Automatic Bubble Density Measurement with the
Hough-Powell System*

R.C. Strand, A.M. Thorndike, and N.W. Webre

April 25, 1963

MASTER

The Brookhaven Bubble Chamber Group is developing a Hough-Powell fast analysis system (HPD)¹ for bubble chamber photographs. High precision measurements are made with a computer controlled flying spot digitizer. We are currently testing the track selection programs for the system. We have just completed a study of a method for automatic bubble density measurements.

Bubble density measurements are useful to identify particles and thereby reduce the number of ambiguous kinematic fits for a bubble chamber event. An accurate determination of bubble density is tedious and time consuming by the individual gap length method. The HPD bubble density measurements are obtained along with the geometry points at a rate of about six seconds per twenty-inch chamber photograph.

We will describe the HPD and its bubble density measurement process before we present the results of our recent tests.

The HPD employs a mechanical flying spot with associated optical and electronic elements that are capable of reducing the information content of a bubble chamber photograph to precise digital form. The first two figures will show how this is done. Figure 1, a view of the 20-inch

hydrogen chamber, exposed to 900 Mev positive pions at the AGS, shows the external fiducials used for rough digitizing at the bottom and the binary data box at the left. The smaller X's in the picture are fiducials for the geometry program. This photograph was read by the HPD which transmitted the coordinates of all hits on bubble images into an IBM 7090 computer. The 7090 CRT display of this data appears in Figure 2. **The horizontal scale is stretched by a factor of four-thirds for plotting convenience. We see that the picture is honestly reproduced and that variations in bubble density are reproduced.**

For the present, event pattern recognition is provided by humans. In Figure 3 we see a scanner making road measurements of an event of interest. All information which lies outside of the roads determined by the rough measurements is discarded by the computer. The centrally located two-prong event in Figure 1 was processed. Some of the hits in the beam track road are shown in Figure 4.

The dots are the road points selected for the track by the FILTER subroutine. The solid squares are background points and the solid triangles are averaged points. Figure 5 shows two tracks in the road and a crossing track.

Returning to bubble density, we expect that the lengths of gaps in a track form a Poisson distribution. Adjacent bubbles frequently coalesce into continuous elements or blobs. If we consider a bubble to be the smallest possible blob, then a track consists of many blobs separated by an equal number of gaps. We combine the flying spot size and the bubble image size into an equivalent HPD scan width, a , for which bubbles can be treated as points. For a track of mean bubble density, k , per micron on the film

$$e^{-ka}$$

is the probability that a miss will occur on a single sweep across the track.

We assume that neither energy loss nor dip angle cause any change in the bubble density over the segment under consideration. We assume that there are no background bubbles near the track. In practice this means that we must turn off the bubble density measurement whenever the track is obscured.

A maximum likelihood estimate of the mean bubble spacing, λ , is given by equation (1)

$$\lambda = s / \ln \left(\frac{M}{M-C} \right) \quad (1)$$

where s is the scan line separation

M is the total number of Misses

C is the total number of gaps.²

In this case there is the additional requirement that

$$a/2 < s < a$$

so that at most one bubble could be digitized only twice. This condition is compatible with the requirements of measurement speed and the FILTER subroutine.

To test the HPD bubble density measurement, we plotted all of the road points for the beam track of the two-prong event in Figure 1. By eye, we selected the hits which were associated with the track and we determined whether a hit or miss occurred on each scan of the track. We plotted the hit-miss structure of the track as shown in Figure 6. For this track we found 68 data cells and 244 misses. The scan line separation was 28 microns and from equation (1) the inverse bubble density, λ , was found to be 86 ± 11 microns. The error is purely statistical. The same track was measured on one of the bubble chamber group's measuring projectors by

our conventional gap measurement method. This yielded

$$\lambda = 83 \pm 8 \text{ microns}$$

Again, the error is statistical.

Recently Neil Webre included automatic bubble density measurement in the FILTER subroutine. Some of the 900 Mev π^+ events were processed. Due to FILTER difficulties it was necessary to follow the computation in detail. We present results for 9 selected tracks that were FILTERed properly. These tracks were also measured on the measuring projector for comparison. The data appears in Table I. The first three tracks in Table I are minimum beam tracks. The remaining tracks cover the range to about five times minimum. Agreement with the results from the measuring projector is poor for the dense tracks. This is thought to be due to our computing the number of misses from the difference between the total number of scans and the total number of hits. We will change this computation to a direct tally of the number of misses. This will greatly reduce the measurement error for dense tracks.

We conclude from measuring the same track repeatedly, that the reproducibility of HPD bubble density measurement is currently of the same order of magnitude as the statistical error. This is mostly caused by the $\pm 5\%$ regulation of the speed of the moving stage. We expect to reduce this to $\pm 2\%$.

Figures 7, 8, and 9 are bubble chamber photographs of some of the tracks that were measured. The HPD mean bubble formation lengths for these tracks are indicated on the figures.

As a result of these tests, we feel that high quality bubble density measurements will be provided by the HPD system.
