriminator*, sequence, the HMM equivalent of a consensus: as we shall report in the section to follow, our model has been "overfitted" to HIV-1 sequences; nevertheless, the boundaries and motifs appear to be satisfactorily aligned.

Approximately 400 HIV and SIV sequences were trained using HMMER version 1.8. The frequency distribution of amino acids in the unaligned HIV and SIV sequences was used as input in place of the default distribution derived from the PIR database. We should first consider the success or failure of the approach with respect to identifying motifs. The envelope protein alignment of an HIV2 sequence (SBL/ISY) to the HMM consensus is instructive in this regard (figure 1): 1) cysteines, denoted by '*', and potential N-linked glycosylation sites, denoted by '^', are aligned as we might expect them to be aligned when doing ordinary alignment assisted by manual input; 2) four noncontiguous residues found in certain HIV-1 subtype B sequences to be essential for CD4 interaction, D, E, W and D (see pp. II-1,2 of NOV 95), are aligned in almost all HIVs and SIVs (tryptophans are in general highly conserved); 3) the gp120/gp41 cleavage site is aligned, as we expect, although an alternative cleavage site may be used in some HIV-2s.

Further confirmation of the alignment comes from BLOCKS analysis: using representative sequences from the Part II HMMER-generated alignments, blocks—gapless arrays of multiply aligned conserved sequences—were constructed using the BLOCKMAKER program [12,13] (http://www.blocks.fhcrc.org). Two different programs are employed by BLOCKMAKER, the MOTIF program and the GIBBS Sampler program. Boundaries for the created blocks were highly conserved in the HMM alignments (Part II), however blocks based on envelope sequences largely coincide with conserved domains, hence other motifs (cysteines, glycosylation sites) must provide the main support for alignment over the more varied regions.

A difficulty encountered by the HMM (and every) alignment method is large indels; we have the least confidence in those. To the extent that these stretches may have arisen through acquisition of genetic material, they may not be intrinsically alignable as they may not be homologous. The reader may want to compare the V1-V2 region alignment in figure 1 with one manually created by Lamers et al. [14]. Alignments in previous publications may be "safer", but they are also more constrained and less informative because they were executed over just highly related sequences. Since the different alignments have different applications, both are made available on the Web site (*http://hiv-web.lanl.gov*).

Nucleotide sequence alignments, by this approach, were produced from the HMM-generated amino acid sequence alignments. The nucleotide alignment was then subjected to HMMER and a nucleotide-specific model was obtained. This approach follows in a general way the approach taken in earlier database publications that were based on the PIMA algorithm of Smith and Smith.

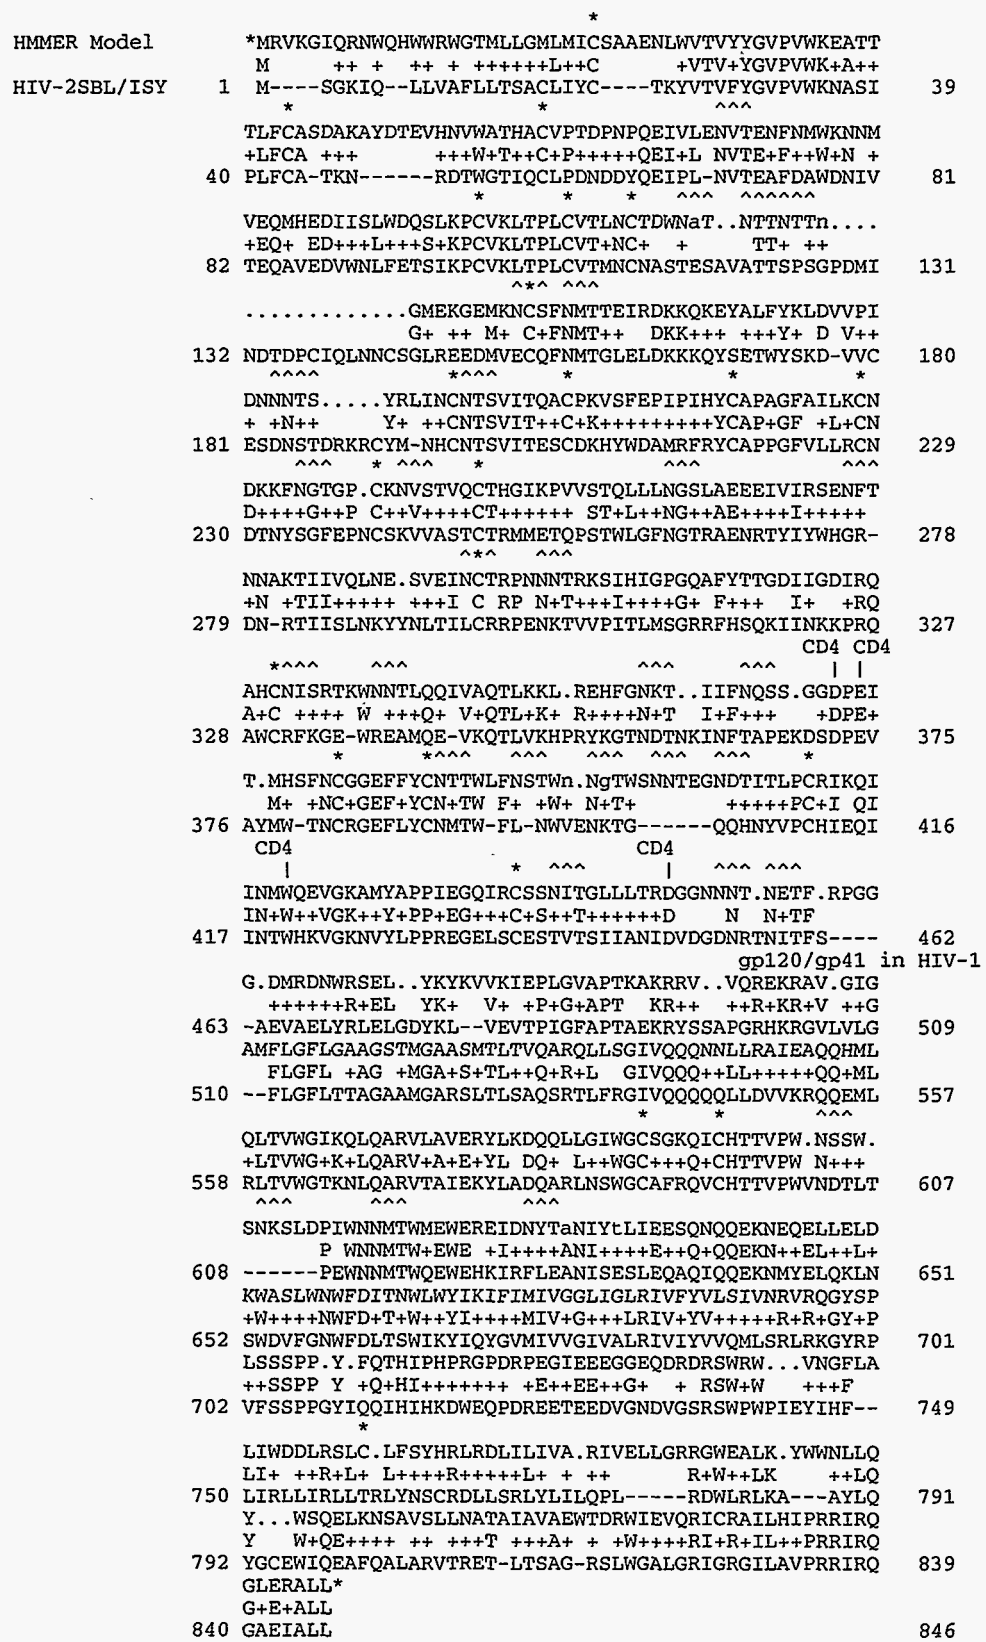
B. DATABASE SEARCHING USING AN HMM APPROACH

An important application of the HMM-generated model is in the discrimination of related sequences from non-related sequences. This is especially useful in connection with database searching. Associated with each sequence in the database is a probability, a log-odds score analogous to a BLAST score, with which the sequence could be generated by the given model. With the HMMER algorithm [10],

$$\text{score} = \log_2 \frac{P(S_i|M)}{P(S_i|R)}$$

where the alignment of each sequence in the database, S_i, is compared to both the HMM generated model, M, and a random model, R. The latter should have the same amino acid composition as the database at large and it should be as likely, *a priori*, as M. The log-odds score corrects for sequence length. A score greater than zero has a better than even chance of being significant, however, as a rule of thumb, a score must be about 20 or more to be deemed significant [9]. The distribution of likelihood scores for all the sequences in the database will provide a measure of discrimination between similar and non-similar sequences. Using the HMM for database searching has the advantage of utilising a great deal more of the information available for a family of sequences than can be captured by query techniques that force one to use only one sequence from the family or, at best, a standard consensus sequence as a query against the database.

Figure 1. Comparison of an HIV-2 Env Sequence to the HMM Model



The HMMER program, used herein, employs the Smith-Waterman (S-W) algorithm for optimizing local alignments. As with BLAST, both identities and equivalencies (conserved amino acid replacements) are scored; unlike BLAST, which is a heuristic search program, the S-W algorithm reports only the best match between the HMM consensus and a given database entry. A general discussion of these somewhat different approaches to database searching is found in reference [15]. Compositional bias may be present in the outcome of a database search, which is to say that spurious matches may arise by virtue of similar compositions only.

The comparison shown in figure 1 of a particular HIV-2 sequence to the HMM model consensus was taken from an S-W/HMMER search of the protein database using the HMM model for envelope. The score (corrected for the model length and the length of the target sequence) was highly significant, 1676, however HIV-1 scores uniformly hovered between 2700 and 2800, which tells us that the model was overfitted to HIV-1s. Scores among HIV-1s of different genetic subtypes did not significantly differ, which was satisfying, but HIV-2 and SIV scores were uniformly lower. The *maximum discrimination* option of HMMER, in contrast to the default *maximum likelihood* improves this situation somewhat [9–10]. Note in figure 1 that the reduction in score for the HIV-2 is mostly due to amino acid differences regarded to be conservative (indicated with a'+'). Although the probability distributions at the various homologous sites did not have adequate representation from the HIV-2 sequences, the alignment, as such, is reasonable. The scores over just the envelope gp41 were closer; and the scores for gag protein were much closer, 1759 for an HIV-1, 1478 for an HIV-2, showing that the fit is more inclusive.

Parallel S-W/HMMER envelope searches were conducted using a database in which HIV and SIV sequences were filtered out. The only non-zero matches to nonprimate lentiviral sequences involved Visna and its close relatives, OMVVSA and CAEV. The log-odds scores for these were less than 10; for example, from the Env gp41,

```
HMM Consensus   NNMTWMEWEREIDNYTaNIYtLIEES
                +N TW++WERE   Y +N + L+ ES
CAEV Env        DNCTWQQWERELQGYDGNLTMLLRES
```

The score for this match was 5.55, suggesting that the cutoff value of 20 should not be too rigidly applied. The highest match score in this search, 12.15, belongs to a horse skeletal muscle sodium channel alpha-subunit, which illustrates the possibility of compositional bias:

```
HMM Consensus   NTTWLFNSTWn.NgTW.SNNTEG.ND
                NTTW  N TW+ N+TW SN+T++ ND
query           NTTWYGNDTWYSNDTWNSNDTWSSND
```

In summary, the HMM-based search is fairly stringent as no significant matches were found to the HIV/SIV envelope model that were not proteins from primate immunodeficiency viruses. Selected examples of envelope matches with weak scores (less than 10) can be found in the accompanying section of Part IV concerned with molecular mimicry. HMM-generated models and database searches were also conducted for Gag, Tat, Vpr-Vpx, Vpu, and Nef, all of which are more evenly fitted than Env to all primate immunodeficiency viruses. Some brief comments regarding the search results follow:

Gag: Significant matches to nonprimate lentiviruses were more common with the HMM consensus for Gag than for Env: Visna, CAEV, EIAV, Jembrana, BIV and FIV all displayed matches, with FIV having the highest score (approximately 85). Most of these matches included the Gag zinc-finger motif, and as a result many matches above a score of 20 were also observed for proteins other than Gag. The tetrahymena cnjB gene product, for instance, scored 35.33, which was comparable to scores for some of the nonprimate lentiviral Gags. Many scores less than 20 were encountered for the zinc-finger motif, for example:

```
HMM Consensus           RKIIKCFNCGKEGHIARNCRAPRKKGCWKCGKEGH
                        R + KCFNC  EGH    C+ P  +GC  CG  GH
C. elegans RNA helicase RGPMKCFNCKGEGHRSAECPEP-PRGCFNCGEQGH
```

The log-odds score for this match was 4.67. We conclude from this search that the HMM model was especially good for picking up zinc-finger motifs of a certain kind.The so-called major homology region (MHR), which in the HMM consensus appears as IRQGPKEPFRDYVDRFYKTL, showed up only in matches with lentiviral Gags or with retroviral type D Gag sequences, such as those of SRV.

Tat: Of the nonprimate lentiviruses, only BIV and the Jembrana disease virus possessed significant match scores to the HMM consensus, 43.75 and 37.94 (versus an HIV-1 or HIV-2 score of about 280). These matches were across the second and third domains of the first coding exon, which encompass cysteine residues involved in intramolecular bonding and the R/KKGLGI motif that is thought to constitute the minimal Tat. EIAV displayed a weaker match, 10.43, and only in the second domain. These findings corroborate earlier judgments in the field that only BIV, and possibly EIAV, among nonprimate lentiviruses, possess a "true Tat" (the Jembrana virus has been sequenced subsequent to that conclusion.) Hence, FIV's match in the fourth domain, with a score of merely 5.26, is not considered Tat-specific:

```
HMM Consensus    KKRRQRRRTPQKS
                 KK RQRRR ++K+
            FIV  KKKRQRRRRKKKA
```

Vpr-Vpx: Given the paralogous relationship between Vpr and Vpx, one HMM Consensus was generated for the two proteins. The highest score against this consensus for sequences other than primate lentiviral sequences was with SA-OMVV, the Visna relative:

```
HMM Consensus    MEQAPWEfPRERIDQGWEWDPQRE
                 ME+A    PR    +G     +RE
      SA-OMVVSA  MEEA----PRR--RPG----GSRE
```

The score was 10.44. A nearly identical score was attained by a ligand for Fas antigen, but clearly due to mere compositional homogeneity:

```
HMM Consensus    GPGGWRRGPPPRNPPSRSMH
                 GPG+ RR PPP++PP+ S +
ligand for Fas   GPGQ-RR-PPPPPPPP-SPL
```

Vpu: In contrast to other HMM consensus sequences, the discriminator for Vpu was generated solely from HIV-1s. Match scores varied significantly—251 for the BAL strain but merely 45.38 for ANT70—suggesting that the model was overfitted to M group viruses. The subtype D virus ELI had a score of 229. Among non-HIV-1s, the highest score, 10.93, was found for a toxin receptor:

```
HMM Consensus    MQPLQILAIVALVVAaIIAIVVW
                 +  L+I A V LV ++  A VVW
C5a anaphylatoxin receptor  ILALVIFAVVFLVGVLGNALVVW
```

Rev sequences from SIV displayed weak similarity with the N-terminus of the HMM model for Vpu:

```
HMM Consensus    MQPLQILAI
                 +Q LQ LAI
      SIV Rev    IQQLQRLAI
```

Nef: With exception of primate immunodeficiency viral sequences, no database sequence displayed striking similarity to regions of the NEF HMM consensus. When mediocre scores were seen, they invariably resulted from compositional homogenity—cysteines, acidic amino acid residues, etc. This result is in contrast to the widespread claims regarding Nef "homologs" (i.e., similarities) in the literature of HIV.

From these preliminary studies, we conclude that the HMM approach to database searching is sensitive and specific. As a supplement to searches based on an HMM consensus, users should consider searching with COBBLER sequences deduced from the BLOCKMAKER program (http://www.blocks.fhcrc.org). Future improvements to the approach will include the introduction of structural information. We shall now turn to structure-prediction and the interplay between primary sequence alignment and structure-based alignment.

C. PROTEIN STRUCTURE PREDICTION

A promising starting point for predicting a structure for a given amino acid sequence is to determine whether that sequence is sufficiently similar to any other sequence for which biophysical data, ideally X-ray crystallographic data, is available. For sure, sequences that are 50% are more similar will have similar structures, while less similar sequences can have similar folds over core regions. The focus herein will be upon weakly similar sequences, in particular upon those of envelopes for which comparatively little biophysical data, beyond limited NMR, is available.

The earliest structure prediction algorithms, such as the Chou-Fasman algorithm, possess a predictive accuracy of no better than about 55%, partly due to the small set of known structures upon which they depend and partly due to their assumptions. Three-state predictions—helix (*H*), sheet (*E*) and coil (*C*)—are more accurate than four-state predictions that include turns (*T*); the accuracy is poorest at the ends of polypeptides and best in the core regions. Secondary stucture prediction in general is most reliable for transmembrane helices. With the buildup of the protein database and the development of more powerful algorithms, which especially take into account multiple sequence alignments, the predictive accuracy for secondary structure can now reach slightly better than 70%.

SOPM (self-optimised prediction method) is an example of a recent approach to protein secondary structure prediction [16–17]. When applied to 239 dissimilar proteins of known structure, this algorithm yields three-state prediction accuracies of 69% to 73%. On the other hand, because it involves sizeable subdatabases of sequences and their known structures, it will take longer to run than the older, less accurate algorithms. The basic ideas used in the SOPM are as follows.

First, a sliding window of a fixed size is applied to the protein sequence of unknown secondary structure to define a set of overlapping peptides. For example, suppose we are given the sequence KPQRNSKSTAAL ... with a window whose size is eight amino acids long and which is moved one amino acid over at each step. The resultant set of octapeptides will be KPQRNSKS, PQRNSKST, QRNSKSTA, RNSKSTAA, NSKSTAAL.... Note that most of the amino acids of the original sequence will belong to successive octapeptides, each differing from the previous peptide by the removal of an amino acid from one end and the addition of an amino acid to the other.

Next, each of the peptides thus derived from the query sequence is now compared to a database of peptides that has been created by similar means from a database of proteins of known secondary structure. If the peptide from the query sequence matches a peptide from the database above a certain threshold of similarity, then the similarity score is added to the conformational scores for each of the amino acids in the peptide. In our example, suppose that the first peptide KPQRNSKS matches a peptide in the database RPQRDTKS whose known structure is *HHCCCEEE*, and that the similarity score between these two peptides is 30. If this score is above the threshold parameter, then 30 will be added to the first two amino acids' helical conformational scores, to the next three amino acids' coil conformational scores and to the last three amino acids' sheet conformational scores. There may be other peptides in the database matching the query peptide with alternative predictions for the secondary structure of each of the amino acids, and all these predictive scores will be added together in each of the conformational categories, resulting in a distribution of scores over the possible secondary structure conformations. After the first query peptide has been compared, the process will continue for each of the remaining peptides in the query set. The final scores for an amino acid belonging to eight successive query peptides will thus include the scores for the comparisons of all eight of these peptides against the entire database of peptides of known structure.

After all comparisons have been made, each amino acid in the original protein will have values associated with its propensity to adopt a conformation in each of the secondary structure classes. From

the method of calculation detailed above it is clear that the empirical evidence for the prediction of the secondary structure of the amino acid weighs most heavily for that class with the highest score.

There are two additional statistics concerning the distribution of the scores over all the classes that can be revealing of the predictive power of this approach. The first is the actual magnitude of the scores for any given amino acid. If these are small relative to the cumulative scores for other amino acids, it may indicate a lack of information for the prediction of the secondary structure conformation of that amino acid. This could happen for two reasons: first, if the amino acid is within the window size to either terminus of the original protein, it will belong to proportionately fewer query peptides and have fewer comparisons with the database that could add to its score; second, the amino acid could belong to a series of peptides that for some reason are poorly represented in the database of known structures, and could thus have few comparisons to the database having a large enough similarity score to be added to the conformational scores for the amino acid. In either case, values that are low in magnitude indicate a lack of information in the database for the amino acid in its given environment.

The second statistic that is pertinent to the predictive value of a set of scores for a given amino acid is the difference between the scores of the highest and next-highest scoring classes of secondary structure. If this difference is small, it may be inferred that the information in the database for the amino acid in this particular environment is conflicting. For example, suppose that approximately half of the peptides contributing to a given amino acid's conformational scores support a helical structure, while the other half support its being classed as an element of a beta sheet. In this scenario, it is likely that the cumulative scores for helix and sheet for this amino acid would be nearly equal, and thus the difference between them would be near zero. In order to make this statistic independent of the magnitudes of the scores (which were accounted for in the former statistic), one may normalize the values by dividing the difference between the highest and next-highest scores by the magnitude of the highest score.

It is the widespread wisdom at this time to evaluate sequences, whenever possible, by more than one algorithmic approach; some methods are better for predicting helices, others for predicting sheets, etc. The SOPMA server (*http://www.ibcp.fr/predict.html*), therefore, submits a sequence to alternative methods of structure prediction—Gibrat, Levin, DPM and the PhD [18–21]—and also generates a consensus over those and the SOPM prediction itself. The HMM-generated "most likely" sequence was submitted to the SOPMA suite, producing predictions using the five individual algorithms as well as a consensus prediction, with the following results(H = helix, E = beta sheet, T = turn, and C = coil; blocks, defined by the MOTIF program in BLOCKMAKER, are indicated).

Although the HMM model has been overfitted in this case to HIV-1, the structures should be somewhat conserved across primate lentiviral boundaries. Gallaher and coworkers have explored this for the surface and transmembrane components of the lentiviral envelope [22,23]. Because the HMM-generated "most likely" sequence embodies information from hundreds of primate immunodeficiency viruses, it offers a reasonable test of their "eclectic" models derived from representative lentiviral sequences [22,23].

The Gallaher model for the surface protein (dependent primarily upon the Chou-Fasman algorithm) identifies five helical regions, all five of which are strongly or moderately predicted by the SOPMA suite: the 1st overlaps the 1st definable block in gp120 (figure 2 and Part II); the 4th is included in the 4th block and the 5th is included in the 5th block. Helices 1, 3 and 5 are strongly evident in HIV-2 sequences such as ROD. Furthermore, SOPMA suggests a small stretch of helix at the C-terminal end of the V3 loop and also at the C-terminal end of the gp120. In general, helices are the most predictable of secondary structures. Turns are weakly predicted following the V2 loop (in the 2nd definable block) and twice within the V3 loop, as we have come to expect. A stronger prediction is for the second turn that follows the third helical region, which separate V3 and V4; this "hinge" coincides with two of the four highly conserved CD4 contact residues and is bordered by the 3rd definable block. The two other contact residues for CD4 interaction occur in the 4th block, which includes the 4th helical region. An examination of predictions for several HIV-1 V3 loop sequences of different subtypes suggests that the Levin, DPM and SOPM methods most consistently predict the putative type II beta turn at the crest of the V3 loop. Further structural analysis of V3 loops is provided by Catasti and Gupta in Part III.

The transmembrane portion of envelope contains more helix than does the surface portion, as determined by circular dichroism, and the structure predictions confirm this for the HMM consensus. An extended helix, encompassed by the 7th definable block, immediately preceeds the immunodominant domain and another, encompassed by the 8th block, follows it. Another predictable helix coincides with the membrane spanning domain, as we would expect. A predicted turn associated with the RQGY peptide that ostensibly signals the terminus of the transmembrane region [24] is not supported by the SOPMA suite.

In the future, we hope to refine the HMM analyses of HIVs and SIVs, first, by addressing the overrepresentation problem of HIV-1s and, second, by integrating the structural information with the primary sequence data.

Global variation in the HIV-1 V3 region

John C. Blouin, Esther A. Guzman and Brian T. Foley

MS K710, Los Alamos National Laboratory, Los Alamos, NM 87545

Introduction

Due to the immunogenicity and functional importance of the V3 loop, there has been a great deal of interest in the V3 region of the envelope protein, resulting in a large international effort to obtain V3 region sequences. This section, which includes sequences taken from 1651 individuals and complete references, provides an overview of the variation of sequences that span this region.

Sequences

To best summarize the spectrum of international HIV-1 variants, only one representative viral sequence was included per infected individual. A complete set of references accompanies the sequence alignments, and nomenclature was preserved from the original papers so individuals and isolates can be clearly identified. HIV1 was deleted from the sequence names in this section, as all sequences included here are HIV1. Included with the references when available are brief descriptions of critical features of the sequences. This includes the health status of the individual from whom the virus was derived, whether or not the virus was cultured, and the year the blood sample was taken.

All sequences are prefaced by a subtype association (see phylogenetic clustering below) and a two letter country code to identify the country that the individual resided in at the time that the blood sample was taken. If the person was a recent immigrant and this information was available, we included the country of origin in the references. The two letter code was developed for Internet (Copyright 1992, Lawrence H. Landwater and the Internet Society), and incorporated here based on a suggestion made by Dr. Francine McCutchan. The key to the country codes follows this introduction. Note that this key has been updated for 1996, with several country codes for eastern european nations added.

Sometimes only one viral sequence was available from a person: a clone from an isolate, or a direct sequence of PCR amplified peripheral blood DNA. For other individuals, up to 80 viral sequences from PCR amplified DNA or RNA from blood samples were available. Consequently, over 8000 sequences are represented by the 1651 included in this section. When two sequences were available from a person, one of the two was randomly selected. When three or more sequences were generated from a person, all available sequences were aligned (without regard to different time points of sampling) and either one representative sequence was chosen, or a consensus of the most common base found in each position in the alignment was generated. If there was a tie (e.g., 10 A's, 10 T's), the top base or amino acid in the alignment was used. If a set of sequences from two or more individuals was epidemiologically linked, and genetically very similar, only one sequence from the set was included, preferably the most recently infected. In the sequence description and references section, the short hand "PCR-direct, peripheral blood DNA" is used to signify that viral DNA was amplified from PBMCs, without culturing, and a single "direct" sequence was obtained from the amplification reaction products. The short hand "Consensus, PCR-clones, peripheral blood DNA" signifies that viral DNA was amplified from PBMCs and a set of clones was generated and sequenced from the PCR amplification products. The cloned sequences were aligned and a consensus was generated. In a handful of cases, a particular gp160 clone from an isolate was shown to be expressed and functional using a vaccinia virus T7 expression system. In these cases, the clone rather than the consensus of all sequences from a particular individual is included.

Phylogenetic clustering

Sequences have been organized according to the phylogenetic subtype association (A-J) of their envelope V3 regions only. The original sequence subtype (A-H) designations were defined based on the phylogenetic relationships determined by using both gag and env genes (when possible), are

approximately genetically equidistant in envelope, and have multiple members. The phylogenetic subtype designations and associations have generally been adopted by the HIV research community, and are now often presented with the publication of new sequences. We have either determined the subtype designations here, if not specified in the original manuscript, or else confirmed the subtype designations of the original manuscripts, and then used the subtypes to organize this section. Generally, confirmations were done by aligning a set HIV-1 V3 region sequences with longer env gene sequences (Part IIIC) that have clear subtype associations, and then using parsimony or neighbor joining trees to determine associations. Some of the shorter gene fragments from this region were given a subtype designation based on Hamming distances, using the similarity function of the MASE program (Faulkner DV, and Jurka J. TIBS 13:321-322 (1988)); these sequences have ".sh" appended to their name to indicate that they were too short for phylogenetic analysis. Parsimony trees were generated using PAUP (David Swofford, Illinois Natural History Survey), and neighbor-joining trees were generated with Kimura distances and a transition to transversion ratio of 1.3 using PHYLIP (Joseph Felsenstein, University of Washington). All available nucleotide sequence information was used for phylogenetic analysis; longer protein sequences were trimmed to be approximately the same length as the majority of the PCR fragments in this region, for the purposes of presentation. Some sequences were difficult to classify, and are included in the "U", or unclassified, section. In addition, it has recently been noted that recombination between HIV-1 occurs when an individual is infected with more than one strain. A meeting was held in Santa Fe, New Mexico in October, 1995 to discuss the implications of recombination and methods for detecting recombinant sequences. Because inter-subtype as well as intra-subtype recombination is known to occur, the subtype designations reported in this section should be interpretted only as pertaining to the V3 region of the envelope gene. For example HIV-1 MAL from Zaire, is known to be recombinant between subtypes A and D, with the V3 loop of env resembling subtype D. D_ZR-MAL is still listed with other subtype D sequences in this study, but may be moved to the U (uncertain) group in the future.

The set of sequences used to help resolve subtype associations included at least two sequences from each subtype (A-H), plus a simian immunodeficiency virus outgroup sequence. The sequences were selected based on being "typical" of the subtype they represent based on phylogenetic analysis. The set has changed as more sequences have accumulated. Thus not all subtype designations were based on the same reference set.

Limitations of phylogenetic analyses

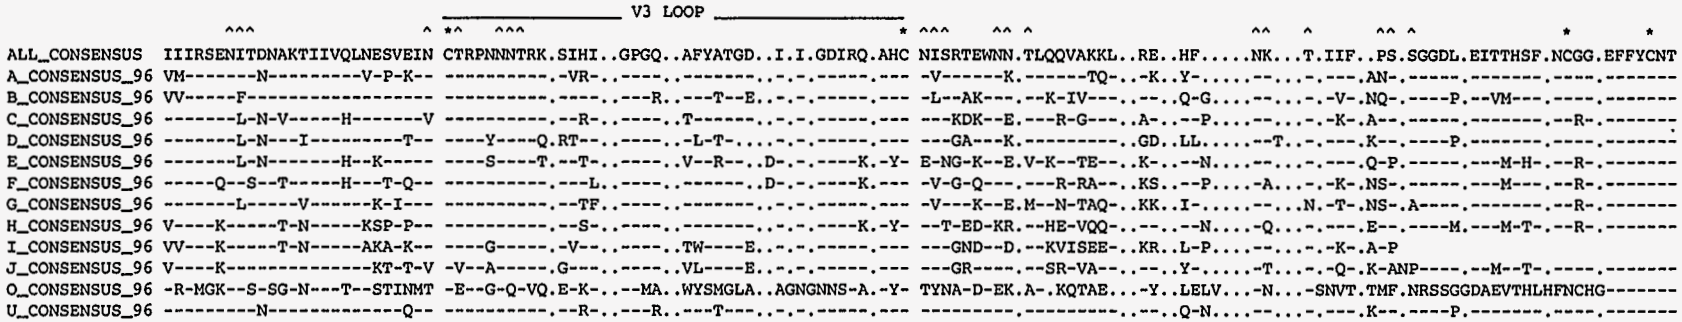
Most of the PCR derived sequences contain a sub-optimal length for phylogenetic analyses, given the level of variability in this region – typically on the order of 250 to 300 nucleotides. Due to this limitation, some of the classifications in this section are uncertain and are our best estimate given the available information. Control studies were performed to compare the phylogenetic clustering of the V3 region using available longer sequences, however, and these studies indicate that our subtype designations based on the V3 region are generally reliable. For 146 sequences, we had an approximately 700 base region of env available representing all of the subtypes A-H. (The limitation in length was due to including the H subtype sequences, which did not cover all of gp120.) After removing positions in the alignment which included gaps, 519 bases were left. When a 298 base V3 region fragment was excised from this set, and neighbor joining trees were constructed using both the 519 base and 298 base long sequences, the phylogenetic subtype designations were consistent in each case. Further, when a subset of longer gp120 sequences was analyzed (92 of the 146), including 935 bases after removing positions in the alignment which included gaps, the subtype designations were again clear in neighbor-joining trees. This indicates that the limited V3 region PCR fragments, which include more than the V3-loop, are generally able to serve as a reliable basis for subtype determination.

Without detailed analysis, genetic recombination between subtypes may obscure phylogenetic relationships between sequences. A characteristic of recombination is an indeterminate place in phylogenetic analyses, and some of the "Uncertain" category sequences may prove to be recombinant genomes upon further inspection. Also, while a subtype designation based on a gene or gene fragment may be correct, recombination events outside the region examined may have occurred. Therefore, care should be taken to not overinterpret the subtype designations. If one is to discuss the subtype

designations of viral isolates based on the data presented here, they should be refer to the designation as "B-like over V3 loop region," rather than as "subtype B".

Limitations of V3 amino acid consensus sequences

The V3 amino acid consensus sequences generated for each subtype have interesting features; however, one should be wary about assuming that any of the consensus sequences may broadly represent their subtype. Certainly many V3 loop variants in each of the subtypes are extremely divergent from the consensus sequences. These divergent forms may have very different biological and immunological characteristics from viruses which are similar to the consensus. Additionally, because of the relatively small sample size of most of the subtypes, consensus sequences can be dominated by a small group of highly similar sequences, which may in turn be a sampling artifact. Hence, these consensus sequences are "evolving" as new sequences from each subtype become available.



Subtype consensus sequences. This V3 region alignment shows a consensus sequence generated for each of the eleven subtypes. The subtype consensus sequences indicate the most common amino acid found in each position among the sequences associated with each subtype. The sequences are aligned to a consensus based on the most common amino acid in the subtype consensus sequences, which approximates a "global" consensus. It was generated in this way (rather than by using all 1651 sequences) to avoid over-representation of the B subtype, which has by far the largest number of available sequences. As is the convention in this compendium, a dash (-) indicates concurrence with the top sequence in the alignment; a period (.) indicates a deletion. The carets show where the N-linked glycosylation sites are found in the consensus. The V3 loop is set off from the surrounding sequence by a space on either side to facilitate viewing. Interesting features of the consensus alignment are: 1) Only in the B subtype is GPGR the most common tip of the V3 loop; globally, GPGQ is more prevalent. 2) A highly conserved N-linked glycosylation site is constitutively absent in the C subtype, proximal to the first cysteine (C) in loop. 3) The D subtype consensus has 34 amino acids from cysteine (C) to cysteine (C) rather than the more common 35; at the point where the deletion occurs, it is not uncommon to find insertions of 2 to 4 amino acids, as can be observed in the sequence alignments. 4) The D subtype has two arginine (R) residues in the V3 loop that are uncharacteristic relative to the other consensus sequences; positively charged amino acids in these positions may result in a syncytia inducing, non-monocytropic phenotype (Fouchier RAM, et al., *J. Virol.* **66**:3183–3187 (1992)). 5) A higher degree of variation is seen in the region just downstream of the V3 loop than within it. This difference is also observed internally among the sequences of the different subtypes. 6) The A, C, G and H consensus sequences have very similar V3 loop sequences.

V3 Loop Amino Acids

The following pages present amino acid alignments of the V3 loop, arranged by phylogenetic subtype. For each subtype, the number of sequences used to construct the alignment is indicated. The top line in each alignment represents the consensus sequence for that subtype, where consensus simply means the most common amino acid found in each position among the sequences of the given subtype. The subscripts record the frequency with which that amino acid is observed at that location among members of the subtype. An amino acid which is conserved 100% is shown with no subscript. Directly beneath the most common amino acid in each position are the other amino acids observed in that position, listed from most common to least common. An asterisk (*) subscript means less than 0.5% of the sequences had the indicated amino acid at that location. A dash (-) indicates a gap inserted to maintain the alignment. Percentages were rounded to the nearest whole number.

For this year's alignment, the HMMER (version 1.8) hidden Markov model software (Sean Eddy, Dept. of Genetics, Washington U. School of Medicine, St. Louis, MO 63110; eddy@genetics.wustl.edu) was used to objectively align all 1651 sequences. The frequency counts are derived from this alignment. Because each subtypes required different numbers and positions of gaps in order to create the full multiple sequence alignment, some sequences with unusual insertions were trimmed from the HMMER alignment, and a few positions were adjusted by hand, using MASE, prior to printing the full alignment which appears following the country codes description. The sequences which were culled from the alignment after counting frequencies, are appended.

Both the untouched HMMER alignment, and the edited version, will be available via ftp from the LANL HIV database (http://hiv-web.lanl.gov). Questions about these alignments should be directed to (btf@t10.lanl.gov) (505-665-1970).

Summary of variations in the tetrameric tip of the V3 loop. This table is a tally of the different tetramers observed in the 1651 individuals analyzed. This tip is thought to form a turn, and is the focal point of the potent neutralizing antibody epitopes that have been mapped to the V3 loop, as well as of T cell epitopes. Each column shows the number of occurrences of a given tetramer in either the entire 976 sequences (combined), or in subsets consisting of subtypes A–O, and the unclassified sequences (U). Underneath the column heading is the number of sequences in each category. The most common form found in each subtype is highlighted in bold lettering. In the B subtype, GPGR is the predominant form, however globally GPGQ is more common.

Summary of variations in the octameric tip of the V3 loop. This table is a tally of the different octamers observed in the 1651 individuals analyzed. This table is structured the same as the tetramer table on the previous pages. Amino acid changes proximal to the tip can influence the specificity of anti-V3 neutralizing antibodies. The forms that were found only once in the data set are not shown here, to save space, and are summarized in a row labeled "unique."

Phenogram of the 14 amino acid tip of the V3 loop.

The immunogenic tip of the V3 loop has been the focus of a large number of serological studies. Here we have organized the 14 amino acid tip of the V3 loop of each sequence according to their amino acid similarities. The four amino acid tip of the loop (the GPGR motif) plus the 5 amino acids on either side were clustered using maximum linkage based on pairwise distance scores using the STR matrix (S. Henikoff and J. G. Henikoff, *Proteins: Structure, Function and Genetics* **17**: 49–61 (1993)). The resulting phenogram of all 1651 is shown, with related sequences grouped into 25 clusters. The y-axis represents the number of sequences included in the phenogram, and the x-axis indicates the level of similarity between amino acid sequences; the higher the score at the branch junction, the more similar the sequences. The 25 clusters were selected such that the sequences within a cluster all are related by scores greater than 30. The alignment of these sequences corresponding to the phenogram is included on pages following the figure. The clusters are numbered on the phenogram and in the alignment. The order of the sequences in the alignment corresponds to the order that the sequences appear in the phenogram, from top to bottom.

There are two things worth noting in the alignment. First is the intermixing of amino acid sequences from different clades—often sequences from phylogenetically distinct subtypes have identical or nearly identical sequences in this region. This is easily noted in clusters 1, 2 and 6 which contain A and C subtypes. Second is the diversity of the D subtype sequences. The two letter country codes can be used to follow geographic associations of similar sequences, or alternatively, the range of variation of a given subtype in a country of interest. When this type of phenogram is computed using the entire 35 amino acids of the V3 loop, a very similar result is obtained (B.T.M. Korber et al., *J. Virol.* **68**:6730–6744 (1994)). When a phenogram is computed using 35 amino acids flanking the V3-loop (20 from the amino side and 15 from the carboxy side), or 14 amino acids (7 from each side of the V3 loop) the resulting phenogram is quite different, with A and C subtype sequences residing on seperate branches.

COUNTRY CODES

It is becoming increasingly useful to name viral isolates and samples with a country code. The following code was captured from Internet files:

gopher://kupe.itu.ch/11/.1/itudoc/public/gophermenus/.1/.un/.edicore/.wp4/.sept95/.rdocs95/.28024
gopher://kupe.itu.ch/00/.1/ITU-Databases/.1/CtryCodes/.full-list.txt

for ISO two-letter codes and for ITU three-letter codes, respectively.
This is a list based on the International Organization for Standardization (ISO) 3166:1993 standard, updated from a list prepared by Mark Horton. Note that the original standard has this same information sorted into about 6 different orders, both in English and French, therefore this is an abbreviated version not to be taken as the entire standard. While it has been checked against the standard, it may possibly contain errors; the standard and registration newsletters should be verified for any critical application. This copy has been updated and is believed to be current through September 1996.

Table of Country Codes from ISO 3166

Country	A 2	A 3	Number
AFGHANISTAN	AF	AFG	004

A Subtype

At this time there are viral sequences from 207 HIV-1 infected individuals associated with HIV-1 subtype A. The A subtype consensus sequence (A_CONSENSUS_96) generated from these sequences was based on the most common amino acid found in each position in an alignment of these sequences. All of these sequences have been published and/or have been made available for printing in the database by their authors.

1) **BJ1.ID#:** These 18 sequences are from female prostitutes, born in either Ghana or Togo, who live in Benin. 15 are from directly sequenced PCR products, derived via RT-PCR from patient serum RNA. 3 (233, 251 and 253) are from cloned PCR products, also by RT-PCR from serum RNA. Another subtype A sequence (366, U61870) is not included here, because it was nearly identical (254 of 255 bases identical) to the SF170 (M66533) sequence from Rwanda isolated in 1988, and thus it likely represents a lab artifact. [Heyndrickx et al.(1996)]. GenBank accession numbers U61854–U61869, U61871 and U61873. Two subtype G isolates were also found in this study.
2) **BY.BLR10A:** This sequence is from Byelorussia. [Lukashov et al.(1995)]. GenBank accession number L38411.
3) **CA.HWCL1:** This sequence is the first published sequence of subtype A HIV-1 in Canada. The patient had moved from Uganda in 1983, and was diagnosed as HIV+ in 1989. Viral RNA was recovered from archived, stored patient serum by binding viral particles to CD4-coated wells of an ELISA plate. The RT-PCR amplification product was cloned and 10 clones were sequenced. It is not clear whether this sequence is from a single clone, or a consensus of all 10. [Montpetit(1995)]. GenBank accession number U34049.
4) **CF1.ID#:** These thirteen sequences are from a set of sequences obtained from 27 symptomatic patients from the Central African Republic, from whom blood was drawn in 1990–1991. The sequences are consensus sequences from cloned PCR products. DNA was isolated from co-cultured PBMCs. [Murphy et al.(1993)] GenBank accession numbers L11457–L11458, L11461–L11463, L11469–L11471, L11474–L11475, L11477–L11479, L11484–L11496, L11498, L11518 and L11523–L11524. Some of them were sequenced again by Schmitt et al. unpublished: U43275, CF1.4023; U43109, CF1.4054; U43139, CF1.11423; U43136, CF1.1286.
5) **CF2.GAN and SAS:** These sequences were kindly provided prior to publication by Dr. MP Kieny of Transgene, Strasbourg, France. They are part of a set of 14 HIV-1 gp120 isolates from Bangui, Central African Republic. The gp120 proteins have been expressed in a hybrid gp160 vaccinia virus expression system. Year of isolation and health status of individuals from which the virus was isolated were not provided. Viruses were isolated in the CAR by C Mathiot and B You (Pasteur Inst., Bangui), grown by F Barre-Sinoussi and A Deslandres (Pasteur Inst., Paris), and cloned and sequenced by D Schmitt and MP Kieny. GenBank accession numbers U43111, U43171, M81063, M81064.
6) **CI1.ID#:** These six sequences are from six different AIDS patients suffering from pulmonary tuberculosis at the Pneumology Hospital of Cocody, Abidja, Ivory Coast. In this study sequences from viral RNA from viruses from serum cocultured on donor PBMCs, proviral DNA sequences from each patients' PBMCs after coculture with donor PBMCs, and proviral DNA sequences directly from uncultured PBMCs were determined. For the cocultured samples viral RNA was harvested from the culture supernatant. PCR or RT-PCR was used to amplify the env V3 region, and 4-7 cloned PCR products were sequenced. A total of 66 sequences from the six patients were published. All 66 were subtype A, and intrapatient sequences were more similar than interpatient sequences. [Audoly et al.(1996)]. GenBank accession numbers U59559–U59624.
7) **CI2.CI-ID#:** These sequences are from 11 of 13 isolates from individuals from Abidjan, Cote d'Ivoire. CI-14 and CI-20 were symptomatic, and the others were asymptomatic. CI-14, CI-45 and CI-47 were serologically dually reactive for HIV-1 and HIV-2. The C2V3 region is part of a 900 bp sequence. Samples were collected between May 1990 and Sept. 1991. Virus was cultured with donor PBMCs, nested PCR amplified, 3–4 clones were sequenced, and the consensus of those clones is presented here. [Janssens et al.(1994a)]. GenBank accession numbers X72024–X72027, X72030–X72039, X72043–X72056, and X72059–X72065.
8) **CM1.CA-ID#:** These sequences are 11 of 17 sequences from a very diverse set of isolates from Yaounde and Douala, Cameroon. The sequences were derived from asymptomatic (CA7, CA11, CA15, CA17, CA18, and CA21) and symptomatic (CA1, CA2, CA6, CA19 and CA22) individuals. Virus was isolated

by culture with donor PBMCs, and nested PCR amplified. A single clone was sequenced representing each HIV-1 isolate. [Nkengasong et al.(1994)]. GenBank accession numbers for the entire set of 17 envelope sequences: X80438–X80454.

9) **CY.HOcon:** This is a consensus sequence from four individuals who were epidemiologically linked to one another: a father, a mother, their child and a woman who was a heterosexual partner of the father. These samples, like others in this study (see also subtypes B, C, F and I) were collected in February 1994 from the AIDS clinic in Nicosia, Cyprus. PBMC DNA was PCR amplified and cloned. Individual clones were sequenced. The father (patient HO34) was 36 years old and asymptomatic. He was known to have been seropositive for at least 2 years and had a CD4 count of 410. The mother (patient HO17) was 35, had been infected for at least two years, had a CD4 count of 2 and died in May 1994. The child (patient HO49) was 2 years old, had been infected since birth, and was asymptomatic, with a CD4 count of 1,211. The partner of the father (patient HO42) was 45 years old, had been infected for at least 4 years, was symptomatic with CD4 count of 80, and died in August 1994. Because of the close epidemiological linkage, a consensus of all 5 sequences is presented here. [Kostrikis et al.(1995)]. GenBank accession numbers U28683 (child); U28674, U28719 (father); U28677 (father's partner); U28665 (mother).
10) **DJ.DJ-ID#:** These three sequences from Djibouti were from a set of HIV-1 viral isolates from Africa. Health status of the individual from which the virus was cultured was unspecified, and the year of viral isolation was probably between 1989–1992. Viruses were cultured with donor PBMCs for 2 to 3 weeks. Full length env (gp160) was amplified, cloned and sequenced. [Louwagie et al.(1995)]. GenBank accession numbers L22939, L22941, and L23064.
11) **GA.VI191:** This sequence from Gabon was from a set of HIV-1 viral isolates from Africa. Health status of the individual from which the virus was cultured was unspecified, and the year of viral isolation was probably between 1989–1992. Viruses were cultured with donor PBMCs for 2 to 3 weeks. Full length env (gp160) was amplified, cloned and sequenced. [Louwagie et al.(1995)]. GenBank accession number L22952.
12) **GA1.ID#:** These 6 sequences are from Gabon. Two (G41, G135) are from 1988-1989 samples from patients with AIDS living in Franceville Gabon. VI685 is from a 1992 sample of an AIDS patient from the Libreville General Hospital. VI1076 is from a 1993 sample of an AIDS patient from the Libreville General Hospital. LBV2310 and LBV23 are from 1988 samples from asymptomatic individuals sampled from the general population. Method of proviral DNA isolation was not described. DNA was PCR amplified and cloned. One clone per isolate was sequenced. [Delaporte et al.(1996)]. GenBank Accession numbers X90914, LBV23; X90915, G135; X90917, G41; X90918, LBV2310; X90921, VI1076; X90924, VI685. See also subtypes C, D, F, G and O sequences from this same study.
13) **GH.D687:** A single sequence from an individual from Ghana. Virus was cocultured on PBMCs and the env gene was PCR amplified. Provided by Georg-Speyer Haus, Frankfurt, Germany (Dr. Ursula Dietrich). [Dietrich et al.(1993)]. GenBank accession numbers L07652, X68407.
14) **IN1.ID#:** These two entries are from 1992 dried blood spot samples from Vellore near Madras, in Tamil Nadu state in southern India. DNA was extracted from the blood spots and PCR amplified. The PCR products were directly sequenced. Samples came from previously identified HIV seropositive homosexual men. Other samples from the same region were all subtype C (see C_IN4.#). [Cassol et al.(1996)]. GenBank accession numbers U53286 and U53291.
15) **KE.K89:** This sequence is named "KENYA" in the GenBank entry, but is identified as K89 in the original manuscript. It is a Kenyan sequence from a set of HIV-1 viral isolates from Africa. Health status of the individual from which the virus was cultured was unspecified, and the year of viral isolation was probably between 1989–1992. Viruses were cultured with donor PBMCs for 2 to 3 weeks. Full length env (gp160) was amplified, cloned and sequenced. [Louwagie et al.(1995)]. GenBank accession number L22943.
16) **KE.KEN-ID#:** These 19 sequences were derived from patients who were part of a 1990–1992 cohort study of maternal risk factors in mother to child transmission, including 22 pregnant women and an infant from Kenya. The C2V3 region was sequenced. [Janssens et al.(1994c)]. GenBank accession numbers for the entire set of 23 patients surveyed in this study: U12984–U13006.
17) **KE1.-ID#:** These 6 sequences were derived from patients who were part of a May-June 1992 study of pregnant women from the Pumwani Maternity Hospital in Nairobi, Kenya. Viral RNA was concentrated from patient serum just prior to delivery, and the envelope C2-V3 region was amplified by RT-PCR. The PCR product was cloned and 20 clones from each patient were sequenced. Two other patients from this

study had viral subtypes C and D. [Zachar et al.(1996a)]. Genbank accession numbers U32658, U33763, U33764, U33766, U33767 and U34905.

18) **NG.IBNG:** An envelope gp120 sequence from Nigeria was kindly provided by Dr. Tom Howard from the University of Southern California (USC) [Howard et al.(1994)] and the complete genome has now been sequenced [Howard & Rasheed(1996)]. Genbank accession numbers U48628 and L39106.
19) **NL1.ID#:** These 13 sequences are from recent immigrants to The Netherlands from various countries. The fist two letters of the ID# represent the two letter country code for the previous residence of the patient. The next two numerals represent the year of isolation. Viral RNA was prepared from patient serum and RT-PCR was used to amplify the V3 region of the env gene. The PCR products were directly sequenced. [Lukashov et al.(1996)]. GenBank accession numbers L76877, GH902304; L76903, GH9401488; L76883, GH915200; L76913, GH9501283; L76893, GH929927; L76896, ZR9303337; L76870, RW890388; L76875, RW893568; L76905, TZ9401664; L76881, KE913514; L76891, UG928308; L76887, AO924646; L76889, TZ925825.
20) **RU1.ID#:** These 4 sequences are from Russia. Bobkov et al. 1996 Unpublished. GenBank accession numbers: U33098, IVA6; U33097, GAN1; U33104 U33105, MLY10; U33106 U33107 U33108, SHL9.
21) **RW.564C** This sequence represents 10 identical sequences generated from PCR amplified plasma RNA from one of three infants in a Dutch mother/infant study. Patient pair 564 was from Rwanda. A sample was collected from the infant at 30 months of age. Samples were also collected from the mother at 12 and 30 months after the birth. Mother sequences are not included in this consensus. [Mulder-Kampinga et al.(1993)]. [Mulder-Kampinga et al.(1995)]. The child 564 Env sequence is from the entry with GenBank accession number Z47881. Mother 564 sequences are in entries with GenBank accession numbers Z47882–Z47902. Mother sequences are not included in this alignment. Gag gene sequences from mother/child pairs are also available in Genbank accession numbers Z47903–Z47911, Z47912–Z47928, Z47929–Z47935 and Z47936–Z47950. The second mother/child pair was from the Netherlands, see G_NL.127C. The third mother/infant pair in this study was from the Netherlands, see B_NL.114C.
22) **RW.SF1703:** This sequence is from Rwandan isolate sf170, a biologically active clone reported to be macrophage-tropic. [Cheng-Mayer et al.(1988)]. GenBank accession number M66533. See also U61870, which is not reported to be from SF170, but is greater than 99% identical to it.
23) **RW1.W2RW-ID#:** Seven sequences from asymptomatic individuals from Rwanda sampled in 1992. Consensus, PCR-clones, cell-culture DNA and RNA. These sequences were provided by the WHO Global Programme on AIDS Vaccine Development Study. The complete set of C2V3 region WHO sequences can be found in the April supplement to the Human Retroviruses and AIDS 1993 database. Relevant papers are: [De Wolf et al.(1994)]; [Osmanov et al.(1994)]; [Gao et al.(1994a)]. GenBank accession numbers U08630–U08640, U08645, U08647–U08665, U08763–U08766, and U08793–U08794. One of these sequences may be mislabelled in the database; U08634 is labelled as patient 016, but is identical to sequences from patient 008. Sequences from samples 92WR020 and 92RW021 were greater than 98each other, so only 92RW021 is presented here.
24) **RW2-ID#:** Nine consensus sequences from Rwanda. Saah, A. Unpublished 1994. GenBank accession numbers U23216–U23373.
25) **RW3.PV#:** Bex,F. et al. Unpublished. These five sequences are from Rwandese patients with AIDS. The sequencing was done by the EEC Centralized Facility for HIV genome characterization, Georg-Speyer-Haus, Frankfurt, Germany. The complete envelope gene for PVP1 is available from a clone obtained after short-term co-culture on donor PBMCs. Two other shorter sequences of PVP1 env direct from patient PBMCs are also available. GenBank accession numbers L07082–L07091. L07088 and L07089 were withdrawn from GenBank by the authors, who felt they may represent PCR artifacts.
26) **RW4.#:** Kampinga,G.A. et al. Unpublished. These 8 consensus sequences and 2 individual sequences, are from 7 infants and 3 mothers in a study of mother-infant transmission in Rwanda. Mother 566 was apparently infected with both subtype A and subtype C HIV-1, but the env regions from the child clones were all subtype A. See also C_RW1.ID#. GenBank accession numbers for child 566 are Z76160–Z76161, Z76167–Z76168, Z76169–Z76176, Z76233–Z76248, Z76262–Z76273 and Z76717–Z76724; mother 730, Z76353–Z76362; child 564, Z76074–Z76083; mother 226, Z76046; child 538, Z76134–Z76143, Z76373–Z76382, Z76393–Z76412; child 074, Z75958; child 082, Z75998–Z76009, Z76650; child 081, Z75959–Z75968; child 618, Z76198–Z76207; mother 439, Z76048–Z76057, Z76064–Z76068 and Z76070.

27) **TZ.TAN-ID#:** These four sequences are from a set of 14 Tanzanian samples from symptomatic individuals, using serum samples taken in 1988 to generate PCR clones from viral RNA for sequencing. [Zwart et al.(1993)]. GenBank accession numbers L01313, L01315–L01316, L01335, L01337–L01339.
28) **TZ2.ID#:** These two sequences were from patients at a clinic in Dar es Salaam, Tanzania. The individuals from which the virus was cultured showed clinical signs of AIDS, and the year of viral isolation was 1988. Viral cDNA was PCR amplified from donor PBMC, and one cloned PCR product per donor was sequenced. [Siwka et al.(1994)]. GenBank accession numbers U12408, U12409.
29) **TZ3.ID#:** These 4 sequences are from the Mara region of rural northwest Tanzania [Robbins et al.(1996)]. Subtype D was also found in this study. GenBank accession numbers U61875–U61878.
30) **UG.1033:** This sequence is a consensus sequence of blood and CSF samples taken from a Ugandan patient 1033, CDC class IV-A. [Keys et al.(1993)]. GenBank accession numbers Z23177, Z23182–Z23184, and Z23220–Z23223.
31) **UG.92UG037:** This sequence is from a complete genome PCR amplified from proviral DNA. The patient was a 31 year old asymptomatic female from Entebe, Uganda. [Gao et al.(1996b)]. GenBank accession number U51190.
32) **UG.964:** A single sequence used in a study of the impact of sequence variation on the distribution and seroreactivity of linear antigenic epitopes. The sequence was derived from PCR amplified DNA from peripheral blood leukocytes. The patient was an asymptomatic individual from Uganda. [Pestano et al.(1995)]. GenBank accession number U11599. See also B_US17.ID#, C_UG1.45, and D_UG7.ID#.
33) **UG.U455:** This sequence is from the 1985 Ugandan isolate U455; the complete genomic sequence is available. [Oram et al.(1990)]. The env ORF in this sequence is interrupted by an in-frame stop codon beyond the COOH end of the V5 region. GenBank accession number M62320.
34) **UG.UG06:** This sequence is from blood collected from the Mulago Teaching Hospital in Kampala, Uganda. Viral RNA was harvested after 10-14 days of coculture with donor PBMCs and reverse-transcribed with AMV-RT. The env V3 region was pCR amplifed and cloned. This sequence is from an individual clone. [Atkin et al.(1993)], [Pestano et al.(1993)]. GenBank accession number M98503.
35) **UG1.W2UG-ID#:** Three sequences from asymptomatic individuals from Uganda in 1992. Consensus, PCR-clones, cell-culture DNA and RNA. These sequences were provided by the WHO Global Programme on AIDS Vaccine Development Study. The complete set of C2V3 region WHO sequences can be found in the April supplement to the Human Retroviruses and AIDS 1993 database. Relevant papers are: [De Wolf et al.(1994)]; [Osmanov et al.(1994)]; [Gao et al.(1994a)]. GenBank accession numbers U08666–U08669, U08767–U08770, U08788–U08792, U08795, U09124, U09125 and U09127
36) **UG2-ID#:** These 11 sequences are part of a set of sequences derived from 22 Ugandans who were attending an AIDS clinic, sampled in 1990. Consensus, PCR-clones, peripheral blood DNA. [Albert et al.(1992)]. GenBank accession numbers M98902–M98905, M98908–M98910, M98914–M98917, M98919, M98924–M98928, M98938–M98941, M98946–M98966, and M98976–M98978.
37) **UG4.UG-ID#:** Two Ugandan sequences from a set of HIV-1 viral isolates from Africa. Health status of the individual from which the virus was cultured was unspecified, and the year of viral isolation was probably between 1989–1992. Viruses were cultured with donor PBMCs for 2 to 3 weeks. Full length env (gp160) was amplified, cloned and sequenced. [Louwagie et al.(1995)]. GenBank accession numbers L22957 and L22951.
38) **UG5.ID#:** These 8 sequences are from Gulu, northern Uganda. They are from direct sequence of PCR product amplified from uncultured PBMCs. Blood samples were drawn from 217 pregnant women attending a clinic in Gulu, northern Uganda. Ages ranged from 17 to 37 years. The 29 seropositive women (13.4% of the 217 tested) were all asymptomatic. [Buonaguro et al.(1995)]. Genbank accession numbers U44878–U44880, U44882, U44883 and U44885–U44887. Two subtype D sequences were also found in this study (see D_UG8).
39) **ZR.Z321:** This sequence is from the 1976 Zairean isolate Z321. [Srinivasan et al.(1989)]. GenBank accession number M15896.
40) **ZR1.ID#:** These ten sequences are part of a set of 14 A and D sequences from women from Zaire; 8 were healthy, 4 showed minor signs of illness, and 2 had AIDS. PCR-direct, peripheral blood DNA. [Potts et al.(1993a)]. GenBank accession numbers L19624–L19626, L19628–L19630, L19632–L19634, and L19636.
41) **ZR3.ID#:** These sequences are from Zaire. They are unpublished, by M. Reitz et al. GenBank accession numbers U43097–U43100.

B Subtype

At this time we have included viral sequences from 975 HIV-1 infected individuals associated with HIV-1 subtype B. The B subtype consensus sequence (B_CONSENSUS_96) generated from these sequences was based on the most common amino acid found in each position in an alignment of these sequences. Please note that none of the studies which have published sequences of only the V3 loop sequences are included here, as the DNA sequences were deemed too short for phylogenetic analyses. (For example, LaRosa G, et al., *Science* **249**:932–935 (1990) and Fouchier RAM, et al., *J. Virol.* **66**:3183–3187 (1992).)

1) **AR.21281:** This sequence is from direct sequencing of PCR product from uncultured PBMCs, from a 1993 sample from Buenos Aires, Argentina. The patient had AIDS and reported promiscuous heterosexual risk behavior. Two other samples taken from unrelated patients in 1993 were subtypes F and one was found to be a subtype B/F recombinant. [Marquina et al.(1996)]. GenBank accession number U68525.
2) **AR1.ID#:** These 11 sequences are from Rosario, Argentina. A total of 24 patients from different risk groups visiting a clinic in Rosario were included in this study. Of the 14 sequences determined, 11 were found to belong to subtype B and 3 were found to belong to subtype F. DNA was extracted from whole blood and PCR amplified. PCR products were directly sequenced. Subtypes of all 24 patients were tested by HMA. [Campodonico et al.(1996)]. GenBank accession numbers U37030, U37031 and U37034–U37042.
3) **AU1.ID#:** Put forth as evidence that coinfection by multiple HIV-1 strains can occur in vivo, these three concensus sequences (MRC1,MRC2, and MRC3) come from an Austrailian homosexual male who had been infected by more than one sexual partner, and harbored three distinct strains of HIV-1 B. The authors also found recombinant sequences, not included here. The sequences were PCR amplified from plasma RNA and PBMC DNA. [Zhu et al.(1995)]. GenBank accession numbers U16372–U16388.
4) **AU2.C18CG:** This sequence is one of a group relating to an Australian blood donor infected with HIV-1 and six Australian recipients, all of whom remain symptom free with normal CD4 counts 10 to 14 years after infection. [Deacon et al.(1995)]. Samples from only the donor, D36 (U37271), and two patients, C18 (U37267, U37270) and C98 (U37268, U37269), appear to have been sequenced. These sequences have deletions in the nef gene and in the region of overlap of nef and the U3 region of LTR. The authors point to the importance of NEF or the U3 region of LTR in determining the pathogenicity of HIV-1 and suggest this strain of HIV-1 as a possible basis for a live attenuated vaccine. The complete genome of the virus from recipient C18 is in the entry with accession number U37270.
5) **BE.SIMI84** One of two cloned env sequences from a patient with AIDS from Belgium. A vaccinia construct that expresses this gene was created to vaccinate the patient's non-infected brother with the goal of immune therapy by adoptive transfer of lymphocytes. [Bex et al.(1994)]. GenBank accession number L07421.
6) **BR.002con** This consensus sequence is from Genbank accession numbers L35489–L35493. These sequences were provided by the WHO Global Programme on AIDS Vaccine Development Study. Ranjbar,S. et al. Unpublished (1994).
7) **BR.BZ** This sequence is from an individual in a Brazilian HIV cohort study. PBMC DNA was PCR amplified in two sequential rounds, and six cloned PCR products were sequenced on both strands. A single clone containing an uninterrupted envelope open reading frame was reported. [da Costa et al.(1995)]. Genbank accession number U28336.
8) **BR1.ID#:** These 21 sequences represent the B env subtype sequences found among 22 Brazilian outpatients with varying degrees of disease progression. They are consensus sequences from cloned PCR products. PCR was performed on PBMC DNA. [Potts et al.(1993b)]. GenBank accession numbers for 21 of the 56 clones from which consensus sequences were calculated: L19225–L19237, L19240–L19246 and L20963.
9) **BR2.W2BR-ID#:** These 13 sequences are from individuals from Brazil. They are consensus sequences from cloned PCR products. Some of the clones were from cell-culture DNA, and some from cell-culture supernatant RNA. These sequences were provided by the WHO Global Programme on AIDS Vaccine Development Study. The complete set of C2V3 region WHO sequences can be found in the April supplement to the Human Retroviruses and AIDS 1993 database. [De Wolf et al.(1994)], [Osmanov et al.(1994)], [Gao et al.(1994a)]. GenBank accession numbers U08670–U08714, U08771–U08778, U08780–U08782, U08792, U08796, U08797–U08800.

10) **BR3.RJ- or SP-ID#:** These 32 sequences came from the Brazilian cities Rio de Janeiro and Sao Paulo. Some of the sequences that are very short, containing V3 loop fragments insufficient for phylogenetic analysis, are not included here (4 of the 36). The full set included 34 viral sequences of the B subtype, an F subtype and a B-F recombinant (see subtypes F and U). The year of isolation for the sequences ranged from 1990–1992 for Rio de Janeiro, and 1992 for Sao Paulo. The only two with CD4+ cells < 200 were RJ636 and RJ27. The CDC clinical class ranged from II-IV. DNA extracted from PBMCs of HIV infected individuals was amplified, and the PCR product was directly sequenced. [Morgado et al.(1994)] and [Sabino et al.(1994c)]. More recent unpublished sequences from the same isolates are also included here. GenBank accession numbers U00400–U00401, U00403, U00405, U00407–U00414, U00416–U00418, U00421, U00424–U00425, U00427, U08975, U31586, U31587 and U31589–U31591.
11) **BR4.BZ-ID#:** These 2 sequences are from seropositive Brazilian patients. Virus was cultured on donor PBMCs and proviral DNA was harvested from positive cultures. PCR was used to generate sequencing templates. [Louwagie et al.(1994)]. GenBank accession numbers L22087 and L22088. The gag gene sequences from these same isolates are also available in L11752 and L11754. See also F_BR2.BZ-ID#.
12) **BR5.ID#:** These 10 sequences are from entries with GenBank accession numbers L19328–L19337. Bandea, C. I. Unpublished (1993).
13) **BR6.ID#:** These six sequences are from patients living in cities in Brazil (P3, Sao Paulo; P4, P6 and P7, Bahia; P8, Parana; P9, Rio de Janeiro) and sampled between 1987 and 1989. Sequences were determined from directly sequenced PCR products (except P6 which was a cloned PCR product), after coculture of patient PBMCs with donor PBMCs. [Couto-Fernandez et al.(1994)]. Genbank accession numbers X78512–X78517.
14) **CH1.ID#:** These 19 sequences came from 24 individuals living in Geneva, Switzerland who were recently infected at the time of blood drawing. Samples were collected between January 1988 and September 1993. Sequences were determined directly from PCR products of uncultured PBMC DNA or serum cDNA. All subjects were asymptomatic, 19 subjects had p24 antigen levels ranging from 5 to 6,357 pg/ml and 5 subjects had no detectable p24 antigen. Two subjects were epidemiologically linked (K11 and K16) so only one of those two is presented here. Two other individuals showed identical DNA sequences over the entire V3 region (K53 and K77) so only one of them is presented here. Three other individuals (K13, K42 and P4) had sequences nearly identical to the LAI (IIIB) laboratory strain of HIV. Although the authors are convinced that these are not contaminants, and that a IIIB-like strain of HIV is circulating in Geneva, they are not included in this alignment. [Antonioli et al.(1995)]. GenBank accession numbers U10957–U10980.
15) **CI.CI-22:** A single B subtype sequence from a set of 13 isolates from individuals from Abidjan, Cote d'Ivoire. CI-22 was symptomatic. The C2V3 region is part of a 900 bp fragment that was sequenced for each individual. Samples were collected between May 1990 and Sept. 1991. Virus was cultured with donor PBMCs, nested PCR amplified, 3 clones were sequenced, and the consensus of those clones is presented here. [Janssens et al.(1994a)]. GenBank accession numbers X72040–X72042.
16) **CM.CA5:** A single B subtype sequence from a set of 17 sequences from a very diverse set of isolates from Yaounde and Douala, Cameroon. The sequences were derived from asymptomatic and symptomatic HIV infected individuals, specifically, patient CA-5 was asymptomatic. Virus was isolated by culture with donor PBMCs, and nested PCR amplified. A single clone was sequenced representing each HIV-1 isolate. [Nkengasong et al.(1994)]. GenBank accession numbers for the full set of 17 sequences which includes CA5 are X80438–X80454.
17) **CN1.-ID#:** These 54 sequences are form the Yunnan Province, China. No information is yet available. Unpublished 1995, Y. Shao and H. Wolf. Several of these sequences (U20009, U20012, U20013, U20018, U20023, U20024) are greater than 96GenBank Accession numbers U20001–U20054.
18) **CN.1798:** This sequence is from a dried blood spot collected in 1992 from the spouse of an IV drug user in China. DNA was extracted from the blood spots and PCR amplified. The PCR products were directly sequenced. [Cassol et al.(1996)]. GenBank accession number U53316.
19) **CU.94CU053:** This sequence is from a bisexual male, most probably infected via heterosexual contact in 1992, in Cuba. Virus was isolate in 1994, 2 years after seroconversion, by cocultivation of patient PBMCs with donor PBMCs. This isolate exhibits a rapid/high, syncytium-inducing phenotype. [Gomez et al.(1996)]. GenBank accession number U48855.
20) **CY1.HO#:** These sequences are from samples, like others in this study (see also subtypes A, C, F and I), which were collected in February 1994 from the AIDS clinic in Nicosia, Cyprus. PBMC DNA was PCR

amplified and cloned. Individual clones were sequenced. Patient 04 was a 24 year old man, asymptomatic with a CD4 count of 516, who had lived abroad, and had been seropositive for at least 4 years. Patient 11 was a 29 year old homosexual man, symptomatic with a CD4 count of 277, and seropositive for at least 7 years. Patient 21 was a 38 year old bisexual man, asymptomatic with a CD4 count of 743, who was infected in Greece and seropositive for at least 4 years. Patient 25 was a 34 year old heterosexual man, asymptomatic with a CD4 count of 650, who had lived in the U.S. and was seropositive for at least 6 years. Patient 27 was a 20 year old homosexual man, asymptomatic with a CD4 count of 709, infected in Cyprus and seropositive for at least 2 years. Patient 28 was a 39 year old homosexual woman, asymptomatic with a CD4 count of 430, infected in Cyprus and seropositive for at least 1 year. Patient 29 was a 49 year old heterosexual man, asymptomatic with a CD4 count of 420, infected in Cyprus and seropositive for at least 2 years. Patient 39 was a 37 year old heterosexual man, asymptomatic with a CD4 count of 470, had lived in Greece and was seropositive for at least 5 years. Patient 40 was a 29 year old heterosexual woman, symptomatic with a CD4 count of 92, who had lived in the U.S. and was seropositive for at least 6 years. Patient 43 was a 36 year old homosexual man, symptomatic with a CD4 count of 396, who had lived in the U.K. and Greece and had been seropositive for at least 6 years. Patient 45 was a 32 year old heterosexual man, asymptomatic with a CD4 count of 453, who was infected in Cyprus and seropostitive for at least 1 year. Patient 46 was a 32 year old heterosexual man, whose partner had died of AIDS, asymptomatic with a CD4 count of 107, had lived in the U.K. and was seropositive for at least 4 years. Patient 48 was a 22 year old hemophiliac man, asymptomatic with a CD4 count of 276, who had been seropositive for at least 11 years. Patient 50 was 32 year old homosexual man, whose partner had AIDS, asymptomatic with a CD4 count of 315, who had been seropositive for at least 1 year. GenBank accession numbers U28663, U28666 (04); U28664 (11); U28667–U28671 (21, 25, 27, 28, 29); U28675, U28676 (39, 40); U28678 (43); U28680–U28682 (45, 46, 48); U28684 (50).

21) **CZ.BTSPR:** This sequence is from a 32 year old homosexual man from Prague, Czech Republic. It was included as part of a study of HIV-1 sequences from the neighboring Slovak Republic. DNA from cocultured PBMCs was PCR amplified and the PCR product cloned. Eight clones were sequenced from each patient, although only one sequence is presented in the publication and in Genbank. It is not stated whether each single sequence is a consensus of the eight clones or a single clone. [Zachar et al.(1996b)]. GenBank accession number U53195.
22) **DE.D31:** This sequence is from isolate D31. [Kreutz et al.(1992)]. It has never been well described, it is only shown as HIV1-D31 in figure 3 of the paper. The complete genome has been sequenced. GenBank accession number U43096.
23) **DE.HAN:** This sequence is from an infectious clone from the German isolate DE.HAN-2. [Sauermann et al.(1990)]. GenBank accession number U43141.
24) **DE.Serocons:** This sequence is a consensus sequence from 7 hemophilia patients who all received the same lot of beta-propiolactone and UV-light inactivated clotting factor in Bonn or Goetingen, Germany, from November 1989 to March 1990. The virus and the patients have been extensively studied over time, since initial seroconversion. The sequences which were combined to create the consensus were from proviral DNA from cultured PBMCs, PCR amplified and cloned. [Kasper et al.(1994)]. GenBank accession numbers S76444 and S76446.
25) **DE1.ID#:** These 7 sequences are from a Neurology thesis by I. Weber of Rostock, Germany. They are from blood and CSF specimens from 6 patients. For each of the patients, phylogenetic analysis showed that blood and CSF sequences were more similar to each other than to other database sequences. For one patient, one of the two blood sequences was different enough from another blood and CSF pair to be included here. GenBank accession numbers Z78482, Z78485-Z78493.
26) **DE2.ID#:** These 4 sequences are from a set containing 15 Dutch homosexuals, 19 Dutch intravenous drug users, 2 German homosexuals, 2 German intravenous drug users, 5 Scottish homosexuals and six Scottish intravenous drug users. The sequences were used in a study of HIV-1 vpr, vpu, and env V3 regions and how they vary between risk groups. [Kuiken et al.(1996b)]. GenBank accession numbers Z68529, Z68530, Z68537 and Z68538.
27) **ES.ID#:** These 36 sequences are from 41 patients sampled in Madrid, Spain between 1985 and 1991. Proviral DNA was extracted from uncultured patient PBMCs and the C2V3 region was PCR amplified. The PCR products were directly sequenced. Two of the sequences reported in this set (D22-28 and D22-48) were 99.5% identical to the LAI (IIIB) lab strain of HIV-1 and are not included here. 3 other goups

of sequences had members that were greater than 98% identical to each other (R1, R2 and R3; THF13-2, THF12-24; S1, S4) and only one of each of them is presented here. [Quinones-Mateu et al.(1996)]. GenBank accession numbers U40533–U40552 and U45286–U45307.

28) **FR.J91:** This sequence is from one of the JBB clones from the French patient Bru. [Wain-Hobson et al.(1991)] and [Guo et al.(1991)]. GenBank accession numbers X57449–X57459 and X57461.

29) **FR.LAI:** This sequence is from the French isolate LAI (formerly BRU) which is also referred to as IIIB. [Wain-Hobson et al.(1985)]. Also see: [Alizon et al.(1986)], [Lukashov & Goudsmit(1995)] and [Wain-Hobson et al.(1991)]. GenBank accession numbers K02013, L23090–L23103, X01762, L48380–L48399, M64178–M64223, M64406–M64415 and M64768–M64775. Other sequences which are of this type include: PV22, K02083; MFA, M33943 [Stevenson et al.(1990)]; un-named, Z11530; BH8, K02011; BH10, M15654; TH4, L31963; MCK1, D86068; PM213, D86069; F12CG, Z11530; and HXB, K03455, M38432, M64775 and M14100. This isolate of HIV-1 has also been extensively studied in cases such as the infected lab worker. See for example [Jr et al.(1994)], [Pincus et al.(1994)] U12030–U12055. Recombinant virus pNL4-3, with envelope from LAI(BRU) and gag-pol from NY5 has also been studied: [Adachi et al.(1986)] GenBank accession number M19921, [Duensing et al.(1995)] GenBank accession number L42371 and [Salminen et al.(1995)] GenBank accession number U26942. Other GenBank entries with IIIB-LAI sequences can be found in the patented sequences section and in the cloning vector section (for example U19867 and A00647).

30) **FR1.ID#:** These 4 sequences are from Toulouse, France. In this study, 4 mother-infant pairs were followed during pregnancy and after birth. The inter- and intra-patient sequence similarities of this set of 308 sequences has been controversial, because some infant sequences were identical to sequences from other mothers. For purposes of this V3 section, only one sequence from each of the 4 infants is presented here. [Briant et al.(1995)], [Korber et al.(1995)] and [Learn et al.(1996)]. GenBank entries for all 308 sequences are found with accession numbers U24717-U24999 and U25001-U25025.

31) **GA.OYI:** This sequence is from the Gabonese isolate OYI (designated elsewhere as isolate 397), isolated from a healthy HIV-1 infected individual. GA.OYI appears to have been the first viral sequence from Africa that phylogenetically clustered with North American viruses. [Huet et al.(1989)]. GenBank accession number M26727.

32) **GB.AIT:** This sequence is from an individual at the time of seroconversion. Proviral DNA was extracted from PBMCs from a patient who was viraemic and had an equivocal HIV-1 antibody status, and the env V3 region was PCR amplified. The PCR products were cloned and the DNA sequence determined for 15 clones. These data showed that the V3 region contained only limited sequence heterogeneity with a major variant (shown here) accounting for 66% of the protein quasispecies present. [Ait-Khaled & Emery(1993)]. GenBank accession number S69598.

33) **GB.CAM1:** This sequence is from the British isolate CAM1. McIntosh A, and Karpas A, Thesis (1991), Cambridge University, England. GenBank accession numbers D10112, D00917.

34) **GB.Man** This sequence was PCR amplified from the 1959 "Manchester sailor" kidney tissue. The sequence of the complete genome is available and clusters with subtype B contemporary HIV-1 sequences. [Zhu & Ho(1995)]. GenBank accession number U23487.

35) **GB.V-ID#:** A set of six sequences from a study of hemophiliacs from Scotland who were originally thought to have been infected by the same batch of factor VIII. (ScV12 is a sequence from a hemophiliac from the U.S., included as a control). All are consensus sequences of multiple direct PCR sequences obtained from limiting dilution of PBMCs. The Scottish hemophiliacs were infected in 1984 and the PBMCs were obtained for analysis in 1989. Although the samples were potentially related, they were deemed sufficiently divergent in this region for inclusion in this set. [Simmonds et al.(1990)], and [Balfe et al.(1990)]. GenBank accession numbers M61327–M61346 and M61391–M61407. GenBank entries with accession numbers M84240–M84317 are more sequences from patient 82, taken over the period from 1984–1991. [Holmes et al.(1992)]. GenBank entries with accession numbers L13488–L13497 are also from these patients [Zhang et al.(1993)]

36) **GB1.CPHL1:** This is a consensus from the British isolate 93–08020, clones 1, 4, 7, 18, 19 and 43. It was referred to as 93–08020 in [Arnold et al.(1995c)] and was isolated from the patient referred to as CPHL1 in [Arnold et al.(1995a)]. CPHL1 is a surgeon and CPHL2 was a patient of his in 1986, approximately 7 years prior to sampling for this study. Because sequences from CPHL1 and CPHL2 are no more similar to each other than to sequences from the general population, transmission cannot

be concluded, and both sequences are included in this alignment. GenBank accession numbers U21100 (clone 1) and U23112–U23116 (clones 18, 19, 4, 43 and 7 respectively).

37) **GB2.CPHL2:** This is a consensus from the British isolate 93–17305, clones 3, 11, 18 and 25 [Arnold et al.(1995c)]. It was isolated from the patient referred to as CPHL2 in [Arnold et al.(1995a)]. GenBank accession numbers U23117–U23120 (clones 11, 18, 25 and 3 respectively).

38) **GB3.CPHL7:** This sequence is a sequence from the British isolate 94–24612, clone 13. [Arnold et al.(1995c)]. It was isolated from the patient referred to as CPHL7 in [Arnold et al.(1995a)]. GenBank accession number U23126. U23127 is a second clone from this same isolate. Sequences from three other patients epidemiologically linked to CPHL7 (CPHL6, accession numbers U23130–U23132; CPHL8, U23128–U23129; CPHL9, U23133–U23135) are not included in this alignment.

39) **GB4.ID#:** These sequences are from British isolates from St. Bartholomew's Hospital, London (M23470, M26864, M30156, M737677 and M737658) and Hammersmith Hospital, London (AC, JB and WB). Sequences were determined from cloned PCR products from PCR amplified DNA from either cocultured (M23470 and M26864) or uncultured (M30156, M737677, AC, JB and WB) patient PBMC proviral DNA. [Douglas et al.(1996)]. Complete envelope gp160 sequences were determined for at least one clone from each patient. Ugandan samples also sequenced in this report were subtypes D or D/A recombinant. GenBank accession numbers for London samples were U36859–U36864, U36869, U36870, U36872–U36880 and U36882.

40) **GB5.ID#:** These 11 sequences are from Scotland. They are part of a set containing 15 Dutch homosexuals, 19 Dutch intravenous drug users, 2 German homosexuals, 2 German intravenous drug users, 5 Scottish homosexuals and six Scottish intravenous drug users, from which regions of vpr, vpu and env were sequenced. The authors found consistent differnces in the sequences between the homosexuals and IV drug users. Only 34 of the 47 patients' sequences are reported in the publication. [Kuiken et al.(1996b)]. See also B_NL12 and B_DE2 sets.

41) **GM.GM6:** A sequence from Gambia, as yet unpublished. Bobkov et al. 1996 unpublished. GenBank accession number U33101. See also Gambian sequences of subtypes C and J.

42) **HT.RF:** This sequence is from the full-length lambda clone HAT-3, from Haitian isolate RF. RF is from a 28 year old Haitian male who had moved to the United States at age 25, in 1980. He had no history of IV drug use, homosexuality or blood transfusions. In October 1983 he had 20 lb weight loss, giardia with diarrhea, thrush, and diffuse lymphadenopathy. His CD4/CD8 ratio was 0.08. He died in December, 1983. Primary culture from a November 1983 blood sample was co-cultured on HUT-78 cells. [Jr et al.(1992)] [Starcich et al.(1986)] [Popovic et al.(1984)]. GenBank accession numbers M17451 and M12508.

43) **HT1.D-ID#:** These seven sequences are from Haitians, and are part of a set of sequences generated as part of the DAIDS variation program in the laboratories of Dr. Beatrice Hahn at the University of Alabama, and Dr. Marcia Kalish at the Centers for Disease Control, Atlanta, GA. Except for D2HA590, the full gp160 was sequenced from clones derived from expanded culture stocks. D2HA590 is a direct sequence from PCR amplified DNA from expanded culture. The sequence ID numbers are abbreviated, for example D2HA590 can be read as DAIDS sequence (D), isolated in 1992 (2), Haitian (HA), patient 301590 (590). Full length env for some of these have been expressed [Gao et al.(1996a)]. GenBank accession numbers: U08441–U08447, U04900. Both U08441 and U08442 are sequences from patient HT1.D1HA651 and are identical over the region of interest. GenBank accession numbers for additional clones derived from these patients: U04901–U04906.

44) **HT2.H-ID#:** These 25 sequences are from Haitians. All sequences were PCR amplified from the infected individuals PBMCs, and this set includes direct sequences of PCR amplification products, consensus sequences of multiple clones of PCR products plus one direct sequence, and single clones of PCR products. Full length env for some of these have been expressed [Gao et al.(1996a)]. These sequences were provided by the Centers for Disease Control, Atlanta, GA USA (Dr. Chin-Yih Ou), and John Hopkins University School of Hygiene and Public Health, Balimore, MD USA (Dr. Neal Halsy), and the Centers for Development and Health, Complexe Medico Sociale de la Cite Soleil, Port-au-Prince, Haiti (Dr. Reginald Boulos). GenBank accession numbers L07145–L07161, L07163–L07165, L07167–L07207, L07209–L07239, L07241–L07246, U08441–U08447.

45) **ID.1701:** This sequence is from a dried blood spot collected in 1992 from a male homosexual patient in Indonesia. DNA was extracted from the blood spots and PCR amplified. The PCR products were directly sequenced. [Cassol et al.(1996)]. GenBank accession number U53317.

46) **IN.IND9:** This sequence was from a heterosexually infected patient from New Delhi, India. DNA was isolated from cocultured PBMCs after one week of culture. PCR product was cloned and a single clone was sequenced. [Tripathy et al.(1996)]. GenBank accession number U31364. See also C_IN3.ID#.
47) **IN1.ID#:** These four sequences were isolated in Hyderabad, Andhra Pradesh, in southern India. The C2V3 region of env was amplified by nested priming from DNA from PBLs from fresh blood samples. Date of sampling and health status of HIV-1 infected individuals is unknown. [Baskar et al.(1994)]. GenBank accession numbers L29091–L29094.
48) **IT.ID#:** These two sequences are consensus sequences from 4 clones each. They were obtained from PCR-amplified proviral DNA from Langerhans cells from skin patches from a deceased AIDS victim in Italy [Sala et al.(1995)]. Small V1-V2 region sequences and V3-loop sequences from the same skin samples were published in [Sala et al.(1994)]. GenBank accession numbers U20670–U20677 used here. GenBank Accession numbers Z34376–Z34458, Z34470–Z34513 and Z34515 were V1-V2 and V3-loop sequences from the same patient.
49) **IT.PD:** This sequence is from the thymus of a 26 year old male with CDC stage III disease. Proviral DNA was PCR amplified from genomic DNA extracted from patient thymocytes, and the PCR product was directly sequenced. A V3 sequence from PBMC proviral DNA was also determined, as were gp41 sequences from both thymus and blood. [Calabro et al.(1995)]. GenBank accession numbers U09254–U09255.
50) **IT1.ID#:** These 10 sequences are from infants infected in utero. The sequences came from PCR amplified DNA of uncultured PBMCs, PCR amplified DNA of cultured PBMCs, or from RNA from serum collected at or shortly after delivery. [Scarlatti et al.(1993)]. GenBank accession numbers L08277–L08286. Sequences from the mothers of these infants are also available in entries with accession numbers L08287–L08372.
51) **IT2.ID#:** These 3 sequences are from unpublished sequences in GenBank entries with accession numbers X92424–X92426.
52) **JP.ETR:** A Japanese isolate from long-term cell culture with a truncated env gene, due to a point mutation of a CAG codon to a TAG stop codon. [Shimizu et al.(1992)]. GenBank accession numbers D12582, D01205–D01207, D12584 and D12571.
53) **JP.GUNA:** A Japanese 1989 isolate HIVGUN, infectious to T cells, was adapted to grow in fibroblast-like BT cells. A single amino acid change at the tip of the V3 loop was shown to be responsible for the change in tropism, GPGR to GSGR. [Takeuchi et al.(1991)]. GenBank accession number M59192.
54) **JP.JH32:** This is a sequence from a lambda clone of Japanese isolate JH3, which was isolated in 1986 from a 10 year old Japanese Hemophiliac. [Komiyama et al.(1989)]. GenBank accession number M21138.
55) **JP.KM03:** This sequence is from a 28 year old hemophilia B patient with CDC stage IV disease and T-cell count of 20, living in Japan. The authors [Hattori et al.(1991)] also sequenced the V3 region from 28 other Japanese individuals, but only the V3-loop amino acid sequence is available from the other patients. GenBank accession number S70936.
56) **JP.JNIH1M:** This sequence is from a Myanmarese (Burmese) individual living in Japan, obtained by direct sequencing of PCR-amplified proviral DNA from peripheral blood mononuclear cells. [Weniger et al.(1994)]. GenBank accession number L32084.
57) **KP.Kr121** This sequence is from an unpublished GenBank entry with accession number X93580.
58) **LT.LIT#:** These 5 sequences are from Lithuania. [Lukashov et al.(1995)]. GenBank accession numbers: L38417, LIT18A; L38412, LIT11A; L38419, LIT21A; L38416, LIT17A; L38420, LIT17A.
59) **MY1.ID#:** These two sequences are from Myanmarese (Burmese) individuals living in Myanmar, obtained by direct sequencing of PCR-amplified proviral DNA from peripheral blood mononuclear cells. [Weniger et al.(1994)]. Patient 02 is a male IV drug user, and 05 is a female prostitute, both were from Mandalay. GenBank accession numbers L32088, L32089.
60) **MY2.ID#:** These 11 sequences are from IV drug using prisoners in a prison in Kuala Lumpur, Malaysia. PCR products amplified from uncultured PBMCs were directly sequenced. [Brown et al.(1996)]. This report also included subtypes C and E in Malaysia. GenBank accession numbers U65538–U65548.
61) **MY3.ID#:** These 5 sequences are from dried blood spots collected in 1992 from a male STD patient (1782), a female prostitute (1739), and 3 IV drug users (1748, 1755 and 1763) in Myanmar. DNA was extracted from the blood spots and PCR amplified. The PCR products were directly sequenced. [Cassol et al.(1996)]. GenBank accession numbers U53304–U53308.

62) **NL.114C** This consensus sequence represents sequences generated from PCR amplified plasma RNA from one of three infants in a Dutch mother/infant study. Samples were collected from the infant at birth, at 6 weeks and at 9 months of age. Samples were also collected from the mother before birth, at birth and after birth. Mother sequences are not included in this consensus. [Mulder-Kampinga et al.(1993)]. [Mulder-Kampinga et al.(1995)]. Infant 114 is from GenBank accession numbers L21111–L21153. Mother 114 sequences are from GenBank accession numbers L21028–L21110. Infant 127 sequences are from GenBank accession numbers Z47817–Z47832. Mother 127 sequences are from GenBank accession numbers Z47833–Z47880. Gag gene sequences from mother/child pairs are also available in Genbank accession numbers Z47903–Z47911; Z47912–Z47928; Z47929–Z47935; Z47936–Z47950. The second mother/child pair was also from the Netherlands, see G_NL.127C. The third mother/infant pair in this study was from Rwanda, see A_RW.564C.

63) **NL.168:** This is a consensus sequence of 3 clones after culturing in PBMC. The isolate was originally from an AIDS patient in Amsterdam. [Wrin et al.(1995)]. GenBank accession numbers U15030–U15032. A V3-loop (105 bp) segment from the original isolate has been previously reported. [Fouchier et al.(1992)]. GenBank accession number L06694.

64) **NL.wolfscon:** This is a consensus sequence from 6 patients infected with the same unit of blood in Amsterdam. [et al(1992)]. GenBank accession numbers U04530–U04537.

65) **NL.X1con:** This is a consensus sequence of 10 clones from a recipient in a donor-recipient study. Sequences from donor Y and recipient X2 are also part of this study, but are not included here. [Cornelissen et al.(1995)]. GenBank accession numbers Z47505–Z47514 are from X1. Other new sequences analyzed in this paper include Z47411–Z47540. Sequences M91828–M91838 (donor H and recipient O, referred to as patients A14 and A13, respectively in [Wolfs et al.(1992)] see B_NL1.A13) were also re-analyzed in this study.

66) **NL1.ID#:** These eight sequences are part of a study of presumed donor-recipient pairs from an HIV-1 transmission study conducted in the Netherlands. If pairs were extremely close or identical, only the recipient is included here. Recipient samples were from the first sample to be antibody positive, and are numbers 1,3,5,7,9, and 13. These sequences are consensus sequences of multiple clones from PCR amplified serum RNA. [Wolfs et al.(1992)]. Recipient A1 was also studied as patient H1 in [Kuiken et al.(1993)] and so is not included here (see B_NL4.H1). GenBank accession numbers M91819–M91827, M91829, M91831–M91832, M91839, M91857–M91870, M91872, M91874, M91881–M91884, M91891, M91893, 91895–M91908, M91910, M91911–M91926. Number 13, and the donor were also analyzed in [Cornelissen et al.(1995)].

67) **NL2.ID#:** These two sequences are part of a Dutch study of mutations occurring over a five year period (starting in 1985) in two patients. Serum RNA was PCR amplified and multiple clones were sequenced. The consensus for each patient is shown. [Wolfs et al.(1991)] and [Zwart et al.(1992)]. GenBank accession numbers M74591–M74684.

68) **NL3.NET-ID#:** These six consensus sequences from the Netherlands are samples from AIDS patients, using serum samples to generate PCR clones from viral RNA for sequencing. [Zwart et al.(1993)]. GenBank accession numbers L01282–L01297.

69) **NL4.ID#:** These 74 sequences represent a study of early seroconverters from different times with different risk factors for transmission during the AIDS epidemic in the Netherlands. The year the sample was taken is indicated in the last part of the sequence name. The risk group of the individual from whom the virus is derived is indicated in the first letter of the sequence name (I, B and H for IVDUs, hemophiliacs, and homosexuals, respectively). Viral genomic RNA from sera was PCR amplified and amplification product was directly sequenced. [Kuiken et al.(1993)]. GenBank accession numbers Z29219–Z29225, Z29256–Z29258, and Z29262–Z29325.

70) **NL5.ID#:** These 18 consensus sequences are from a study of patients with, and without, AIDS dementia complex (ADC) in the Netherlands. Not all patients were from the Netherlands. Samples were collected between 1986 and 1992. Viral genomic RNA from sera and/or cerebral spinal fluid was reverse transcribed and PCR amplified and clones were sequenced. [Kuiken et al.(1995)] GenBank accession numbers Z37531–Z37534, Z37734–Z37963, Z37970–Z37971

71) **NL6.ID#:** 16 is a consensus sequences of four sequences used in a study of HIV-1 envelope-mediated syncytium formation. The consensus represents four clones from one patient, two clones of the consensus are SI and two are NSI. 320 is a single SI clone. The sequences were derived from PCR amplified DNA

from provirus cultured in MN cells. [Andeweg et al.(1992)]. GenBank accession numbers L08655–L08662.

72) **NL7.ID#:** These two consensus sequences are from sets of sequences (GenBank accession numbers U05797, U13240, U13241, U13243–U13247 for consensus 537 and U13242, U13248–U13252 for 1058) used in a study on the dynamics of HIV sequence changes in vivo and the utility of heteroduplex analysis. Both sequences were derived from PCR amplified PBMC DNA. Consensus 537 represents a set of sequences from a Dutch patient with a relatively stable CD4+ cell count at 62 months post-seroconversion. Consensus 1058 represents sequences from another Dutch patient whose CD4+ cell count at 73 months post-seroconversion was declining faster than 537's. [Delwart et al.(1994)]. See also US10.ID#.

73) **NL8.672** This is a sequence from a patient early in infection, before, or around the time of seroconversion. Three other patients studied in this paper (537, 1058 and 594), had previously been reported. See B_NL4.594, B_NL7.1058con and B_NL7.537con. [Shpaer et al.(1994)] and [Delwart et al.(1995)]. GenBank accession numbers U23651–U23663, U23667, U23670. See also US11.ID#.

74) **NL9.h#:** These sequences are from a cohort of homosexual men living in Amsterdam who seroconverted between 1985 and 1989. The sequences are from direct sequencing of PCR products after RT-PCR from serum RNA. Samples for h1, h139, h491, h1140 and h1234 were obtained at seroconversion. Samples for h138 and h1136 were obtained 12 months and 29 months after seroconversion respectively. The sequence for h320 was obtained from proviral DNA, 2 months after seroconversion. [Zwart et al.(1994a)] and [Zwart et al.(1994b)]. GenBank accession numbers L25884 and U05786–U05808. More sequences from this same cohort of men were published in [Kuiken et al.(1996b)] and [Kuiken et al.(1996a)] GenBank accession numbers Z67875–Z67876, Z67885–Z67939, Z67941–Z67960, Z68015–Z68089, Z68109–Z68110. Some vpr, vpu and other region sequences are available from some of these patients as well. Some of the GenBank entries for this set appear to be duplicates of sequences reported in other studies, for example patient H537 entries U05797 and

75) **NL10.ID#:** These 13 sequences are from recent immigrants to The Netherlands from various countries. The fist two letters of the ID# represent the two letter country code for the previous residence of the patient. The next two numerals represent the year of isolation. Viral RNA was prepared from patient serum and RT-PCR was used to amplify the V3 region of the env gene. The PCR products were directly sequenced. [Lukashov et al.(1996)]. GenBank accession numbers L76878, SR903853; L76897, SR9304737; L76879, SR911515; L76874, UM893272; L76912, UM9403860; L76888, SR925752; L76890, SR926969; L76894, GQ9301341; L76882, MA913670; L76886, SR923572; L76873, BR891413; L76910, UM9403051; L76885, GF921953.

76) **NL11.ID#:** These 2 sequences are consensus sequences of 81 clones (patient N) and 105 clones (patient F) from serum, sigmoid tissue and fecal matter from each patient. All sequences from patient N were more similar to other sequences from patient N than to any other sequence in the database. Likewise all sequences from patient F were most similar to other patient F sequences. van der Hoek et al. In Press (1996). GenBank accession numbers Z76463–Z76648.

77) **NL12.ID#:** These sequences are part of a set containing 15 Dutch homosexuals, 19 Dutch intravenous drug users, 2 German homosexuals, 2 German intravenous drug users, 5 Scottish homosexuals and six Scottish intravenous drug users, from which regions of vpr, vpu and env were sequenced. The authors found consistent differnces in the sequences between the homosexuals and IV drug users. Only 34 of the 47 patients' sequences are reported in the publication. [Kuiken et al.(1996b)]. See also B_GB5 and B_DE2 sets. Some of the patients in this study have been previously studied. For example, entries with accession numbers Z68061 and U05787 are both from the same patient.

78) **NO1.ID#:** These 36 sequences are from unpublished Norwegian sequences with Genbank accession numbers X92902–X92912, X92915, X92916, X92919–X92941. Four subtype C sequences were also part of this set (X92913, X92914, X92917, X92918).

79) **PR1.D-ID#:** These four sequences are from Puerto Rico, and were generated as part of the DAIDS variation program in the laboratory of Dr. Marcia Kalish at the the Centers for Disease Control, Atlanta, GA. The C2V3 region was directly sequenced from PCR amplification of DNA from viral culture. The sequence ID numbers are abbreviated; for example D2PR732 can be read as DAIDS sequence (D), isolated in 1992 (2), Puerto Rico (PR), patient 301732 (732). A full description of these sequences can be found in the April 1994 supplement to the HIV database, part III. GenBank accession numbers U04926–U04929.

80) **PY.ID#:** Ten sequences from 10 patients living in Asuncion, Paraguay. All 10 were male patients with symptoms of AIDS. Virus was propagated in tissue culture for an unstated length of time prior to

harvesting proviral DNA for PCR and sequencing. PCR products were directly sequenced. PY.3614, PY.3615 and PY.12837 were syncytium-inducing and the other 7 were not. The tenth sequence, PY.3614p was PCR amplified directly from patient PBMCs with no culturing. The significant differences between the cultured sequence from this patient (PY.3614c) and the direct sequence, indicates that the virus that grew out in culture was a minority of the virus present in PBMC. The sequence of PY.3614c is not included in this alignment. [Cabello et al.(1995)]. GenBank accession numbers U28949–U28959.

81) **RU.RUS#:** These 2 sequences are from [Lukashov et al.(1995)]. GenBank accession numbers: L38405, RUS3A; L38407, RUS4A.
82) **RU2.ID#:** These 15 sequences are from homosexuals living in St. Petersburg, Russia. Malykh et al unpublished (1995). GenBank accession numbers U40283–U40285 and U40319–U40330.
83) **SE.pt11s113:** This sequence is from one (patient 11 sample 113, collected in 1988) of a set of 13 sample from 9 epidemiologically linked individuals. The index case (patient 1) was a Swedish male who is believed to have contracted HIV while visiting Haiti in 1980. Six Swedish females were infected (patients 2,4,5,7,8 and 11) by patient 1. Two males (patients 6 and 10) were then infected by these females, and two HIV-infected children (patients 3 and 9) were born to the women. Sequences from each patient were determined by PCR amplification from uncultured PBMCs and direct sequencing. Heterogeneous sites were indicated with IUPAC codes. Extensive phylogenetic analysis was done to determine which methods accurately reconstructed the true phylogeny. [T. Leitner et al.(1996)]. GenBank accession numbers U68496–U68521.
84) **SE1.ID#:** Seven sequences that are consensus sequences of blood and CSF samples taken from each patient. The CDC disease stage class for the patients are as follows: II pts 930, 2815; III pt 931; IV-E pt 2951; IV-A pt 1032; and IV-C2 pts 1433, 1866. [Keys et al.(1993)]. GenBank accession numbers Z23178–Z23181, Z23185–Z23187, Z23192–Z23195, Z23200–Z23219, Z23224–Z23227, Z23232–Z23235, and Z23240–Z23255.
85) **SE2.ID#:** These five sequences are from patients in Goetebotg, Sweden each of whom had recently seroconverted at the time of sampling in 1985-1990. Sequences from the sexual partners of all five patients who were believed to have transmitted the virus to these recipients were also determined, but are not shown here due to the great similarity to the recipient sequences (94% to 99% identity). Three of the recipients (R1, R3 and R4) were homosexual, and the other two were heterosexual. [Furuta et al.(1994)]. GenBank accession numbers U10929–U10950.
86) **SK1.ID#:** These nine sequences are from homosexual men living in the inner city of Bratislava, in the Slovak Republic. Patients 11, 12, 15 and 23 were classified as CDC stage A1 and were not taking any medication. Patients 18 and 20 were CDC stage B2 and were taking AZT. Patients 9 and 28 were CDC stage C3 and were taking AZT. No information is available for patient 22. Two other patients (10 and 51) were included in this study, but their sequences are not shown here because after their sequences proved to be similar to sequences from patients 9 and 28, respectively, epidemiological investigation indicated that they (9 and 10; 28 and 51) had been sexual partners. DNA from cocultured PBMCs was PCR amplified and the PCR product cloned. Eight clones were sequenced from each patient, although only one sequence is presented in the publication and in Genbank. It is not stated whether the single sequence is a consensus of the eight clones or a single clone.[Zachar et al.(1996b)]. GenBank accession numbers U53192–U53194, U53196–U53203.
87) **TH.93TH067:** This sequence is from Thailand. It is one of several complete env gene sequences obtained for the World Health Organization. HMA subtyping as well as sequence-determined subtyping was done on each one. Sequences were PCR amplified from cocultured PBMCs. Two to three clones from each isolate were sequenced. [Penny et al.(1996)]. GenBank accession numbers U39258 and U39259.
88) **TH.T8174:** This sequence comes from a study of the genetic heterogeneity and epidemiological distribution of HIV1 in Thailand. The host was an intravainous drug user and the sequence was obtained from PCR amplified PBMC DNA. [Ou et al.(1993)]. GenBank accession number L19238. See also E_TH.T8178.
89) **TH1.ID#:** These ten sequences are from individuals from Thailand. PCR-direct, peripheral blood PBMC DNA. [Ou et al.(1992b)] and [Ou et al.(1993)]. (Published erratum appears in Lancet **342**:250 (1993).) GenBank accession numbers L07442, L07449–L07456 and L07460.
90) **TH2.ID#::** The TB132 sequence is from a set of isolates from HIV seropositive individuals from Thailand. PCR, PBMC co-culture, DNA. Full env sequence is available. [McCutchan et al.(1992)]. Please note:

the TB132 locus name in the database corresponds to the McCutchan et al. "BK132" isolate. GenBank accession number L03697. The CM237 sequence is from PBMC proviral DNA. [Mascola et al.(1994)]. GenBank accession number L14570. See also B_US14

91) **TH3.W2TH-ID#:** 2 sequences from Thailand from asymptomatic individuals. Consensus, PCR-clones, cell-culture DNA and RNA. These sequences were provided by the WHO Global Programme on AIDS Vaccine Development Study. The complete set of C2V3 region WHO sequences can be found in the April 1994 supplement to the *Human Retroviruses and AIDS 1993* database. [De Wolf et al.(1994)]; [Osmanov et al.(1994)]; [Gao et al.(1994a)]. GenBank accession numbers U08715–U08718, U08801–U08802, and U08783–U08784.

92) **TH4.ID#:** These twelve sequences are B subtype sequences from Thailand. Ten were genetically most similar to HIV-1 found in the Americas and Europe; these sequences were derived from people infected prior to 1988 (diagnosed in 1986 or 1987). The other two (N762 and N763) were designated B' and were isolated from people with more recent infections, 1988 and 1992. The sequences were obtained from PCR amplified PBMC DNA. The naming of the sequences submitted to GenBank does not correspond with the naming of the sequences in the paper. [Kalish et al.(1994)]. GenBank accession numbers for the entire set of thirteen sequences studied in this publication: U15576–U15588.

93) **TH5.ID#:** These three sequences are B subtype sequences from Thailand. Two individuals believed to be dually infected with subtypes B and E were analyzed. It is not clear from the paper or the GenBank entries, which sequences came from individual 1 and which from 2. [Artenstein et al.(1995)]. Genbank accession numbers U21471, U21473, U21475. See also E_TH6.ID#.

94) **TH6.ID#:** These 4 entries are from 1992 dried blood spot samples from Thailand. DNA was extracted from the blood spots and PCR amplified. The PCR products were directly sequenced. Samples came from 3 previously identified HIV seropositive IV drug users (58, 11, 15) and a homosexual (86). Other samples from the same region were all subtype E (see E_TH8.#). [Cassol et al.(1996)]. GenBank accession numbers U53310, U53311, U53314 and U53315.

95) **TH7.ID#:** These 70 sequences are from IV drug users in Bangkok, Thailand, who were undergoing methadone treatment at 14 treatment clinics. Blood samples were collected between January and April, 1994. Uncultured PBMC DNA from each patient was PCR amplified, and the PCR product was directly sequenced (except for patient 108, in which PCR product was cloned and 2 clones were sequenced, one shown here). Of the 84 patients sampled, 69 were Thai B, one (091) was typical subtype B, and 14 were subtype E. [Kalish et al.(1995)]. GenBank accession numbers U22543–U22547, U22549–U22552, U22554–U22556, U22558–U22560, U22562–U22566, U22568–U22574, U22576–U22603, U22605–U22608, U22610, U22613–U22616, U22618–U22623 and U22626. See also E_TH9.

96) **TT.QZ5489:** This sequence is from Trinidad. W. Blattner et al. Unpublished 1995. Genbank accession number U32396.

97) **TW1.ID#:** These 16 sequences are from healthy HIV-1 carriers or AIDS patients from Taiwan [Chang et al.(1996)]. Three subtype B sequences in this set were greater than 97% identical to the HXB2/LAI lab strain (see B_FR.LAI) of HIV-1, and are not included here (TW83, U73049; TW271, U73059; and TW335, U73061). The manuscript reports that 123 of 143 sequences from Taiwan were subtype B, but only 27 of the 143 sequences were submitted to the sequence databases. Other subtypes found in Taiwan in this study were E (17 cases), C (1 case), F (1 case) and G (1 case). GenBank accession numbers for B subtype are U73045–U73054, U73056, U73057, U73059, U73061 and U73063–U73069.

98) **US.ACP1:** This virus was cultured from a seronegative man with Kaposi's sarcoma. (See: [Ho et al.(1989)]). ACP1 was the sequenced after one passage in PBMCs. GenBank accession number M80660. The sequence AC-H9 (GenBank M80661) was also derived from this patient. [Ashkenazi et al.(1991)].

99) **US.ADA:** This sequence is from the monocytropic U.S. isolate ADA. [Westervelt et al.(1991)]. GenBank accession number M60472.

100) **US.ALA1:** This sequence is from an infectious clone of the 1985 U.S. isolate AL-1, taken from a patient with AIDS. Buckler-White, A. et al., Unpublished (1988). GenBank accession number M38430.

101) **US.BAL1:** This sequence is from the macrophage tropic U.S. isolate BAL, harvested from lung alveolar tissue. Reitz M, et al., Unpublished (1990). GenBank accession numbers M68893, M68894. GenBank entry M63929 is 98% identical to this sequence and is also derived from the BAL isolate [Hwang et al.(1991)].

102) **US.BCSG3:** This is a fragment of a full genomic sequence from the provirus SG3, cloned as a single proviral unit. This clone replicates more efficiently in chimpanzeee than in human lymphocytes, and is extremely cytopathic in immortalized human T-cell lines. [Ghosh et al.(1993)]. GenBank accession number L02317.

103) **US.BRVA:** This sequence is from U.S. isolate BRVA, which was taken from the brain tissue of a AIDS patient with neurological disorders. [Anand et al.(1989)]. GenBank accession number M21098.

104) **US.BWB:** This consensus sequence is from sequences derived from PCR amplified PBMC DNA from brain tissue. [Monken et al.(1995)]. GenBank accession numbers L17088–L17126.

105) **US.CDC42:** This sequence is from an infectious clone of the U.S. isolate CDC-451. [Desai et al.(1986)]. GenBank accession number M13137.

106) **US.Diaz:** This sequence is one of a set of 124 closely related sequences. All 124 sequences came from patients who had been infected by a common source. Unpublished (1995) Diaz,R., Zhang,L., Busch,M., Mosley,J. and Mayer,A. Genbank accession numbers for all 124 sequences are U29433–U29437, U29956–U30054, and U43035–U43054. Gag sequences from 12 clones are also available in GenBank entries U31573–U31584.

107) **US.JFL:** This sequence is from a non-infectious clone from the monocytropic U.S. isolate JFL. [McNearney et al.(1990)]. GenBank accession number M31451. Other sequences from HIV-1 isolates epidemiologically linked to this isolate can be found in GenBank entries with accession numbers L06256–L06273. [McNearney et al.(1993)].

108) **US.JM:** This sequence, along with B_US.WM, came from viral isolates after short term culture in PBMCs, PCR amplification, and cloning of PCR products. Both are from asymptomatic, seropositive individuals. [Ashkenazi et al.(1991)]. GenBank accession number M80662.

109) **US.JRCSF:** This sequence is from an infectious clone of the 1986 U.S. isolate JRCSF, derived from from the CSF of a patient who died with Kaposi's sarcoma and severe AIDS encephalopathy. The infectious clone JRFL was isolated from the brain of the same patient. [O'Brien et al.(1990)]. GenBank accession numbers U63632, M38429, U45960. Also see: [Pang et al.(1991)], [Klasse et al.(1996)].

110) **US.MN:** This sequence is from 1984 U.S. isolate MN, taken from a 6 year old male pediatric AIDS patient from the Newark, New Jersey area in 1987. His mother was an IV drug user who died of pneumonia in 1982. His father was also HIV seropositive. A complete genome of isolate MN is found in M17449. Other sequences from this patient from the 1984 blood sample and from a 1987 sample taken shortly before death (U72495) are available also. [Jr et al.(1992)] [Gurgo et al.(1988)]. GenBank accession number M17449. See also L48364–L48379 [Lukashov & Goudsmit(1995)].

111) **US.NY5CG:** This sequence is from the 1984 U.S. isolate NY5. [Willey et al.(1986)]. GenBank accession number M38431. See also GenBank accession number K03346. A recombinant between NY5 and LAI has also been extensively studied, see B_FR.LAI entry.

112) **US.P896:** This sequence represents a molecular clone from an primary isolate derived from a Jamaican man who immigrated to Philadelphia 15 years earlier. At the time of viral isolation, he had no antiviral therapy, but was an AIDS patient with $<$ 10 CD4 cells per mm3. The infectious molecular clone from which this sequence was derived is both macrophage-tropic and extremely cytopathic in lymphocytes. [Collman et al.(1992)] and [Kim et al.(1995)]. GenBank accession numbers M96155, U39362.

113) **US.RJS:** This is a consensus of six biologically characterized clones from patient RJS, isolate 4. The HIV-1 infected individual had been infected for five years at the time of isolation. Complete env sequence is available. [Daniels et al.(1991)] and [Fisher et al.(1988)]. GenBank accession numbers M37491 and M37573–M37577.

114) **US.SB(A-C):** These three sequences are from 1988 U.S. isolates taken from a woman, her daughter and her sexual partner. The three viruses are epidemiologically linked, however the amino acids sequences appeared sufficiently divergent in this region to merit the inclusion of all three samples. Sequences were directly sequenced from PCR amplification products after the virus was briefly cultured. [Burger et al.(1991)]. GenBank accession numbers M77228–M77230.

115) **US.SC:** This sequence is from the 1984 U.S. isolate SC, from an AIDS patient. [Gurgo et al.(1988)]. GenBank accession number M17450.

116) **US.SF128:** This clone was isolated from the spinal cord tissue of a patient with dementia, after coculture with PBMCs, and infects macrophages but not T-cells [Liu et al.(1990)]. GenBank accession numbers M95292 and M38673. The ability to infect macrophages vs. HUT 78 cells was mapped to the region

between a StuI site in env and a XhoI site in nef, by replacing this region in SF2 with the same region from SF128.

117) **US.SF162:** This sequence is from an infectious clone from the U.S. isolate SF162, cultured from the cerebrospinal fluid of a patient with toxoplasmosis. [Cheng-Mayer et al.(1990)]. GenBank accession numbers M38428, M65024.

118) **US.SF2:** This sequence is from an infectious clone from the U.S. isolate ARV-2. ARV-2/SF2 was isolated from a patient with oral candidiasis after co-culture with mitogen-stimulated PBMCs in 1984 [Levy et al.(1984)]. [Sanchez-Pescador et al.(1985)]. GenBank accession numbers K02007 and I07977. HIVSF13 (GenBank accession number L07422) is a more infectious virus taken from the same patient five months later, when he had developed Kaposi's sarcoma and Pneumocystis carinii pneumonia [Cheng-Mayer et al.(1991)]. SF2 and SF13 are 98% identical to one another.

119) **US.SF33:** This sequence is from an infectious clone from the 1984 U.S. isolate SF33. [York-Higgins et al.(1990)]. GenBank accession number M38427.

120) **US.TN-ID#:** These eight sequences are from asymptomatic individuals identified after donating blood in Memphis, Tennessee, USA. [Slobod et al.(1994)]. GenBank accession numbers U09140–U09175.

121) **US.twinABcon:** This sequence is a consensus of a set of 27 env sequences from a pair of heterozygotic perinatally HIV-1 infected twins who were observed during their first 2 years of life. Twin A remained asymptomatic through her first 2 years while twin B developed AIDS at six months and died at 22 months of age. Patient PBMCs were cocultured with donor PBMCs, prior to DNA extraction and PCR amplification. Approximately 500 copies of HIV proviral DNA per PCR reaction were used. PCR products were cloned prior to sequencing. Viral phenotypes from both infants, and all time points were also assessed. All were found to be non-syncytium inducing, but they differed in their ability to infect primary macrophages. Overall, it seems that the production of neutralizing antibodies by the healthy twin was the most important clinical factor. [Hutto et al.(1996)]. GenBank accession numbers U47562-U47588 for the envelope sequences and U47589-U47613 for tat sequences from the same blood samples.

122) **US.WM:** This sequence, along with B_US.JM, came from viral isolates after short term culture in PBMCs, PCR amplification, and cloning of PCR products. Both are from asymptomatic, seropositive individuals. [Ashkenazi et al.(1991)]. GenBank accession number M80663.

123) **US.WMJ22:** This sequence is from the isolate WMJ22, isolated from a person of Haitian descent living in the U.S. Virus was cocultured on an immortalized T-cell line. [Hahn et al.(1986)] and [Starcich et al.(1986)]. GenBank accession numbers M12507, K03457.

124) **US.WR27:** This sequence is from a complete genome. It represents first complete PCR-derived sequence of a U.S. clinical isolate of genotype B expanded only in primary PBMC. This provirus harbors a uniquely truncated V3 loop. [Salminen et al.(1995)]. GenBank accession number U26546.

125) **US.YU:** This is a consensus sequence of eight lambda phage clones and 12 PCR amplified clones derived from the uncultured brain tissue of a patient with AIDS dementia complex. A macrophage tropic clone (YU-2) is almost identical to the consensus sequence of YU in this region, with only a single amino acid change (K to N) 10 amino acids from the carboxy-terminal end of the sequence. [Li et al.(1991)]. Complete genomic sequences are available for two of the HIV1YU clones, along with biological characterizations of four of the HIV1YU clones: [Li et al.(1992)]. The GenBank accession numbers for the YU-10 and YU-2 complete genomes are M93259 and M93258, respectively. GenBank accession numbers for the other clones are M89972–M89984.

126) **US1.HC-ID#:** These are forty 1990–1991 U.S. samples, from the study of the dentist who was thought to have been the source of HIV-1 infection of six of his patients. Only the dentist's viral sequence and the Florida control sequences are shown here; the six epidemiologically and genetically linked patients are excluded from this alignment because their viral sequences were very similar to the dentist's. All sequences were PCR amplified from patient PBMCs. Most are direct sequences from the amplification products, although some are consensus sequences of multiple clones of PCR products and one direct sequence. [Ou et al.(1992a)]. GenBank accession numbers for the 75 sequences in this set: M90847–M90853, M90881–M90886, M90894–M90900, M90907–M90912, M90914–M90956, M90958–M90964, M92100–M92133, L22590–L22606 and U06872-U06919. See also [Korber & Myers(1992)], [Crandall(1995)], [Smith & Waterman(1992)], [DeBry et al.(1993)], [Palca(1992b)], [Palca(1992a)], [Abele & DeBry(1992)], [Hillis & Huelsenbeck(1994)], [Ciesielski et al.(1992)] and [Ciesielski et al.(1994)].

127) **US2.D-ID#:** These 15 sequences are from the USA, and are part of a set of sequences generated as part of the DAIDS variation program in the laboratory of Dr. Marcia Kalish at the the Centers for Disease Control, Atlanta, GA. The C2V3 region was directly sequenced from PCR amplification products of DNA from viral culture. The sequence ID numbers are abbreviated, for example D2US711 can be read as DAIDS sequence (D), isolated in 1992 (2), United States (US), patient 301711 (711). A full description of these sequences can be found in the April 1994 supplement to the HIV database, part III. Full length envelope genes from some of these clones have been expressed, [Gao et al.(1996a)]. GenBank accession numbers U04907–U04915, U04918 and U04921–U04925, U08448–U08452.

128) **US3.D-ID#:** These four sequences are from the US, and are part of a set of sequences generated as part of the DAIDS variation program in the laboratory of Dr. Beatrice Hahn at the University of Alabama. gp160 sequences of clones from expanded culture stocks are available. The sequence ID numbers are abbreviated, for example D2US711 can be read as DAIDS sequence (D), isolated in 1992 (2), United States (US), patient 301711 (711). A full description of these sequences can be found in the April 1994 supplement to the HIV database, part III. GenBank accession numbers U08448–U08449 and U08451–U08452. GenBank accession numbers for additional clones from these patients: U04916–U04917 and U04919–U04920,

129) **US4.ZhuPt-ID#:** Sequences from five primary seroconverters. Consensus, PCR-clones, peripheral blood PBMC DNA. Although sequences were also available from two of the donors, only sequences from five recipients are shown here. [Zhu et al.(1993)]. GenBank accession numbers L21224–L21324, L21372–L21373, L21376–L21377, L21380–L21381, L21384–L21389, L21393–L21394, L21397–L21398, L21400–L21401, L21404, L21405, L21408, L21410–L21411, L21414, L21417–L21418, L21426–L21427, L21430–L21432, L21434–L21437, L21440–L21442, L21445, L21447, L21449–L21450, L21453–L21454, L21457, L21459, L21462–L21463, L21519–L21520, L21522–L21523, L21525–L21526, L21528–L21533, L21535–L21536, L21538–L21539, L21541, L21543, L21545–L21546, L21548, L21550–L21551, L21553–L21554, L21556, L21558–L21559, L21561–L21569, L21571–L21578, L21580, L21582, L21584, L21586, L21588 and L21590.

130) **US5.pt-ID#:** A consensus of PCR-clones, peripheral blood DNA. These two sequences were part of a study of blood sequences compared to brain sequences from six individuals. [Korber et al.(1994)]. GenBank accession numbers U05360–U05568.

131) **US6.-ID#:** Each sequence is a consensus sequence of several cloned PCR products from PBMC proviral DNA from an individual infant. These sequences were part of a study of mother-infant transmission. Infant blood samples were taken from 1 week (infant 7) to 34 months (infant 4) post-partum. Dates of sample collection were: Infant 1, 10/25/91; Infants 2–4, 10/31/91; Infant 5, 2/6/92; Infant 6, 8/30/93; Infant 7 5/13/93. Maternal sequences were also reported as part of this set, but are not used in building these consensus sequences. [Ahmad et al.(1995)]. GenBank accession numbers U16390–U16652.

132) **US7.-ID#:** Each sequence is a consensus sequence of several cloned PCR products from PBMC proviral DNA from an individual patient. These sequences were part of a study of early samples (1984-1986) from the San Francisco region. One of the samples (552-3) was HIV negative but was determined to be contaminated with blood from another (565-3) so the six samples from 552-3 and 565-3 are made into one consensus here (565). Another sample (552-5) from patient 552 was not contaminated, and it is presented as B_US11.552, because a larger region was reported in that publication. [Sabino et al.(1994b)] GenBank accession numbers L20371–L20380. More V3 and tat sequences from these individuals are discussed in [Sabino et al.(1994a)]. GenBank accession numbers U00243–U00399 and U01513–U01529.

133) **US8.-ID#:** These sequences were from a study of three recipients of contaminated blood. Recipient 1 (R1) and recipient 2 (R2) each received blood from different donors. A third recipient, not presented here, received blood from both donors. All three recipients were neonates. R1 received erythrocytes from donor 1 on 19 October, 1984 at the age of 3.5 weeks. For R1 the sequence of one of the two clones (2E) is presented here. R2 received erythrocytes from donor 2 on 24 September, 1984 at the age of 2 months. For R2 a consensus of 6 clones is presented here. Blood samples for this study were drawn in March 1986. R1 had slow weight gain, and R2 had lymphadenopathy at time of sample collection. [Diaz et al.(1995)]. GenBank accession numbers U11188 = R1–2E, U11189 not used; U11203, U11196, U11199, U11192–U11194 = R2 six clones. The tat and envelope V4-V5 regions of clones from these same individuals are also available in U11173–U11178, U11180, U11205–U11209.

134) **US9.-ID#:** These are consensus sequences for samples taken over a range of time from four different subjects. Blood samples for S1 were drawn in Nov '85, Jul '87, Jan '88 and May '89. Blood samples for S2 were drawn in May '85, Apr '87 and Oct '87. Blood samples for S3 were drawn in Jun '87 and Dec '87. Blood samples for S4 were drawn in Jan '85, Jan '89 and Jun '89. S2, S3 and S4 had decreasing CD4 counts during the study period. S1 had fluctuating CD4 counts. [McNearney et al.(1992)]. GenBank accession numbers L03430–L03453 and L23575–L23588 = S1; L03454–L03477 and L23618–L23633 = S2; L03478–L03490 and L23589–L23600 = S3; L03491–L03515 and L23601–L23617 = S4.

135) **US10.ID#:** These three consensus sequences are from sets of sequences used in a study on the dynamics of HIV sequence changes in vivo and the utility of heteroduplex analysis. All sequences were derived from PCR amplified PBMC DNA. The MA145 consensus represents sequences (GenBank accession numbers U00821, U00822, U00831–U00839) taken from an asymptomatic male from Massachusetts over a period of 4.5 years starting April 1989. Patient MA, from the US, was infected in 1984 or 1985, and had been experiencing neurological disorders prior to 1989 [Kusumi et al.(1992)]. The SFBU and SFPE consensuses represent sequences (GenBank accession numbers U13373–U13380 and U13381–U13388 respectively) taken from two patients with AIDS from San Francisco. [Delwart et al.(1994)]. Other sequences from patient MA can be found in GenBank entries with accession numbers U00804–U00822, U00831– U00850, U00873–U00888, M79342–M79354 and M90025–M90046. Other SFBU sequences can be found in U13240–U13252. See also NL7.ID#.

136) **US11.ID#:** These four consensus and seven individual sequences came from patients early in infection, before, or around the time of seroconversion. Sequences for 306, 419, 349, and 074 are consensus sequences. [Shpaer et al.(1994)] and [Delwart et al.(1995)]. GenBank accession numbers U23664–U23666, U23668, U23669, U23671–U23708, L20381. See also B_NL8.ID#.

137) **US12.ID#:** These sequenses were used in an investigation into the transmission of HIV-1 from one child (CHA), who had received zidovudine, to another child (CHB), who harbored a zidovudine-resistant strain. The presence of the zidovudine-resistant strain in child 1 and 2, and the lack of such a strain in child 2's mother was used to show that child 2 was infected by child 1 and not by child 2's mother. LC sequences are from children used as local controls. All sequences were derived from PCR amplified PBMC DNA. [Fitzgibbon et al.(1993)]. GenBank accession numbers L12751–L12756, L19695, L19697, S66942. L12756 is listed as "isolate 100" in GenBank, but seems to be the "group B consensus sequence" used for phylogenetic analysis.

138) **US13.ID#:** These three consensus sequences are from three IV drug users in Florida. Proviral DNA sequences were obtained from blood, cerebrospinal fluid and dorsal root ganglia from each of the three individuals. Sequences for V1-V5 of env, were PCR amplified, cloned and sequenced. [Shapshak et al.(1995)]. [Xin et al.(1995)]. The sequence for patient 149 is a consensus of all 24 clones in GenBank accession numbers U16094–U16117. The sequence for 141 is a consensus of GenBank entries labelled as being from patient 141 with the exception of: R5D, R6D, R7D, R2D and R4D, which were similar to IIIB strains of HIV-1; and R1R, R3R, R7R, R8R and R9R, which were similar to samples from patient 144. The sequence for 144 is a consensus of GenBank entries labelled as being from patient 144 with the exception of: R3R, R6R, R9R, R12R, R13R and L1D, which were similar to IIIB strains of HIV-1; and C3D, C4D, C7D, C8D and C10D, which were similar to samples from patient 141. While infection of each individual with multiple strains of HIV (including one very similar to the IIIB lab strain) is a possible explanation of these findings, we are only including one consensus sequence from each patient for this alignment. The authors are currently (1996) resequencing new samples from these patients. GenBank accession numbers for patients 141 and 144 are U16032–U16093.

139) **US14.ID#:** These four sequences are from DNA from PBMC. [Mascola et al.(1994)]. GenBank accession numbers L14573–L14576. See also B_TH2, E_TH2.

140) **US15.ID#:** These six consensus sequences are from a study of infants. Blood samples were collected from six infants over time. [Strunnikova et al.(1995)]. GenBank accession numbers U22682–U22810, U22834 and U22835.

141) **US16.ID#:** These two consensus sequences were used in a study of the impact of sequence variation on the distribution and seroreactivity of linear antigenic epitopes. Both sets of sequences were from PCR amplified DNA from peripheral blood leukocytes. Patient ARTC1 was an asymptomatic individual from New York and ARTC3 was an AIDS patient from New York. [Pestano et al.(1995)]. GenBank accession numbers U11586–U11594. See also A_UG1.964, C_UG1.45, and D_UG7.ID#.

142) **US17.ID#:** CB7 is a consensus sequence for 12 clones from two different samples (six clones each) from the same patient, collected in 1988 and 1990, plus two more clones as yet unpublished. The patient seroconverted in 1985. The patient did not receive any antiviral therapy until 1992. The patients CD4 count was 1035 in 1988 and 807 in 1990. The patient's PBMS were cocultured with donor PBMC for an unspecified length of time before cultured DNA was isolated and PCR amplified. Individual clones of PCR product were then sequenced. [Wang et al.(1995)]. GenBank accession numbers U16324–U16335 and U19706–U19711. The other 8 sequences are individual clones from 8 different patients, all from the same clinic in Boston, MA. Individual CB7 was again included in this study, [Wang et al.(1996a)] [Wang et al.(1996b)]. GenBank accession numbers U60152–U60162 and U27658–U27669.

143) **US18.ID#:** These 22 sequence are from a study of a HIV-1 infected dentist and many of his HIV-1 infected patients. In this case, no evidence was found for dentist to patient, patient to dentist, or patient to patient transmission. [Jaffe et al.(1994)]. GenBank accession numbers U11454–U11490. Unfortunately the dentist sequences are not available from GenBank.

144) **US19.ID#:** These two sequences are from a comparison of a mother who transmitted HIV to her infant and a mother who did not. One of the sequences (nontransmitter-283 accession number U07839) was 99.4% identical to the LAI strain of HIV-1 and is not included here. Sequences from the transmitter and nontransmitter were highly similar with the exception of sequence nontransmitter-217 (U07836). Thus a consensus of the similar sequences is included here as VA1-consensus, and the nontransmitter-217 outlyer is presented seperately as VA2. [Ayyavoo et al.(1996)]. GenBank accession numbers U07833–U07841 and U07891–U07917.

145) **US20.ID#:** These three sequences are from a study of mother-infant transmission. Only child consensus sequences are used here, but mother and child clonal sequences are reported in [Roth et al.(1996)]. Proviral DNA was PCR amplified from uncultured patient PBMCs. Cloned PCR products were sequenced. Child 1 was 27 months old, child 2 was 5 months old and child 3 was 21 months old when blood was drawn for sequencing. Sequences, including those from the mothers, are in GenBank entries with accession numbers U47745–U47807.

146) **US21.ID#:** These six sequences are from six different patients, all men from the Chicago, Illinois, USA MACS cohort. In the study, P1 & P2 were rapid progressors, P3 & P4 normal progressors, and P5 & P6 non-progressors. Their estimated years of seroconversion are as follows: P1, 1985; P2, 1985; P3, 1986; P4, 1986; P5, 1985; and P6, 1984. A total of 292 sequences of the C2-V5 region of envelope were completed. In the database entries the sample numbers are of the form Px.y-z, where x stands for the patient number, y is the number of months after the estimated date of seroconversion, and z is the clone number. Each of the six sequences presented here is a consensus of all clones from that patient. [Wolynsky et al.(1996)]. GenBank accession numbers U35895–U36185.

147) **US22.ID#:** These 12 sequences are from a study of variability of tat and env genes. Lorenzo et al (1996) Unpublished. GenBank accession numbers U57104–U57216. Tat sequences from these clones are also available (U57217–U57304).

148) **US23.ID#:** These 3 sequences are from a study of variability of vif and env genes. [Sova et al.(1995)]. Uncultured or short-term cultured PBMC proviral DNA was PCR amplified, and several clones from each PCR reaction were sequenced. Only one clone sequence from each patient is presented here. GenBank accession numbers U50615–U50628. Vif sequences from these patients are also available (U41055, U41056, U41179–U41182 and U42229–U42282).

149) **US24.ID#:** These 5 sequences are from unpublished GenBank entries by Schwartz et al. GenBank accession numbers U49518–U49640, U51311–U51326 and U45860–U45876.

150) **VE.ID#:** These 8 sequences are from 8 individuals in Venezuela. Patient PBMCs were cocultured with donor PBMCs. Proviral DNA was harvested PCR-amplified. PCR products were directly sequenced. Nearly complete env gp120 sequences were determined, as well as pol gene sequences. [Quinones-Mateu et al.(1995)]. GenBank accession numbers U16764–U16778, even numbers are env, odd numbers are pol.

151) **VN1.HCM9:** This sequence is from South Vietnam. [Menu et al.(1996)]. The sequence is from Ho Chi Minh city, from a woman infected by her HIV seropositive sexual partner who was thought to have been infected while traveling in Europe. Three other sequences in this study were found to be subtype E. Genbank accession number U29209.

152) **ZA.ID#:** These 7 sequences are from 7 individuals in South Africa. ZA504 was from a 33 year old white male homosexual with AIDS and the virus was syncytium-inducing (SI). ZA508 was from a 32

year old white male bisexual with ARC and the virus was NSI. ZA509 was from a 30 year old white male homosexual with AIDS and the virus was SI. ZA524 was from a 49 year old white male bisexual with AIDS and the virus was NSI. ZA510 was from a 29 year old white male heterosexual with ARC and the virus was SI. ZA512 was from a 26 year old white male homosexual with ARC and the virus was SI. ZA513 was from a 3 year old black male blood transfusion recipient with AIDS and the virus was SI. All samples were collected at the Tygerberg Hospital in the Western Cape region of South Africa between 1984 and 1992. DNA was harvested from cocultured PBMCs and the env gene was PCR amplified and cloned into pBSKS+ for sequencing. Each sequence is from a single cloned PCR product. [Engelbrecht et al.(1995)]. GenBank accession numbers L48063–L48066, L48069, L48071 and L48073. GenBank entries U33770 and U33774–U33779 are shorter env gene fragments from these same clones.

C Subtype

At this time there are viral sequences from 119 HIV-1 infected individuals associated with HIV-1 subtype C. The C subtype consensus sequence (C_CONSENSUS_96) generated from these sequences was based on the most common amino acid found in each position of an alignment. All of these sequences have been published and/or have been made available for printing in the database by their authors.

1) **BR.W2BR025:** This sequence is part of a gp160 sequence from an asymptomatic individual from Brazil, sampled in 1992. A clone was derived from an expanded viral culture, expressed and sequenced. This sequence was provided by the WHO Global Programme on AIDS Vaccine Development Study. The complete set of C2V3 region WHO sequences from this patient can be found in the April supplement to the Human Retroviruses and AIDS 1993 database. Relevant papers are: [De Wolf et al.(1994)]; [Osmanov et al.(1994)]; [Gao et al.(1994a)]. GenBank accession number U15121. Entries with accession numbers U08720, U08785, U09126, U09132 and U09133 are also from W2BR025.
2) **BR1.HSP203** Although this sequence is listed as unpublished in the database, it seems to be an extension of work published in [Morgado et al.(1994)] and [Sabino et al.(1994c)]. It is from San Paulo, Brazil. GenBank accession number U31585.
3) **BR2.91BR015:** This sequence is from Brazil. It is one of several complete env gene sequences obtained for the World Health Organization. HMA subtyping as well as sequence-determined subtyping was done on each one. Sequences were PCR amplified from cocultured PBMCs. Two to three clones from each isolate were sequenced. 91BR015 is similar to another WHO sample; 92BR025. [Penny et al.(1996)]. GenBank accession numbers U39234 and U39238.
4) **BU1.ID#:** These sequences are from Burundi. They are part of several complete env gene sequences obtained for the World Health Organization. HMA subtyping as well as sequence-determined subtyping was done on each one. Sequences were PCR amplified from cocultured PBMCs. Two to three clones from each isolate were sequenced. 91BU009 groups with subtype D in a neighbor- joining tree of the V3 region and is presented as an undetermined subtype in the section of the compendium. [Penny et al.(1996)]. GenBank accession numbers U39252 and U39233, 91BU001; U39248 and U39237, 91BU002; U39239 and U39242, 91BU003; U39241 and U39243, 91BU004; U39240 and U39257, 91BU005; U39244 and U39246, 91BU006; U39245, U39247 and U39249, 91BU007; U39250 and U39251, 91BU008; U39253 and U39254, 91BU009.
5) **BY1.ID#:** These 3 sequences are from Byelorussia. [Lukashov et al.(1995)]. GenBank accession numbers: L38410, BLR9A; L38409, BLR8A; L38408, BLR5A.
6) **CF1.15166:** A single sequence from a set of sequences obtained from 27 symptomatic patients from the Central African Republic, from whom blood was drawn in 1990–1991. It is a consensus from PCR clones from cultured proviral DNA. [Murphy et al.(1993)]. GenBank accession number L11525. Other sequences from this study were subtypes A and E.
7) **CY.HO02:** This is a sequence from a 51 year old woman whose husband had died of AIDS. She was born and lived in Zambia, before moving to Cyprus. She was asymptomatic, with a CD4 count of 200, and she had been seropositive for at least 6 years. This sample, like others in this study (see also subtypes A, B, F and I) was collected in February 1994 from the AIDS clinic in Nicosia, Cyprus. DNA was extracted from patient PBMCs and PCR amplified. After a second round of PCR, products were cloned and sequenced. Two clones from patient 02 were sequenced. [Kostrikis et al.(1995)]. Genbank accession numbers U28321 and U28661.
8) **DJ1.DJ-ID#:** These two sequences from Djibouti were from a a set of HIV-1 viral isolates from Africa. Health status of the individual from which the virus was cultured was unspecified, and the year of viral isolation was probably between 1989–1992. Viruses were cultured with donor PBMCs for 2 to 3 weeks. Full length env (gp160) was amplified, cloned and sequenced. [Louwagie et al.(1995)]. GenBank accession numbers L22940 and L23065.
9) **ET2.ID#:** These nine sequences of Ethiopian isolates were part of a cohort considered to be heterosexually infected. PBMC DNA was PCR amplified and directly sequenced. [Salminen et al.(1996)]. For patient 2220, who had slim disease and AIDS, almost full length HIV-1 genome was PCR amplified from PBMC DNA and cloned. Proviral DNA from others in the cohort was PCR amplified and directly sequenced. Other regions of the genome are available for these isolates as well. [Salminen et al.(1996)]. GenBank accession numbers U45481–U45502 (V3 region), U15060–U15066 and U45503–U45504 (LTR NF-kB/NRE regions), M64001–M64009 (gag p7 region), M64015–M64018 (env gp41 region) and U46016 (C2220 complete genome).

10) **GA1.ID#:** These 2 sequences are from Gabon. G134 is from a 1988 or 1989 sample from a patient with AIDS living in Franceville, Gabon. LBV105 is from a 1988 sample from an asymptomatic individual sampled from the general population of Libreville. Method of proviral DNA isolation was not described. DNA was PCR amplified and cloned. One clone per isolate was sequenced. [Delaporte et al.(1996)]. GenBank Accession numbers X90912, G134; X90913, LBV105. See also subtypes A, D, F, G and O sequences from this same study.
11) **GB1.00513:** This sequence is from the British isolate 93–00513. [Arnold et al.(1995c)]. GenBank accession number U21099.
12) **GM.GM3:** A sequence from Gambia, as yet unpublished. Bobkov et al. 1996 unpublished. GenBank accession number U33098. See also Gambian sequences of subtypes B and J.
13) **IN1.D-ID#:** These four sequences are from samples from high risk patients in India, PCR clones, DNA, PBMC culture. [Dietrich et al.(1993)]. GenBank accession numbers L07651 and L07653–L07655; X65638–X65640 and X68406.
14) **IN2.D-ID#:** These five sequences are from samples from high risk patients in India, primarily stage I. They were nested PCR amplified from DNA obtained from uncultured PBMC from patients serologically defined as HIV-1/HIV-2 mixed infections. [Grez et al.(1994)]. GenBank accession numbers U07098 and U07100–U07103.
15) **IN3.IN#:** These 8 sequences sequence were isolated from Pune and New Delhi, India. All 8 sequences were from heterosexually infected patients from New Delhi, or Pune, India. DNA was isolated from cocultured PBMCs after one week of culture. PCR product was cloned and a single clone was sequenced. [Tripathy et al.(1996)]. GenBank accession numbers U29179, U29694–U29698, U31362 and U31363. See also B_IN.IND9.
16) **IN4.ID#:** These 24 sequences are from 1992 dried blood spot samples from Vellore near Madras, in Tamil Nadu state in southern India. DNA was extracted from the blood spots and PCR amplified. The PCR products were directly sequenced. Samples came from previously identified HIV seropositive STD patients (1, 3, 5, 6, 7, 11, 12, 13, 19, 20, 23, 29, 33), spouses of infected men (2, 4, 10, 16, 22, 26, 27), female prostitutes (36, 37) or bisexual men (8, 32). Two homosexual men from the same region had subtype A HIV-1 (see A_IN1.9 and 14). [Cassol et al.(1996)]. GenBank accession numbers U53278–U53285, U53287–U53290, U53292–U53303.
17) **KE.NA113:** This sequence was derived from a patient who was part of a May-June 1992 study of pregnant women from the Pumwani Maternity Hospital in Nairobi, Kenya. Viral RNA was concentrated from patient serum just prior to delivery, and the envelope C2-V3 region was amplified by RT-PCR. The PCR product was cloned and 20 clones from the patient were sequenced. Seven other patients from this study had viral subtypes A and D. [Zachar et al.(1996a)]. Genbank accession number U33762.
18) **MW.SM750:** This sequence is from cloned PCR amplified cocultured PBMC DNA. SM750 was a black male sampled in the gold mines in Malawi in 1989. [Becker et al.(1995)]. GenBank accession number U06719.
19) **MW1.ID#:** These 13 sequences are from pregnant women with risk factors from Malawi. PCR-direct, peripheral blood DNA. [Orloff et al.(1993)]. GenBank accesssion numbers L07427–L07441, L15721–L15735.
20) **MW2.D-ID#:** These two sequences are from individuals from Malawi, generated as part of the DAIDS variation program in the laboratory of Dr. Beatrice Hahn at the University of Alabama. The C2V3 was excised from full gp160 sequences, derived from clones from expanded culture stocks. The sequence ID numbers are abbreviated, for example D3MA959 can be read as DAIDS sequence (D), isolated in 1993 (3), Malawi (MA), patient 301959 (959). GenBank accession numbers U08453–U08454.
21) **MY.ID#:** These 2 sequences are from IV drug using prisoners in a prison in Kuala Lumpur, Malaysia. PCR products amplified from uncultured PBMCs were directly sequenced. Both of these prisoners had received medical treatment in India which included blood transfusion and organ transplants, and it is likely that they were infected in India. [Brown et al.(1996)]. This report also included subtypes B and E in Malaysia. GenBank accession numbers U65549–U65550.
22) **NL1.ID#:** These 2 sequences are from a Dutch woman whose partner was a recent immigrant to The Netherlands from Zaire, and from a recent immigrant to The Netherlands from either Zambia or Zaire. The fist two letters of the ID# represent the two letter country code for the previous residence of the patient (UN = unknown). The next two numerals represent the year of isolation. Viral RNA was prepared

from patient serum and RT-PCR was used to amplify the V3 region of the env gene. The PCR products were directly sequenced. The sequence from the Dutch/Zaire patient is not unequivocably a subtype C sequence, it may be subtype A or unclassifiable. [Lukashov et al.(1996)]. GenBank accession numbers L76908, NL9402418; L76898, UN9305091.

23) **NO1.ID#:** These 4 sequences are from unpublished Norwegian sequences with Genbank accession numbers X92913, X92914, X92917 and X92918. Thirty-six subtype B sequences were also part of this set (see B_NO1.ID#:).
24) **RU.ID#:** These 4 sequences are from Russia. [Lukashov et al.(1995)]. GenBank accession numbers: L38418, RUS20A; L38404, RUS2A; L38406, RUS1A; L38414, RUS13A.
25) **RU1.ID#:** This sequence is from Russia. Bobkov et al. 1996 Unpublished. GenBank accession number U33109.
26) **RW1.ID#:** These two sequences are consensus sequences of many clones from mothers infected in Rwanda. Mulder-Kampinga et al., Unpublished (1996). Mother 566 was apparently dually infected with HIV-1 subtypes A and C. See also A_RW4.ID#. GenBank accession numbers for mother 566 are Z76183, Z76188–Z76197, Z76284–Z76293, Z76295–Z76299, Z76301, Z76303–Z76311, Z76322–Z76342 and Z76725–Z76732; for mother 134, Z76039–Z76042 and Z76044.
27) **SN.SE364:** A Senegalese sequence from a set of HIV-1 viral isolates from Africa. Health status of the individual from which the virus was cultured was unspecified, and the year of viral isolation was probably between 1989–1992. Viruses were cultured with donor PBMCs for 2 to 3 weeks. Full length env (gp160) was amplified, cloned and sequenced. [Louwagie et al.(1995)]. GenBank accession number L22944.
28) **SO.1574:** This sequence is a consensus sequence of blood and CSF samples taken from the Somalian patient 1574, CDC classification II. [Keys et al.(1993)]. GenBank accession numbers Z23188, Z23190–Z23191, and Z23228–Z23231.
29) **SO.SM145:** A Somalian sequence from a set of HIV-1 viral isolates from Africa. Health status of the individual from which the virus was cultured was unspecified, and the year of viral isolation was probably between 1989–1992. Viruses were cultured with donor PBMCs for 2 to 3 weeks. Full length env (gp160) was amplified, cloned and sequenced. [Louwagie et al.(1995)]. GenBank accession number L22946.
30) **TW1.252** This sequence is one of a set of sequences from Taiwan. Other sequences in the set were subtypes B, E, F or G. [Chang et al.(1996)]. GenBank accession number U73055.
31) **UG.45:** A single sequence used in a study of the impact of sequence variation on the distrinution and seroreactivity of linear antigenic epitopes. The sequence was derived from PCR amplified DNA from peripheral blood leukocytes. The patient was an asymptomatic individual from Uganda. [Pestano et al.(1995)]. GenBank accession number U11597. See also A_UG1.964, B_US17.ID#, and D_UG7.ID#.
32) **UG.UG268:** A Ugandan sequence from a set of HIV-1 viral isolates from Africa. Health status of the individual from which the virus was cultured was unspecified, and the year of viral isolation was probably between 1989–1992. Viruses were cultured with donor PBMCs for 2 to 3 weeks. Full length env (gp160) was amplified, cloned and sequenced. [Louwagie et al.(1995)]. GenBank accession number L22948.
33) **ZA.NOF:** This sequence is from a South African individual who was part of a study of HIV-1 strains in India. This sequence was found to be closer to the Indian sequences, than are other isolates from Africa. PCR amplified DNA from PBMC cultures were sequenced. [Dietrich et al.(1993)] and [Becker et al.(1995)]. GenBank accession numbers L07426 and U06716. See also C_IN3.ID#, B_IN.IND9.
34) **ZA1.ID#:** These 2 sequences are from 2 individuals in South Africa. ZA514 was from a 59 year old mixed-race male heterosexual with AIDS and the virus was NSI. ZA517 was from a 33 year old mixed-race male heterosexual with ARC and the virus was NSI. The samples were collected at the Tygerberg Hospital in the Western Cape region of South Africa between 1984 and 1992. DNA was harvested from cocultured PBMCs and the env gene was PCR amplified and cloned into pBSKS+ for sequencing. Each sequence is from a single cloned PCR product. [Engelbrecht et al.(1995)]. GenBank accession numbers L48067–L48068. GenBank entries U33781 and U33782 are shorter env gene fragments from these same clones. See also B_ZA and D_ZA sequences from this same study.
35) **ZA2.ID:** These sequences are from clones from PCR amplified cocultured PBMC DNA. Dlu was a black male sampled at the Tygerberg Hospital in Cape Town, South Africa in 1990. Gom was a black male sampled at the Tygerberg Hospital in Cape Town, South Africa in 1990. BooyD was a mixed-race female mother sampled at the Tygerberg Hospital in Cape Town, South Africa in 1990. A short sequence from

a seropositive child of BooyD is presented in Genbank entry U07015. [Becker et al.(1995)]. GenBank accession numbers U07237, U06717 and U06718.

36) **ZM1.ZAM-ID#:** Two sequences from Zambia, from a set of HIV-1 viral isolates from Africa. Health status of the individual from which the virus was cultured was unspecified, and the year of viral isolation was probably between 1989–1992. Viruses were cultured with donor PBMCs for 2 to 3 weeks. Full length env (gp160) was amplified, cloned and sequenced. [Louwagie et al.(1995)]. GenBank accession numbers L22954 and L22956.

37) **ZW.2647:** This sequence is a consensus sequence taken from blood and CSF samples taken from Zimbabwe patient 2647, CDC classification II. [Keys et al.(1993)]. GenBank accession numbers Z23196–Z23199 and Z23236–Z23239.

D Subtype

At this time there are viral sequences from 107 HIV-1 infected individuals associated with HIV-1 subtype D. The D subtype consensus sequence (D_CONSENSUS_96) generated from these sequences was based on the most common amino acid found in each position of an alignment. All of these sequences have been published and/or have been made available for printing in the database by their authors.

1) **BI.BU009con:** This is a consensus sequence from 8 clones from a 36 year old female with CDC stage IV AIDS and pulmonary tuberculosis, from Bujumbura, Burundi. PBMCs from the patient were cocultured with donor PBMCs for 2 weeks, at which time large syncytia formed and the culture became antigen positive. The env region was then PCR amplified by nested PCR and cloned. [Ranjbar et al.(1995)] and [Ranjbar(1995)]. GenBank accession numbers L35452–L35459.
2) **CF.4020:** This sequence was the only D subtype from a set of sequences obtained from 27 symptomatic patients from the Central African Republic, from whom blood was drawn in 1990–1991. It is a consensus from cloned PCR products, derived from cultrued proviral DNA. [Murphy et al.(1993)]. A full gp120 sequence from this isolate was kindly provided prior to publication by Dr. MP Kieny of Transgene, Strasbourg, France. It is a part of a set of 14 HIV-1 gp120 isolates from Bangui, Central African Republic. The gp120 proteins have been expressed in a hybrid gp160 vaccinia virus expression system [Richalet-Secordel et al.(1994)]. The year of isolation and health status of individuals from which the viruses were isolated were not provided. Viruses were isolated in the CAR by C Mathiot and B You (Pasteur Inst., Bangui), grown by F Barre-Sinoussi and A Deslandres (Pasteur Inst., Paris), and cloned and sequenced by D Schmitt and MP Kieny. GenBank accession numbers L11472–L11473, U43138.
3) **CI.CI-13:** A single D subtype sequence from a set of 13 isolates from individuals from Abidjan, Cote d'Ivoire. CI-13 was symptomatic, and serologically dually reactive for HIV-1 and HIV-2. The C2V3 region is part of a 900 bp fragment that was sequenced for each individual. Samples were collected between May 1990 and Sept. 1991. Virus was cultured with donor PBMCs, nested PCR amplified, 3–4 clones were sequenced, and the consensus of those clones is presented here. [Janssens et al.(1994a)]. GenBank accession numbers X72028–X72029.
4) **GA1.ID#:** These 2 sequences are from 1988 or 1989 samples from patients with AIDS living in Franceville Gabon. Method of proviral DNA isolation was not described. DNA was PCR amplified and cloned. One clone per isolate was sequenced. [Delaporte et al.(1996)]. GenBank Accession numbers X90919, G109; X90920 G141. See also subtypes A, C, F, G and O sequences from this same study.
5) **GB1.CPHL4:** This sequence is a consensus from the British isolate 93–43424, clones 2, 6 and 35. It was referred to as 93–43424 in [Arnold et al.(1995c)] and as CPHL4 in [Arnold et al.(1995a)]. GenBank accession numbers U21098 (clone 35) and U23121–U23122 (clones 2 and 6 respectively). CPHL4 is a female who is believed to have contracted the virus from CPHL5 through heterosexual contact. Sequences from CPHL5 are not included in this alignment due to this epidemiological relationship.
6) **KE.NA116:** This sequence was derived from a patient who was part of a May-June 1992 study of pregnant women from the Pumwani Maternity Hospital in Nairobi, Kenya. Viral RNA was concentrated from patient serum just prior to delivery, and the envelope C2-V3 region was amplified by RT-PCR. The PCR product was cloned and 20 clones from the patient were sequenced. Seven other patients from this study had viral subtypes A and C. [Zachar et al.(1996a)]. Genbank accession number U33765.
7) **KE1.KEN-ID#:** These three patients were part of a 1990–1992 cohort study of maternal risk factors in mother to child transmission, including 22 pregnant women and an infant from Kenya. The C2V3 region was sequenced. [Janssens et al.(1994d)]. GenBank accession numbers for sequences from the entire set of 23 patients studied in this publication: U12984–U13006.
8) **NL.A11:** This sequence is from a Dutch study of presumed HIV-1 donor-recipient pairs. This sequence is from a recipient at the time of seroconversion; the donor was a Zairean woman living in the Netherlands (patient A12 GenBank Accession numbers M91840–M91848). The sequences from both donor and recipient were extremely similar, so only the recipient (patient A11) is shown here. This sequence is a consensus sequences of multiple clones from PCR amplified serum RNA. [Wolfs et al.(1992)]. GenBank accession numbers M91849–M91856.
9) **NL2.ID#:** These 7 sequences are from recent immigrants to The Netherlands from various countries. The first two letters of the ID# represent the two letter country code for the previous residence of the patient. The next two numerals represent the year of isolation. Viral RNA was prepared from patient serum and RT-PCR was used to amplify the V3 region of the env gene. The PCR products were

directly sequenced. [Lukashov et al.(1996)]. GenBank accession numbers L76900, UG9307184; L76907, ZR9402261; L76892, ZR929193; L76904, UG9401525; L76895, AO9302187; L76872, ZR891183; L76876, ZR901100.

10) **RU.RUS14A** This sequence is from [Lukashov et al.(1995)]. GenBank accession number: L38415.
11) **SN.SE365:** A Senegalese sequence from a set of HIV-1 viral isolates from Africa. Health status of the individual from which the virus was cultured was unspecified, and the year of viral isolation was probably between 1989–1992. Viruses were cultured with donor PBMCs for 2 to 3 weeks. Full length env (gp160) was amplified, cloned and sequenced. [Louwagie et al.(1995)]. GenBank accession number L22945.
12) **TZ1.TAN-ID#:** These ten sequences are from a set of 14 Tanzanian samples from symptomatic individuals, using serum samples taken in 1988 to generate PCR clones from viral RNA for sequencing. [Zwart et al.(1993)]. GenBank accession numbers L01298–L01339.
13) **TZ2.ID#:** These eight sequences were from patients at a clinic in Dar es Salaam, Tanzania. The individuals from which the virus was cultured showed clinical signs of AIDS, and the year of viral isolation was 1988. Viral cDNA was PCR amplified from donor PBMC, and one cloned PCR product per donor was sequenced. [Siwka et al.(1994)]. GenBank accession numbers U12406, U12407, U12410–U12415.
14) **TZ3.ID#:** These 4 sequences are from the Mara region of rural northwest Tanzania [Robbins et al.(1996)]. Subtype A was also found in this study. GenBank accession numbers U61875 and U61879–U61881.
15) **UG.U44342:** This sequence is from a Ugandan. Consensus of PCR-clones, peripheral blood DNA. Intact env sequences are available from this sample. [Bruce et al.(1993)]. GenBank accession numbers M98408–M98416.
16) **UG.UG23:** This sequence is from blood collected from the Mulago Teaching Hospital in Kampala, Uganda. Viral RNA was harvested after 10-14 days of coculture with donor PBMCs and reverse-transcribed with AMV-RT. The env V3 region was PCR amplifed and cloned. This sequence is from an individual clone. [Atkin et al.(1993)], [Pestano et al.(1993)]. GenBank accession number M98504.
17) **UG1.W2UG-ID#:** Twelve sequences from asymptomatic individuals from Uganda in 1992. Each sequence is a consensus from cloned PCR products derived from cell-cultured proviral DNA or culture supernatant RNA. These sequences were provided by the WHO Global Programme on AIDS Vaccine Development Study. The complete set of C2V3 region WHO sequences can be found in the April supplement to the Human Retroviruses and AIDS 1993 database. [De Wolf et al.(1994)]; [Osmanov et al.(1994)]; [Gao et al.(1994b)]. GenBank accession numbers U08721–U08741, U08786–U08787, U08803–U08809 and U08821–U08824.
18) **UG2.ID#:** These twelve sequences are from 1986–1987 Ugandan samples. Each sequence is a consensus from cloned PCR products derived from uncultured proviral DNA harvested directly from patient PBMCs. [Oram et al.(1991)]. No GenBank entries exist for these sequences.
19) **UG3.ID#:** These 11 sequences are part of a set of sequences derived from 22 Ugandans who were attending an AIDS clinic. Blood samples were obtained in 1990. Each sequence is a consensus from cloned PCR products derived from uncultured proviral DNA harvested directly from patient PBMCs. [Albert et al.(1992)]. GenBank accession numbers L00614–L00618, L00733–L00737, M98894–M98899, M98901, M98906–M98907, M98911–M98913, M98918, M98920–M98923, M98929–M98937, M98942–M98945 and M98967–M98975.
20) **UG4.ID#:** One to 4 clones of each these Ugandan isolates were sequenced, but only one clone is shown here. [Douglas et al.(1996)]. Other Ugandan isolates sequenced in this study were subtype D/A recombinant. London subtype B clones were also reported. Complete envelope gp160 sequences were reported for all isolates. GenBank accession numbers U36867, U36868, U36871, U36884–U36887.
21) **UG5.UG-ID#:** Three Ugandan sequences from a set of HIV-1 viral isolates from Africa. Health status of the individuals from which the virus was cultured was unspecified, and the year of viral isolation was probably between 1989–1992. Viruses were cultured with donor PBMCs for 2 to 3 weeks. Full length env (gp160) was amplified, cloned and sequenced. [Louwagie et al.(1995)]. GenBank accession numbers L22947 and L22949–L22950.
22) **UG6.ID#:** Three Ugandan sequences from a set of HIV-1 viral isolates from Africa. All three individuals from which the virus was cultured had AIDS, and the year of viral isolation was 1987. Viruses were cultured with HUT-78 cells for an unspecified length of time. The V3 region of env (gp160) was amplified, cloned and sequenced. [von A. et al.(1995)]. GenBank accession numbers U15005, U15006 and U15007.

23) **UG7.ID#:** These sequences were used in a study of the impact of sequence variation on the distribution and seroreactivity of linear antigenic epitopes. Both sets of sequences were from PCR amplified DNA from peripheral blood leukocytes. All patients were asyptomatic individuals reporting for regular blood drawing at the Nakasero blood transfusion service, Kampala, Uganda. [Pestano et al.(1995)]. GenBank accession numbers U11595, U11596, and U11598. See also A_UG1.964, C_UG1.45, and D_UG7.ID#.
24) **UG8.#:** These 2 sequences are from Gulu, northern Uganda. They are from direct sequence of PCR product amplified from uncultured PBMCs. Blood samples were drawn from 217 pregnant women attending the clinic in Gulu, northern Uganda. Ages ranged from 17 to 37 years. The 29 seropositive women (13.4%) were all asymptomatic. [Buonaguro et al.(1995)]. Genbank accession numbers U44881 and U44884. Eight subtype A sequences were also found in this study (see A_UG5).
25) **US.AMK:** This sequence comes from a student living in Alabama, who moved from Zaire to the US in 1988. Virus was isolated from the patients PBMCs; this isolate was PCR amplified, and amplification products from both gag (U08192) and env were subcloned and sequenced. His CD4 count was < 5 cells/mm3, and he was symptomatic at the time of viral isolation. [Gao et al.(1994b)] and [Gao et al.(1996a)]. AMK is also known as 93ZR001. GenBank accession numbers U08193, U27419.
26) **ZA.ID#:** These 5 sequences are from 5 individuals in South Africa. ZA500 was from a 41 year old white male homosexual with ARC and the virus was non-syncytium-inducing (NSI). ZA501 was from a 24 year old white male bisexual with AIDS and the virus was SI. ZA505 was from a 36 year old white male homosexual with AIDS and the virus was SI. ZA506 was from a 33 year old white male homosexual with AIDS and the virus was SI. ZA507 was from a 37 year old white male homosexual with AIDS and the virus was SI. All samples were collected at the Tygerberg Hospital in the Western Cape region of South Africa between 1984 and 1992. DNA was harvested from cocultured PBMCs and the env gene was PCR amplified and cloned into pBSKS+ for sequencing. Each sequence is from a single cloned PCR product. [Engelbrecht et al.(1995)]. GenBank accession numbers L47608, L48061, L48062, L48070 and L48072. GenBank entries U33769, U33771–U33773 and U33780 are shorter env gene fragments from these same clones. See also B_ZA and C_ZA1 sequences from this same publication.
27) **ZR.ELI:** This sequence is from the Zairean isolate ELI. [Alizon et al.(1986)] and [Goodenow et al.(1989)]. The complete genomic sequence and an infectious clone are available. GenBank accession numbers M27949, K03454 and X04414.
28) **ZR.JY1:** This sequence is from Zairean isolate Z-84, clone JY1. [Yourno et al.(1988)]. GenBank accession number J03653.
29) **ZR.MAL:** This sequence is from a non-infectious clone of the Zairean isolate MAL. [Alizon et al.(1986)]. The complete genomic sequence and an infectious clone from the isolate MAL are available. MAL is known to be recombinant between subtypes A and D. GenBank accession numbers K03456 and X04415.
30) **ZR.NDK:** This sequence is from an infectious clone of the Zairean isolate NDK. The molecular clone is highly cytopathic in vitro. [Spire et al.(1989)]. The complete genomic sequence is available. GenBank accession number M27323.
31) **ZR.Z2Z6:** This sequence is from an infectious clone of Zairean isolate Z2. Theodore T, and Buckler-White A, unpublished. The complete genomic sequence is available. GenBank accession number M22639. See also [Srinivasan et al.(1987)]. GenBank entry with accession numbers K03458 and M16322, which is from the same isolate.
32) **ZR1.ID#:** These four sequences are part of a set of 14 A and D sequences from women from Zaire. 8 were healthy, 4 showed minor signs of illness, and 2 had AIDS. Sequences were determined by directly sequencing PCR products derived from uncultured proviral DNA harvested directly from patient PBMCs. [Potts et al.(1993a)]. GenBank accession numbers L19623, L19627, L19631 and L19635.

E Subtype

At this time there are viral sequences from 124 HIV-1 infected individuals associated with HIV-1 subtype E. The E subtype consensus sequence (E_CONSENSUS_96) generated from these sequences was based on the most common amino acid found in each position of an alignment. All of these sequences have been published and/or have been made available for printing in the database by their authors.

1) **CF.90CR402** 90cr402, previously named CAR-E 4002, was obtained from a man from Bangui, Central African Republic, who had lymphadeopathy, diarrhea, severe weight loss and recurrent respiratory infections. He was infected through heterosexual contact, but the year of infection is unknown. The virus was first adapted to growth in chimpanzee cells, expanded in chimpanzee cells, and then re-expanded in human PBMCs before lamba cloning and sequencing. [Gao et al.(1996b)]. The complete genome is found with GenBank accession number U51188.
2) **CF.4039:** This is a subtype E virus from the Central African Republic. Schmitt,D. et al. unpublished (1995). GenBank accession number U43112.
3) **CF1.ID#:** These eight sequences are from a set of sequences obtained from 27 symptomatic patients from the Central African Republic, from whom blood was drawn in 1990–1991. Consensus, PCR-clones, cell culture, DNA. [Murphy et al.(1993)]. GenBank accession numbers L11459–L11460, L11463–L11468, L11476, L11480–L11481, L11504–L11505, L11511–L11513, L11519–L11521 and U43137.
4) **CF2.ID#:** These three sequences were kindly provided prior to publication by Dr. M.P. Kieny of Transgene, Strasbourg Cedex, France. They are part of a set of 14 HIV-1 gp120 isolates from Bangui, Central African Republic. The gp120 proteins have been expressed in a hybrid gp160 vaccinia virus expression system. Year of isolation and health status of individuals from which the virus was isolated were not provided. Viruses were isolated in the CAR by C. Mathiot and B. You (Pasteur Inst., Bangui), grown by F. Barre-Sinoussi and A. Deslandres (Pasteur Inst., Paris), and cloned and sequenced by D. Schmitt and M.P. Kieny. Genbank accession numbers U43110, U43170 and U43173.
5) **CM.CA10:** A single E subtype sequence from a set of 17 sequences from a very diverse set of isolates from Yaounde and Douala, Cameroon. The sequences were derived from asymptomatic and symptomatic HIV infected individuals, specifically, CA10 was symptomatic. Virus was isolated by culture with donor PBMCs, and nested PCR amplified. A single clone was sequenced representing each HIV-1 isolate. [Nkengasong et al.(1994)]. GenBank accession numbers for the entire set of 17 sequences in this publication: X80438–X80454.
6) **GB1.11643:** This sequence is from the British isolate 94–11643. The sequence was determined from PCR-amplified lymphocyte DNA. The gag gene from this isolate was subtype A, as is the gag gene from all subtype E virus studied to date. The patient is thought to have contracted the virus in Thailand, but currently lives in the United Kingdom. [Arnold et al.(1995c)]. GenBank accession number U21109.
7) **JP1.ID#:** These three sequences are from one Japanese and two Thai individuals living in Japan, obtained by direct sequencing of PCR-amplified proviral DNA from peripheral blood mononuclear cells. [Weniger et al.(1994)]. NIH3J is from a male Japanese national. NIH2T and NIH4T are from Thai female prostitutes, living in Japan. GenBank accession numbers L32085–L32087.
8) **MY.92-14103:** This sequence is from a Thailand infant who was adopted by Malaysians, and now lives in Malaysia. PCR products amplified from uncultured PBMCs were directly sequenced. [Brown et al.(1996)]. This report also included subtypes B and C in Malaysia. GenBank accession number U65551.
9) **MY.1786:** This sequence is from a dried blood spot collected in 1992 from a Female STD patient in Myanmar. DNA was extracted from the blood spots and PCR amplified. The PCR products were directly sequenced. [Cassol et al.(1996)]. GenBank accession number U53309.
10) **NL.TH94037:** This sequence is from a recent immigrant to The Netherlands from Thailand. The blood sample was collected in 1994. Viral RNA was prepared from patient serum and RT-PCR was used to amplify the V3 region of the env gene. The PCR product was directly sequenced. [Lukashov et al.(1996)]. GenBank accession number L76911.
11) **TH.93TH253:** This sequence is from a 21-year-old man from Chiang Mai, Thailand and was previously named CMU010 or 302053. The patient had end-stage AIDS. The mode and year of infection are unknown. 93th253 was isolated in 1993 and expanded in human PBMCs, then expanded in H9 cells, and followed by lambda cloning and sequencing. The complete genome has been sequenced. [Gao et al.(1996b)]. GenBank accession number U51189.

12) **TH.CM240:** This sequences is from a 21 year old asymptomatic man from northern Thailand. The route of infection is believed to be heterosexual transmission. The blood sample was collected in 1990. The patient's PBMSCs were codultured with stimulated donore PBMCs and proviral DNA was harvested for PCR amplification and sequening of a cloned full-length genome PCR product. [Carr et al.(1996)]. The complete genome is found in GenBank with accession number U54771.
13) **TH.T8178:** This sequence comes from a study of the genetic heterogeneity and epidemiological distribution of HIV1 in Thailand. The host was a female prostitute and the sequence was obtained from PCR amplified PBMC DNA. [Ou et al.(1993)]. GenBank accession number L19239. See also B_TH.T8174.
14) **TH.N764:** This sequence is from a survey of IV drug using prisoners in Thailand. 12 of 13 sequences from Thai prisoners were of subtype B; N764, from patient (THP13) represents the only subtype E sequence identified in this set, from a prisoner infected in 1989. The sequences were obtained from PCR amplified PBMC DNA. [Kalish et al.(1994)]. GenBank accession number U15588.
15) **TH1.ID#:** These twelve sequences are from a set of 23 individuals from Thailand. PCR-direct, peripheral blood PBMC DNA. Referred to as Thai subtype A in [Ou et al.(1992b)] and [Ou et al.(1993)]. (Published erratum appears in *Lancet* **342**:250 (1993).) GenBank accession numbers L07443–L07445, L07447–L07448, L07457–L07459 and L07461–L07464.
16) **TH2.ID#:** Six of these eight sequences are from 16 isolates from HIV seropositive individuals from Thailand. Sequences were from PCR products derived from co-cultured PBMC DNA. The full length envelope gene sequences are available. [McCutchan et al.(1992)]. Please note: the "TN-ID#" locus names in the database correspond to the McCutchan et al.'s "CM-ID#" isolates. GenBank accession numbers L03698–L03701 and L03703–L03704. The other two (TH238, TN240) are also from Thailand, DNA from PBMC. [Mascola et al.(1994)]. GenBank accession numbers L14571, L14572.
17) **TH3.W2TH-ID#:** Fifteen sequences from asymptomatic individuals from Thailand in 1992. Consensus, PCR-clones, cell-culture DNA and RNA. These sequences were provided by the WHO Global Programme on AIDS Vaccine Development Study. The complete set of C2V3 region WHO sequences can be found in the April supplement to the Human Retroviruses and AIDS 1993 database. [De Wolf et al.(1994)]; [Osmanov et al.(1994)]; and [Gao et al.(1994a)]. GenBank accession numbers U08810–U08811, U08825–U08836 and U08742–U08761. Entry with accession number U09131 is also TH_W2TH022.
18) **TH4.D-ID#:** These three sequences are part of a set of sequences generated for the DAIDS variation program in the laboratory of Dr. Beatrice Hahn at the University of Alabama. They are clones from expanded culture stocks, and are excised from full gp160 sequences. The sequence ID numbers are abbreviated, for example D3TH966 can be read as DAIDS sequence (D), isolated in 1993 (3), Thai (TH), patient 301966 (966). [Gao et al.(1996a)]. GenBank accession numbers U08456–U08458.
19) **TH5.ID#:** These seventeen consensus and five individual sequences are from twenty two patients with AIDS involved in a study of genotypic and phenotypic characteristics of Thai HIV-1. Blood samples were collected between July and December 1993. All sequences were derived from PCR amplified PBMC DNA, after patient PBMCs were cocultured with virus-free donor PBMCs. CMU01, CMU03, CMU04, CMU05, CMU07, and CMU10 are NSI, the rest are SI, as determined by syncytium formation in the cocultured cells. CM = Chaing Mai University Hospital. KH = Kavila Army Hospital. All subjects were males and reported past contact with commercial female sex workers, but no history of drug injection, blood transfusion or homosexual contact. [Yu et al.(1995)]. GenBank accession numbers U25550–U25626. Longer sequences from samples KH003, KH005, KH008, CMU02, CMU08 and CMU010 were determined in 1996 [McCutchan et al.(1996)]. GenBank accession numbers U48264–U48269.
20) **TH6.ID#:** These three sequences are E subtype sequences from Thailand. Two individuals believed to be dually infected with subtypes B and E were analyzed. It is not clear from the paper or the GenBank entries which sequences came from individual 1 and which from 2. [Artenstein et al.(1995)]. Genbank accession numbers U21472, U21474, U21476. See also B_TH5.ID#.
21) **TH7.ID#:** These two sequences are from samples collected in 1993 in Thailand. Patients 1018 and 1110 were asymptomatic. [McCutchan et al.(1996)]. GenBank accession numbers U48273–U48274.
22) **TH8.ID#:** These two sequences were from dried blood spots collected in 1992 from a heterosexual (0289) and an IV drug user (0103). DNA was extracted from the blood spots and PCR amplified. The PCR products were directly sequenced. [Cassol et al.(1996)]. GenBank accession numbers U53312 and U53313.
23) **TH9.ID#:** These 14 sequences are from 84 IV drug users in Bangkok, Thailand, who were undergoing methadone treatment at 14 treatment clinics. Blood samples were collected between January and April,

1994. Uncultured PBMC DNA from each patient was PCR amplified, and the PCR product was directly sequenced. Of the 84 patients sampled, 69 were Thai B, one (091) was typical subtype B, and 14 were subtype E. [Kalish et al.(1995)]. GenBank accession numbers U22542, U22548, U22553, U22557, U22561, U22567, U22575, U22604, U22609, U22611, U22612, U22617, U22624 and U22625. See also B_TH7.

24) **TH10.ID#:** These sequences are from Thailand. They are part of several complete env gene sequences obtained for the World Health Organization. HMA subtyping as well as sequence-determined subtyping was done on each one. Sequences were PCR amplified from cocultured PBMCs. Two clones from each isolate were sequenced. [Penny et al.(1996)]. GenBank accession numbers U39256 and U39260, 92TH002; U39255 and U39261, 92TH011.
25) **TW1.ID#:** These 3 sequences are from healthy HIV-1 carriers or AIDS patients from Taiwan [Chang et al.(1996)]. Other subtypes found in Taiwan in this study were B, C, F and G. Genbank accession numbers U73060, U73062 and U73070.
26) **US.POC30506:** This sequence is from a U.S. serviceman who aquired an HIV-1 infection while deployed in Thailand. He was asymptomatic when the sample for this sequence was collected in 1993. [McCutchan et al.(1996)]. GenBank accession number U48272.
27) **UY.ID#:** These four sequences are from Uruguayan servicemen who aquired HIV-1 infections while deployed as United Nations peacekeepers in Cambodia in 1993. All four were asymptomatic when samples were collected for these sequences in 1993. [McCutchan et al.(1996)]. GenBank accession numbers U48275–U48278.
28) **VN1.ID#:** These 3 sequences are from South Vietnam. [Menu et al.(1996)]. The sequences were from IV drug users in Ho Chi Minh city and Dong Nai, and a female prostitute in Can Tho. A fourth sequence, from Ho Chi Minh city, was found to be subtype B. Genbank accession numbers U29206-U29208.
29) **VN2.ID#:** These 4 sequences are from South Viet Nam. VN1 and VN2 were from healthy 17 and 25 year old female prostitutes from Can Tho and An Giang. VN3 and VN 4 were from male IV drug users. VN3 was 43, had pruritus and splenomegaly, and was from Nha Trang. VN4 was 31, healthy and was also from Nha Trang. [Nerurkar et al.(1996)]. Genbank accession numbers U45239, U45240, U48719 and U48720.

NOTE:

1) While the sequences in this subtype were distinct over this region of env from the other four env subtypes, in the gag gene it is not possible to make a distinction between this subtype and subtype A. What this means is that the isolates for which both gag and env are sequenced which cluster together as the "A" subtype in gag, are very distinctive in env and are broken down into two subtypes. env "A" and env "E". This holds true for the E subtypes sequences that originated in Thailand, as well as the E subtype isolate from the Central African Republic for which gag sequence was obtained. [McCutchan et al.(1992)]; [Louwagie et al.(1993)]; and [Murphy et al.(1993)]. Complete genomes of subtype A and subtype E viruses became available in late 1996 [Gao et al.(1996b)], genbank accession numbers U51188–U51190.
2) The relative lack of diversity in the Thai sequences in this subtype relative to the other subtypes is likely to be a consequence of the short time span of the HIV-1 subtype E epidemic in Thailand. [McCutchan et al.(1992)], and [Ou et al.(1992b)].

F Subtype

At this time there are viral sequences from 59 HIV-1 infected individuals associated with HIV-1 subtype F. The F subtype consensus sequence (F_CONSENSUS_96) generated from these sequences was based on the most common amino acid found in each position of an alignment. All of these sequences have been published.

1) **AR1.ID#:** These two sequences are from direct sequencing of PCR products from uncultured PBMCs, from 1993 samples from Buenos Aires, Argentina. Patient 21280 had AIDS and reported IV drug abuse. Patient 20016 was asymptomatic and HIV risk behavior was unknown. Two other samples taken from unrelated patients in 1993 were subtypes B or B/F recombinant. [Marquina et al.(1996)]. GenBank accession numbers U68522 and U68524.
2) **AR2.ID#:** These 3 sequences are from Rosario, Argentina. A total of 24 patients from different risk groups visiting a clinic in Rosario were included in this study. Of the 14 sequences determined, 11 were found to belong to subtype B and 3 were found to belong to subtype F. DNA was extracted from whole blood and PCR amplified. PCR products were directly sequenced. Subtypes of all 24 patients were also tested by HMA. [Campodonico et al.(1996)]. GenBank accession numbers U37032, U37033 and U37043.
3) **BR.7944:** This sequence represents a single env F subtype sequence found among 22 Brazilian outpatients with varying degrees of disease progression. It was identified by Potts et al. as the single sequence which did not cluster with North American sequences in phylogenetic analysis. Consensus, PCR clones, peripheral blood PBMC DNA. [Potts et al.(1993b)]. GenBank accession number L19237.
4) **BR.RJI03:** An F subtype sequence from Rio de Janeiro, Brazil. 26 additional B and a B-F recombinant were also observed in this set. Year of isolation for RJI03 was 1993, from a woman of CDC clinical stage II. [Morgado et al.(1994)]. DNA was amplified directly from PBMCs of an HIV infected woman with CDC stage II disease, and the PCR product was directly sequenced. GenBank accession number U00422. See also [Sabino et al.(1994c)] GenBank accession number U08974.
5) **BR1.BZ-ID#:** Three sequences from Brazil of the F subtype. Full length env (gp160) was amplified from proviral DNA of cultured PBMCs, cloned and sequenced. [Louwagie et al.(1994)]. GenBank accession numbers L22082, L22084 and L22085. The gag gene of these same isolates is found in L22083, L22086 and L11751. The gag region of BZ126 seems to be a subtype A outlier with a strong similarity to subtype C at the 3' end. See also B_BR4.BZ-ID#.
6) **BR2.HSP#:** These 5 sequences are from Sao Paulo Brazil. Although these sequences are listed as unpublished in the database, they seem to be an extension of work published in [Morgado et al.(1994)] and [Sabino et al.(1994c)]. GenBank accession numbers U31588, U31592–U31595.
7) **BR3.93BR029:** This sequence is from Brazil. It is one of several complete env gene sequences obtained for the World Health Organization. HMA subtyping as well as sequence-determined subtyping was done on each one. Sequences were PCR amplified from cocultured PBMCs. Two to three clones from each isolate were sequenced. [Penny et al.(1996)]. Another env sequence from this same patient was determined by a second group. [Gao et al.(1996a)]. GenBank accession numbers U27413, U39235 and U39236.
8) **CM.CA-ID#:** These sequences are 3 of 17 sequences from a very diverse set of isolates from Yaounde and Douala, Cameroon. The sequences were derived from asymptomatic and symptomatic HIV infected individuals; specifically patients CA16 and CA20 were asymptomatic and patient CA4 was symptomatic. Virus was isolated by culture with donor PBMCs, and nested PCR amplified. A single clone was sequenced representing each HIV-1 isolate. The F subtype designation of these sequences is tentative. Although the F subtype sequences from Cameroon and Brazil consistently form a clade in phylogenetic analyses, the branch lengths between isolates from the two countries are typical of inter-subtype distances, and sequences from the two countries each form their own distinct clade within the F subtype (HIV database and Wouter Janssens, personal communication). [Nkengasong et al.(1994)]. GenBank accession numbers for the entire set of 17 sequences studied in this publication: X80438–X80454.
9) **CY.HO44-1:** This is a single sequence from two individuals who were heterosexual partners of one another. Patient 16 was a 29 year old bisexual male who was born and lived in Zaire, before moving to Cyprus. He was symptomatic with a CD4 count of 60 and had been seropositive for at least 6 years. Patient 44 was a 32 year old heterosexual female. She was asymptomatic with a CD4 count of 1,136. These samples, like others in this study (see also subtypes A, B, C, and I) were collected in February 1994

from the AIDS clinic in Nicosia, Cyprus. DNA was extracted from patient PBMCs and PCR amplified. After a second round of PCR, products were cloned and sequenced. One clone from patient 16 and one from patient 44 were sequenced. [Kostrikis et al.(1995)]. Because of the close epidemiological linkage, only the clone from patient 44 is presented here. Genbank accession numbers U28662 (16) and U28679 (44).

10) **GA1.VI354:** This sequence is from a 1989 sample from a patient with AIDS living in Libreville, Gabon. Method of proviral DNA isolation was not described. DNA was PCR amplified and cloned. One clone per isolate was sequenced. [Delaporte et al.(1996)]. GenBank Accession number X90923. See also subtypes A, C, D, G and O sequences from this same study.
11) **NL1.ID#:** These 3 sequences are from recent immigrants to The Netherlands from Brazil and Zaire. The fist two letters of the ID# represent the two letter country code for the previous residence of the patient. The next two numerals represent the year of isolation. Viral RNA was prepared from patient serum and RT-PCR was used to amplify the V3 region of the env gene. The PCR products were directly sequenced. [Lukashov et al.(1996)]. GenBank accession numbers L76899, ZR9306911; L76871, ZR890819; L76901, BR9400960.
12) **RO1.ID#:** These nine sequences are from isolates from Romanian children, in different clinical stages. All isolates showed cytopathic properties in peripheral blood mononuclear cells. DNA sequences are direct sequences of PCR products amplified from co-cultured PBMCs. The patients are also known as RM(A-J). [Dumitrescu et al.(1994)]. GenBank accession numbers L19571–L19579.
13) **RO2.RM-ID#:** These 24 sequences are from isolates from orphaned Romanian children, ranging in age from 2.5 to 6 years, admitted to a clinic in Tirgu Mures, Romania. All children were referred to this clinic with serious infections and are believed to have been infected horizontally in different orphanages. Virus was isolated after coculture with donor PBMCs. Proviral DNA from cocultured PBMCs was PCR amplified and the PCR products were directly sequenced. [Holm-Hansen et al.(1995)]. GenBank accession numbers X77964–X77987.
14) **TW1.252:** This sequence is one of a set of sequences from Taiwan. Other sequences in the set were subtypes B, C, E or G. [Chang et al.(1996)]. GenBank accession number U67765.

G Subtype

At this time there are viral sequences from 23 HIV-1 infected individuals associated with HIV-1 subtype G. The G subtype consensus sequence (G_CONSENSUS_96) generated from these sequences was based on the most common amino acid found in each position of an alignment. All of these sequences have been published and/or have been made available for printing in the database by their authors.

1) **BJ1.ID#:** These 2 sequences are from female prostitutes, born in either Ghana or Togo, who live in Benin. 43 is from directly sequenced PCR product, derived via RT-PCR from patient serum RNA. 259 is from cloned PCR product, also by RT-PCR from serum RNA. [Heyndrickx et al.(1996)]. GenBank accession numbers U61872 and U61874. Subtype A sequences were also determined in this study.
2) **CF.4067:** This sequence was associated with the C subtype in first analysis of the C2V3 region ([Murphy et al.(1993)]), but when a full gp120 sequence became avaliable from this isolate, and phylogenetic analysis was performed including some of the new subtype G sequences, it was more closely associated with G. The full length sequence was kindly provided prior to publication by Dr. MP Kieny of Transgene, Strasbourg Cedex, France. It is part of a set of 14 HIV-1 gp120 isolates from Bangui, Central African Republic. The gp120 proteins have been expressed in a hybrid gp160 vaccinia virus expression system. Year of isolation and health status of individuals from which the virus was isolated were not provided. Viruses were isolated in the CAR by C Mathiot and B You (Pasteur Inst., Bangui), grown by F Barre-Sinoussi and A Deslandres (Pasteur Inst., Paris), and cloned and sequenced by D Schmitt and MP Kieny. GenBank accession numbers L11499 and L11500, U43169.
3) **GA.LBV21-7:** A sequence from Gabon from a set of HIV-1 viral isolates from Africa. This sequence was derived from a clone of PCR amplified DNA from cultured PBMCs. It represents a fragment of a full length env sequence. [Janssens et al.(1994b)]. GenBank accession number U09664.
4) **GA.VI525:** A sequence from Gabon from a set of HIV-1 viral isolates from Africa. Health status of the individual from which the virus was cultured was unspecified, and the year of viral isolation was probably between 1989–1992. Viruses were cultured with donor PBMCs for 2 to 3 weeks. Full length env (gp160) was amplified, cloned and sequenced. [Louwagie et al.(1994)] and [Janssens et al.(1994b)]. GenBank accession numbers L22953 and U09665. The same isolate was classified as subtype H in gag, [Louwagie et al.(1993)], GenBank accession number L11792.
5) **GA1.ID#:** These 2 sequences are from Gabon. G98 is from a 1988 or 1989 sample from a patient with AIDS living in Franceville, Gabon who moved there from Niger. VI526 is from a 1990 sample from an AIDS patient at the Libreville General Hospital. Method of proviral DNA isolation was not described. DNA was PCR amplified and cloned. One clone per isolate was sequenced. [Delaporte et al.(1996)]. GenBank Accession numbers X90916, G98; X90922, VI526. See also subtypes A, C, D, F and O sequences from this same study.
6) **GB1.22:** This sequence is a consensus of three clones from an infected infant in a mother-infant transmission study. The sequences were obtained via PCR from cell lysates, with sequencing of cloned PCR products. The infant was 3 months old at the time of blood drawing, and had pneumonia. [Arnold et al.(1995b)]. GenBank accession numbers U26304–U26306. Envelope sequences for the mother are found in GenBank entries U26301–U26302, and gag sequences for mother and infant are in U26303 and U26307.
7) **KP.Kr121** This sequence is from an unpublished GenBank entry with accession number X93469.
8) **NG1.ID#:** These four sequences are G subtype sequences from Nigeria [Abimiku et al.(1994)]. JP882 and JV832 were derived from AIDS patients, and G3 and G9 from healthy women. G9 was cultured on the T cell line CEM-SS, and the other three isolates were cocultured with uninfected donor PBMCs. DNA from viral cultures was PCR amplified, cloned and sequenced. GenBank accession numbers U13208–U13209, U13211 and U13213.
9) **NL.127C** This consensus sequence represents sequences generated from PCR amplified plasma RNA from one of three infants in a Dutch mother/infant study. A sample was collected from the infant at 1.5 months of age. Samples were also collected from the mother before birth, at birth and after birth. Mother sequences are not included in this consensus. [Mulder-Kampinga et al.(1993)]. [Mulder-Kampinga et al.(1995)]. Infant 127 sequences are from GenBank accession numbers Z47817–Z47832. Mother 127 sequences are from GenBank accession numbers Z47833–Z47880. Gag gene sequences from mother/child pairs are also available in Genbank accession numbers Z47903–Z47911; Z47912–Z47928;

Z47929–Z47935; Z47936–Z47950. The second mother/child pair was also from the Netherlands, see B_NL.114C. The third mother/infant pair in this study was from Rwanda, see A_RW.564C.

10) **NL1.ID#:** These 4 sequences are from recent immigrants to The Netherlands from Brazil and Zaire. The fist two letters of the ID# represent the two letter country code for the previous residence of the patient. The next two numerals represent the year of isolation. Viral RNA was prepared from patient serum and RT-PCR was used to amplify the V3 region of the env gene. The PCR products were directly sequenced. [Lukashov et al.(1996)]. GenBank accession numbers L76880, ZR911976; L76906, LR9401885; L76884, UM9210113; L76902, GH9401230.
11) **RU.RUS12A:** This sequence is from [Lukashov et al.(1995)]. GenBank accession number L38413.
12) **RU1.ID#:** This sequence is from Russia. Bobkov et al. 1996 Unpublished. GenBank accession numbers U33095, U33096.
13) **TW1.267:** This sequence is from directly sequenced PCR product from uncultured PBMCs from Taiwan. [Chang et al.(1996)]. Most of the Taiwanese sequences determined in this study were subtype B, but subtypes C, E and F were also found. GenBank accession number U73058.
14) **UG.JW3:** This single sequence of G HIV1 is from a female patient with stage IV disease and CD4 count of 20, from Uganda. The patient had recently migrated to the United Kingdom from Uganda, but contracted the HIV in Uganda. The sequence is referred to as JW3 in [Kaleebu et al.(1995)] but was previously referred to as K1, by the HIV database. It has been given the name 92UG975.10 by the World Health Organization. GenBank accession numbers U22010, U27426.

H Subtype

At this time there are viral sequences from 2 HIV-1 infected individuals associated with HIV-1 subtype H. The H subtype consensus sequence (H_CONSENSUS_96) generated from these 2 sequences was based on the most common amino acid found in each position of an alignment. Both of these sequences have been published and/or have been made available for printing in the database by their authors. Eight sequences that are too short for classification are closer to H than to other subtypes. The locus names (ID's) and sources of the sequences are:

1) **CM.CA13:** A sequence from Cameroon from a set of HIV-1 viral isolates from Africa used to define the prototype G and H env sequences. This sequence was derived from a clone of PCR amplified DNA from cultured PBMCs. It represents a fragment of a 900 base pair sequence. [Janssens et al.(1994d)] and [Nkengasong et al.(1994)]. The H subtype association is not always clearly apparent using some sets of background sequences for comparison, and neighbor joining trees (HIV database, Wouter Janssens, personal communication), although parsimony trees confirmed the original association documented in [Janssens et al.(1994b)]. GenBank accession number U09667.
2) **ZR.VI557:** A sequence from Zaire from a set of HIV-1 viral isolates from Africa used to define the prototype G and H env sequences. This sequence was derived from a clone of PCR amplified DNA from cultured PBMCs. It represents a fragment of a 900 base pair sequence. [Janssens et al.(1994b)]. GenBank accession number U09666.

I Subtype

At this time there are viral sequences from 2 HIV-1 infected individuals associated with HIV-1 subtype I. The subtype I consensus sequence reflects the sequencing of two clones from one individual and one clone from the other. Both of these sequences have been published.

1) **CY.HOcon:** This is a consensus sequence from two individuals who were heterosexual partners of one another, and former IV drug users. They had lived for several years in Athens, Greece as well as in Cyprus. These samples, like others in this study (see also subtypes A, B, C, and F) were collected in February 1994 from the AIDS clinic in Nicosia, Cyprus. Patient HO31 was a 24 year old asymptomatic female known to have been HIV seropositive for at least 5 years. Patient HO32 was a 35 year old asymptomatic male, also seropositive for at least 5 years. DNA was extracted from patient PBMCs and PCR amplified. After a second round of PCR, products were cloned and sequenced. Two clones from HO32 and one from HO31 were sequenced. [Kostrikis et al.(1995)]. Genbank accession numbers U28672, U28673 and U28685.

J Subtype

At this time there are viral sequences from 5 HIV-1 infected individuals associated with HIV-1 subtype J. The J subtype consensus sequence (J_CONSENSUS_96) generated from these sequences was based on the most common amino acid found in each position of an alignment. All of these sequences have been published or made available to the database for printing.

1) **SE1.SE#:** Two sequences from Sweden, both from patients who were recent immigrants from Zaire. [Leitner et al.(1995)]. Sample 2022 as collected in December 1993 from an asymptomatic female with a CD4 count of 184. Her first know seropositive sample is from May 1990, but epidemiological investigation indicated that she was infected in Zaire between 1981 and 1986. Sample 7887 was collected in October 1994 from an asymptomatic male who had tested seronegative in Sweden in January 1993, and who had a seropositive sample in August 1994. His CD4 count was normal at 567. Both patients were heterosexual and a thorough epidemiological investigation revealed no contact or shared contacts between the two. The two sequences were 95% identical to each other over 255 bases of env and 98% identical to each other over 460 bases of gag. GenBank accession numbers L41176 and L41177. Gag gene sequences from these same individuals are in L41178 and L41179.
2) **GM1.GM#:** Three sequences from Gambia, as yet unpublished, which seem to cluster with the two Swedish sequences by Leitner. GenBank accession numbers U33099, U33100, U33102. Bobkov et al. 1996 unpublished. See also Gambian sequences of subtypes B and C.

O Subtype

At this time there are viral sequences 13 HIV-1 infected individuals associated with HIV-1 subtype O that have been published and/or have been made available for printing in the database by their authors. The O subtype consensus sequence (O_CONSENSUS_96) generated from these sequences was based on the most common amino acid found in each position of the alignment; when there was no consensus in a position an "X" was used. These sequences represent a set of sequences that are extremely divergent relative to other HIV-1's. The subtypes A-H have been grouped together under the heading "M" for main. "O" sequences are as different from one another as are sequences from different "M" subtypes. A more complete discussion of O-group viral sequences is also included in this section of the Compendium (Korber, B.T., Loussert-Ajakai, I. Blouin, J. and Saragosti, S. 1996 A Comparison of HIV-1 Group M and Group O Functional and Immunogenic Domains in the Gag p24 Protein and the C2V3 Region of the Envelope Protein).

1) **CM.CA9:** This sequence is from an individual living in Cameroon. [Janssens et al.(1994e)]. No GenBank entry is yet available. The pol gene from this isolate has GenBank accession number X78476.
2) **FR.DUR:** This sequence is as yet unpublished, by J.H.M. Cohen et al. GenBank accession number X84327.
3) **GA1.VI686:** This sequence is from a 1992 sample from a Gabonese woman with AIDS, taken at the Libreville General Hospital in Gabon. Method of proviral DNA isolation was not described. DNA was PCR amplified and cloned. One clone per isolate was sequenced. [Janssens et al.(1994e)], [Delaporte et al.(1996)]. GenBank accession number X96526. The pol gene from this isolate has GenBank accession number X78477. See also subtypes A, C, D, F and G sequences from this same study.
4) **CM.ANT70:** The complete viral genome has been sequenced from this viral isolate derived from a symptomatic Cameroonian, CDC stage III. [R. et al.(1990)] and [Vanden Haesevelde et al.(1994)]. GenBank accession number M31171. LTR and partial env sequences were also presented in L20587 and L23119.
5) **CM.MVP5180:** The complete viral genome has been sequenced from an isolate derived from a Cameroonian woman, sampled in 1991; the donor died of AIDS in 1992. The viral isolate MVP-5180 was grown in several human T-cell lines and the monocytic U937 line. [Gurtler et al.(1994)]. GenBank accession number L20571.
6) **ES.1158:** This sequence was from a 35 year old man from Spain. Two blood samples from this same man were collected in April and September 1995. The V3 region was PCR amplified from uncultured PBMCs, cloned into pGEM-5ZF and an indiviudal clone sequenced. The April sequence is shown here. The sequence from the September blood sample (681, GenBank accession number U62617) is also available. GenBank accession number U62618.
7) **FR.VAU:** This sequence was derived from an isolate from a French woman who died of AIDS in 1992. DNA was extracted from VAU infected PBMCs, PCR amplified, cloned, and gp160 env was sequenced. The viral isolate was highly cytopathic. [Charneau et al.(1994)]. GenBank accession number X80020.
8) **FR.CF#:** These seven consensus sequences are from Cameroonian patients living in France. [Loussert-Ajaka et al.(1995)]. PBMC proviral DNA was PCR amplified and 3-6 clones from each patient were sequenced. The consensus of the 3-6 clones is presented. GenBank accession numbers U24562–U24568. Gag gene sequences for these patients are also available with GenBank accession numbers U24706–U24712.

Uncertain Classification

At this time there are viral sequences from 15 HIV-1 infected individuals that are not clearly associated with any of the HIV-1 genetic subtypes A through J. They either appeared distinct from the subtypes A-J in phylogenetic analysis, or else the subtype association was unclear, with different associations in different analyses. For some of the shorter gene fragments, subtype associations might have been established if more sequence information was available or if a different set of sequences was included in the background set used to define subtype associations. Some of these sequences may be representatives of subtypes as divergent as A-J, but only a single limited sample is yet available. Still others may represent recombinant genomes.

1) **AR.20021:** This B/F recombinant sequence is from direct sequencing of PCR product from uncultured PBMCs, from a 1993 sample from Buenos Aires, Argentina. The patient was asymptomatic and HIV risk behavior was unknown. Three other samples taken from unrelated patients in 1993 were subtypes F (2) or B (1). [Marquina et al.(1996)]. GenBank accession number U68523.
2) **BR3.RJI01** This sequence is B-F recombinant in the V3 region. DNA was amplified directly from PBMCs of an HIV infected woman with CDC stage II/A disease in August, 1992, and the PCR product was directly sequenced [Morgado et al.(1994)]. More V3 region sequences from this individual (RJ549 from April 1992) and her sexual partner (RJ548 from April 1992) were also sequenced [Sabino et al.(1994c)]. GenBank accession numbers U00420, U08953–U08955, U08957–U08960, U08962–U08964, U10019–U10029, U08972, U08973 and U08965–U08971.
3) **BU1.91BU009:** This C/D sequence is from Burundi. It is one of several complete env gene sequences obtained for the World Health Organization. HMA subtyping as well as sequence-determined subtyping was done on each one. Sequences were PCR amplified from cocultured PBMCs. Two to three clones from each isolate were sequenced. 91BU009 groups with subtype D in a neighbor- joining tree of the V3 region and with subtype C in other regions. [Penny et al.(1996)]. GenBank accession numbers U39253 and U39254.
4) **CF1.ID#:** These four sequences are from a set of sequences obtained from 27 symptomatic patients from the Central African Republic, from whom blood was drawn in 1990–1991. Consensus, PCR-clones, cell culture, DNA. [Murphy et al.(1993)]. GenBank accession numbers L11482–L11483, L11497, L11508–L11510 and L11514–L11515. Janssens et al. classified 4056 as an H subtype sequence [Janssens et al.(1994d)]. D. Schmitt provided an unpublished sequence of CF.4081, U43174.
5) **KE.K124:** A Kenyan sequence from a set of HIV-1 viral isolates from Africa. Health status of the individual from which the virus was cultured was unspecified, and the year of viral isolation was probably between 1989–1992. Viruses were cultured with donor PBMCs for 2 to 3 weeks. Full length env (gp160) was amplified, cloned and sequenced. [Louwagie et al.(1995)]. This isolate is not clearly associated with D subtype; however, Louwagie and colleagues found that it associated with the D subtype in env, and the A subtype in gag. Using parsimony analysis, we found that it was difficult to determine a clear association, and this observation was confirmed by Wouter Janssens (personal communication). GenBank accession number L22942.
6) **KE.KEN976** This is a single unclassified sequence from a set of patients who were part of a 1990–1992 cohort study of maternal risk factors in mother to child transmission, including 22 pregnant women and an infant from Kenya. The C2V3 region was sequenced. [Janssens et al.(1994a)]. GenBank accession number U12992.
7) **NL.RW94028:** This sequence is from a recent immigrant to The Netherlands from Rwanda. The blood sample was collected in 1994. Viral RNA was prepared from patient serum and RT-PCR was used to amplify the V3 region of the env gene. The PCR product was directly sequenced. [Lukashov et al.(1996)]. GenBank accession number L76909.
8) **UG1.ID#:** Two clones from each of these two D/A recombinant Ugandan isolates were sequenced, but only the sequences of 92UG035 clone 21 and C6080 clone 09 are shown here. [Douglas et al.(1996)]. The publication shows C6080 as subtype A, but analyses done at Los Alamos indicate that it is a D/A recombinant, like 92UG035. Other Ugandan isoaltes sequenced in this study were subtype D. London subtype B clones were also reported. Complete envelope gp160 sequences were reported for all isolates. GenBank accession numbers U36865, U36866, U36881 and U36883.
9) **SE.KI4803:** This sequence is from patient number 24 described in [Asjo et al.(1986)]. Several molecular clones from this patient have been extensively characterized in [Tan et al.(1993)]. Complete env gp120

sequences for 8 clones were determined in [McKeating et al.(1996)] and one of the 8 sequences (clone 13) is presented here. Genbank accession numbers for 7 if the 8 clones (clone 32 does not apear in GenBank) are U57788–U57794.

10) **ZM.ZAM184:** This Zambian sequence is an outlier, though in some phylogenetic analysis it appears most closely associated with the A subtype. In particular it is closely associated with A_CF.SAS U43171 (100/100 replicates in parsimony analysis of gp120). Health status of the individual from which the virus was cultured was unspecified, and the year of viral isolation was probably between 1989–1992. Viruses were cultured with donor PBMCs for 2 to 3 weeks. Full length env (gp160) was amplified, cloned and sequenced. [Louwagie et al.(1995)]. GenBank accession number L22955.
11) **ZR.Z3:** This sequence is from the 1983 Zairean isolate Z-3 (non-infectious, possibly due to frame-shift). [Willey et al.(1986)]. GenBank accession number K03347.

Structural Studies Involving Different HIV-1 V3 Loops

Paolo Catasti and Goutam Gupta

MS K710, Los Alamos National Laboratory, Los Alamos, New Mexico 87545

Introduction

Studies on the feasibility of a subunit vaccine to protect against human immunodeficiency virus (HIV) infection have principally focused on the third variable (V3) loop of the envelope surface protein. One of the neutralizing determinants of HIV-1 is located inside the V3 loop. However, progress toward a vaccine based on neutralizing determinants has been impeded by the amino acid sequence variability in the V3 loop of different HIV isolates. The elusive nature of the V3 loop structure prompted us to carry out a systematic study on different isolates in an attempt to identify a common structural motif in the V3 loop regardless of the amino acid sequence variability. We have performed 2D NMR structural studies on three different V3 loop peptides: MN, Haiti (Haiti 6004; L07201), and RF (Catasti *et al.*, 1995 & 1996). The three V3 loops were all 35 residues long and S-S bridged at the terminals. The NMR studies were carried out first in water, then in a 70%/30% mixture of water/trifluoroethanol 1 (TFE). TFE is a solvent widely used in NMR on peptides, for its property to unmask helical propensities of hydorphobic residues.

Figure 1 shows that similar secondary structures are observed for the three different V3 loops: a GPG(K/R) crest in the center of the neutralizing determinant, two extended regions flanking the central crest, and a helical region in the C-terminal domain observed only in the water/TFE mixture. The RF V3 peptide did not dissolve in the water/TFE mixture, therefore we could run the experiments only in an aqueous solution. Structural prediction studies revealed that the variability in sequence and structure of the V3 loop is confined to the N and C-terminal side of the conserved GPG crest. Figure 2 is a summary of the NMR secondary structural assignments (Catasti *et al.*, 1995 & 1996), and the results of several secondary prediction algorithms. With the exception of the PSA method, most of the algorithms fail to identify the alpha helix in the C-terminal portion of the V3 loops.

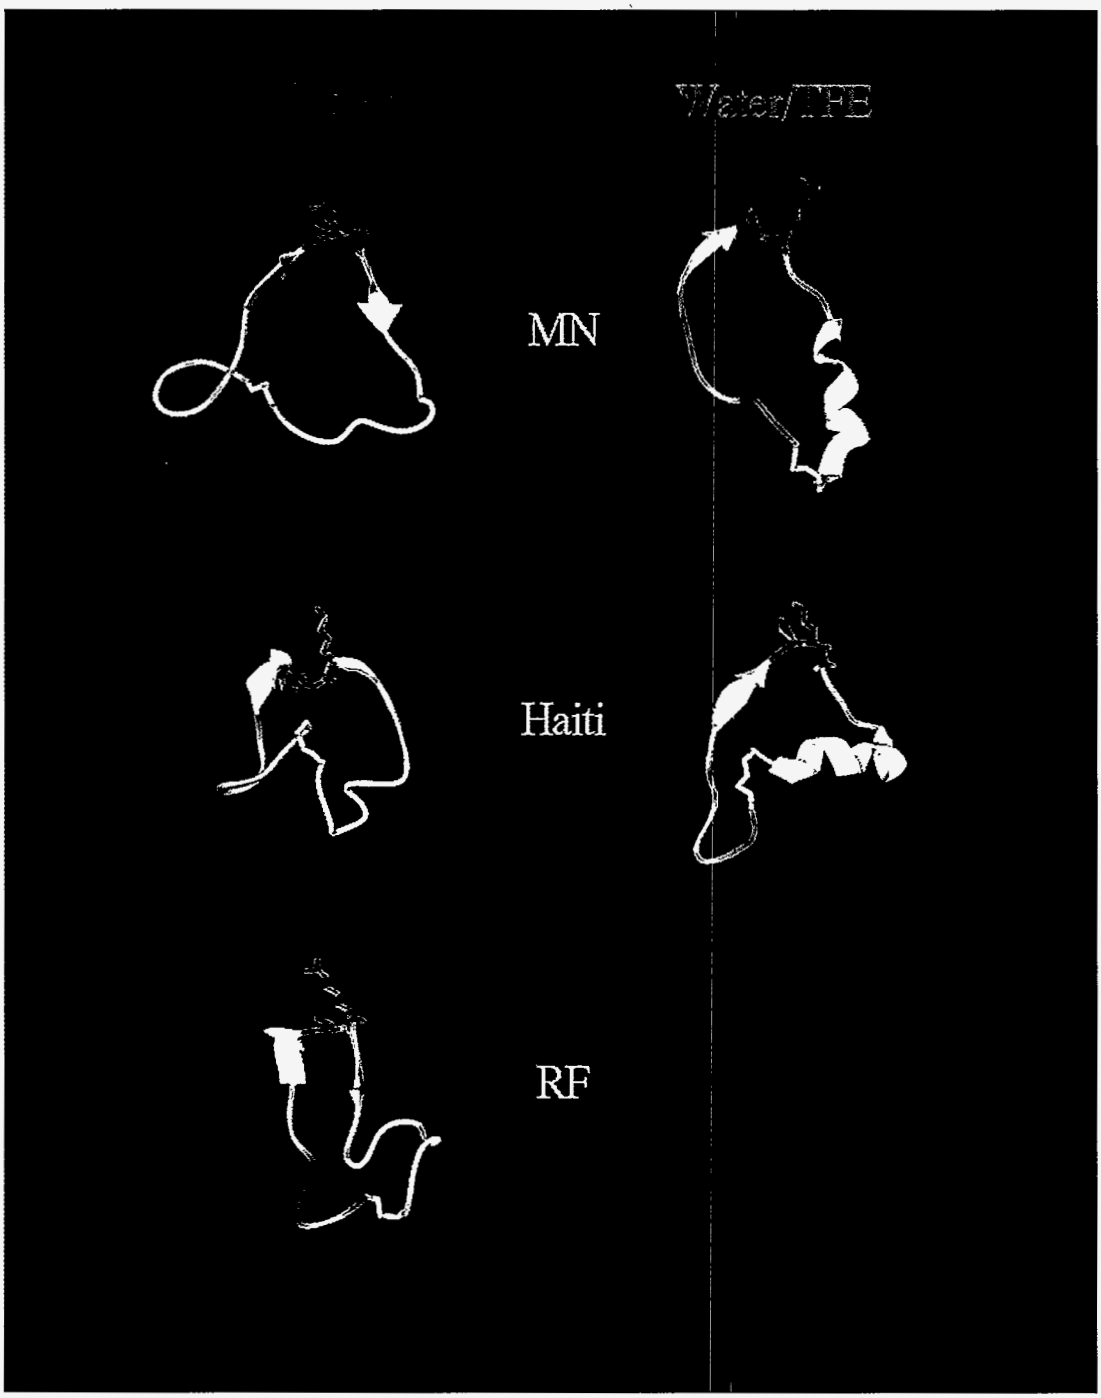

Figure 1. Ribbon diagram showing the average folding patterns of the structures of the MN, Haiti and RF V3 loops in water and in a mixture of 70%/30% water/TFE. In each case the average is done over 70 sampled low energy structures. Note that, in each case, the neutralizing epitope containing the central GPG(R/K) sequence forms a protruding loop even though the local structure and presentation of the loop in the different cases are noticeably different. Structures that satisfy the NMR constraints of the V3 loops in water show a higher degree of flexibility than those in agreement with the NMR data in the mixed water/ TFE solvent. This is due to the formation of the alpha helix in the mixed solvent. Color code is as follows: GPG(R/K) crest is red, extended regions are green, disulfide bridges are yellow and the alpha helical region is cyan.

Introduction

The emergence of drug-resistant variants of HIV continues to be of prime interest in the fields of HIV disease pathogenesis and antiretroviral chemotherapy. Drug resistance is the inevitable consequence of incomplete suppression of HIV replication. The rapid replication rate of HIV and its inherent genetic variation lead to the generation of a seemingly limitless number of viral variants that exhibit drug resistance. The growing number of drug resistance mutations listed in these revised tables stands as a testimony to the genetic flexibility of HIV. When the first resistance table was published in 1994 (*International Antiviral News* 2(5):72–75) only 42 different mutations were listed. This new update lists 143 mutations, a 240 per cent increase over a 2-year period. The revised tables include, for the first time, sections on HIV binding/fusion inhibitor resistance, and multidrug resistance. Although the tables are quite comprehensive, the reader should be reminded that the mutations described are predominately found in clade B virus and not in other HIV genotypes.

These tables are presented here in a modified format courtesy of the International Medical Press, which previously published them in *International Antiviral News* August, 1996 4(6):95–107.

Acknowledgments

The authors would like to gratefully acknowledge their colleagues for assistance in assembling this table, and in particular the following: E Anton, J Balzarini, CAB Boucher, RW Buckheit, JM Cherrington, J Condra, R D'Aquila, MP de Bethune, K De Vreese, E De Clercq, LM Demeter, R Deziel, JA Este, J Eberle, E Emini, JW Erickson, A Fridland, S Gulnik, D Havlir, JP Kleim, D Lamarre, P-F Lin, TC Merigan, M Moermans, A Molla, T North, AK Patick, W Shao, S Sharma, R Swanstrom, A-M Vandamme, K Van Rompay, MA Wainberg, G Werner, SS Yang, SD Young, S Yuasa, and H Zhang. The authors wish to thank A Juodawlkis for her excellent assistance with the table. This work was supported in part by the Department of Veterans Affairs and the Georgia VA Research Center for AIDS and HIV Infections.

Mutations in HIV-1 RT that confer drug resistance, ordered by position.

Mutations in Protease that confer drug resistance, ordered by position.

Amino Acid Change	Codon Change	Class of Drug	Compound	In vitro	In vivo	Fold-resistance	Cross-resistance (-fold)	Comments	Refs
A 71 V	GCT to GTT	Protease Inhibitor	ABT-538 (ritonavir)	Y	Y			K20R/M36I/I54V/A71V/V82T: 28-fold; M36I/I54V/A71V/V82T: 8-fold; I54V/A71V/I/V82A/L90M: 7-fold; In vivo, V82 occurs first, often followed by changes at I54, A71 and M36	
A 71 V	GCT to GTT	Protease Inhibitor	AG1343 (nelfinavir)	Y	?	5		D30N/A71V: 7-fold; M46I/L63P/A71V/I84V: 30-fold	(100,101)
A 71 V	GCT to GTT	Protease Inhibitor	BILA 1906 BS	Y	?			V32I/A71V: 3-fold; V32I/A71V/M46I/I84V: 500-1,000-fold	(99,104,105)
A 71 V	GCT to GTT	Protease Inhibitor	BILA 2011 (palinavir)	Y	?				
A 71 V	GCT to GTT	Protease Inhibitor	MK-639 (L-735,524, indinavir)	Y	Y			V32I/M46L/A71V/V82A: 14-fold	(86)
A 71 V	GCT to GTT	Protease Inhibitor	SC-52151	Y	?			A71V/V75I/P81T: 20- to 30-fold; L24V/G48V/A71V/V75I/P81T: 1000-fold; N88D or I11V/M46I/F53L/A71V/N88D:10- to 20-fold	(93,94)
V 75 I	GTA to ATA	Protease Inhibitor	SC-52151	Y	?			L24V/G48V/A71V/V75I/P81T: 1000-fold; A71V/V75I/P81T: 20- to 30-fold; L24V/G48V/A71V/V75I/P81T: 1000-fold	(93,94)
V 77 I		Protease Inhibitor	AG1343 (nelfinavir)	Y	Y				
P 81 T	CCT to ACT	Protease Inhibitor	SC-52151	Y	?			A71V/V75I/P81T: 20- to 30-fold; L24V/G48V/A71V/V75I/P81T: 1000-fold	(93,94)
I 82 T	ATC to ACC	Protease Inhibitor	A-77003	Y	?			G48V/I82T: 100-fold (82T was derived from in vitro passage of 82I)	(111)

Mutations in Protease that confer drug resistance, ordered by position.

Amino Acid Change	Codon Change	Class of Drug	Compound	In vitro	In vivo	Fold-resistance	Cross-resistance (-fold)	Comments	Refs
V 82 A	GTC to GCC	Protease Inhibitor	A-77003	Y	?			Rare; seen with M46F; V32I appears first; progression to V32I/M46V and V32I//M46V/A71V/V82A occurs even in the absence of drug	(87,103,111)
V 82 A	GTC to GCC	Protease Inhibitor	ABT-538 (ritonavir)	N	Y	2		In vivo, V82 occurs first, often followed by changes at I54, A71 and M36	(97,98)
V 82 A	GTC to GCC	Protease Inhibitor	BMS 186,318	Y	?			A71T/V82A: 15-fold	(112,113)
V 82 A	GTC to GCC	Protease Inhibitor	MK-639 (L-735,524, indinavir)	Y	Y			V32I/M46L/V82A: 3-fold; V32I/M46L/A71V/V82A: 14-fold	(86,95,107,114)
V 82 A	GTC to GCC	Protease Inhibitor	P9941	Y	?	6-8			(115)
V 82 A	GTC to GCC	Protease Inhibitor	SC-52151	Y	?			G48V/V82A, G48V/L63P/V82A or I54T: 10- to 20-fold	(93,94)
V 82 A		Protease Inhibitor	SKF108922	Y	?				
V 82 A	GTC to GCC	Protease Inhibitor	XM323	Y	?			V82A/M46L: 7-fold; V82A/M46L/L97V: 11-fold; L10F/V82A: 2-fold; V82A/L97V: 3-fold	(92)
V 82 F	GTC to TTC	Protease Inhibitor	ABT-538 (ritonavir)	Y	Y			V82F/I84V: 8- to 10-fold; M46I/L63P/A71V/V82F/I84V: 27-fold	(97,98)
V 82 F	GTC to TTC	Protease Inhibitor	MK-639 (L-735,524, indinavir)	?	Y				(95,107)
V 82 F	GTC to TTC	Protease Inhibitor	XM323	Y	?			V82F/I84V: 92-fold	(92)
V 82 I	GTC to ATC	Protease Inhibitor	A-77003	Y	?			No resistance alone but V32I and V82I are synergistic mutations yielding 20-fold enzyme resistance (82T was derived from in vitro passage of 82I)	(87,111)
V 82 I	GTC to ATC	Protease Inhibitor	XM323	Y	?	< 2			(92)
V 82 S	GTC to TCC	Protease Inhibitor	ABT-538 (ritonavir)	N	Y	6		In vivo, V82 occurs first, often followed by changes at I54, A71 and M36	(97,98)

Mutations in Protease that confer drug resistance, ordered by position.

Amino Acid Change	Codon Change	Class of Drug	Compound	In vitro	In vivo	Fold-resistance	Cross-resistance (-fold)	Comments	Refs
V 82 T	GTC to ACC	Protease Inhibitor	ABT-538 (ritonavir)	N	Y	3		In vivo, V82 occurs first, often followed by changes at I54, A71 and M36; V82T has reduced replication efficacy in natural background; M36I/I54V/A71V/V82T: 8-fold; I54V/V82T: 9-fold	
V 82 T	GTC to ACC	Protease Inhibitor	MK-639 (L-735,524, indinavir)	N	Y			M46I/L63P/V82T: 4-fold; L10R/M46I/L63P/V82T: 4-fold; L10R/M46I/L63P/V82T/I84V: 8-fold	(95,107)
V 82 T		Protease Inhibitor	SKF108842	Y	?				(116)
I 84 A	ATA to GCA	Protease Inhibitor	BILA 1906 BS	Y	?				(99,104,105)
I 84 A	ATG to ATA	Protease Inhibitor	BILA 2011 (palinavir)	Y	?			I84A is the most common mutation	(99,104,105)
I 84 V	ATA to GTA	Protease Inhibitor	ABT-538 (ritonavir)	Y	Y			M46I/L63P/A71V/V82F/I84V: 27-fold; V82F/I84V: 8- to 10-fold; M46I/L63P/A71V/V82F/I84V: 27-fold	(97,98)
I 84 V	ATA to GTA	Protease Inhibitor	AG1343 (nelfinavir)		?			M46I/L63P/A71V/I84V: 30-fold	(100,101)
I 84 V	ATA to GTA	Protease Inhibitor	BILA 1906 BS	Y	?			V32I/A71V/M46I/I84V: 500-1,000-fold	(99,104,105)
I 84 V	ATA to GTA	Protease Inhibitor	DMP 450	Y	?			S1 subsite	(88,89)
I 84 V	ATA to CTA	Protease Inhibitor	MK-639 (L-735,524, indinavir)	N	Y			G48V/I84V/L90M: 30-fold; L10R/M46I/L63P/V82T/I84V: 8-fold	(95,107)
I 84 V	ATA to GTA	Protease Inhibitor	Ro 31-8959 (saquinavir)	Y	?				(86)
I 84 V	ATA to GTA	Protease Inhibitor	RPI-312	Y	?	5			(117)
I 84 V		Protease Inhibitor	SKF108842	Y	?				(116)
I 84 V	ATA to GTA	Protease Inhibitor	VB 11,328	Y	?			L10F/I84V: 8-fold	(86,90)
I 84 V	ATA to GTA	Protease Inhibitor	VX-478 (141W94)	Y	?				(108)

Mutations in Protease that confer drug resistance, ordered by position.

Amino Acid Change	Codon Change	Class of Drug	Compound	In vitro	In vivo	Fold-resistance	Cross-resistance (-fold)	Comments	Refs
I 84 V	ATA to GTA	Protease Inhibitor	XM323	Y	?	12		V82F/I84V: 92-fold; L10F/K45I/I84V: 50-fold	(86,92)
N 88 D		Protease Inhibitor	AG1343 (nelfinavir)	Y	Y			D30N and N88D are most common in vivo after 24 weeks of therapy; they do not cause cross-resistance to other protease inhibitors	(100,101)
N 88 D	AAT to GAT	Protease Inhibitor	SC-52151	Y	?			N88D or I11V/M46I/F53L/A71V/N88D:10- to 20-fold	(93,94)
N 88 S	AAT to AGT	Protease Inhibitor	SC-55389A	Y	?	20		N88S/L10F: 10-fold	(93,94)
L 90 M	TTG to ATG	Protease Inhibitor	ABT-538 (ritonavir)	N	Y			82A/54V/I/71V/90L/M: 7-fold	(97,98)
L 90 M	TTG to ATG	Protease Inhibitor	AG1343 (nelfinavir)	N	Y			Rare in patients	(100,101)
L 90 M	TTG to ATG	Protease Inhibitor	MK-639 (L-735,524, indinavir)	?	Y				(95,107)
L 90 M	TTG to ATG	Protease Inhibitor	Ro 31-8959 (saquinavir)	Y	Y			G48V/L90M: >100-fold enzyme resistance; double mutant rare in vivo; L90M most common in vivo; G48V/I84V/L90M: 30-fold	(109)
L 97 V	TTA to GTA	Protease Inhibitor	XM323	Y	?			No resistance alone; V82A/L97V: 3-fold; V82A/M46L/L97V: 11-fold	(92)

Mutations in Envelope that confer drug resistance, ordered by position.

Amino Acid Change	Codon Change	Class of Drug	Compound	In vitro	In vivo	Fold-resistance	Cross-resistance (-fold)	Comments	Refs
S 113 N	AGT to AAT	Fusion/Binding Inhibitor	Dextran sulphate (DS)	Y	?			S113N/S134N/K269E/Q278E/N293D/N323S/R387I: 250-fold; 113 is in the V1 loop region	(118,119)
S 134 N	AGC to AAC	Fusion/Binding Inhibitor	Dextran sulphate (DS)	Y	?			V2 loop region; S113N/S134N/K269E/Q278E/N293D/N323S/R387I: 250-fold	(118,119)
F 145 L	TTC to TTA	Fusion/Binding Inhibitor	JM-3100	Y	?			Combination of mutations: 2- to 100-fold	(120,121)

Mutations that confer multiple drug resistance, ordered by position.

Amino Acid Change	Codon Change	Class of Drug	Compound	In vitro	In vivo	-Fold -resistance	Cross-resistance (-fold)	Comments	Refs
A 62 V	GCC to GTC	Multiple Drug Resistance	AZT+ ddI/ddC	N	Y	Nil		Associated with 75, 77, 116 & 151; A62V/V75I/F77L/F116Y/Q151M: AZT 190-fold	(123,124)
V 75 I	GTA to ATA	Multiple Drug Resistance	AZT+ ddI/ddC	N	Y	Nil		Associated with 77, 116 & 151; A62V/V75I/F77L/F116Y/Q151M: AZT 190-fold	(123,124)
F 77 L	TTC to CTC	Multiple Drug Resistance	AZT+ ddI/ddC	N	Y	Nil		Associated with 75, 116 & 151; A62V/V75I/F77L/F116Y/Q151M: AZT 190-fold	(123,124)
F 116 Y	TTT to TAT	Multiple Drug Resistance	AZT+ ddI/ddC	N	Y	Nil		Associated with 75, 77 & 151; A62V/V75I/F77L/F116Y/Q151M: AZT 190-fold	(123,124)
Q 151 M	CAG to ATG	Multiple Drug Resistance	AZT+ ddI/ddC	N	Y	AZT: 10; ddI/ddC: 5		Pivotal MDR mutation (first to occur and is then found in association with various of the other four mutations); A62V/V75I/F77L/F116Y/Q151M: AZT 190-fold; ddI 50-fold; ddC 20-fold; d4T > 10-fold	(123,124,125)

Abbreviations

Amino acids

A	alanine
C	cysteine
D	aspartate
E	glutamate
F	phenyalanine
G	glycine
H	histidine
I	isoleucine
K	lysine
L	leucine
M	methionine
N	asparagine
P	proline
Q	glutamine
R	arginine
S	serine
T	threonine
V	valine
W	tryptophan
Y	tyrosine

Compounds

1592U89	(1*S*,4*R*)-4-[2-amino-6-cyclopropyl-amino)-9*H*-purin-9-yl]-2-cyclopentene-1-methanol succinate (a carbovir analogue, Glaxo Wellcome)
3TC	(-)-β-L-2′,3′-dideoxy-3′-thiacytidine (Glaxo Wellcome)
α-APA R18893	α-nitro-anilino-phenylacetamide
A-77003, A-75925 and A-80987	C2 symmetry-based protease inhibitors (Abbott Laboratories)
AAP-BHAP	bisheteroarylpiperazine analogue (Pharmacia & Upjohn)
ABT-538	C2 symmetry-based protease inhibitor (Abbott Laboratories)
AZdU	3′-azido-2′,3′-dideoxyuridine
AZT	3′-azido-3′-deoxythymidine (Glaxo Wellcome)
AZT-p-ddI	3′-azido-3′-deoxythymidilyl-(5′,5′)-2′,3′-dideoxyinosinic acid (Ivax)
BHAP	bisheteroarylpiperazine
BILA 1906	*N*-{1*S*-[[[3-[2*S*-(1,1-dimethylethyl)amino]carbonyl-4*R*-]3-pyridinylmethyl)thio]-1-piperidinyl]-2*R*-hydroxy-1*S*-(phenylmethyl)propyl]amino]carbonyl]-2-methylpropyl}-2-quinolinecarboxamide (Bio-Mega/Boehringer Ingelheim)
BILA 2185	*N*-(1,1-dimethylethyl)-1-[2*S*-[[2-2,6-dimethyphenoxy)-1-oxoethyl]amino]-2*R*-hydroxy-4-phenylbutyl]4*R*-pyridinylthio)-2-piperidine-carboxamide (Bio-Mega/Boehringer Ingelheim)
BM+51.0836	thiazolo-isoindolinone derivative
BMS 186,318	aminodiol derivative HIV-1 protease inhibitor (Bristol-Myers Squibb)

Abbreviations (cont)

Compounds (cont)

d4API	9-[2,5-dihydro-5-(phosphonomethoxy)-2-furanel]adenine (Gilead Sciences)
d4C	2′,3′-didehydro-2′,3′-dideoxycytidine
d4T	2′,3′-didehydro-3′-deoxythymidine (Bristol-Myers Squibb)
ddC	2′,3′-dideoxycytidine (Roche)
ddI	2′,3′-dideoxyinosine (Bristol-Myers Squibb)
DMP 266	a 1,4-dihydro-2*H*-3,1-benzoxazin-2-one
DMP 450	[4*R*-(4-α,5-α,6-β,7-β)]-hexahydro-5,6-bis(hydroxy)-1,3-bis(3-amino)phenyl]methyl)-4,7-bis(phenylmethyl)-2*H*-1,3-diazepin-2-one-bismesylate (Avid Therapeutics)
DXG	(-)-β-D-dioxolane-guanosine
EBU-dM	5-ethyl-1-ethoxymethyl-6-(3,5-dimethylbenzyl)uracil
E-EBU	5-ethyl-1-ethoxymethyl-6-benzyluracil
DS	dextran sulphate
E-EPSeU	1-(ethoxymethyl)-(6-phenylselenyl)-5-ethyluracil
E-EPU	1-(ethoxymethyl)-(6-phenyl-thio)-5-ethyluracil
(-)-FTC	(-)-β-L-2′,3′-dideoxy-5-fluoro-3′-thiacytidine (Triangle Pharmaceuticals)
HBY 097	(*S*)-4-isopropoxycarbonyl-6-methoxy-3-(methylthio-methyl)-3,4-dihydroquinoxalin-2(1*H*)-thione
HEPT	1-[(2-hydroxyethoxy)methyl]6-(phenylthio)thymine
JM2763	1,1′-(1,3-propanediyl)-bis-1,4,8,11-tetraazacyclo-tetradecane (Johnson Matthey)
JM3100	1,1′-[1,4-phenylenebis-(methylene)]bis-(1,4,8,11-tetraazacyclotetradecane) octahydrochloride dihydrate (Johnson Matthey)
KNI-272	(2*S*,3*S*)-3-amino-2-hydroxy-4-phenylbutyric acid-containing tripeptide
L-697,593	5-ethyl-6-methyl-3-(2-phthalimido-ethyl)pyridin-2(1*H*)-one
L-697,661	3-[(-4,7-dichloro-1,3-benzoxazol-2-yl)methyl]amino-5-ethyl-6-methylpyridin-2(1*H*)-one
L-FDDC	(-)-β-L-5-fluoro-2′,3′-dideoxy-cytidine
L-FDOC	(-)-β-L-5-fluoro-dioxolane cytosine
MK-639	hydroxy-aminopentane amide HIV-1 protease inhibitor (Merck & Co)
MKC442	6-benzyl-1-ethoxymethyl-5-isopropyluracil (I-EBU, Triangle Pharmaceuticals/Mitsubishi)
nevirapine	11-cyclopropyl-5,11-dihydro-4-methyl-6*H*-dipyridol[3,2-b:2′,3′-e] diazepin-6-one (Boehringer Ingelheim)
NNRTI	non-nucleoside reverse transcriptase inhibitor
NSC648400	1-benzyloxymethyl-5-ethyl-6-(alpha-pyridylthio)uracil (E-BPTU)
P9941	[2-pyridylacetyl-IIePheAla-y(CHOH)]$_2$ (Dupont Merck)
PFA	phosphonoformate (foscarnet, Astra)
PMEA	9-(2 phosphonylmethoxyethyl)adenine (Gilead Sciences)
PMPA	(*R*)-9-(2-phosphonyl-methoxypropyl)adenine (Gilead Sciences)
Ro 31-8959	hydroxyethylamine derivative HIV-1 protease inhibitor (Roche)

Abbreviations (cont)

Compounds (cont)

RPI-312	1-[(3*S*)-3-(n-alpha-benzyloxycarbonyl)-l-asparginyl)-amino-2-hydroxy-4-phenyl-butyryl]-*n*-tert-butyl-l-proline amide (peptidyl protease inhibitor)
RT	reverse transcriptase
S-2720	6-chloro-3,3-dimethyl-4-(isopropenyl-oxycarbonyl)-3,4-dihydro-quinoxalin-2(1*H*)thione
SC-52151	hydroxyethylurea isostere protease inhibitor (Searle)
SC-55389A	hydroxyethyl-urea isostere protease inhibitor (Searle)
TIBO R82150	(+)-(5*S*)-4,5,6,7-tetrahydro-5-methyl-6-(3-methyl-2-butenyl)-imidazo[4,5,1-*jk*][1,4]-benzodiazepin-2(1*H*)-thione (Janssen)
TIBO 82913	(+)-(5*S*)-4,5,6,7,-tetrahydro-9-chloro-5-methyl-6-(3-methyl-2-butenyl)-imidazo-[4,5,1-*jk*]-[1,4]benzo-diazepin-2(1it H)-thione (Janssen)
TSAO-m^3T	[2′,5′-bis-*O*-(tert-butyl-dimethylsilyl)-3′-spiro-5′-(4′-amino-1′,2′-oxathiole-2′,2′-dioxide)]-β-D-pentofuranosyl-N^3-methylthymine
U-90152	1-[3-[(1-methylethyl)-amino]-2-pyridinyl]-4-[[5-[(methylsulphonyl)-amino]-1*H*-indol-2yl]carbonyl]-piperazine
UC	thiocarboxanilide derivatives (Uniroyal Chemical Co)
UC-781	*N*-[4-chloro-3-(3-methyl-2-butenyloxy)phenyl]-2-methyl-3-furan-carbothioamide
UC-82	*N*-[4-chloro-3-(3-methyl-2-butenyloxy)phenyl]-2-methyl-3-thiophene-carbothioamide
VB 11,328	hydroxyethyl-sulphonamide protease inhibitor (Vertex Pharmaceuticals)
VX-478	hydroxyethylsulphonamide protease inhibitor (Vertex Pharmaceuticals)
XM 323	cyclic urea protease inhibitor (Dupont Merck)

Related Sequences

HIV and Cellular Factors

Kuan-Teh Jeang

Molecular Virology Section, LMM, NIAID, National Institutes of Health, Bethesda, MD 20892-0460, USA

Introduction

Viruses are obligatory parasites of cells. Thus it is expected that host cell factors contribute importantly to the life-cycle of viruses. In this section, we survey, for HIV-1, four types of virus-cell interactions. These four areas include: 1) DNA-binding proteins that recognize target motifs in proviral LTR; 2) RNA-binding proteins that bind HIV-1 RNAs; 3) cellular factors that form protein-protein complexes with HIV-1 regulatory proteins; and 4) cellular genes which are modulated upon viral infection. With rapid increases in knowledge in the area of virus-cell interactions, we anticipate that this initial survey would be expanded extensively in future editions of the data base. Additional discussions on HIV-cell interactions are found elsewhere (Jones and Peterlin, 1994; Jeang and Gatignol, 1994; Garcia and Gaynor, 1994; Gatignol *et al.*, 1996; Dayton, 1996).

I. DNA-binding Proteins

The promoter-enhancers of the human immunodeficiency virus (HIV) are contained in the U3 of the viral long terminal repeat (LTR). HIV-1 U3 is typically 454 nucleotides long and has binding sites for many transcription factors. Some of these are diagrammed in figure 1. With the exception of NF-kB and Sp1 (Ross *et al.*, 1991; Kim *et al.*, 1993; Huang and Jeang, 1993; Huang *et al.*, 1994), verification of the importance of the various sequences in viral contexts has not been directly performed.

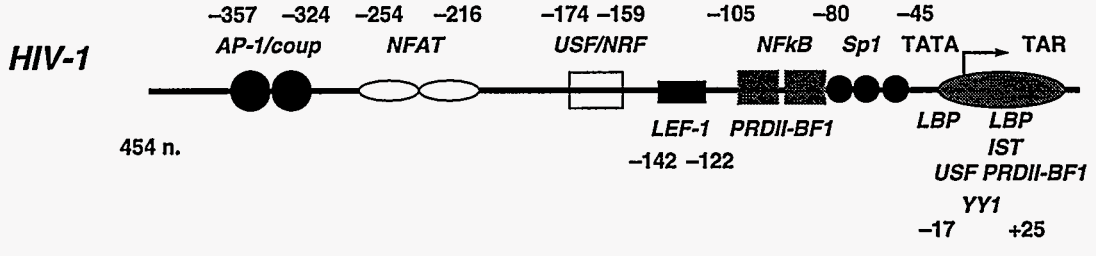

Fig. 1. Diagrammatic representation of the positions in U3 and R for some of the DNA-binding proteins that recognize the HIV-1 LTR.

Subgenomic assays in cultured cells indicate that the primary contributors to HIV-promoter activity are the NF-kB, Sp1, and TATAA (sequences from +1 to –105; Berkhout and Jeang, 1992). Nonetheless, it is likely that other DNA-binding factors also contribute *in vivo*. Beginning directionally from the 5′ end of U3, binding sites for AP-1 (a fos/jun hetero-complex; van Straaten *et al.*, 1983; Hattori *et al.*, 1988) and COUP (a member of the steroid/thyroid receptor superfamily; Cooney *et al.*, 1991) are found between –324 to –357. Both COUP and AP-1 are expressed in human T-cells, and thus could compete with each other for the same proviral DNA sites during HIV-1 infection.

More proximally, between –216 and –254 are binding motifs for nuclear factor from activated T-cells (NFAT; Shaw *et al.*, 1988). NFAT is an intermediating transducer of signals initiated at the T-cell antigen receptor. Recent evidence suggests that NFAT binding activity is composed of three discrete polypeptides, NFATp (McCaffrey *et al.*, 1993), Fos and Jun (Yaseen *et al.*, 1993).

In the region between –159 to –174 is a binding consensus sequence for USF (Gregor *et al.*, 1990). USF was characterized initially as a positive activator of adenovirus major-late-promoter transcription. In the HIV context, there is conflicting information on whether this factor has moderating (and thus be regarded as a negative regulatory factor; NRF; Lu *et al.*, 1990) or stimulating (Maekewa *et al.*, 1991) effects. Interestingly, USF also binds a second unrelated sequence (–5 to +11) that surrounds the HIV-1 initiator (Hu *et al.*, 1993). USF interaction at the initiator-proximal site activates strong expression from the TATAA-promoter (Hu *et al.*, 1993). Of note, a factor distinct from USF, but which binds the same DNA-sequence, has also been cloned and characterized (TFE3; Bechmann and Kadesch, 1991).

LEF-1 is a T-cell specific transcription factor (Waterman and Jones, 1990). Once bound to its cognate site, LEF-1 bends DNA and thereby facilitates the assembly of nucleoprotein complexes at the promoter (Giese *et al.*, 1992; reviewed in Jones and Peterlin, 1994). A high affinitiy LEF-1 binding site is present at –122 to –143. Two low affinity binding sites exist at –37 to –51 and +17 to +32 (Waterman and Jones, 1990).

NF-kB (Nabel and Baltimore, 1987) and Sp1 (Jones and Tjian, 1985; Jones *et al.*, 1986) motifs are perhaps the best characterized sequence elements in the HIV-1 LTR. These sequences directly impact viral replication (Ross et al, 1991; Kim *et al.*, 1993; Huang and Jeang, 1993; Huang *et al.*, 1994), viral transcription (Harrich *et al.*, 1990; Berkhout and Jeang, 1992; Pazin *et al.*, 1996), and Tat transactivation (reviewed in Jones and Peterlin, 1994; Jeang and Gatignol, 1994). For more extensive discussions of the biochemical and functional properties of NF-kB (Ghosh *et al.*, 1990; Kieran *et al.*, 1990; Nolan *et al.*, 1991; Liou *et al.*, 1991; and references cited therein) and Sp1 (Dynan and Tjian, 1983; Briggs *et al.*, 1986; Kadonaga *et al.*, 1987; and references cited therein), readers should consult elsewhere.

PRDII-BF1 is a 300 kDa zinc-finger containing protein (Baldwin *et al.*, 1990; Seeler *et al.*, 1994). PRDII-BF1 recognizes and binds the NF-kB motif; however, it also binds a divergent sequence in R (+27 to +52; Seeler *et al.*, 1994).

Positioned at the junction of U3 and R are sites for LBP (Yoon *et al.*, 1994) and YY1 (Useheva and Shenk, 1994; Seto *et al.*, 1991). While the role for LBP in HIV-1 transcription is not wholly understood (Jones *et al.*, 1988; Kato *et al.*, 1991), binding of YY1 to the LTR has been shown to repress HIV-1 expression and production of virions (Margolis *et al.*, 1994). Besides LBP and YY1, a DNA-mediated activity for the induction of short transcripts (IST) has also been mapped to the same general vicinity (–5 to +26; Sheldon *et al.*, 1993). The cDNA for the cellular factor that mediates IST-activity has not been isolated, and thus the authentic identity of this factor is unknown. HIP 116 is another newly cloned cDNA that binds to the TATA/initiator of the HIV-1 promoter (Sheridan *et al.*, 1995).

There are a number of reports of sites for DNA-binding proteins in the HIV-1 genome that occur downstream of the +1 start for transcription. These include NF-kB motifs (Mallardo *et al.*, 1996) and sites for AP-1, AP-3-like, DBF-1, and Sp-1 (El Kharroubi and Martin, 1996). The full implication of these downstream DNA-motifs in the setting of HIV-1 infection remains to be clarified.

II. RNA-binding Proteins

In recent years, it has become evident that RNA-binding proteins play important roles in gene regulation (see reviews, Keene and Query, 1991; Mattaj, 1993; Burd and Dreyfuss, 1994). For HIV-1, cellular proteins that bind viral regulatory RNAs have been studied in detail. In particular, at least eight host cell factors have been described to bind TAR RNA. Similarly, two RRE-binding factors have been characterized. There are also biologically compelling reasons as to why TAR- and RRE- binding proteins are meaningful contributors to the HIV-1 lifecycle.

The HIV-1 leader RNA, TAR, forms a stem-bulge-loop structure of approximately 60+ nucleotides (Muesing *et al.*, 1987; Berkhout and Jeang, 1989). Early, it was reported that many human cellular proteins bound TAR RNA (Gatignol *et al.*, 1989; Gaynor *et al.*, 1989). Since then, some of these factors have been defined further. Tabulating from extant studies, eight proteins associate with either the bulge, loop, or stem of TAR RNA (see fig. 2). TAR loop-binding proteins include p68 (Marciniak *et al.*, 1990), and TRP1/TRP185 (185 kDa; Sheline *et al.*, 1991; Wu *et al.*, 1991), while TRP2 (70–110 kDa; Sheline *et al.*, 1991) binds to TAR-bulge. Proteins that complex with the double-stranded stem of TAR RNA

consist of P1/dsI (newly renamed as PKR; McCormack et al., 1992; Roy *et al.*, 1991), SBP (140 kDa; Rounseville and Kumar, 1992), and TRBP (Gatignol *et al.*, 1991; Gatignol *et al.*, 1993). Two human autoantigens have been identified as TAR RNA-binding factors: Lupus antigen Ku (Kaczmarski and Khan, 1993) binds to the loop of TAR, while La (Chang *et al.*, 1994; Svitkin *et al.*, 1994) recognizes U-residues within the overall context of the TAR secondary structure.

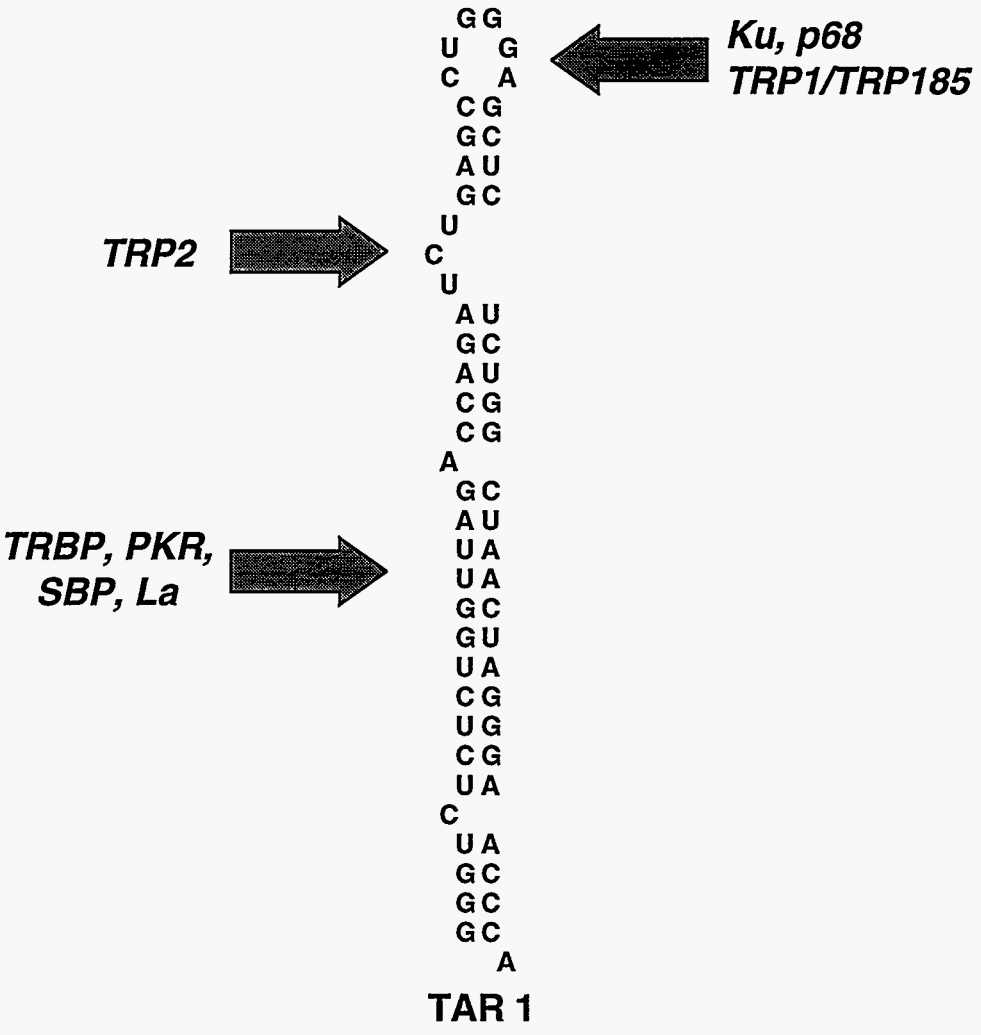

Fig. 2. Structure of the HIV-1 TAR RNA. Identities of the proteins that bind to the loop, bulge or stem of the TAR hairpin are indicated.

Recently, additional TAR-RNA-binding proteins and co-factors have been reported. Wong-Staal and colleagues have described the binding of TARBP-b (Reddy *et al.*, 1995) to the bulge structure of TAR. A set of cellular co-factors that enhances the binding of TRP 185 and RNA polymerase II (RNAP II) to TAR have been described by Gaynor and colleagues (Wu-Baer *et al.*, 1996a; 1996b). Finally, Hart and co-workers have characterized the elusive human chromosome 12-associated TAR loop-binding factor as an 83-kilodalton primate cell-specific protein whose expression is constitutively absent in hamster cells (Hart *et al.*, 1995).

RRE-binding proteins have also been studied extensively. We know that TRBP also can bind RRE (Park *et al.*, 1994). A 56 kDa factor (Vaishnav *et al.*, 1992) and a 49 kDa protein that belongs to

the heterogeneous nuclear ribonuclear protein family (Xu *et al.*, 1996) have been reported to bind RRE. Two other factors of 120 kDa and 60 kDa in molecular size have been reported to be primate-specific RRE-binding factors that are not expressed in rodent cells (Shukla *et al.*, 1994). It is expected that other RRE-factors would emerge from future studies. How these, as yet poorly characterized, factors might contribute to Rev/RRE function is reviewed in detail elsewhere (Dayton, 1996).

III. Protein-protein interactions

Protein-protein interactions are well-documented to be important in gene regulation (see reviews, Lewin, 1990; Greenblatt, 1991). Recent studies suggest that many HIV-1 proteins complex with host cell factors. We briefly describe below some examples pertaining to Tat, Rev, Gag, and Nef.

Although Tat is best known for transcription, it has other functions (Huang *et al.*, 1994; reviewed in Chang *et al.*, 1995; Goldstein, 1996) and has been reported to be a secretable factor that promotes the growth of Kaposi-like cells (Ensoli *et al.*, 1990). There is evidence that Tat can be taken up actively into cells (Frankel and Pabo, 1988) through binding to a cell-surface protein (Weeks *et al.*, 1993) implicated to be $\alpha_v\beta_5$ integrin (Vogel *et al.*, 1993). Once inside cells, Tat interacts with multiple partners in activating transcription (see also Tat Structure and Function section; Part III).

Two factors that bind Tat are themselves critical components of the eucaryotic RNA polymerase II transcription machinery. Genetic evidence supports a critical role for Sp1 in HIV-1 Tat-mediated transactivation (Harrich *et al.*, 1989; Kamine *et al.*, 1991; Southgate and Green, 1991; Berkhout and Jeang, 1992). Interestingly, direct protein-protein interactions between Tat and Sp1 (Jeang *et al.*, 1993) and Tat and the thyroid hormone receptor (which in certain cells bind at the Sp1 sites in the HIV-1 LTR; Desai-Yajnik *et al.*, 1995) have been documented. In addition, there is evidence that Tat also contacts TBP (Kashanchi *et al.*, 1994) and that Tat-Sp1-TFIID could present as a multiprotein complex (Huang *et al.*, 1993) inside cells. The critical nature of Tat-TBP contact has been questioned recently (Wang *et al.*, 1996). These investigators found that a trans-activation defective Tat protein bound TBP with the same avidity as wild type Tat protein, suggesting that binding to TBP cannot solely reflect the trans-activation property of Tat.

A large family of proteins related to the 26S protease from human erythrocytes (Dubiel *et al.*, 1994) are Tat-binding polypeptides. Members of this family include TBP-1 (Nelbock *et al.*, 1990; Ohana *et al.*, 1993), TBP-7 (Ohana *et al.*, 1993; Shaw and Ennis, 1993), MSS1 (Shibuya *et al.*, 1992), and SUG1 (Swaffield *et al.*, 1992). The exact role of this family of proteins in cellular metabolism is not wholly clear; however, the 26S protease seems to regulate the degradation of some cyclins and in this manner has been implicated in modulating the stability of oncoproteins such as c-Mos, c-Myb, c-Myc and p53 (Dubiel *et al.*, 1994).

Other cellular proteins, a 36 kDa protein (Desai *et al.*, 1991), a 60 kDa protein (Kamine *et al.*, 1996), and different cellular protein kinases (Hermann and Rice, 1993; McMillan *et al.*, 1995; Zhou and Sharp, 1996; Chun and Jeang, 1996), have been reported to bind Tat. Mavankal and colleagues have suggested that RNA polymerase II (RNAP II) is itself a specific Tat-binding protein (Mavankal *et al.*, 1996). The findings that RNAP II and kinases that phosphorylate RNAP II are Tat-binding factors suggest that these components contribute a part to explaining Tat function in transcription.

Multiple cellular factors also interact with Rev. Rev localizes to the nucleoli, and work by Laemmli and colleagues (Fankhauser *et al.*, 1991) and others (Miyazaki *et al.* 1995; Szebeni *et al.*, 1995) have demonstrated a tight association between the basic nuclear-localizing domain of Rev and nucleolar B23 protein. This protein-protein complex likely directs the subcellular localization of Rev.

By contrast, many investigators have studied the nuclear export function of Rev (Fischer *et al.*, 1994; 1995; Wen *et al.*, 1995; Myer *et al.*, 1996; Fridell *et al.*, 1996). Using the yeast two-hybrid cloning approach, three groups have isolated closely related nucleoporin proteins that bind wild type but not mutant Rev (Fritz *et al.*, 1995; Bogerd et al., 1995; Stutz *et al.*, 1995). These results suggest that the nucleoporin class of proteins are the Rev activation-domain specific co-factors involved in the nuclear to cytoplasmic export of RNAs.

Rev function can also be modulated by associations with other cellular factors. Two additional proteins have been shown to bind Rev. These are translation factor eIF-5A (Ruhl *et al.*, 1993; Bevec *et al.*, 1996), and serine-arginine (SR)-rich factors (Gontarek and Derse, 1996) such as the p32 protein (Luo *et al.*, 1994; Tange *et al.*, 1996) originally characterized by Krainer and colleagues (Krainer *et al.*, 1991) as a splicing factor-SF2-associated polypeptide. SR-rich proteins can also bind to the basic domain of the HIV-1 and HIV-2 Tat proteins (Trinh and Jeang, unpublished observation; B.R. Cullen, personal communication).

Other less-characterized Rev-binding proteins include human prothymosin alpha (Kubota et al, 1995) and nuclear lamin B (Nikolakaki et al, 1996).

Both HIV Gag and Nef also have cellular partners. p55 and p24 Gag bind cyclophilin A and cyclophilin B proteins (Luban *et al.*, 1993). The cyclophilins are cellular polypeptides originally characterized for their specific binding to cyclosporin A.

Nef has been found to bind β-COP, a coat protein from non-clathrin-coated vesicles (Benichou *et al.*, 1994). This interaction may be important in promoting the intracellular sequestration of CD4. Nef has also been shown to interact directly with CD4 (Rossi *et al.*, 1996). Recently many kinases have been described to associate with Nef (Sawai *et al.*, 1994; Saksela *et al.*, 1995; Bodeus *et al.*, 1995; Luo and Garcia, 1996). The identity of some of these kinases include Lck (Salghetti *et al.*, 1995; Collette *et al.*, 1996), Hck (Lee *et al.*, 1995), and PAK (Nunn and Marsh, 1996). Undoubtedly, there is much more to be learned from this area of research.

IV. Cellular Genes Modulated by HIV

Infection of cells by HIV results in activation and repression of many cellular genes. Because of the complexity of ambient gene expression inside cells, it is logistically difficult to dissect those genes that are upregulated from those that are downregulated from others that remain unperturbed. Nevertheless, several examples of genes that respond to HIV infection are known. Some of these include IL-2 (Westendorf *et al.*, 1994), IL6 (Scala *et al.*, 1994), and TGF-β (Buonaguro *et al.*, 1994; Rasty *et al.*, 1996).

Recent investigations have shown that HIV-1 proteins such as Tat and Nef potently affect cellular metabolism. Tat, for example, has been shown to modulate the expression of cytokines including MIP-1 alpha (Sharma *et al.*, 1996), second messengers including nitric oxide (Barton *et al.*, 1996), and housekeeping genes such as Bcl2 (Zauli *et al.*, 1995a). Both Tat and Nef participate in signal transduction pathways that include NF-kB (Demarchi *et al.*, 1996), phosphatidylinositol kinase (Zauli et al; 1995b; Gramagli et al., 1996), and protein kinase C (Conant *et al.*, 1996)

The identification of genes modulated by HIV has been based on classical approaches; however, with the advent of mRNA differential display technology (Liang and Pardee, 1992) the exhaustive characterization of cellular genes that respond to infection by HIV should be accomplished with greater ease. One such example has recently been reported. Zeichner and colleagues, using a differential display approach, found that expression of the human glucose transporter protein (GLUT3) is upregulated by HIV-1 infection. We anticipate reports on others, shortly.

HIV and Molecular Mimicry

Gerald Myers and Hong Lu

MS K710, Los Alamos National Laboratory, Los Alamos, New Mexico 87545

For more than three decades, molecular mimicry has been considered a contributing factor in viral pathogenesis. The phenomenon comes about when viral antigens share epitopes with host cell proteins. Because tolerance is thought never to be complete, the mimicking microbe can induce anti-self antibodies, a state of autoimmunity, with resulting immunopathogenesis. This mode of attack seems preeminently possible with immunosuppressive viruses such as HSV-1 and HIV; it is also thought likely when cross-species-induced pathogenesis is involved. For some general discussions of molecular mimicry and autoimmunity brought about by viruses, see [1,2].

In the context of AIDS pathogenesis, some have argued over the years that HIV mimicry could be the crucial factor in the disease expression, for example [3–7]. If this be so, clearly the chances for a safe and successful HIV vaccine are seriously weakened [8,9]. Thus it is of considerable interest to examine mimicry claims that have been brought forward over the last decade of AIDS research. In this section, we offer a general critique of mimicry claims in so far as they have been based upon sequence similarities; experimentally-derived data will be cited on occasion, however the focus is primarily upon amino acid sequences and peptide structures. For his reason, this section appears in both the genetic and immunologic sections of the 1996 database compendium.

A. PROLEGOMENA

An important distinction that is often blurred in the literature is the distinction between *similarity* and *homology*. The correct meaning of similarity, according to the prevailing school of thought, is as an empirical relationship that can be quantified; whereas homology is an inference, a qualitative prediction about common ancestry [10–12]. Accordingly, it is impossible to prove that any two sequences are not homologous [12]. Two sequences can be similar without being homologous as a result of evolutionary convergence, and we imagine this to be the basis for viral molecular mimicry.

From this point of view, it is careless to speak of homologies in the context of mimicry, which by definition implies similarity. A pair of sequences, or a pair of structures, can be 10%, 30%, 95%... similar, but they are either homologous or they are not; philosophers speak of the first kind of judgement as determinate, whereas the judgement about homology is indeterminate. Finally, the term similarity usually makes allowances for equivalencies as well as identities: the amino acids serine and threonine may be regarded as equivalent in certain positions in a character string, and a scoring matrix would assign partial credit to one substituted for the other.

Sequences with similarity of 50% or more will typically have similar structures, although it is now well-known that two identical pentapeptides could have different shapes or presentations in space [13]. On the other hand, sequences that are marginally similar, say 30%, may have equivalent structures, thus it is not a trivial matter to show that two dissimilar sequences are also structurally dissimilar. While the emphasis herein will be upon sequence similarities, the complex relationship between sequence space and shape space must be held in mind throughout.

Moreover, it may be the case that for effective breakthrough of tolerance a mimicking epitope of a virus will not be perfectly identical to the host "self" protein. For example, an experimentally-verified mimicry between rabbit myelin basic protein (MBP) and hepatitis B virus polymerase (HBVP) is [2]:

```
MBP    TTHYGSLPQK
         YGSLPQ
HBVP   IGCYGSLPQE
```

In other cases, however, it is known that a single amino acid replacement can alter binding of an antibody to a protein [14].

We understand that some epitopes are discontinuous. Mimicry involving these epitopes will not be addressed herein. Antigen presentation is yet another complexity that will be sidestepped.

It is tempting to evaluate mimicry claims by invoking secondary structure prediction algorithms such as SOPM, discussed in an accompanying Part III section of the 1996 compendium. But we must also keep in mind long-range interactions, oligomerization, and protein residue modification (phosphorylation, glycosylation, etc.), all of which can invalidate judgements based on the primary sequence comparison and secondary structure prediction. Furthermore, we must ask whether the putative mimicking epitope on the viral antigen represents a host "self" peptide that is similarly presented on a surface [15].

It would appear from these manifold complications that mimicry can only be satisfactorily critiqued from an experimental standpoint, and indeed Oldstone emphasizes testability in his review of viral mimicry (see figure 1 in reference 2, for example). Be that as it may, untested mimicry hypotheses fill the literature of HIV—some have gained strength from time alone—and therefore critique at the sequence level might provide some insight in the absence of experimental test.

It occurs to us, in particular, that many mimicry claims made on the basis of suspected sequence similarities in the 1980's should be revisited today when the database is orders of magnitude larger. If mimicry is a pervasive factor in AIDS pathogenesis, then the sequence/structural similarity would probably be observed across many diverse variants and homologous types. In 1987, for example, a borderline similarity between HIV envelope and a molecule called neuroleukin was claimed; the story was an intriguing one in so far as it offered a basis for AIDS neuropathogenesis [16]. An experiment performed with an SIV envelope accompanied the sequence claim, but unfortunately the authors neglected to also assess the similarity between the SIV envelope and the so-called neuroleukin molecule, which turned out to be weaker than borderline. It was subsequently shown that the putative neuroleukin was, in fact, a commonplace enzyme; yet the neuroleukin hypothesis for AIDS-related neuropathy persisted in the literature after the sequences and experiment had been fully critiqued [3].

In the following section, we shall first discuss the potential contribution of compositional similarities to mimicry. Subsequent sections will include, among other things, a catalog of mimicry claims related to HIV envelope protein. At a later time, this discussion might be expanded to cover other HIV proteins, especially Gag and Nef epitopes, which are also thought to be involved in mimicry (see Part III section on Alignments, Database Searching, and Structure Prediction).

B. COMPOSITIONAL CONSIDERATIONS

One strategy for discovering similarities between HIV antigens and host proteins is to start with the amino acid composition of the former. Lentiviruses have skewed base compositions (high A, low C) and unusual codon preferences that result in significant compositional differences from what is generally seen in the PIR and Swiss-Prot protein databases [17]. HIV has a relatively high tryptophan content, for example, and tryptophan is one of the least frequently found amino acids in eukaryotes and most viruses. Polar residues are relatively high in HIV. Starting from this fact, Fitzgerald and coworkers cataloged microbial sequences that shared with HIV the unusual base composition [18]. Of these, most were bacterial virulence factors, *i.e.*, surface antigens, hence the authors speculated about similarities of immune dysfunction brought about by such diverse pathogens as protozoans, Pneumocystis, Treponema, and HIV. While the Fitzgerald study does not direct itself to HIV mimicry of host antigens (so much as it is concerned with antigen switching), the overall premise is heuristic: mimicry probably begins with gross similarities—similar charge, similar presentation, similar extent of glycosylation, etc. PROPSEARCH (http://www.heidelberg.de/aaa.html) and AACompIdent (http://expasy.chuge.ch/ch2d/aacompi.html) are two programs accessible through Internet for identifying a protein from its amino acid composition.

Taking a more focused approach from what has just been described for HIV and compositional similarities, Douvas and Sobelman conducted sweeping sequence comparisons involving three preselected sequence sets: a set of nuclear antigens, some of which are known to be involved in autoimmune disorders; a set of viral proteins, some of which are related to immunosuppression; and a set of 41 control proteins not known to have autoimmune significance [19]. Pentameric and hexameric similarities were

found to the human nuclear antigens in both the viral and control sets, but an excess of "hits" was observed for viral proteins and two nuclear antigens—the 70 kDa component of RNP particles, which is characteristically involved in mixed connective tissue disease (MCTD), and CENP-B, a centromere protein which is associated with scleroderma. Both proteins are highly hydrophilic. Several viruses, HIV-1, HSV-1, EBV, SRV-1, and CMV, were implicated. The proposed matches to HIV were to both gp120 and gp41, and because the strongest instances involved the 70 kDa splicing protein, the authors followed that up in [20].

The similarity between HIV-1 gp41 and the hydrophilic COOH-terminus of the 70 kDa ribonucleoprotein component has undeniable compositional implications, as is evident below

```
HMM Consensus (gp41)    GPDRPEGIEEEGGEQDRDR
                        GPD P G EE G ++DR R
U1-snRNP 70 kDa         GPDGPDGPEEKGRDRDRER
```

A comparable situation of sequence compositional bias is found with a stretch of the HIV/SIV Nef protein and the CENP-B centromere antigen studied in [19]:

```
HMM Consensus (Nef)     DDWDDEDEEEVGFP
                        DD D+ED +EV +P
CENP-B                  DDDDEEDGDEVPVP
```

These alignments were taken from a Smith-Waterman (S-W) search using an HMM-generated consensus for HIVs, as described in an accompanying section of Part III of the 1996 compendium. The log-odds score in each case (in bits) is about 1, which implies a two-fold greater than even probability that the similarity does not obtain from chance alone; as a rule a score should be 20 or more to have high specificity. The similarities and the marginal scores seen in these alignments stem from the low complexity (relative monotony) of the sequences involved.

The HMM Env consensus, which was generated from about 400 HIV and SIV sequences, extends the observations of [19] and [20] to primate immunodeficiency viral sequences in general, but it also reveals the ease with which such a weak match can be found: for comparison, the similarity score between the relevant region of gp41 and the *homologous* CAEV transmembrane protein is 5.5, not a high score but more than twenty-fold higher than the score implied by 1. This is not itself a judgment that the mimicry claim is false; rather, it merely points to a weakness in the sequence argument that led to, and helps sustain, the claim. Supporting the claim are the observations that: 1) the COOH-terminus of the 70 kDa can itself beget autoantibodies (which can interfere with splicing function); 2) the region of gp41 involved is known to be immunogenic; 3) similarities, however lacking in complexity, are found in clusters rather than at a single locus; 4) the authors find a 50 to 100% enhancement over control sera of binding of anti-RNP antibodies to gp41 in an ELISA assay; and 5) HIV sera show reactivity to snRNP 70 kDa in western blotting [20].

In the face of weak similarities such as those shown above, it is instructive to search a database larger than 41 control proteins to discover the ease with which matches to the 70 kDa and gp41 regions in question are encountered. Running a BLASTP search with the 70 kDa splicing protein sequence (BLAST also computes log-odds scores), more than 900 matches can be uncovered which have scores and Poisson probabilities superior to those associated with the relevant gp41 fragment. Among viruses, many represent more likely matches to 70 kDa peptides than does HIV gp41; and not all of these possibly mimicking viruses are immunosuppressive (*e.g.* human papillomaviruses). Hence, what we might call "dry mimicry" (computer-based similarity) of the 70 kDa splicing protein may be commonplace; it remains to be seen how extensive the "wet mimicry" will be.

If gp41 mimics the 70 kDa splicing protein, it might also have the potential to mimic other cellular proteins on the same basis of hydrophilicity. BLASTing the database for other matches to just the relevant C-terminal portion of the HMM consensus gp41 sequence produces an array of weak matches to several cellular proteins. One of the strongest of these borderline matches is indeed the 70

kDa RNP (Poisson probabilities between 0.07 and 0.11). This is in some contrast to the comparatively weaker score from the S-W search based on the entire HMM consensus for Env (see above).

Mimicry analyses can also be fruitfully conducted using the BLOCKS database, version 9.1, which consists of 3300 multiply aligned, gapless arrays of similarities and which features position-dependent scoring [21,22] (http://www.blocks.fhcrc.org). The snRNP family of proteins is represented in the BLOCKS database as three blocks, BL00030A,B,C, the third of which is most representative of the COOH-terminus of the 70 kDa splicing protein. One of the distinct advantages of the BLOCKS search strategy is that clusters of similarity can be identified. A search of the database using the relevant COOH-terminus of the gp41 consensus sequence did not reveal a significant match to any of the 3300 blocks. We will have reason to return to the BLOCKS search strategy below. At this point in our assessment, we have some experimental evidence in support of the claim, but the sequence arguments that underpin the claim appear to be insignificant.

Before leaving the topic of compositional bias, a brief comment about probabilities is in order. *A priori* probabilities based on the fraction 1/20 raised to some power are generally neither accurate nor useful for sequences of epitope length; they typically underestimate the likelihood of meaningless similarities, especially when compositional bias is present. In general, statistical relationships between a query sequence and target database sequences will be strongly affected by sequence length and composition, and the presumption of a normal distribution in sequence searching can distort the results [23]. Log-odds scores, used in PAM matrices, BLAST, and HMM-related database searching, are more trustworthy. For example, the HMM/S-W search strategy [24],

$$\text{score} = \log_2 \frac{P(S_i|M)}{P(S_i|R)}$$

where the alignment of each sequence in the database, S_i, is compared to both the HMM generated model, M, and a random model, R. The latter should have the same amino acid composition as the database at large and it should be as likely, *a priori*, as M. The log-odds score corrects for sequence length. With BLAST, as we have seen in a previous paragraph, Poisson probabilities are also calculated and reported alongside the log-odds score [25]. Output from a BLOCKS search includes a nomogram to assist the user in interpreting the probability of a chance similarity.

C. SEQUENCE DEGENERACY and MIMICRY

A second mimicry claim regarding HIV envelope and the 70kDa splicing protein involves the well-studied gp120 V3 loop of the former and the nucleic acid binding sequence of the latter, both of which are immunogenic [20]. In this instance, low complexity, or compositional uniformity, is not obviously involved; on the other hand, widespread variability in the V3 loop calls into question the breadth of the claim:

```
                    HIV-1 IIIB   RGPGRAFVTIGK
                  U1-snRNP 70 kDa  KPRGYAFIEYEH
HIV-1 B subtype consensus      IGPGRAFYTTGE
                               mawrkvwfar-d
                               lqlkqtlhr-eq
                               v qwssvv-ark
                               t f ggiigidg
                               f a -ryrsnkr
                               k g  qmwvkta
                               r v  xsdysnn
                               s s   tt yqh
                               y t   x  pss
                               m       xp
```

The authors in [20] took note of the similarity between the HIV-1 IIIB V3 loop and the 70 kDa splicing protein, shown in the top two lines of the alignment. Shown below them is the comparison

with the B subtype consensus sequence and in lowercase letters, in descending order of frequency, the observed replacements at the various positions in B subtype loops as catalogued in Part III of the HIV database compendium. Other HIV-1 subtypes, A, D, E, O, etc., manifest variable V3 loops and HIV-2s have a very different sequence and structure altogether. This raises the question whether mimicry occurs with select variants when it doesn't occur throughout a viral type.

We do not find that the HMM consensus for the HIV/SIV V3 loop region takes part in any significant matches in a S-W/HMM search. Furthermore, a meaningful similarity is not found in a BLOCKS database, even though the 70 kDa region of interest, the nucleic acid binding sequence, is represented as block BL00030B. On the other hand, reactivities between anti-RNP sera and the IIIB V3 antigen in an ELISA assay were found to be as great as those between HIV positive sera and the IIIB loop. Furthermore, in one MCTD patient who was infected with HIV, anti-V3 and anti-70 kDa titers were observed to vary in tandem [20]. Finally, we should note that an established case of mimicry, the rabbit myelin basic protein and the hepatitis B viral polymerase discussed above, would not yield significant BLAST similarity.

We must tentatively conclude that some serological effects are being captured, yet we must also wonder how extensive they can be given the well-documented sequence degeneracy. (It is conceivable that some of the V3 loop sequences in the database were taken from defective viruses, but it is also certainly the case that the IIIB loop sequence is not the only viable sequence.) Finally, it is simply possible that the effects seen for the IIIB V3 and the 70 kDa RNP component are not biologically significant, in spite of the cross-reactivities and some sequence similarity (however weak) [26].

HIV is one of the most degenerate (variable) microbial pathogens. The previous example suggests that hypotheses based on sequences from the earliest characterized HIV-1 strains, such as IIIB, may not be indicative of a general picture of mimicry, unless viral mimicry is thought to be sometimes particular, rather than being uniformly generic. The following table of mimicry claims in the literature involving HIV envelope and host-cell proteins sequences attempts to summarize this situation. The summary is not exhaustive, but it covers the majority of claims about mimicry involving HIV gp120 and gp41 and known host protein sequences. The table lists the original claim, reports a best individual match set (first three columns), then presents the claim in light of the variation encountered in both the viral and the cell protein (fourth column). HMM-generated consensus sequences have been taken from Part II of the 1996 database compendium; their generation is discussed in a separate section of Part III. In some instances, a consensus could be deduced for the cellular protein (fourth column).

One immediately notes that a major fraction of the HIV envelope mimicry claims involve immune-related host proteins—HLA, Ig, complement, etc. This is partly an historical artifact: many of these claims were brought forward in the 1980's when an overabundance of immunoglobulin-related sequences was present in the protein libraries, hence a database search with any query sequence was likely to stumble upon borderline matches to immune-related molecules [23,27]; and in the case of an HIV sequence query, any connection to immunopathology is suggestive. This situation was of course exacerbated by the fact that the full range of HIV variation was unappreciated at the time.

Many of the claims included in the table have been critiqued at the bench by Neurath and coworkers, who simply conclude that "immunization with gp120/gp160 is unlikely to elicit harmful autoimmune responses" [8].

D. CONCLUDING REMARKS

Molecular mimicry involving viral peptides does occur, however the extent and specificity are not easy to establish. By the nature of the problem, short, typically hydrophilic, sequences are involved, making rigorous similarity searches difficult. At a minimum, sequence analysts must critique their claims with respect to 1) compositional factors; 2) statistical significance; and 3) sequence degeneracy. Other important considerations include secondary and tertiary structure, amino acid modifications, and insignificant cross-reactivities, that is to say in vitro cross-reactivities that have no biological meaning. Whether autoimmune complications play a major or a negligible role in AIDS pathogenesis remains to be seen.

V

Communications

Part V of *Human Retroviruses and AIDS 1996* is divided into two sections. The first introduces ways of accessing HIV information from the World Wide Web (WWW), the second is a list of references.

HIV Information on the World Wide Web

All of the information in *Human Retroviruses and AIDS 1996*, its predecessors in 1994 and 1995, as well as numerous sequence and alignment data files, are available to the public through the World Wide Web, a system of links between Internet locations that can be navigated with graphical "browsing tools" such as Mosaic and Netscape. We are strenuously urging our subscribers to make use of our Web site. Using electronic documents and data offers many advantages over the production and use of paper documents.

- It saves paper, ink, metal, solvents, plastics, postage, fossil fuels, and time that go into the printing and distribution of hundreds of copies of this large book.
- Electronic documents that contain all the formatting and complex graphics of a printed document can now be produced and placed on the Web where users may view and print them. For example, an exact replica of this entire document, *Human Retroviruses and AIDS 1996* is available from our Web site.
- Electronic documents are readily corrected and kept up to date. As we prepared sections of this year's compendium we have been "prepublishing" them on our Web site. In this way the latest and most accurate information is always available to users.
- There is also the possibility of interaction between users and the database staff at Los Alamos. Just as documents and data can be retrieved from the Web site, so can they be posted to the site.
- Data and documents on the Web, far from being static pieces of paper, are embedded in a system that allows searching for items of interest—references, sequences, author names, etc. Our search capabilities are relatively primitive now but will become more powerful in the future.
- The Web, as its name implies, is a system of links spread throughout the world. Our Web site provides links to other sites that are useful to virologists and sequence biologists.

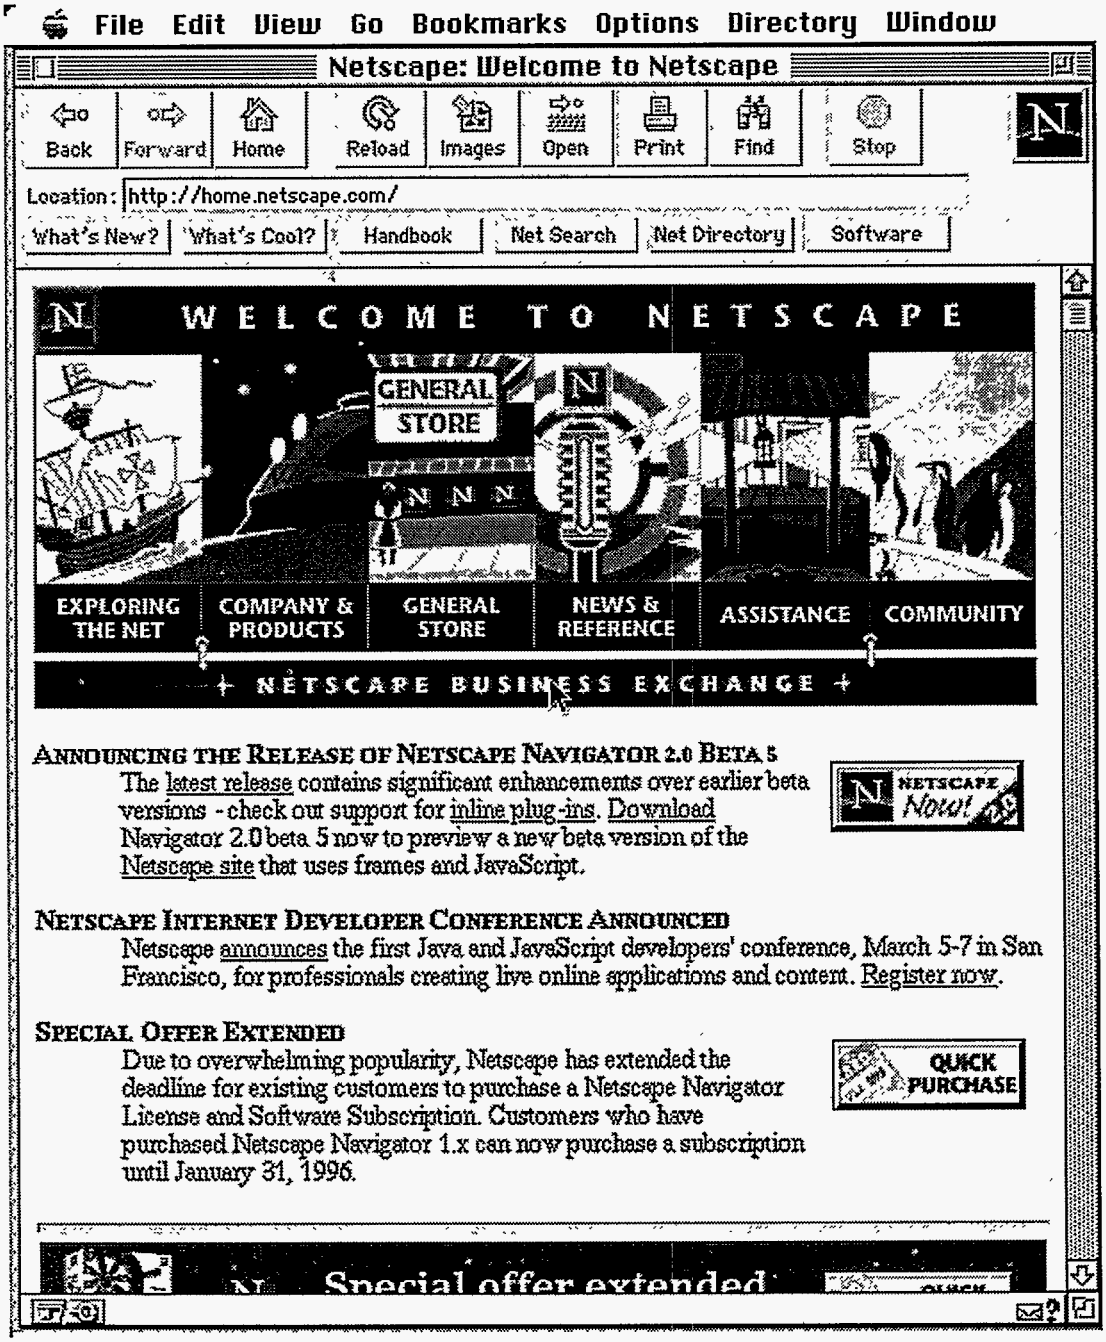
In order to access the WWW, you must have, (1) a windowing capability such as X Windows, MS Windows, or Apple Macintosh, (2) an Internet Protocol (IP) connection, and (3) a copy of a browser program such as Mosaic or Netscape for the appropriate windows environment. If you are not already using Mosaic (a free program) you can get a copy by anonymous ftp from `ftp.ncsa.uiuc.edu`. Netscape may be purchased by sending e-mail to `sales@netscape.com` or phoning 415-528-2555. Our use of Netscape in the following description of our Web site is purely illustrative and should not be construed as an endorsement of that product.

The browsing tools designed for the WWW make it easier than before to locate and acquire information on the Internet because, instead of typing arcane commands into your computer, you simply point and click at text and objects on your screen. These objects are either links to files, which cause the files to be sent to your local computer, or they are links to other machines from which files may be accessed. "Files" can mean words, pictures, sounds, or movies. The WWW address (or "URL") for the HIV database is:

`http://hiv-web.lanl.gov`

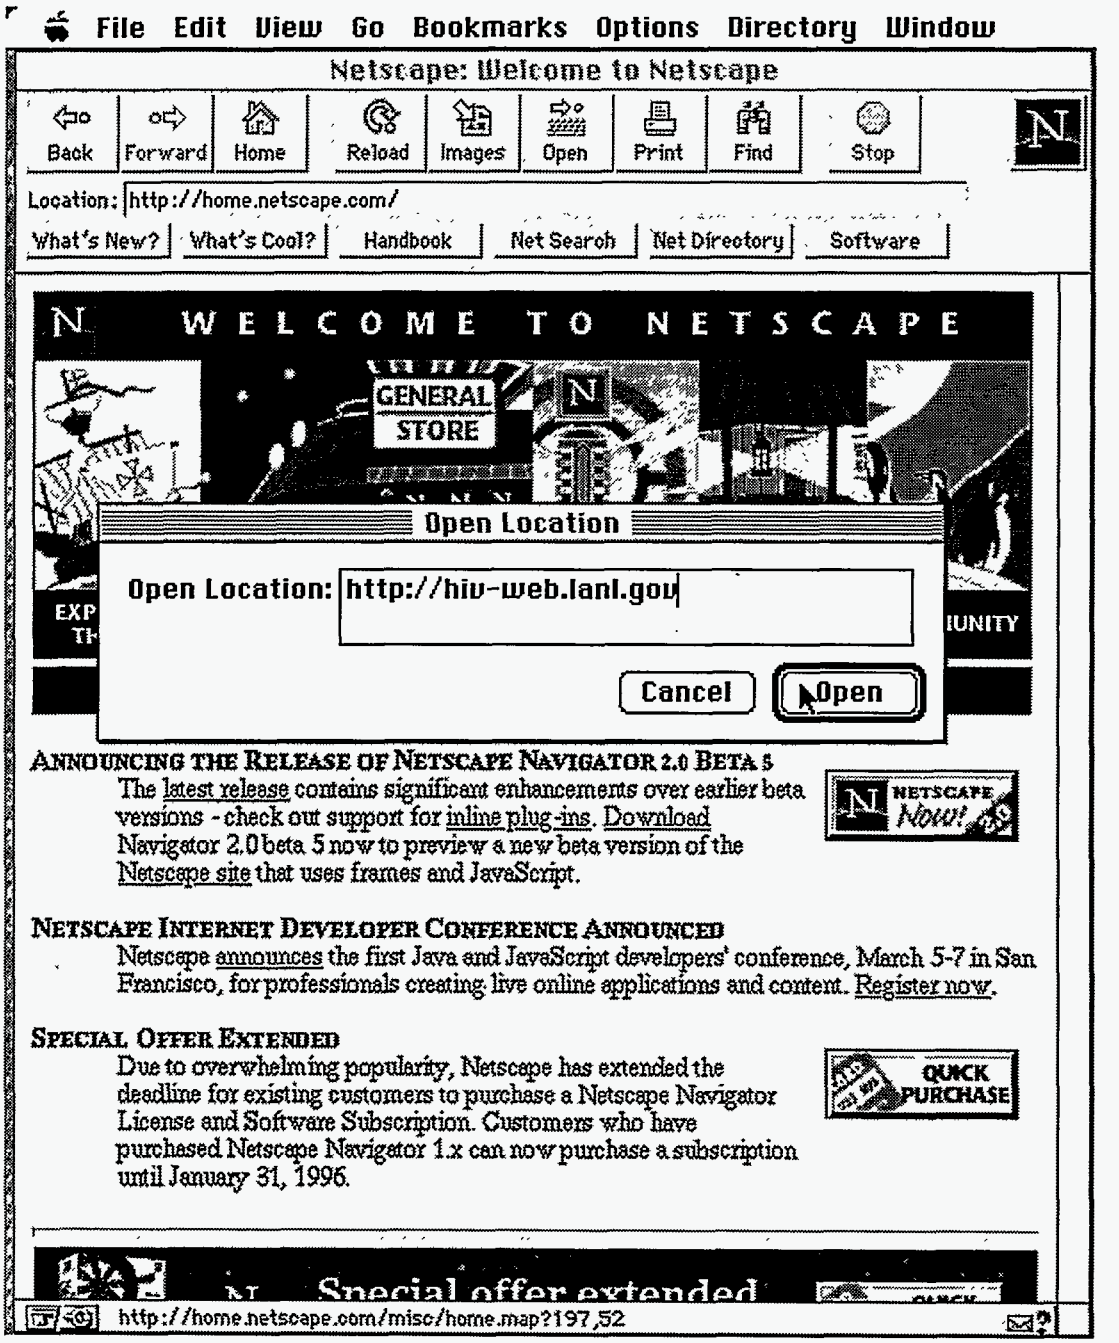
Tour of the World Wide Web

We reprint here the short tour of our Web site which we originally published in last year's Compendium. It will give the uninitiated a feel for how the Web works. You begin by "launching" your browser program. (The browser in the illustrations here is Netscape.) In the Netscape window on your screen there appears the starting point for your navigation of the Web (Screen 1). This starting point can be any address you have specified, it could even be the HIV database URL; by default it is the Netscape "home page."



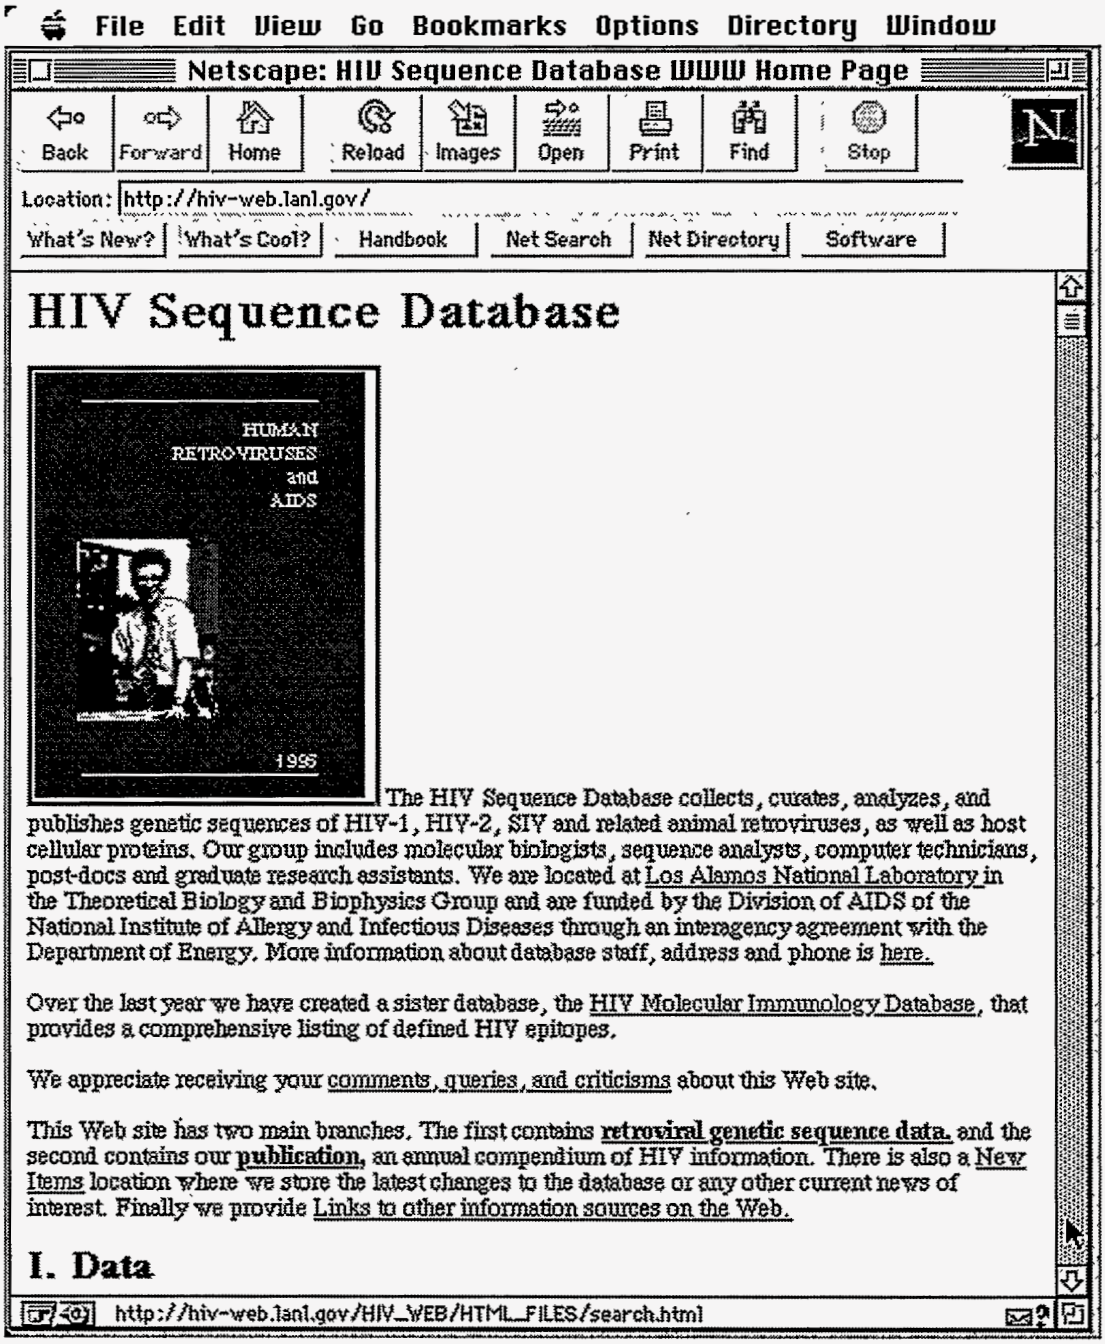
Screen 1

From your starting point you select "Open Location" from the File menu in the upper left corner of the window. A small window entitled Open Location appears, you type in the URL of the HIV Database `http://hiv-web.lanl.gov` in the space provided (Screen 2), and click Open. You can also store frequently visited URLs in a list called "bookmarks" or "hotlist" and select your destination from this list rather than typing its URL.



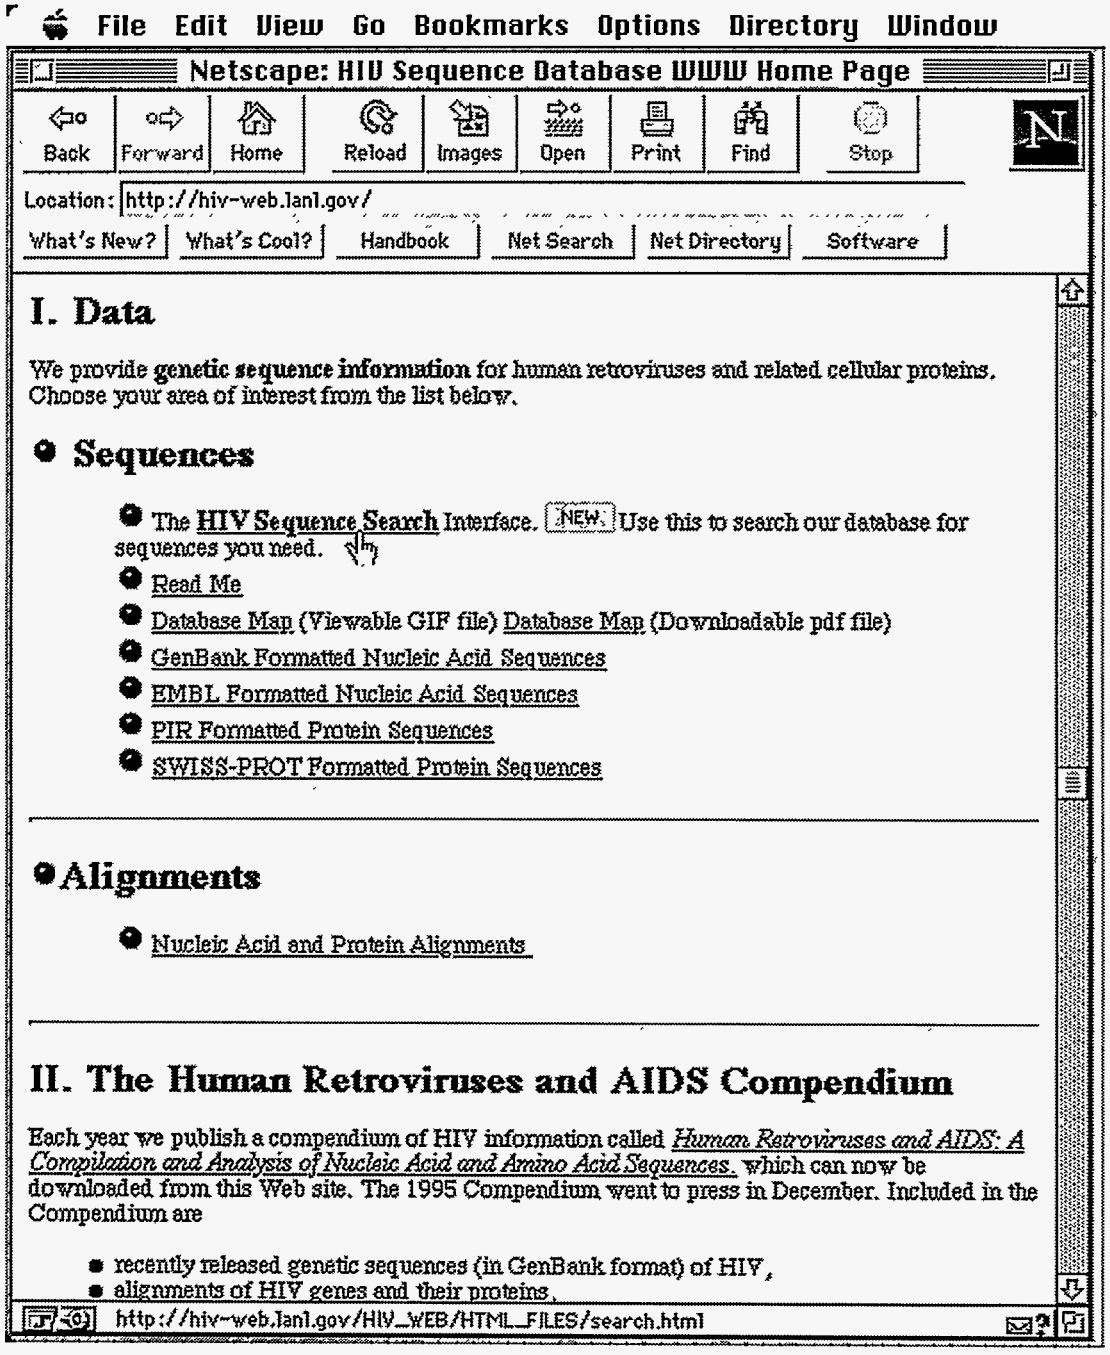
Screen 2

After a few seconds a new image appears in the window (Screen 3), the home page of the HIV Database. The text in the window is formatted and pleasantly readable. All the text on the home page cannot fit on the screen at once, but you can scroll through it by clicking your mouse on the down arrow in the lower right.



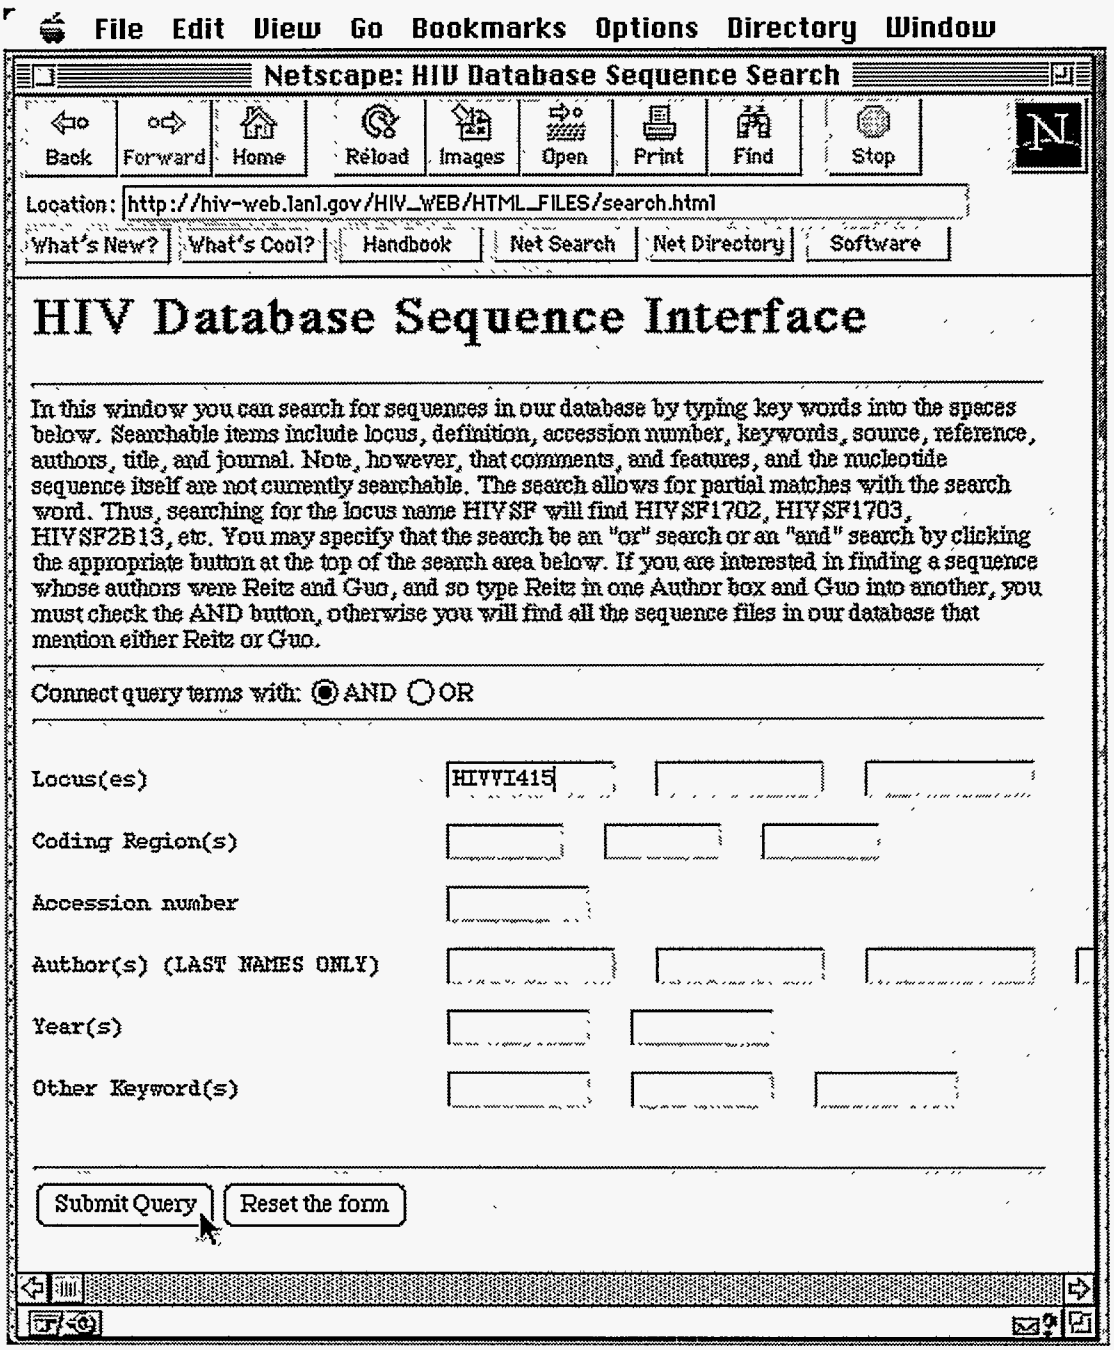
Screen 3

As you move down in the document you come to an area labeled "I. Data" (Screen 4). Some of the text is underlined and, on color monitors, shows in a different color. These underlined words are links to other locations on the WWW. The locations may be local or they may be on computers half way around the world; the links to them look exactly the same and are activated in the same way. If we position our cursor arrow at one of the links, as we have in Screen 4, the arrow turns into a pointing hand. Pressing the mouse button transfers us quickly and automatically to the location attached to that link. In our example the finger points to HIV Sequence Search.



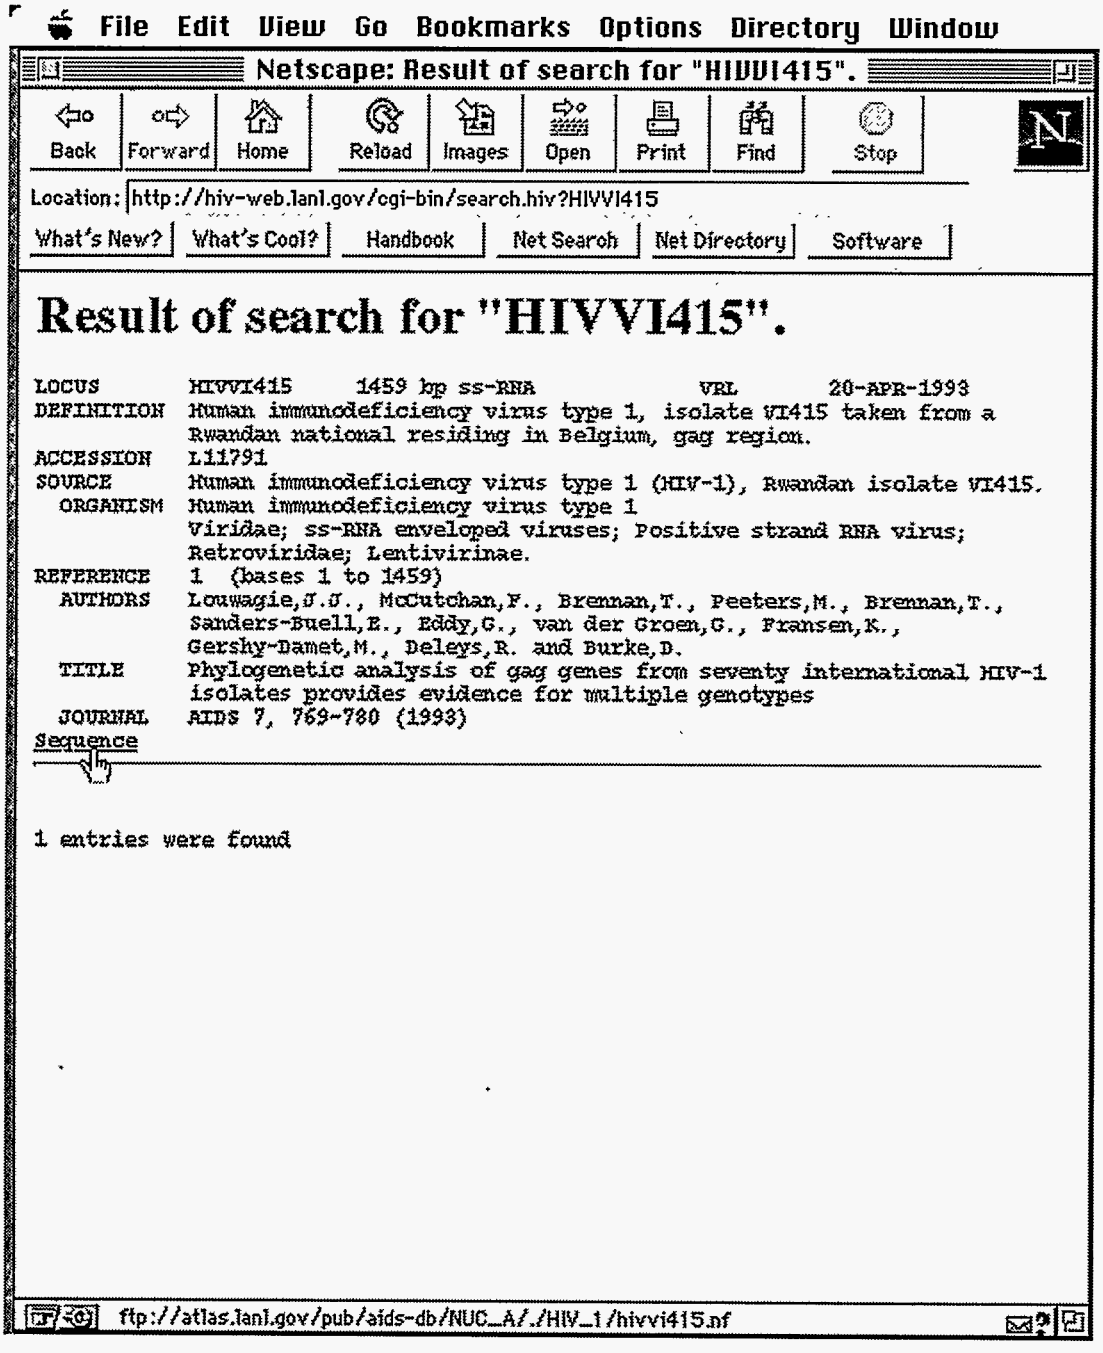
Screen 4

Upon clicking HIV Sequence Search the search area appears on the screen (Screen 5). An explanation of how to use the search utility is included. We type in a search pattern—in this example HIVVI415, a GenBank locus name—and hit the carriage return.



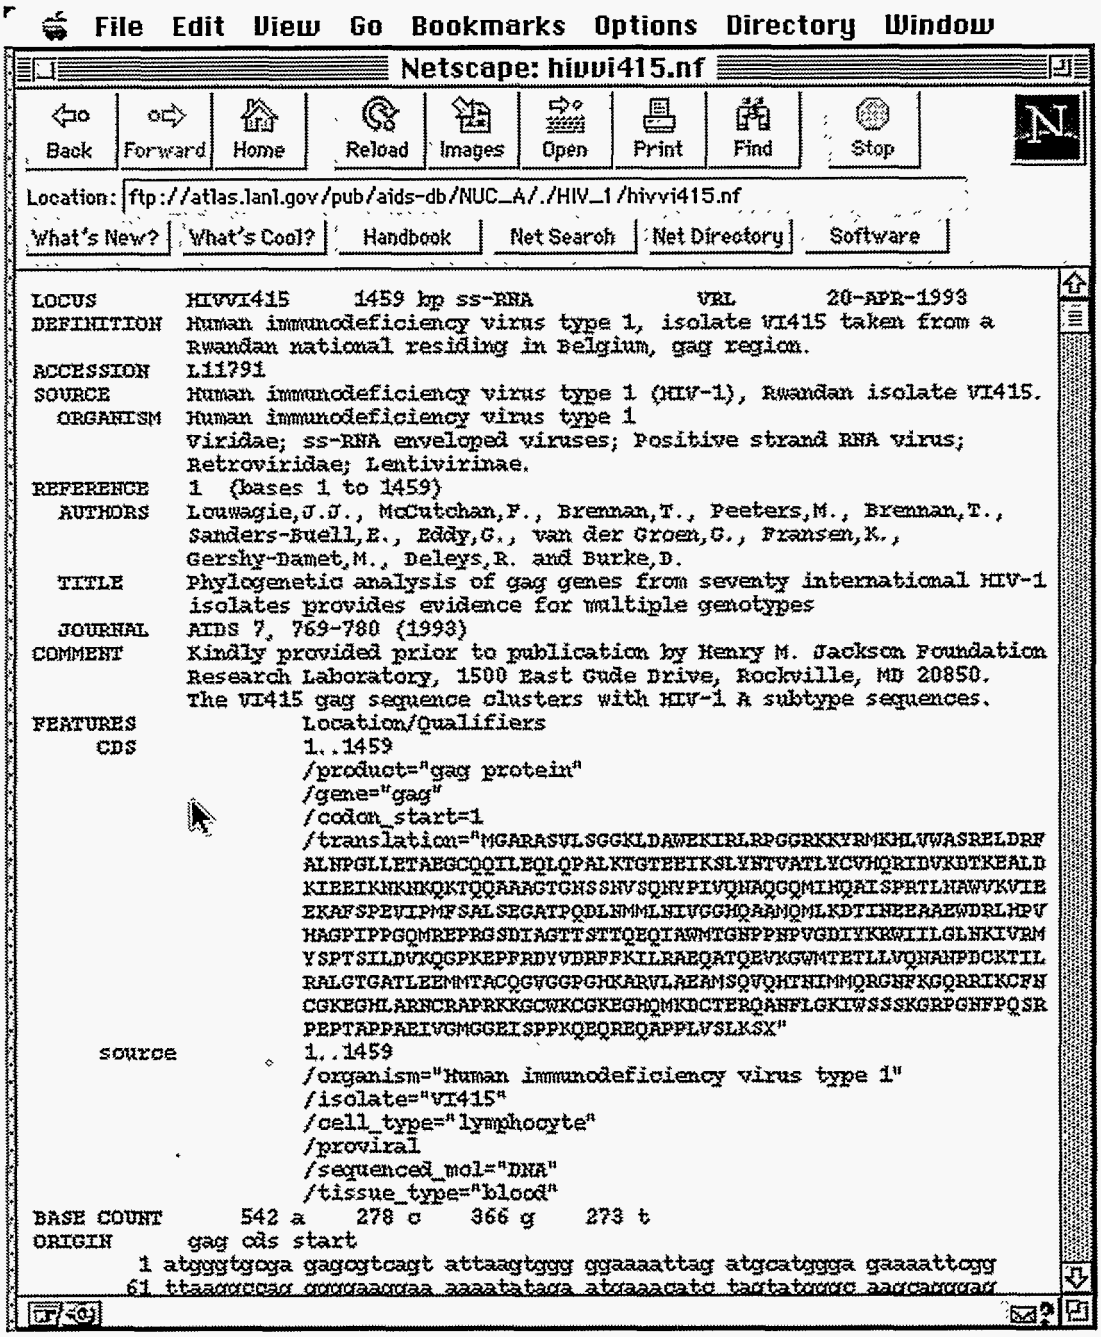
Screen 5

The result of the search, an abbreviated GenBank file, appears (Screen 6). We can retrieve the entire file by positioning the pointing hand on the link in Screen 6 called Sequence and clicking.



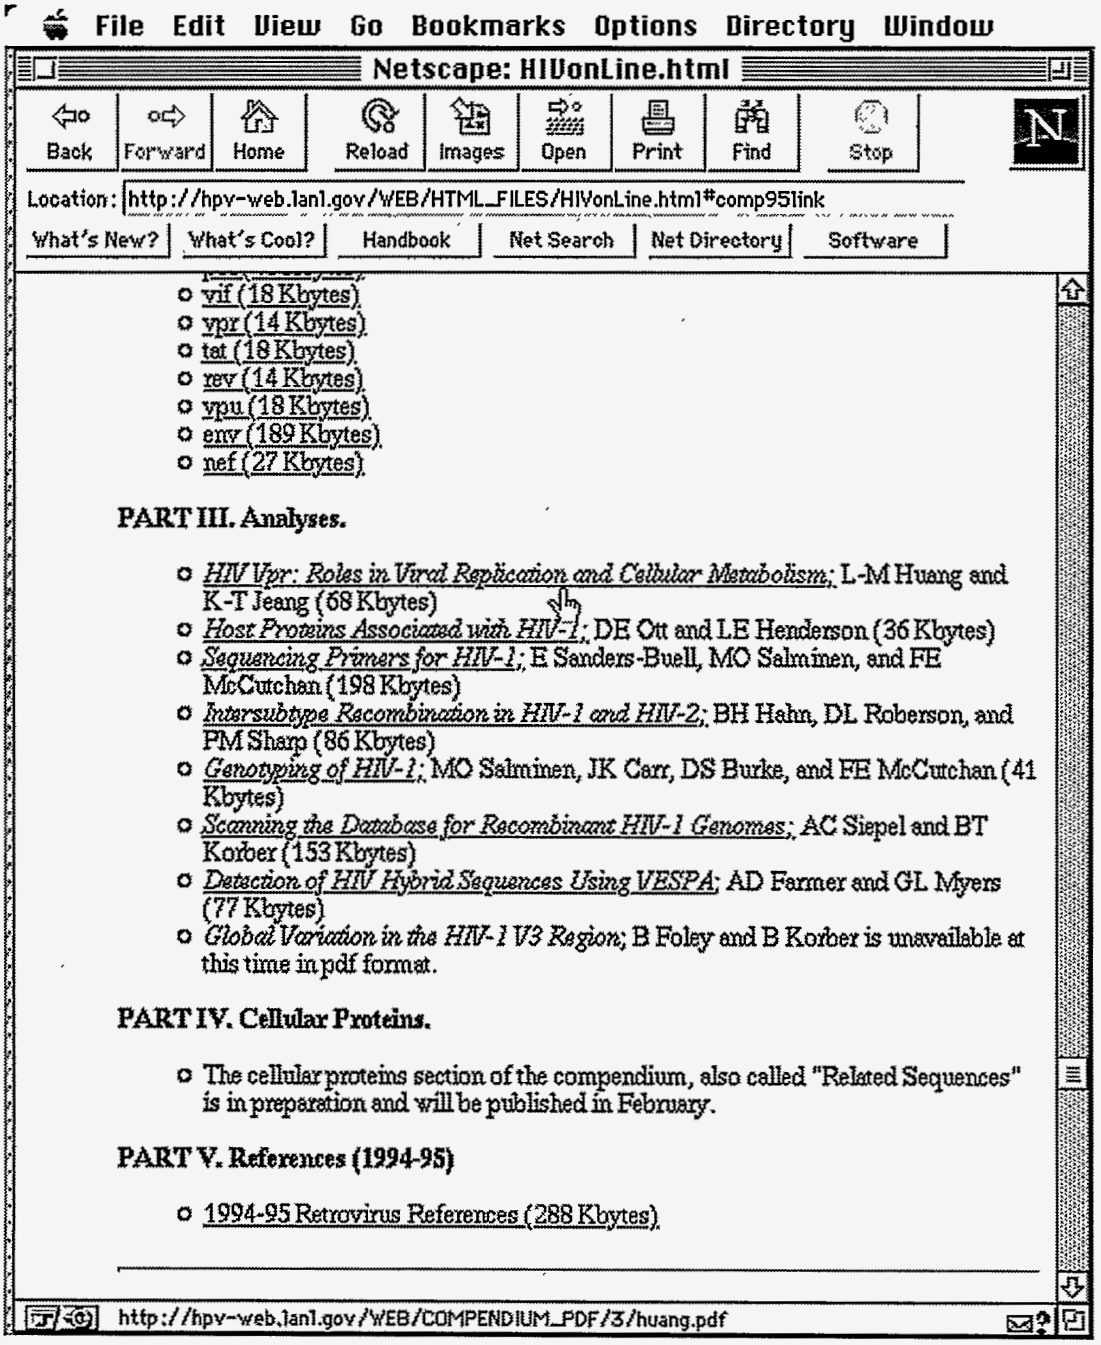
Screen 6

The result is shown in Screen 7, the complete GenBank file. This file may be transferred to your local computer in its entirety by clicking on "File" in the menu bar at the top of the screen and selecting "Save As . . . " from that menu.



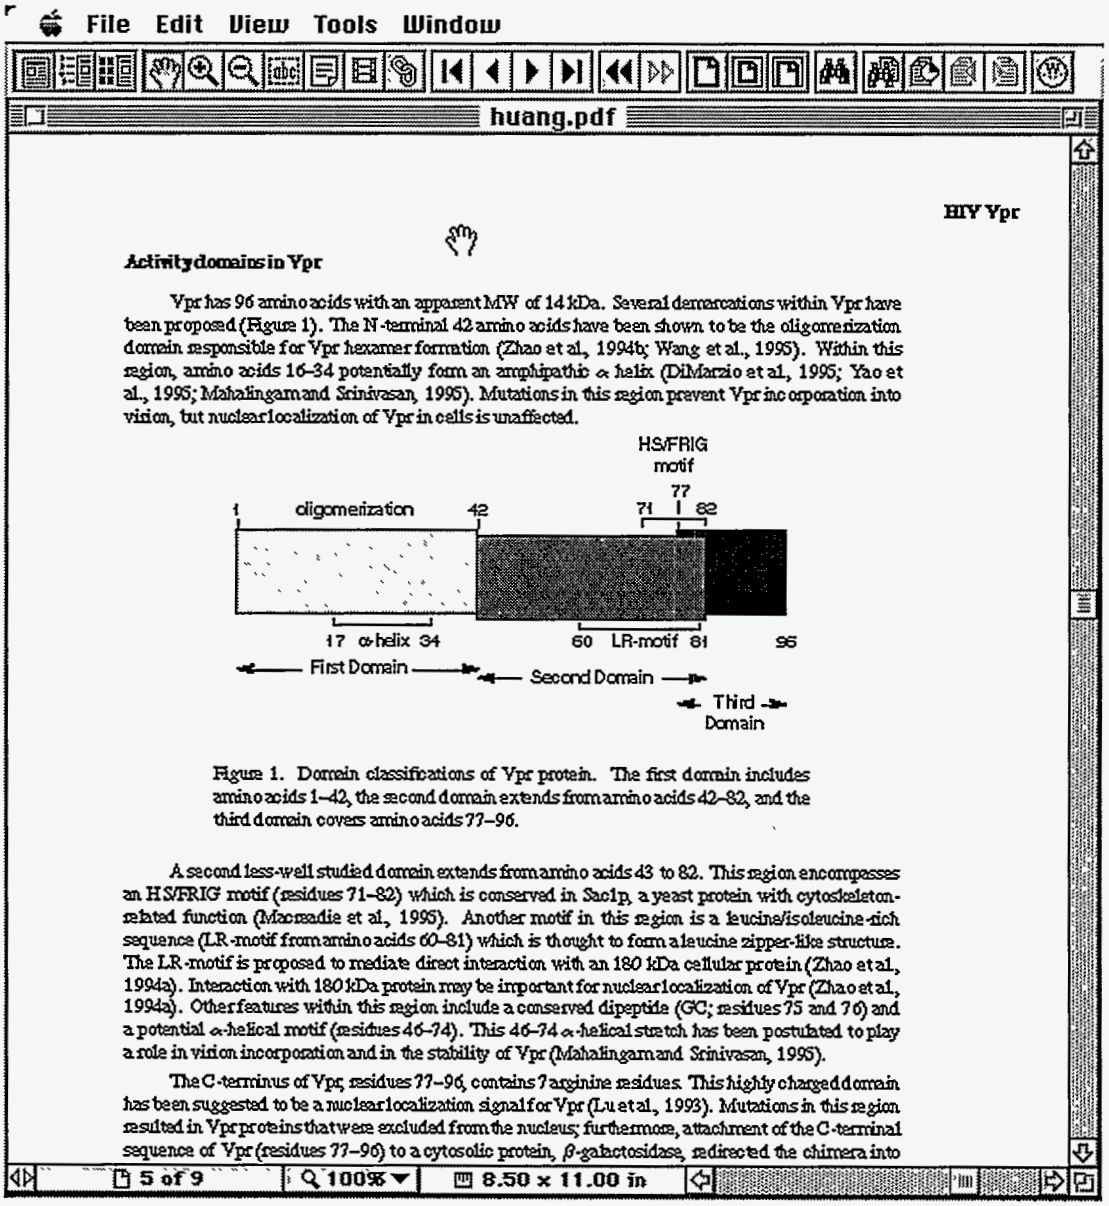
Screen 7

As we follow a series of links on the WWW, the browser remembers the places we have been and allows us to return to them by clicking the "Back" button located at the top left corner of the window. If we return to the HIV home page (Screen 3) we can follow a different path of links (not shown here) that carries us to another area of the site, the "on-line version of the *Human Retroviruses and AIDS* compendium." Screen 8 shows a part of the table of contents. The pointing hand is about to retrieve an article on HIV Vpr. This link, though it looks the same as others, behaves differently. A copy of the Vpr article is automatically transferred to your local computer and the Adobe Acrobat viewer is automatically launched. Acrobat is a "helper application" used to read files that are in a format which is nonstandard for the WWW. Our Web site shows you how to obtain a copy of the Acrobat viewer.



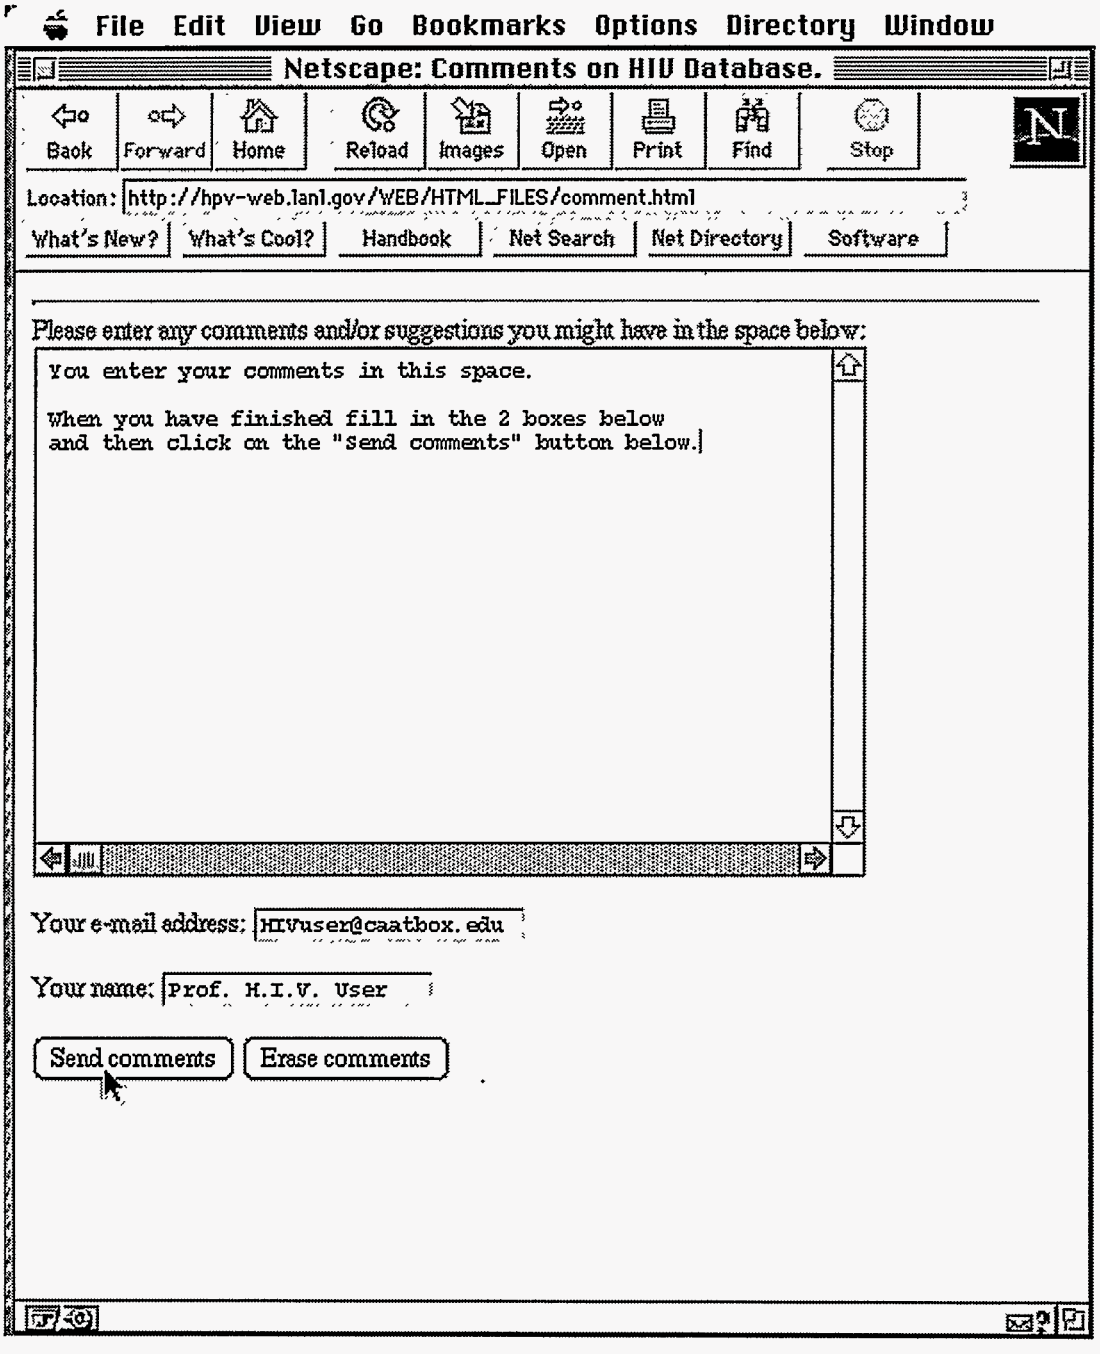
Screen 8

The Acrobat viewer, available free from the WWW (`http://www.adobe.com/Acrobat`), displays the Vpr article (Screen 9), which is written in "portable document format" (PDF) and allows you to print out a perfect copy of it, exactly as it appears in the printed compendium. Acrobat viewer has a search mechanism that allows you to search in a document for words that might lead you to a subject of interest. For example, Part V of the compendium lists hundreds of HIV references. Those references are searchable with Acrobat Viewer. Searches for specific nucleotide sequences in Part I (e.g. `AATAAA`) will be less useful because of the way GenBank files are formatted, with spaces and sequence numbers embedded in the file.



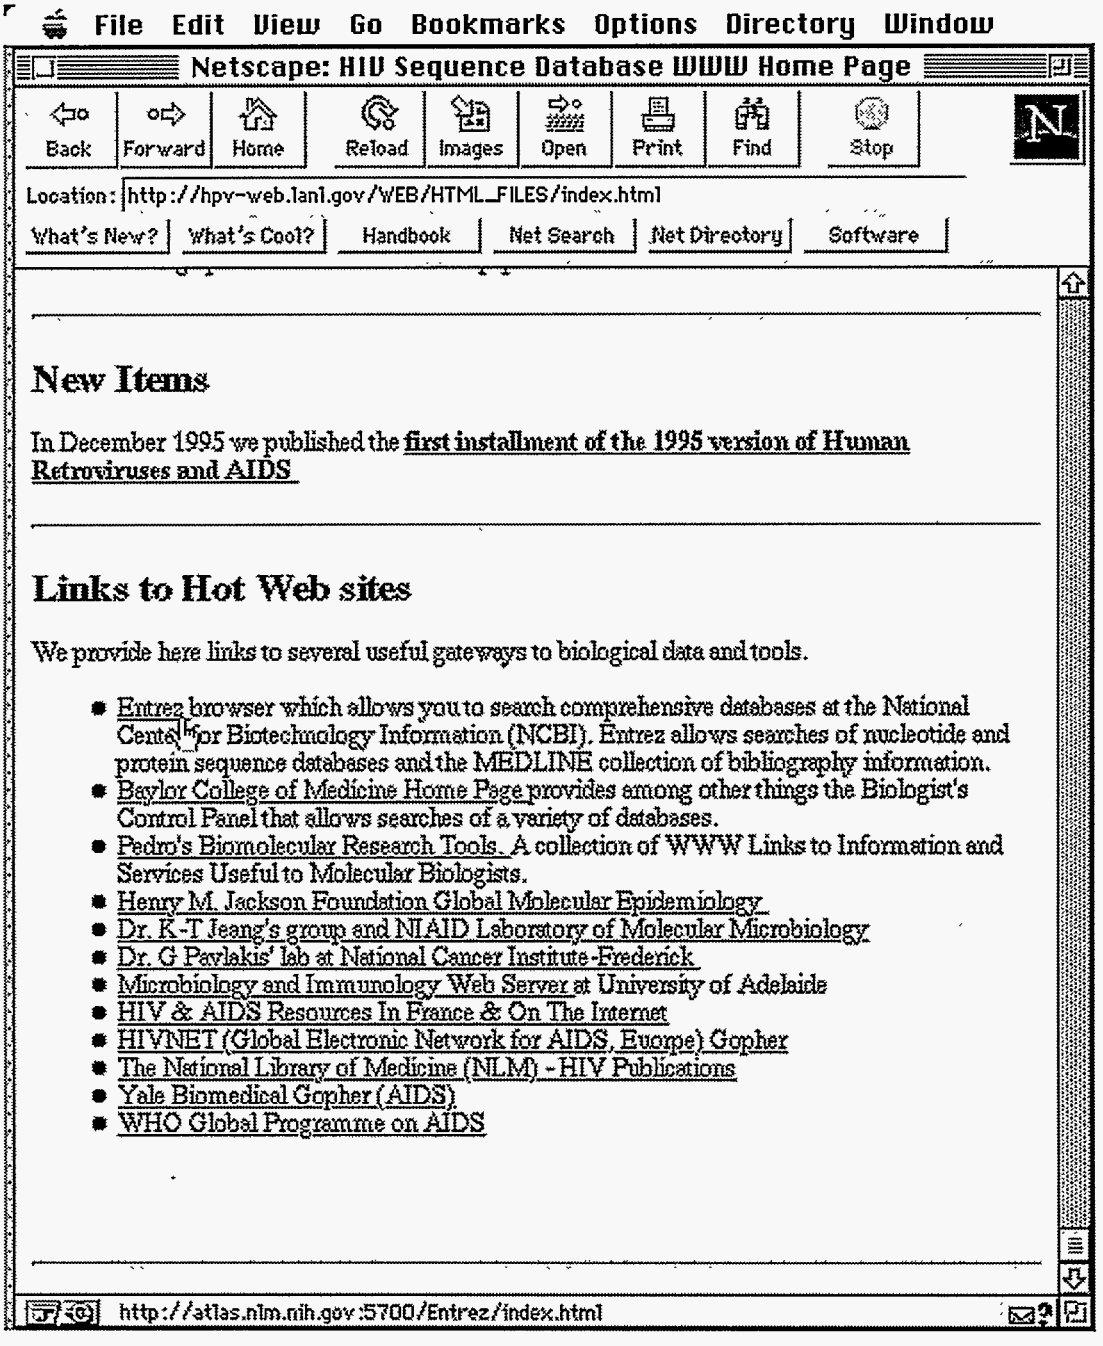
Screen 9

Our Web site provides users an opportunity to communicate with us from several points on the site. An electronic "comments" form (Screen 10) can be activated that allows you to write us a letter to which we promise to respond.



Screen 10

Finally, we have connected our site to several other locations of utility to biologists as shown on Screen 11, below.



Screen 11

Data Access by FTP

The complete database of sequences and alignments are also available electronically from a server here at Los Alamos called "atlas". In the first section of Part V we described accessing this, and other, information using the WWW. You may also retrieve information from atlas by the "anonymous ftp" method. In the following instructions for accessing atlas, what you actually type at your terminal is shown in **boldface** type [with an explanation shown in square brackets]. What the server responds with is shown indented in italic type.

---

ftp atlas.lanl.gov [this ftp command connects your computer to atlas]
Name (atlas.lanl.gov): [atlas asks for your user name]
anonymous [for offsite users anonymous is the only name that works]
Guest login ok, send ident as password.
Password:
[enter your e-mail address or your name as ident]
Guest login ok. access restrictions apply.
cd pub [change to the directory called pub]
CWD command successful
cd aids-db
ls [this lists the files and directories inside of aids-db]
AIDS_A.TAR.Z, AIDS_E.TAR.Z, NUC_A, PRO_A, ALIGN, NUC_E, PRO_E, PROGS, README.TXT, ROADMAP
pwd [to show your location in the file hierarchy]
"/pub/aids-db" is current directory.
cd NUC_A/HIV_1 [move down 2 directories]
ls [all the GenBank format files are listed]
get hivr1s4 [this copies the file hivr1s4 to your home computer]
mget *.nf [this copies all files in the current directory with the suffix .nf to your home computer]
bye [this disconnects you from the server]
A map of the aids-db directories and files on atlas is reproduced on the following page. Many of the directories contain ReadMe files that describe the contents.

[Expression of HIV-1 epitopes included in particles formed by human hepatitis B virus nucleocapsid protein]
Biokhimiia 61: 532-45 (1996)

Isel C; Ehresmann C; Ehresmann B; Marquet R
Determining the conformation of RNAs in solution. Application to a retroviral system: structure of the HIV-1 primer binding site region and effect of tRNA(3Lys) binding.
Pharm Acta Helv 71: 11-9 (1996)

Isel C; Lanchy JM; Le Grice SF; Ehresmann C; Ehresmann B; Marquet R
Specific initiation and switch to elongation of human immunodeficiency virus type 1 reverse transcription require the post-transcriptional modifications of primer tRNA3Lys.
EMBO J 15: 917-24 (1996)

Iversen AK; Shafer RW; Wehrly K; Winters MA; Mullins JI; Chesebro B; Merigan TC
Multidrug-resistant human immunodeficiency virus type 1 strains resulting from combination antiretroviral therapy.
J Virol 70: 1086-90 (1996)

Jacobsen H; Haenggi M; Ott M; Duncan IB; Andreoni M; Vella S; Mous J
Reduced sensitivity to saquinavir: an update on genotyping from phase I/II trials.
Antiviral Res 29: 95-7 (1996)

Jacobsen H; Haenggi M; Ott M; Duncan IB; Andreoni M; Vella S; Mous J
Reduced sensitivity to saquinavir: an update on genotyping from phase I/II trials.
Antiviral Res 29: 95-7 (1996)

Jacobsen H; Hanggi M; Ott M; Duncan IB; Owen S; Andreoni M; Vella S; Mous J
In vivo resistance to a human immunodeficiency virus type 1 proteinase inhibitor: mutations, kinetics, and frequencies.
J Infect Dis 173: 1379-87 (1996)

Jacque JM; Fernandez B; Arenzana-Seisdedos F; Thomas D; Baleux F; Virelizier JL; Bachelerie F
Permanent occupancy of the human immunodeficiency virus type 1 enhancer by NF-kappa B is needed for persistent viral replication in monocytes.
J Virol 70: 2930-8 (1996)

Janvier B; Lasarte JJ; Sarobe P; Hoebeke J; Baillou-Beaufils A; Borras-Cuesta F; Barin F
B cell epitopes of HIV type 1 p24 capsid protein: a reassessment.
AIDS Res Hum Retroviruses 12: 519-25 (1996)

Jeffs SA; McKeating J; Lewis S; Craft H; Biram D; Stephens PE; Brady RL
Antigenicity of truncated forms of the human immunodeficiency virus type 1 envelope glycoprotein.
J Gen Virol 77 (Pt 7): 1403-10 (1996)

Jenkins TM; Engelman A; Ghirlando R; Craigie R
A soluble active mutant of HIV-1 integrase: involvement of both the core and carboxyl-terminal domains in multimerization.
J Biol Chem 271: 7712-8 (1996)

Jeyaseelan R; Kurabayashi M; Kedes L
Doxorubicin inhibits Tat-dependent transactivation of HIV type 1 LTR.
AIDS Res Hum Retroviruses 12: 569-76 (1996)

Jeyaseelan R; Kurabayashi M; Kedes L
Doxorubicin inhibits Tat-dependent transactivation of HIV type 1 LTR.
AIDS Res Hum Retroviruses 12: 569-76 (1996)

Ji J; Clegg NJ; Peterson KR; Jackson AL; Laird CD; Loeb LA
In vitro expansion of GGC:GCC repeats: identification of the preferred strand of expansion.
Nucleic Acids Res 24: 2835-40 (1996)

Ji X; Klarmann GJ; Preston BD
Effect of human immunodeficiency virus type 1 (HIV-1) nucleocapsid protein on HIV-1 reverse transcriptase activity in vitro.
Biochemistry 35: 132-43 (1996)

Jiang MC; Lin JK; Chen SS
Inhibition of HIV-1 Tat-mediated transactivation by quinacrine and chloroquine.
Biochem Biophys Res Commun 226: 1-7 (1996)

Jiang MC; Lin JK; Chen SS
Inhibition of HIV-1 Tat-mediated transactivation by quinacrine and chloroquine.
Biochem Biophys Res Commun 226: 1-7 (1996)

Joag SV; Li Z; Foresman L; Stephens EB; Zhao LJ; Adany I; Pinson DM; McClure HM; Narayan O
Chimeric simian/human immunodeficiency virus that causes progressive loss of CD4+ T cells and AIDS in pig-tailed macaques.
J Virol 70: 3189-97 (1996)

Joag SV; Li Z; Foresman L; Stephens EB; Zhao LJ; Adany I; Pinson DM; McClure HM; Narayan O
Chimeric simian/human immunodeficiency virus that causes progressive loss of CD4+ T cells and AIDS in pig-tailed macaques.
J Virol 70: 3189-97 (1996)

John S; Marais R; Child R; Light Y; Leonard WJ
Importance of low affinity Elf-1 sites in the regulation of lymphoid-specific inducible gene expression.
J Exp Med 183: 743-50 (1996)

Johnson HM; Torres BA; Soos JM
Superantigens: structure and relevance to human disease.
Proc Soc Exp Biol Med 212: 99-109 (1996)

Johnson VA
Combination therapy for HIV-1 infection-overview: preclinical and clinical analysis of antiretroviral combinations.
Antiviral Res 29: 35-9 (1996)

Johnson VA
Combination therapy for HIV-1 infection-overview: preclinical and clinical analysis of antiretroviral combinations.
Antiviral Res 29: 35-9 (1996)

Jungheim LN; Shepherd TA; Baxter AJ; Burgess J; Hatch SD; Lubbehusen P; Wiskerchen M; Muesing MA
Potent human immunodeficiency virus type 1 protease inhibitors that utilize noncoded D-amino acids as P2/P3 ligands.
J Med Chem 39: 96-108 (1996)

Jurcevic S; Praud C; Coppin HL; Bertrand A; Ricard S; Thomsen M; Lakhdar-Ghazal F; De Preval C
Role of polymorphic residues of human leucocyte antigen-DR molecules on the binding of human immunodeficiency virus peptides.
Immunology 87: 414-20 (1996)

Just JJ; Casabona J; Bertran J; Montane C; Fortuny C; Rodrigo C; Mur A; Bosque M; Jovane L; King MC
MHC class II alleles associated with clinical and immunological manifestations of HIV-1 infection among children in Catalonia, Spain.
Tissue Antigens 47: 313-8 (1996)

Kakizawa J; Ushijima H; Morishita Y; Oka S; Ikeda Y; Muller WE
Diversity of HIV type 1 envelope V3 loop region in saliva.
AIDS Res Hum Retroviruses 12: 561-3 (1996)

Kalams SA; Johnson RP; Dynan MJ; Hartman KE; Harrer T; Harrer E; Trocha AK; Blattner WA; Buchbinder SP; Walker BD
T cell receptor usage and fine specificity of human immunodeficiency virus 1-specific cytotoxic T lymphocyte clones: analysis of quasispecies recognition reveals a dominant response directed against a minor in vivo variant.
J Exp Med 183: 1669-79 (1996)

Kamine J; Elangovan B; Subramanian T; Coleman D; Chinnadurai G
Identification of a cellular protein that specifically interacts with the essential cysteine region of the HIV-1 Tat transactivator.
Virology 216: 357-66 (1996)

Kang MS
Uptake and metabolism of BuCast: a glycoprotein processing inhibitor and a potential anti-HIV drug.
Glycobiology 6: 209-16 (1996)

Kaplan AH; Manchester M; Smith T; Yang YL; Swanstrom R
Conditional human immunodeficiency virus type 1 protease mutants show no role for the viral protease early in virus replication.
J Virol 70: 5840-4 (1996)

Karczewski MK; Strebel K
Cytoskeleton association and virion incorporation of the human immunodeficiency virus type 1 Vif protein.
J Virol 70: 494-507 (1996)

Karlsson GB; Gao F; Robinson J; Hahn B; Sodroski J
Increased envelope spike density and stability are not required for the neutralization resistance of primary human immunodeficiency viruses.
J Virol 70: 6136-42 (1996)

Karsten V; Gordon S; Kirn A; Herbein G
HIV-1 envelope glycoprotein gp120 down-regulates CD4 expression in primary human macrophages through induction of endogenous tumour necrosis factor-alpha.
Immunology 88: 55-60 (1996)

Kashiwada Y; Hashimoto F; Cosentino LM; Chen CH; Garrett PE; Lee KH
Betulinic acid and dihydrobetulinic acid derivatives as potent anti-HIV agents.
J Med Chem 39: 1016-7 (1996)
