NATIONAL LABORATORY

Los Alamos National Laboratory, an affirmative action/equal opportunity employer, is operated by the University of California for the U.S. Department of Energy under contract W-7405-ENG-36. By acceptance of this article, the publisher recognizes that the U.S. Government retains a nonexclusive, royalty-free license to publish or reproduce the published form of this contribution, or to allow others to do so, for U.S. Government purposes. Los Alamos National Laboratory requests that the publisher identify this article as work performed under the auspices of the U.S. Department of Energy. Los Alamos National Laboratory strongly supports academic freedom and a researcher's right to publish; as an institution, however, the Laboratory does not endorse the viewpoint of a publish; on or guarantee its technical correctness.

Roberta N. Mulford and Damian C. Swift Los Alamos National Laboratory, MS E530, Los Alamos, New Mexico 87545

Reactive flow models for explosives are usually developed by choosing an empirical form for the reaction rate and calibrating parameters against initiation experiments. In shock wave initiation, experimental data almost always comprise mechanical measurements such as shock speed, material speed, compression, and pressure. However, we know from chemistry that reaction rates depend on temperature as well as on the mechanical state. This is one reason why mechanically-based reaction rates do not extrapolate well outwith the range of states used to normalize them. For instance, mechanical reaction models which match single-shock initiation generally fail to reproduce multiple-shock initiation phenomena.

We have previously developed reactive flow models for military explosives which include temperature as well as the mechanical state. These models reproduced multiple-shock initiation behavior much more accurately than did reactive flow models with a purely mechanical reaction rate, and they were also capable of being used to simulate cook-off problems.

We have recently extended the temperature-based model for use with ANFO-type formulations. Reactive material is treated as a heterogeneous mixture of components, each of which has its own model for response to dynamic loading (equation of state, strength model, reactions.) A finite-rate equilibration model is used to determine the overall response of the mixture to dynamic loading. In the initial model of ANFO, the ammonium nitrate and the fuel oil are treated as separate components in the unreacted mixture. The ammonium nitrate reacts with a rate that depends on its thermodynamic state, with an additional contribution for brittle failure caused by shear under non-isotropic strain. The reaction products are oxygen-rich. The fuel oil decomposes as a function of its thermodynamic state, and the decomposition products are allowed to react with the excess oxygen from the ammonium nitrate with a diffusion-limited rate which depends on the thermodynamic state. This model is also suitable for other oxidizer-fuel mixtures.

There is a relative paucity of data on initiation in ANFO formulations, so our calibrations and simulations to date are to an extent sensitivity studies of a set of equations. More experiments are needed before the model can be regarded as accurate for predictive work.

Temperature-Based Reactive Flow Models for ANFO

12th Detonation Symposium San Diego, California August 11-16, 2002

Outline

- Motivation
- Overview of Model
- Equations of State
- Reaction Rate
- Performance

Developing a predictive capacity motivates mesoscale model

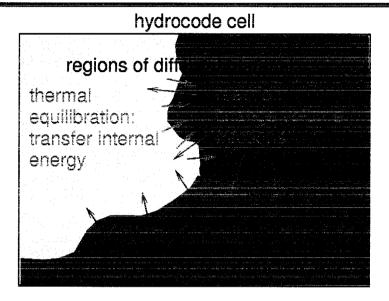

Want to predict initiation and blast given:

- Variations in composition
- Variations in morphology
- Different loading conditions

Previous work on military explosives: need physically-based model rather than just mechanical calibrations

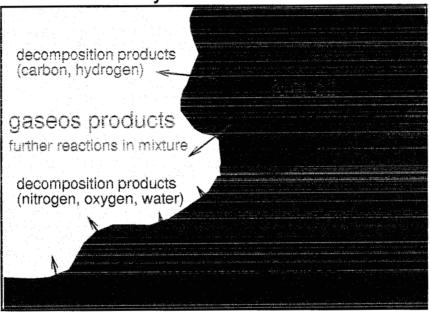

Model encompasses various spatial regions

- Equation of state for each component (spatial region)
- Equilibration process for temperature and stress.
- Chemical reactions transfer mass between components.
- Regions may comprise separate chemical components.
- Oxidiser/fuel process: oxidiser decomposes leaving oxygen-rich products;
 the oxygen reacts with the fuel.

Heterogeneous model for ANFO

hydrocode cell

- Initial porosity modelled as product fraction (at STP).
- Ammonium nitrate reacts with temperature-dependent rate.
- Fuel oil heated by reaction.
- Fuel oil reacts with AN products with temperature-dependent rate
- Pore collapse → increased heating.

Unreacted equations of state: quasiharmonic

Need accurate temperature

- → thermodynamically complete.
- -- Cold curve (T = 0 isotherm) + vibrational modes.
- -- Cold curve deduced from mechanical EOS fitted to shock data, with Γ (ρ) model for off-Hugoniot states.
- -- Assumed value for ρ (T=0) not particularly sensitive.
- -- Estimated vibrational modes ω_i from structure of molecule.
- -- Deduced $d\omega_i$ / dv to reproduce STP state.

Used to calibrate $\varepsilon(\rho,T)$ and $\rho(\rho,T)$.

Quasiharmonic equation of state

T = 0 isotherm
$$\varepsilon_c(\rho) \rightarrow \rho_c(\rho) = -d\varepsilon_c/dv$$

Vibrational modes $\omega_i(\rho)$

Specific internal energy:

$$\varepsilon_{\rm c}(\rho, T) = \varepsilon_{\rm c}(\rho) + \frac{1}{m} \sum_{i} \hbar \omega_{i}(\rho) \{ \exp(-\hbar \omega_{i}(\rho)/k_{\rm B}T) - 1 \}^{-1} + \frac{1}{2}$$

Pressure:

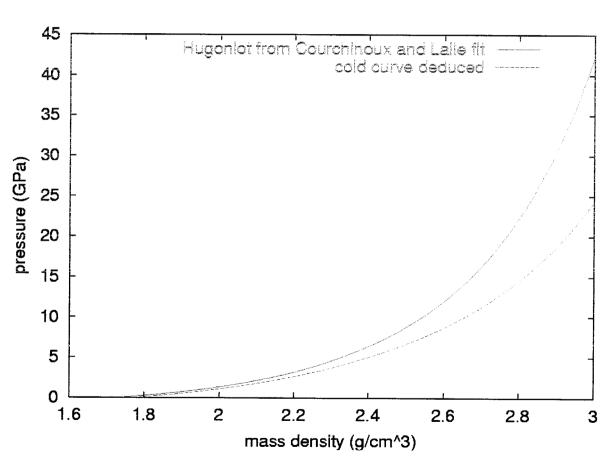

$$p(\rho,T) = p_c(\rho) - \frac{1}{m} \sum_i \hbar \frac{d\omega_i}{dv} \{ \exp(-\hbar\omega_i(\rho)/k_B T) - 1 \}^{-1} + \frac{1}{2}$$

Tabulated (Sesame format); used as (ρ , ϵ) EOS.

Ammonium nitrate: mechanical EOS

Steinberg-style Gr neisen form:

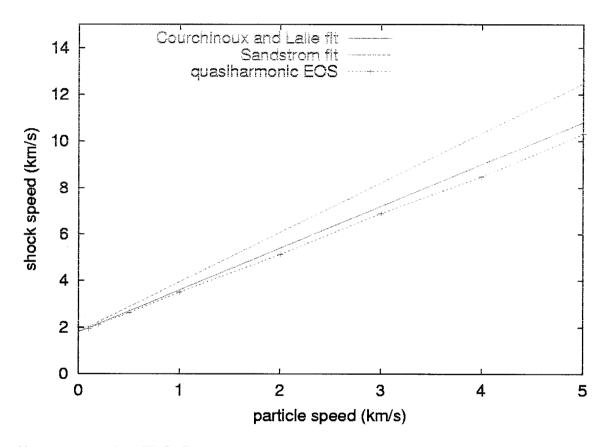

Ammonium nitrate: thermal contributions

mode	wavenumber, cm ⁻¹	degeneracy (modes per molecule)
O-H bending	1300	1
O-H stretching	3700	1
NH₃ umbrella	1400	3
NH ₃ stretch (as)	3145	3
NH ₃ scissor	1680	2
NH ₃ stretch (s)	3040	1
O-NH ₃ torsion	150	1
O-NO ₂ torsion	456	1
O-NO ₂ i.p. bend	710	1
O-NH ₃ bending	300	2
N-O bending	450	1
N-O bending	630	1
NO ₂ scissor	800	1
O-NH ₃ stretching	900	1
NO ₂ stretch (s)	1300	1
NO ₂ stretch (s)	1760	1

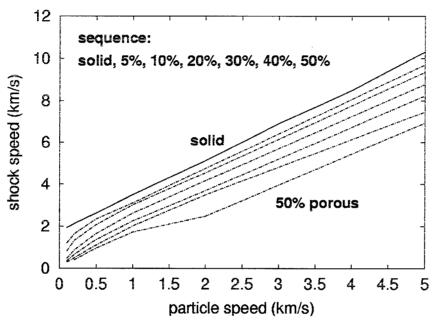

Ammonium nitrate: comparison with Hugoniot

-- quasiharmonic EOS is reasonably consistent with Gr neisen; temperatures are probably accurate.

Ammonium nitrate: porous Hugoniot

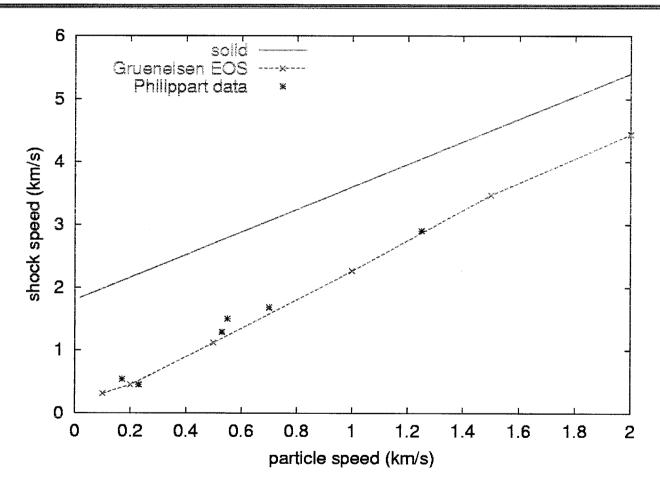

- Heterogeneous mixture model → treats porosity automatically.
- Particle size → equilibration rates.
- More useful for simulations than empirical rules for adjusting Hugoniot.

Los Alamos

- Developed for military explosives: porosity ~1%, works well to > 45%.
- Example: air in pores, infinitesimal particles (ideal mixture).

Porosity model compares well with Hugoniot data

45% porous, compared with ANFO Hugoniot data

Paraffin: mechanical EOS

Steinberg-style Gr neisen EOS, fitted to Hugoniot data:

Steinberg-style Gr neisen EOS, fitted to Hugoniot data:
$$u_s = c_0 + \sum_{i=1}^n s_i \left[\frac{u_p}{u_s} \right]^{i-1} u_p \text{ for all } 0$$

$$u_s = c_0 + \sum_{i=1}^n s_i \left[\frac{u_p}{u_s} \right]^{i-1} u_p \text{ for all } 0$$

Paraffin: complete equation of state Comparison with Hugoniot data:

Comparison with Hugoniot data:

-- reasonably consistent below ~20 GPa;

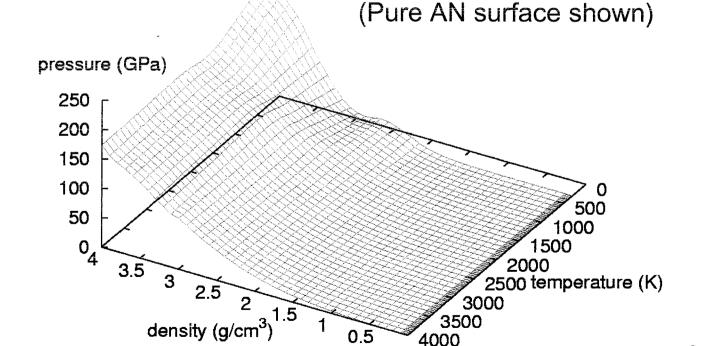

probably need more accurate treatment of frequencies at higher pressures.

Product Equation of State Generated with Cheetah

Varying AN/FO compositions requires construction of surface in ρ, T and p

Reaction rates

- Generalised Arrhenius: $\lambda = R_0 e^{(-T/T^*)}$ T* and R_0 may be functions of ρ , ϵ (not used here).
- Depletion terms for chemical species.
- T may include correction for non-equilibrium vibrations in a shock (not used here).
- Additional hotspot term using T for other components of mixture.
- R₀ estimated from typical atomic vibration frequencies for key bonds, ~ 10¹⁴/s.
- Energy release calculated from heats of formation.
- AN: T* estimated from (sparse) shock initiation data.
- FO: T* chosen by comparison with RX-HD.

Continuum mechanics simulations

Based on Edinburgh C++ testbed hydrocode

- Lagrangian finite difference predictor-corrector scheme
- Equation of state, strength, spall, mixtures, reactions
- Object-oriented: state stored depends on material type
- Internal evolution (equilibration, reactions, plastic flow, etc. are operator-split form hydrodynamics

Heterogeneous reactive flow

- Material comprises a set of simple constituents ρ_i , T_i , f_i .
- Calculate p for each.
- Finite equilibration rates for p and T: relaxation times $\tau_{\rm p}$ and $\tau_{\rm T}$.
- Reaction: rate for each constituent to transform to other(s).
- Equilibration and reaction are subcycled.
- Rates: bulk + surface (homogeneous).
- Surface area depends on volume fraction f_i
 through general function.
- Chemical reactions in products.

Mechanical equilibration

$$p_i = p(s_i)$$

$$p = p(s) &$$

$$\phi_r \equiv \phi_s (1 - e^{\Delta t/\tau} m)$$

$$\frac{\partial p_{i}}{\partial f_{i}} = \frac{c_{i}^{2}(s_{i}) \rho_{i}}{f_{i}}$$

$$\Delta f_i = \phi_r(p_i - p) \frac{\partial p_i}{\partial f_i}^{-1}$$

$$p'_{i} = p_{i} + \frac{\partial p_{i}}{\partial f_{i}} \frac{\Delta f_{i}}{2}$$

$$\Delta e_i = \underline{p'_i \Delta f_i}$$

$$f_i \rho_i$$

component pressure material mean pressure

relaxation factor

stiffness (adiabatic)

volume fraction change (raw)

effective pressure

energy change (raw)

(Volume and energy are adjusted for exact conservation Los Alamos

Thermal equilibration

$$T_i \equiv T(s_i)$$

$$\overline{\mathsf{T}} \equiv \mathsf{T}(\mathsf{s})$$

$$\phi_r \equiv \phi_s \left(1 - e^{-(\Delta \tau / \tau_T)} \right)$$

$$\Delta \epsilon_i = \& - \phi_r c_v(s_i) (T_i - \overline{T})$$

component temperature

material mean temperature

relaxation factor

energy change (raw)

(Energy is adjusted for exact conservation.)

Heterogeneous reaction model

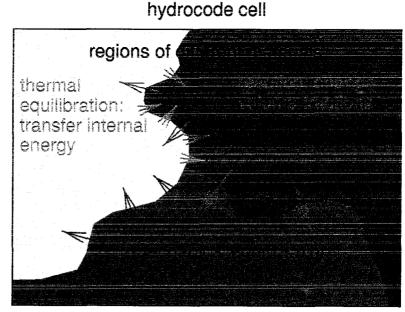

$$\lambda_{s}^{*} \equiv R_{b}(s_{i}, p(s_{j}), T(s_{j}))$$
 surface rate
$$V_{f} = V_{f}\rho_{i}, T(s_{j}))$$
 flame speed
$$A_{s} = A(f_{i})$$
 surface area
$$\Delta \lambda_{s} = A_{s}v_{f}\Delta t$$
 surface burn fraction (raw)
$$\lambda_{b}^{*} \equiv R_{b}(s_{i}, p(s_{i}), T(s_{i}))$$
 bulk rate
$$\Delta \lambda_{b} = (1 - f_{i} - \Delta \lambda_{s}) \lambda_{b}^{*}$$
 bulk burn fraction (raw)
$$\Delta \lambda = \Delta \lambda_{b} + \Delta \lambda_{s}$$
 total burn

(Surface contribution ignored if $\lambda_s' \Delta t < 1$.) Burn fractions limited to ensure $0 < f_i < 1$ and $\Sigma_i f_i = 1$.)

Hydrocode implementation

- Any number of materials per cell.
- For each: volume fraction f_i, state (ρ_i,...) and EOS.
 No further internal structure (shape functions etc).
- State depends on material type: may include other parameters (e.g. plastic strain).

- Explicit mechanical and thermal equilibration between regions; exponential time constant for each; operator-split from hydrodynamics and subcycled.

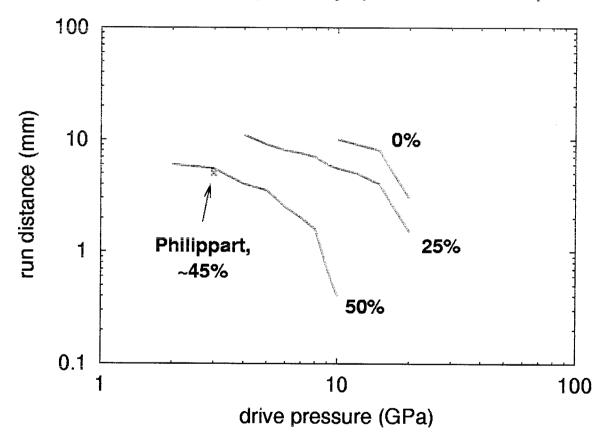

EOS functions: ρ , ϵ , p, T, c_v , c^2

- -- relatively simple requirement.
- Reaction rates R_{ij} between each pair of regions; operator-split from hydrodynamics and subcycled.

Predicted Pop plots fo AN

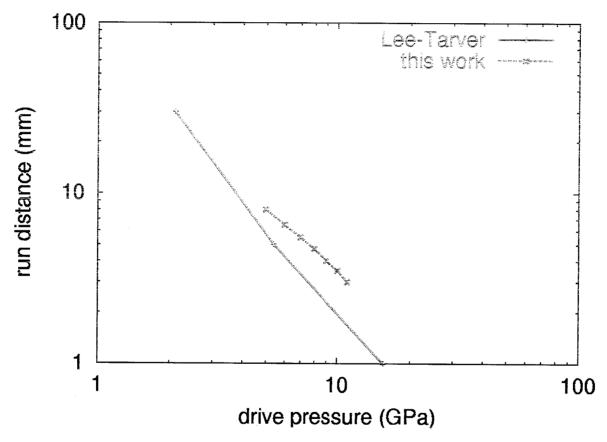

Variation with porosity, pore size, composition.

Parameters: R_0 = 10¹⁴ /s, T* = 12500 K, τ_p = 0.1 μ s, τ_T = 1.0 μ s, 0.1 mm mesh.

RX-HD Pop plots are Predicted

AN Parameters: R_0 = 10¹⁴ /s, T* = 12500 K, FO Parameters: R_0 = 10¹⁴ /s, T* = 15000 K, τ_p = 0.1 μ s, τ_T = 1.0 μ s, 0.1 mm mesh.

Summary and Conclusions

- Physically-based reactive flow model for ANFO.
- Complete equations of state:
 fairly rigorous, consistent with Gr neisen EOS.
- Model can predict effect of composition, porosity, particle size.
- Preliminary trials: comparable with empirical data / models.

Future work

- Minor adjustments to numerical scheme; re-calculate parameters more carefully.
- Off-Hugoniot data for AN etc.
 (e.g. Trident shots, diamond anvil, spectroscopy).
- Equilibrium chemistry for equation of state of reaction products.
- Use of / comparison with diameter effect data.
- Investigation of other fuels.
- Desensitisers as chemical species: model short-lived radicals.
