ABSTRACT

This report is an addendum to a previous report¹ concerning a method of stress analysis for irradiated graphite which may be used for Molten Salt Breeder Reactor (MSBR) core design. To provide a refined analysis, the present method includes the effect of a variable creep coefficient which is caused by the nonuniform temperature distribution. To facilitate a simple formulation, it is assumed that the temperature dependence of the elastic response of the material is approximated to be inversely proportional to the creep rate. It is shown that the problem reduces to the solution of several associated (fictitious) elastic problems which have a common elastic modulus inversely proportional to the creep rate of the irradiated graphite. Numerical examples in the previous report were recalculated based on the present theory. It shows, for large dose values, an improvement to the previous method. A computer program is written for the purpose and can include the previous solution as a special case.

Keywords: stress analysis, graphite, neutron irradiation, dimensional change, temperature, viscoelasticity, lifetime, MSBR, creep coefficient.

INTRODUCTION

The graphite moderator located in a Molten Salt Breeder Reactor (MSBR) is subjected to intense neutron irradiation and temperature change. The irradiated graphite is known to exhibit the properties of creep and dimensional change which depend significantly on temperature. A report¹ was written to provide a method of stress analysis

¹S. J. Chang, C. E. Pugh, and S. E. Moore, "Viscoelastic Analysis of Graphite Under Neutron Irradiation and Temperature Distribution," ORNL-TM-2407 (October 1969); and Fifth Southeastern Conference on Theoretical and Applied Mechanics, Raleigh, North Carolina, April 1970.

for the purpose of MSBR core design. It applied the theory of linear viscoelasticity and reduced the problem to the stress analysis of several fictitious elastic problems. It was illustrated that the method can analyze the effects of any two-dimensional geometry, boundary tractions, temperature distribution, and neutron-induced dimensional change by calculating several elastic problems.

The method, however, was based on the assumption that the creep rate $K(T)$ was independent of temperature change throughout the cross section. This assumption, as shown in the next section, will lead to some error according to the preliminary analyses given in the previous report.¹ It is the intention of the present report to provide a modified method so that the variation of $K(T)$ with respect to temperature is included in the formulation. The resulting analysis in the text shows that the modified formulation can also reduce the problem to the solution of several associated elastic problems. But these associated elastic problems have a common nonuniform elastic modulus, inversely proportional to $K(T)$.

The numerical examples of the previous report were recalculated. The results show an improvement of the method of analysis. The computer program in the present case includes the previous one as a special case.

REVISED CONSTITUTIVE EQUATIONS

The purpose of this revision is to provide a reasonable concern about the variation of the creep rate $K(T)$ with temperature in the creep function. The necessity of this modification is supported by the numerical values shown below.

The preliminary analyses for the temperature profile of the Molten Salt Breeder Reactor (MSBR) presented in a former report¹ indicated that the temperature ranges from 670°C to 760°C as shown in Fig. 4 of that report. The resulting variation in $K(T)$, as well as its consequence in the range of large neutron dose, will provide us the obvious reason why the modified analysis in the present report is necessary. In fact, the formula shown in Eq. (55) of the earlier report shows a difference

of 14% in $K(T)$ for the temperature range from 670°C to 760°C . With a neutron dose value of $D = 3 \times 10^{22}$ nvt this will lead to a difference in creep function, shown in Eq. (19) of that report, of

$$\Delta K(T)D = 8.4 \times 10^{-6}$$

when $K(T)$ is computed at $T = 700^{\circ}\text{C}$. The value of $\frac{1.5}{E}$ in the creep function is 8.8×10^{-7} . $\frac{1.5}{E}$ is understood to be the sum of the instantaneous and primary creeps. Therefore, the change in $K(T) \cdot D$ in the creep function because of the temperature difference is important as compared with $\frac{1.5}{E}$. Furthermore, the term $K(T) \cdot D$ itself in the creep function for $D = 3 \times 10^{22}$ nvt has a higher order of magnitude as compared with $\frac{1.5}{E}$ in the creep function. These facts indicate that, in creep analyses, the variation of $K(T)$ with temperature is not negligible and the variation of $\frac{1.5}{E}$ is of less importance. The latter fact will be used below as the approximation in our modified creep function as shown in the next paragraph. This creep function will be used later.

With the above concern, it is therefore reasonable to approximate the creep function in the following form

$$J(D) = \frac{K(T)}{K_0} J_0(D) \quad (1)$$

with

$$J_0(D) = \frac{1}{E} + \frac{1}{2E} \left(1 - e^{-\frac{A_0 D}{K_0}} \right) + K_0 \cdot D \quad (2)$$

K_0 is the creep coefficient $K(T)$ computed at some average temperature and A_0 is a large constant. Therefore, the initial response is represented approximately but the creep rate is exact. Hence the method is more effective for large dose range, and for temperature sensitive $K(T)$. For lower dose range the method of the previous report¹ is more accurate. Since the present method will include the method developed previously as a special case, the solution for small dose can be obtained readily by assuming $K(T)$ to be constant throughout the cross section in the present method. The reason that this form of approximation is proposed

is that in Eq. (1), $J(D)$ can be factored into two parts, one depending on the space coordinates, the other on dose. This factorization still can facilitate the inversion operation in a series of derivations shown in the last section of this report. The constitutive equations based on Eq. (1) for a three-dimensional body can therefore be derived similarly to that in our previous report.

With the understanding of the new form of $J(D)$, the constitutive equations for the transversely isotropic graphites, as possessed by many kinds of graphite, are

$$\epsilon_x = J_x * (d\sigma_x - \mu_x d\sigma_y) - \mu_z J_z * d\sigma_z + \alpha_x T + \psi_x(T, D) \quad , \quad (3)$$

$$\epsilon_y = J_x * (d\sigma_y - \mu_x d\sigma_x) - \mu_z J_z * d\sigma_z + \alpha_x T + \psi_x(T, D) \quad , \quad (4)$$

$$\epsilon_z = J_z * (d\sigma_z - \mu_z d\sigma_x - \mu_z d\sigma_y) + \alpha_z T + \psi_z(T, D) \quad , \quad (5)$$

$$\gamma_{xy} = 2(1 + \mu_x) J_x * d\tau_{xy} \quad , \quad (6)$$

$$\gamma_{yz} = J_{zx} * d\tau_{yz} \quad , \quad (7)$$

$$\gamma_{zx} = J_{zx} * d\tau_{zx} \quad , \quad (8)$$

where z axis is assumed to be the axis of mechanical symmetry and both Poisson ratios, μ_x and μ_z , to be constant. The Poisson ratio μ_x is defined as the ratio of induced lateral strain to longitudinal strain for a uniaxial test when both directions lie in the plane of isotropy (x, y). Whereas, μ_z is the ratio of the lateral strain induced in a direction in the plane of isotropy to the longitudinal strain in the direction normal to the isotropic plane. When these ratios are dose dependent, two creep functions, in addition to J_x , J_z , and J_{zx} , are required for the stress-strain representation. The notation (*) is used to represent a convolution relation, e.g.,

$$J * d\sigma = \int_0^D J(D - D') \frac{\partial \sigma}{\partial D'} dD' \quad . \quad (9)$$

The terms αT and $\psi(T,D)$ represent the strains due to thermal expansion and dimensional changes resulting directly from neutron irradiation, respectively.

The generalized plane-strain conditions are defined by the case when the normal strain in a given direction, say the z direction, assumes a constant value ϵ_0 , all derivatives with respect to z vanish, such that the net resultant force in the z direction vanishes. Under these conditions the system of equations, Eqs. (3)-(8), reduces to an equivalent two-dimensional case

$$\begin{aligned} \epsilon_x = & (J_x - \mu_z^2 J_z) * d\sigma_x - (\mu_x J_x + \mu_z^2 J_z) * d\sigma_y \\ & + (\alpha_x + \mu_z \alpha_z) T + \psi_x + \mu_z \psi_z - \mu_z \epsilon_0 , \end{aligned} \quad (10)$$

$$\begin{aligned} \epsilon_y = & (J_x - \mu_z^2 J_z) * d\sigma_y - (\mu_x J_x + \mu_z^2 J_z) * d\sigma_x \\ & + (\alpha_x + \mu_z \alpha_z) T + \psi_x + \mu_z \psi_z - \mu_z \epsilon_0 , \end{aligned} \quad (11)$$

$$\gamma_{xy} = 2(1 + \mu_x) J_x * d\tau_{xy} . \quad (12)$$

For an isotropic graphite, the following simplifications can be made in the generalized plain-strain formulation:

$$\mu_z = \mu_x = \mu , \quad (13)$$

$$J_x = J_z = J , \quad (14)$$

$$\alpha_x = \alpha_z = \alpha , \quad (15)$$

$$\psi_x = \psi_y = \psi , \quad (16)$$

and it follows that

$$\epsilon_x = (1 - \mu^2) J * \left(d\sigma_x - \frac{\mu}{1 - \mu} d\sigma_y \right) + (1 + \mu)(\alpha T + \psi) - \mu \epsilon_o \quad , \quad (17)$$

$$\epsilon_y = (1 - \mu^2) J * \left(d\sigma_y - \frac{\mu}{1 - \mu} d\sigma_x \right) + (1 + \mu)(\alpha T + \psi) - \mu \epsilon_o \quad , \quad (18)$$

$$\gamma_{xy} = 2(1 + \mu) J * d\tau_{xy} \quad . \quad (19)$$

Thus, it is seen from Eqs. (17)-(19) that the viscoelastic stress analysis of an isotropic graphite requires the determination of only one creep function, $J(D)$, and one Poisson ratio, μ .

FORMULATION AND SOLUTION

In this section, a method of viscoelastic stress analysis is made to correspond to several equivalent elastic problems. These fictitious elastic problems have the same moduli of elasticity, inversely proportional to the creep coefficient $K(T)$. This differs from our previous analysis. Consider an arbitrary two-dimensional cross section where the neutron flux is assumed to be uniform over the entire section and the creep function $K(T)$ depends on the temperature distribution. As used before,¹ the stress function, φ , is introduced by

$$\sigma_x = \frac{\partial^2 \varphi}{\partial y^2} \quad , \quad (20)$$

$$\sigma_y = \frac{\partial^2 \varphi}{\partial x^2} \quad , \quad (21)$$

$$\tau_{xy} = - \frac{\partial^2 \varphi}{\partial x \partial y} \quad , \quad (22)$$

which will satisfy the equations of equilibrium. After substituting Eqs. (20), (21), and (22) into the equation of compatibility

$$\frac{\partial^2 \epsilon_y}{\partial x^2} + \frac{\partial^2 \epsilon_x}{\partial y^2} = \frac{\partial^2 \gamma_{xy}}{\partial x \partial y} \quad , \quad (23)$$

the governing equation of φ is

$$J_0 * d \left[\frac{\partial^2}{\partial x^2} \frac{K(T)}{K_0} \left(\frac{\partial^2 \varphi}{\partial x^2} - \frac{\mu}{1-\mu} \frac{\partial^2 \varphi}{\partial y^2} \right) + \frac{\partial^2}{\partial y^2} \frac{K(T)}{K_0} \left(\frac{\partial^2 \varphi}{\partial y^2} - \frac{\mu}{1-\mu} \frac{\partial^2 \varphi}{\partial x^2} \right) + \frac{2}{1-\mu} \frac{\partial^2}{\partial x \partial y} \frac{K(T)}{K_0} \frac{\partial^2 \varphi}{\partial x \partial y} \right] = \frac{-\mu}{1-\mu} \nabla^2 [\psi(D, T) + \alpha T] \quad (24)$$

where

$$J_0 = \frac{1}{E} + \frac{1}{2E} \left(1 - e^{-A_0 D} \right) + K_0 D \quad (25)$$

After inversion, φ satisfies

$$\frac{\partial^2}{\partial x^2} \left[\frac{K(T)}{K_0} \left(\frac{\partial^2 \varphi}{\partial x^2} - \frac{\mu}{1-\mu} \frac{\partial^2 \varphi}{\partial y^2} \right) \right] + \frac{\partial^2}{\partial y^2} \left[\frac{K(T)}{K_0} \left(\frac{\partial^2 \varphi}{\partial y^2} - \frac{\mu}{1-\mu} \frac{\partial^2 \varphi}{\partial x^2} \right) \right] + \frac{2}{1-\mu} \frac{\partial^2}{\partial x \partial y} \left[\frac{K(T)}{K_0} \frac{\partial^2 \varphi}{\partial x \partial y} \right] = \frac{-\mu}{1-\mu} G_0 * d \nabla^2 [\psi(D, T) + \alpha T] \quad (26)$$

where G_0 is related to J_0 by²

$$\int_0^D G_0(D - D') \frac{\partial}{\partial D'} J_0(D') dD' = H(D) \quad (27)$$

and $H(D)$ is the unit step function. The function G_0 which corresponds to J_0 given by Eq. (25) is

$$G_0(D) = \frac{E}{\sqrt{(E \cdot K_0 + 1.5A_0)^2 - 4E \cdot K_0 \cdot A_0}} \left[(k_1 + A_0) e^{k_1 D} - (k_2 + A_0) e^{k_2 D} \right] \quad (28)$$

where

$$k_1 = -0.5 (E \cdot K_0 + 1.5A_0) + 0.5 \sqrt{(E \cdot K_0 + 1.5A_0)^2 - 4E \cdot K_0 \cdot A_0} \quad (29)$$

²E. H. Lee, "Viscoelastic Stress Analysis," Chap. 53, Handbook of Engineering Mechanics, edited by W. Flugge, McGraw-Hill, New York, 1962.

$$k_2 = -0.5(E \cdot K_0 + 1.5A_0) - 0.5 \sqrt{(E \cdot K_0 + 1.5A_0)^2 - 4E \cdot K_0 \cdot A_0} \quad (30)$$

Both k_1 and k_2 are seen to be negative. For prescribed boundary traction, the boundary conditions are

$$\frac{\partial \phi}{\partial y} = \int_C T_x \, ds \quad (31)$$

and

$$\frac{\partial \phi}{\partial x} = - \int_C T_y \, ds \quad (32)$$

where T_x and T_y are the x and y components of the boundary traction acting on the boundary, C, of the cross section of the body.

If the temperature-dependent neutron-induced dimensional change is given by³

$$\psi(D, T) = A_2(T) D^2 + A_1(T) D \quad (33)$$

then the right-hand side of Eq. (26) reduces to

$$\frac{-1}{1 - \mu} \left\{ G_0(D) \alpha \nabla^2 T + \nabla^2 A_2(T) \int_0^D G_0(D - D') \cdot 2D' \cdot dD' + \nabla^2 A_1(T) \int_0^D G_0(D - D') \, dD' \right\} \quad (34)$$

where the temperature distribution is assumed to be applied suddenly at $D = 0$ and to be kept constant for $D > 0$. The left-hand side of Eq. (26) is seen to be the same as that used in the elastic problem with nonuniform elastic modulus. The solution to the present problem can therefore be expressed by

³P. R. Kasten et al., "Graphite Behavior and Its Effects on MSBR Performance," Nuclear Engineering and Design 9(2), 157-195 (1969).

$$\varphi(x, y, D) = \varphi^a(x, y) + \varphi^b(x, y) \frac{G_o(D)}{G_o(0)} + \varphi^c(x, y) F_1(D) + \varphi^d(x, y) \cdot F_2(D), \quad (35)$$

where φ^a , φ^b , φ^c , and φ^d are elastic solutions, corresponding to boundary tractions, thermal expansion, dimensional change $A_1(T)$, and dimensional change $A_2(T)$, respectively, and

$$F_1(D) = \frac{1}{G_o(0)} \int_0^D G_o(D - D') dD' \quad (36)$$

and

$$F_2(D) = \frac{1}{G_o(0)} \int_0^D G_o(D - D') 2D' dD' . \quad (37)$$

The proof of the statement Eq. (35) can be carried out by a similar procedure as shown previously.¹ The elastic solutions are understood to be found from a nonuniform elastic medium with the common elastic modulus, $\frac{E \cdot K_o}{K(T)}$. From this consideration, the problem of irradiated graphite of an arbitrary two-dimensional cross section can be found, provided that a computer program is available to calculate the elastic thermal stress.

The displacement for the present problem due to the dimensional change and the thermal loading is the same as that obtained from a corresponding elastic problem. This result is due to the fact that the solution is independent of the creep function $J_o(D)$.

With the present formulation, a simple correspondence is made between the viscoelastic solution and the elastic solutions. The effort to solve the problem therefore reduces to the solutions φ^a , φ^b , φ^c , and φ^d . The time-dependent solution is connected with them by $F_1(D)$ and $F_2(D)$ which can be calculated from Eq. (28).

NUMERICAL EXAMPLE

Based on the theoretical formulation of the last section, the numerical examples of the previous report were recalculated. To compare the results, the curves corresponding to Figs. 6, 7, 8, 11, and 12 of

ORNL-TM-2407 are drawn and labeled as Figs. 1, 2, 3, 4, and 5 in the present report. The temperature distributions are the same as the former ones and, therefore, will not be shown here. The material constants as well as the thermal loading are the same as shown from page 13 to page 16 of the previous report. Therefore, to avoid repetition, we shall not rewrite them here.

To solve the problem numerically, we have to solve the elastic problems with the nonuniform elastic constants. Let u_i ($i = 1, 2, 3$) denote the radial displacements due to the volume expansions αT , $A_1(T)$, and $A_2(T)$. We recall that α is the coefficient of the linear thermal expansion shown in Eq. (15), and $A_1(T)$ and $A_2(T)$ are given by Eq. (33) and more specifically by reference 3. The problem reduces mathematically to the solution of a second-order linear ordinary differential equation of the following form:

$$\frac{d}{dr} \left[\left(\frac{\lambda + 2\mu}{E} \right) \frac{du_i}{dr} \right] + \frac{\lambda + 2\mu}{E} \frac{1}{r} \frac{du_i}{dr} - \frac{\lambda + 2\mu}{E} \frac{u_i}{r^2} + \left(\epsilon_i + \frac{u_i}{r} \right) \frac{d}{dr} \left(\frac{\lambda}{E} \right) = \frac{d}{dr} \left[\frac{3\lambda + 2\mu}{E} F_i \right] \quad (i = 1, 2, 3) \quad (38)$$

where $F_1 = \alpha T$, $F_2 = A_1(T)$, and $F_3 = A_2(T)$. In Eq. (38), ϵ_i ($i = 1, 2, 3$) correspond to the three axial strains because the problems are solved under the assumption of the generalized plane strain. λ and μ are respectively defined by

$$\frac{\lambda}{E} = \frac{\sigma}{(1+\sigma)(1-2\sigma)} \frac{K_o}{K(T)} \quad (39)$$

and

$$\frac{\mu}{E} = \frac{1}{2(1+\sigma)} \frac{K_o}{K(T)}, \quad (40)$$

where $K(T)$ is defined by Eq. (1) and K_o and E are the values of $K(T)$ and Young's modulus when T is evaluated at the inner surface of the concentric cylinder $r = a$. σ is the Poisson's ratio. Since T varies along r so do λ and μ .

The two integration constants for Eq. (38) and ϵ_i are to be determined by the boundary conditions

$$\lambda \left(\frac{du_i}{dr} + \frac{u_i}{r} + \epsilon_i \right) + 2\mu \frac{du_i}{dr} - (3\lambda + 2\mu) F_i = 0 \quad (41)$$

at $r = a$ and $r = b$ and by the condition that the axial resultant force is zero, that is

$$\int_a^b \lambda \left[\left(\frac{du_i}{dr} + \frac{u_i}{r} \right) - (3\lambda + 2\mu) F_i \right] r dr + \epsilon_i \int_a^b (\lambda + 2\mu) r dr = 0 \quad (42)$$

The problems are solved by the method of finite differences. An iterative procedure is used to determine ϵ_i . We first assume $\epsilon_i = 0$, then u_i is calculated from Eq. (38) and the boundary conditions Eq. (41). With the known value of u_i , the first approximation of ϵ_i is calculated from Eq. (42). The process continues up to a difference of the two successive ϵ_i 's smaller than 10^{-6} which is approximately equivalent to a relative error of 0.1% in the present case.

After u_i ($i = 1, 2, 3$) as well as ϵ_i ($i = 1, 2, 3$) are solved, the corresponding elastic stress components are calculated by the constitutive equations

$$\sigma_r^i = \lambda \left(\frac{du_i}{dr} + \frac{u_i}{r} + \epsilon_i \right) + 2\mu \frac{du_i}{dr} - (3\lambda + 2\mu) F_i$$

$$\sigma_\theta^i = \lambda \left(\frac{du_i}{dr} + \frac{u_i}{r} + \epsilon_i \right) + 2\mu \frac{u_i}{r} - (3\lambda + 2\mu) F_i$$

$$\sigma_z^i = \lambda \left(\frac{du_i}{dr} + \frac{u_i}{r} + \epsilon_i \right) + 2\mu \epsilon_i - (3\lambda + 2\mu) F_i$$

and the final dose-dependent stress components are calculated by

$$\sigma_r(D, r) = \sigma_r^1 \frac{G(D)}{E} + \sigma_r^2 F_1(D) + \sigma_r^3 F_2(D)$$

$$\sigma_\theta(D, r) = \sigma_\theta^1 \frac{G(D)}{E} + \sigma_\theta^2 F_1(D) + \sigma_\theta^3 F_2(D)$$

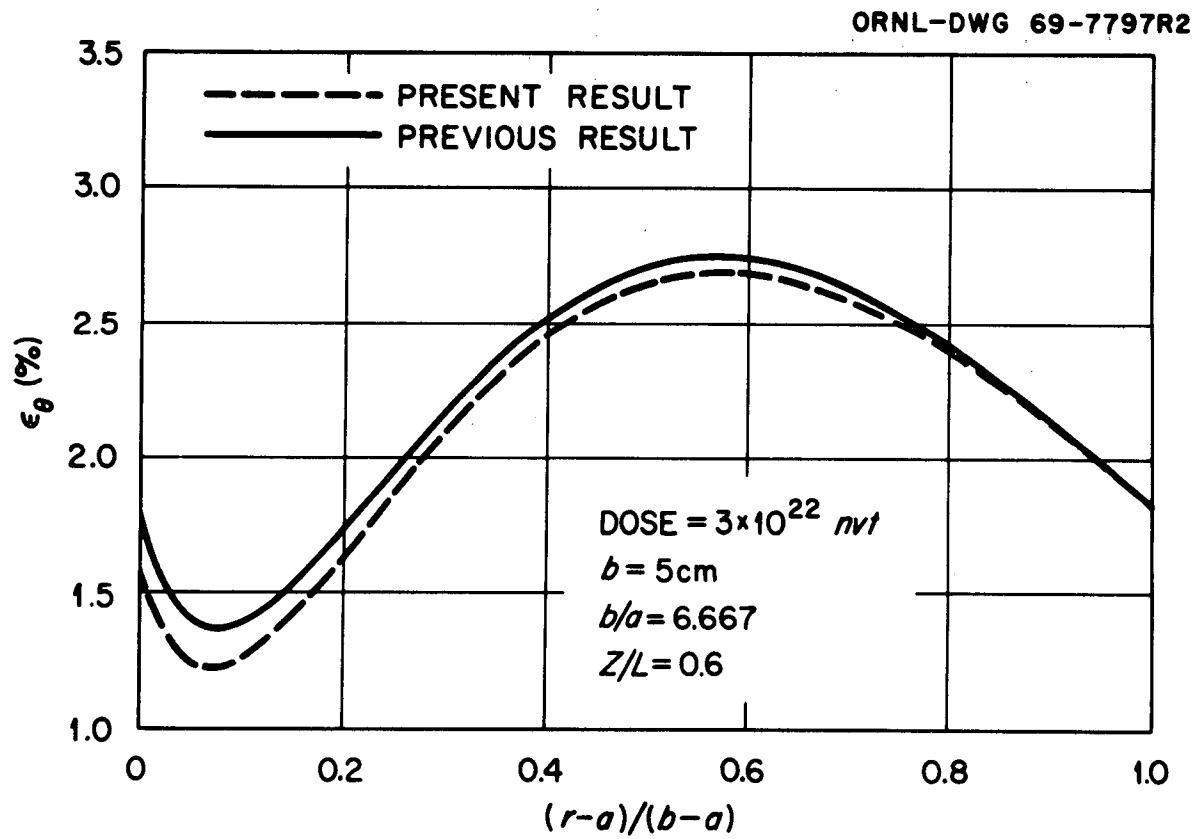

Figure 1. Circumferential Strain As a Function of Radial Position

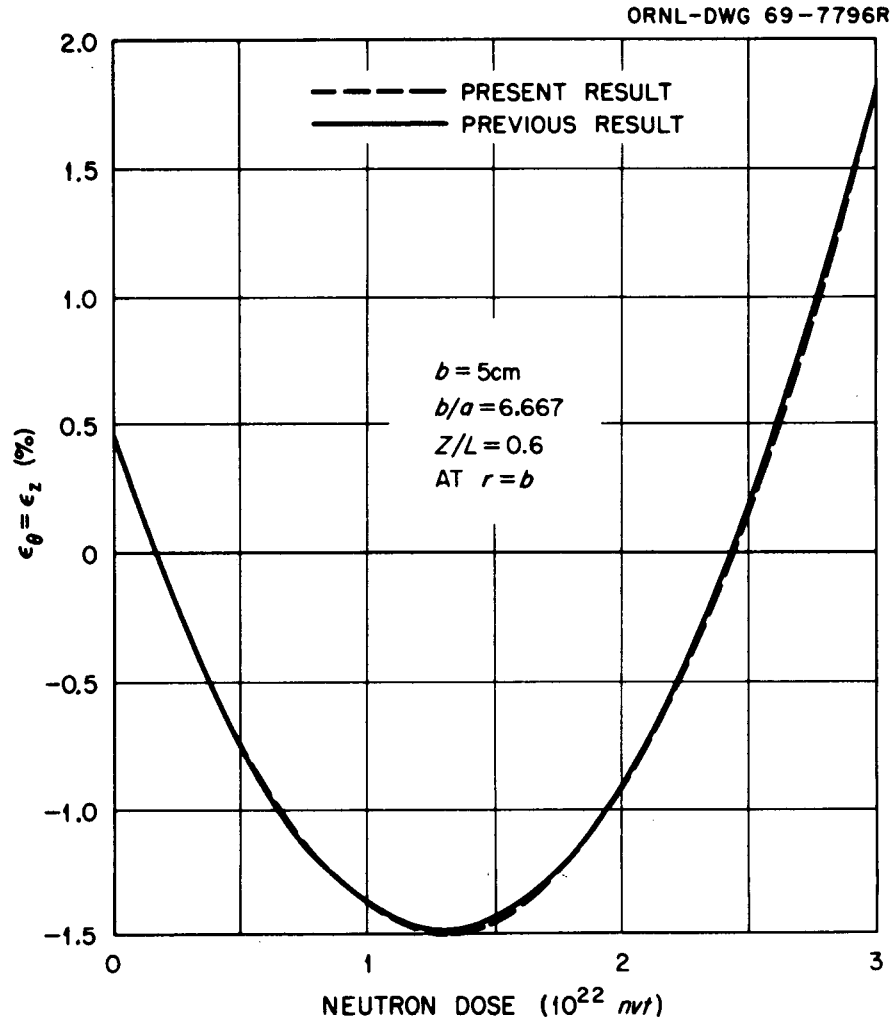

Figure 2. Circumferential Strain at Outside Surface As a Function of Fluence Level

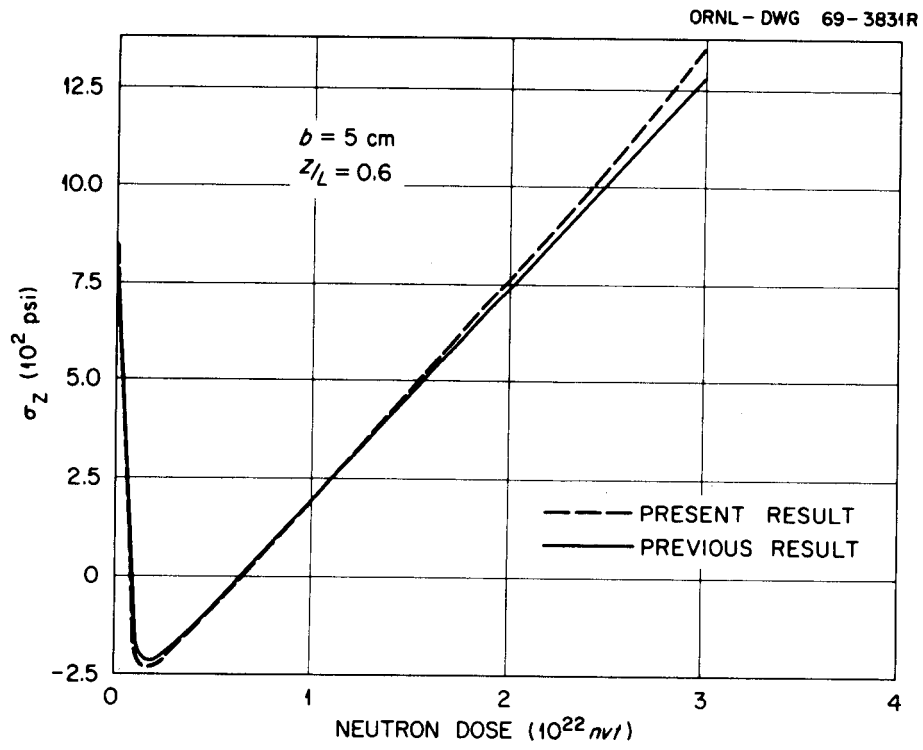

Figure 3. Axial Stress at the Outer Surface As a Function of Fluence Level

ORNL - DWG 69-3835AR

Figure 4. Lifetime of MSBR Graphite Core Cylinders As a Function of Axial Position According to the Volumetric Distortion Criterion

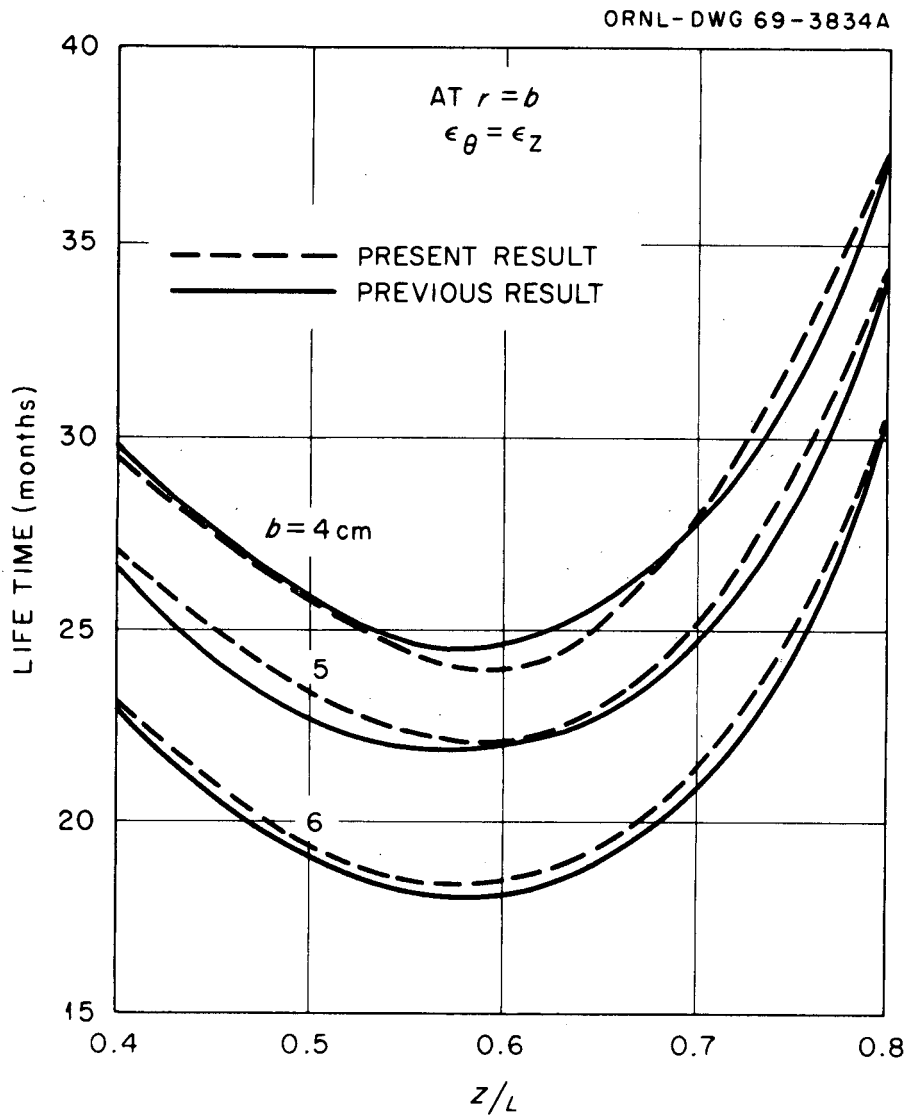

Figure 5. Lifetime of MSBR Graphite Core Cylinders As a Function of Axial Position According to the Axial Strain Criterion

$$\sigma_z(D, r) = \sigma_z^1 \frac{G(D)}{E} + \sigma_z^2 F_1(D) + \sigma_z^3 F_2(D) .$$

The final solution of the displacement and the strain components are calculated according to

$$u = u_1 + u_2 D + u_3 D^2 ,$$

$$\epsilon_r = \frac{du}{dr} ,$$

$$\epsilon_\theta = \frac{u}{r} ,$$

$$\epsilon_z = \epsilon_1 + \epsilon_2 D + \epsilon_3 D^2 .$$

The numerical values of temperature T ; displacement u ; strain components ϵ_r , ϵ_θ , and ϵ_z ; stress components σ_r , σ_θ , and σ_z are calculated at 41 points along the radial directions of the cylinders of $b = 4, 5, 6$ cm. The above values are calculated at each cross section of $Z/L = 0.1, 0.2, \dots, 0.9$ for the neutron dose level D (10^{22} nvt) = $0.0, 0.2, \dots, 4.0$. The total computation time for an IBM 360 Model 91 machine is on the order of 4 minutes. The computing time can be reduced considerably if we reduce the error bound of ϵ_i in the iterative process.

To indicate the numerical results, typical curves are presented in Figs. 1-5 which indicate the difference from Figs. 6, 7, 8, 11, and 12 of ORNL-TM-2407. We superimposed the corresponding plots for the purpose of comparison. The reason for the difference is certainly because of a modification of $J(D)$. The detailed explanation has been written in the paragraph following Eq. (2). The improvement is shown in Fig. 3 where σ_z at $D = 3 \times 10^{22}$ nvt is 13,200 psi, an increase of 6% of the previous value. This confirms our prediction.

CONCLUSION

The modified method shown in the present report has considered the effect of temperature on the creep coefficient. A difference of 6% between the components was obtained for a neutron dose level of

3×10^{22} nvt. The method is therefore important in cases when the creep coefficient is more sensitive to temperature and when the temperature gradient within the cross section is steep. The difference caused by this modification becomes more significant with increasing dose values. As the trend of the development in reactor technology is toward the higher operating temperature and the larger neutron dose level, the method presented here is therefore compatible to the need in the future. However, the instantaneous elasticity and the primary creep have an inaccurate temperature dependence imposed by the method. Therefore, the resulting solutions can be considered accurate only above some small dose value (less than $1/2 \times 10^{22}$ nvt). Below this dose value, use should be made of the previous method¹ which can be calculated by assuming a constant $K(T)$ in the present method.

As can be seen from the derivation if the creep coefficient $K(T)$ is taken to be constant, then the analysis will reduce to the case of our previous one. Therefore, the present computer program includes the previous one as a special case.

ACKNOWLEDGMENT

The authors express their appreciation to B. L. Greenstreet, head of the Applied Mechanics Section, for his supervision. Thanks are also due to C. E. Pugh of Applied Mechanics Section for many stimulating discussions and with whom the authors have been working for a part of the Molten Salt Breeder Reactor program.

APPENDIX

Date: 23 June 1970

Name of Program: VATCRP

Programmers: S. J. Chang, J. A. Carpenter, D. W. Altom

Description: VATCRP is a double-precision Fortran program which calculates the stress and the displacement fields for a Molten Salt Breeder Reactor graphite core under neutron irradiation and temperature distribution. VATCRP treats the creep coefficient as a function of temperature. The program is based upon the theoretical derivations and is intended to follow the proposed numerical scheme in the main text.

Three concentric cylinders are used to simulate the design study. The radius of the outer cylinder is designated B and is input to the program. The radius A of the inner cylinder is given by $B/A = 6.667$.

Input: The user must provide four data cards to VATCRP in the following order:

	<u>VARIABLE NAMES</u>	<u>CARD FORMAT</u>
Card 1:	BIN, DB, NB	(2D10.3, I10)
BIN -	initial value of the radius B of the outer cylinder (in centimeters)	
DB -	increment in the value of B (in centimeters)	
NB -	total number of B-values, i.e., $BIN \leq B \leq BIN + (NB-1)DB$	
Card 2:	ZLIN, DZL, NZL	(2D10.3, I10)
ZLIN -	initial value of Z/L where L is the length of the cylinders and Z is the distance measured from the bottom of the cylinders to the point of interest, i.e., $0. \leq Z/L \leq 1$.	
DZL -	increment in the value of Z/L	
NZL -	total number of Z/L-values, i.e., $ZLIN \leq Z/L \leq ZLIN + (NZL-1)DZL$

C .....
C SUBROUTINE DQTFE
C
C PURPOSE
C TO COMPUTE THE VECTOR OF INTEGRAL VALUES FOR A GIVEN
C EQUIDISTANT TABLE OF FUNCTION VALUES.
C
C USAGE
C CALL DQTFE (H,Y,Z,NDIM)
C
C DESCRIPTION OF PARAMETERS
C H - DOUBLE PRECISION INCREMENT OF ARGUMENT VALUES.
C Y - DOUBLE PRECISION INPUT VECTOR OF FUNCTION VALUES.
C Z - RESULTING DOUBLE PRECISION VECTOR OF INTEGRAL
C VALUES. Z MAY BE IDENTICAL WITH Y.
C NDIM - THE DIMENSION OF VECTORS Y AND Z.
C
C REMARKS
C NO ACTION IN CASE NDIM LESS THAN 1.
C
C SUBROUTINES AND FUNCTION SUBPROGRAMS REQUIRED
C NONE
