## 1 Introduction

Acoustic surveys targeting blue whiting (*Micromesistius poutassou*) spawning and post spawning aggregations in the north east Atlantic have been carried out by the Institute of Marine Research (IMR) Norway since the early 1970s. In the early 1980s a coordinated acoustic survey approach was adopted, with both Russia and Norway participating to estimate the size of this migratory stock within the main spawning grounds to the west of Ireland and Britain. Since 2004, an International coordinated survey program has expanded to include vessels from the EU (Ireland and the Netherlands) and the Faroes.

Due to the highly migratory nature of the stock a large geographical area has to be surveyed. Spawning takes place from January through to April along the shelf edge from the southern Porcupine Bank area northwards to the Faroe/Shetland Ridge including offshore areas as the Rosemary, Hatton and Rockall Banks. Peak spawning occurs between mid-March and mid April and acoustic surveys are timed to occur during this phase. To facilitate a more coordinated spatio-temporal approach to the survey participating countries meet annually to discuss survey methods and define effort allocation at the ICES led Working Group International Pelagic Surveys (WGIPS).

Data from the annual spawning stock abundance survey (March/April, western waters), juvenile surveys (May, Norwegian Sea and January-March, Barents Sea trawl survey) and commercial landings data are presented annually at the ICES Working Group of Widely Distributed Stocks (WGWIDE). Ultimately, combined data inputs into the management and catch advice for this international cross boundary stock.

The 2014 survey was part of an international collaborative survey using the vessels RV *Celtic Explorer* (Ireland), FV *Fridtjof Nansen* (Russia), RV *Tridens* (Netherlands) and the RV *Magnus Heinason* (Faroes). The total combined area coverage extended from the Faroe Islands in the north (62° N) to south of Ireland (52° N), with east -west extension from 4°-19° W.

International survey participants meet shortly after the survey to present data and produce a combined relative abundance stock estimate and report. The combined survey report is presented annually at the WGIPS meeting held in January. The information presented here relates specifically to the Irish survey.

## 2 Materials and Methods

### 2.1 Scientific Personnel

<i>Organsiation</i>	<i>Name</i>	<i>Capacity</i>
FEAS	Ciaran O'Donnell	Acoustics (SIC)
FEAS	Grahan Johnston	Acoustics
FEAS	Eugene Mullins	Acoustics
FEAS	Robert Bunn	Acoustics
FEAS	Dermot Fee	Biologist

Birdwatch Irl	Jackie Hunt	SBO
GMIT	William Hunt	PhD
Liv Uni	Nealy Carr	PhD
Liv Uni	Calum Preece	PhD

### 2.2 Survey Plan

#### 2.2.1 Survey objectives

The primary survey objectives are listed below:

- Collect acoustic data on blue whiting spawning aggregations within the pre-determined areas based on terms agreed at the WGIPS meeting 2014
- Collect biological samples from directed trawling on fish echotraces to determine age structure and maturity state of survey stock
- Determine an age stratified estimate of relative abundance of blue whiting within the survey area using acoustic survey techniques
- Collect physical oceanography data as horizontal and vertical profiles from a deployed sensor array
- Submit survey data (acoustic, biological and hydrographic) to the internationally coordinated database
- Conduct a sighting survey of marine mammals and seabirds

#### 2.2.2 Survey design and area coverage

The survey covered the core spawning area of blue whiting to the west of Ireland and Scotland (Figure 1). Coverage extended from the shelf slopes (250 m) westward into the Rockall Trough and was carried out in continuity from south to north.

Transect design and effort allocation was pre-agreed for each vessel at the WGIPS meeting in 2014. A parallel transect design was used to allow transect interlacing in co-surveyed target areas (east-west orientation). Offshore, transects extended to 15° W. Transect spacing was set at 30 nmi for individual vessels and maintained throughout the survey.

In total, the Irish survey covered 58,392 nmi<sup>2</sup> using 2,134 nmi of transects. Survey design and methodology adheres to the methods laid out in the WGIPS acoustic survey manual.

## 2.3 Equipment and system details and specifications

### 2.3.1 Acoustic array

Equipment settings for the EK60 are based on established settings employed on previous surveys (O'Donnell *et al.*, 2004) and are shown in Table 1.

Acoustic data were collected using the Simrad ER60 scientific echosounder. A Simrad ES-38B (38 kHz) split-beam transducer is mounted within the vessels drop keel and lowered to the working depth of 3.3 m below the vessels hull or 8.8 m below the sea surface. Three other frequencies were used during the survey (18, 120 and 200 kHz) for trace recognition purposes, with the 38 kHz data used solely to generate the abundance estimate.

While on track the vessel is normally propelled using DC twin electric motor propulsion system with power supplied from 1 main diesel engine, so in effect providing "silent cruising" as compared to normal operations (ICES, 2002). Cruising speed is maintained at a maximum of 10 Kts (knots) where possible. During fishing operations normal 2 engine operations were employed to provide sufficient power to tow the net.

### 2.3.2 Calibration of acoustic equipment

The EK60 was calibrated in Dunmanus Bay on March 23 at the start of the survey and again in Donegal Bay on April 8 at the end. The results of the first calibration (38 kHz transducer) are shown in Table 1.

### 2.3.3 Inter-vessel calibration

Inter-vessel acoustic calibrations are carried out when participant vessels are working within the same general area and time and weather conditions allow for an exercise to be carried out. The procedure follows the methods described by Simmonds & MacLennan 2007.

No inter-calibration exercise was carried out in 2014.

### 2.3.4 Acoustic data acquisition

EK60 "RAW files" were logged via a continuous Ethernet connection to the vessels server and the EK60 hard drive as a backup. Sonar Data's Echoview® Echolog (Version 4.8) live viewer was used to display the echogram during data collection to allow the scientists to scroll through echograms noting the locations and depths of fish shoals. A member of the scientific crew monitored the equipment continually. Time and location (GPS position) data was recorded for each transect within each target area. This log was used to monitor the time spent off track during fishing operations and hydrographic stations plus any other important observations.

### 2.3.5 Echogram scrutinisation

Acoustic data was backed up onto the vessels server every 24 hrs and scrutinised using Echoview.

EK60 "Raw" files were imported into Echoview for post-processing. The echograms were divided into transects. Echo integration was performed on regions defined by enclosing selecting marks or scatter that belonged to one of the target species categories. Echograms were analysed at a threshold of -70 dB and, where necessary, plankton were filtered out by thresholding to -65 dB.

Echograms were scrutinised into one of the following categories:

- a). Blue whiting (further classified as; Definitely, Probably, Possibly and Mixed)
- b). Mesopelagic fish
- c). Plankton
- d). Pelagic fish (Including herring and mackerel)

### 2.3.6 Biological sampling

A single pelagic midwater trawl with the dimensions of 70 m in total length and a fishing circle of 768 m was employed during the survey (Figure 12). Mesh size in the wings was 12.5 m through to 20 mm in the cod-end. The net was fished with a vertical mouth opening of approximately 50 m and was observed using a cable linked "BEL Reeson" netsonde (50 kHz). The net was also fitted with a Scanmar depth sensor. Spread between the trawl doors was monitored using Scanmar distance sensors, all sensors being configured and viewed through a Scanmar Scanbas system.

All components of the catch from the trawl hauls were sorted and weighed; fish and other taxa were identified to species level. Fish samples were divided into species composition by weight. Species other than blue whiting were weighed as a component of the catch. Age, length, weight, sex, stomach fullness and maturity data were recorded for individual blue whiting within a random 50 fish sample from each trawl haul with a further 100 random length and weight measurements were also taken. All blue whiting were aged onboard. The appropriate raising factors were calculated and applied to provide length frequency compositions for the bulk of each haul.

Decisions to fish on particular echo-traces were largely subjective and an attempt was made to target marks in all areas of concentration not just high density shoals. No bottom trawl gear was used during this survey.

### 2.3.7 Oceanographic data collection

Oceanographic stations were carried out during the survey at predetermined locations along the track (Figure 5). Data on temperature, depth and salinity were collected using a Seabird 911 sampler from 1 m subsurface to 1000 m where depth allowed or to within 10 m of the bottom on shelf slopes.

## 2.4 Analysis methods

### 2.4.1 Echogram partitioning and abundance estimates

The recordings of area back scattering strength per nautical mile (NASC) were averaged over one nautical mile elementary distance sampling units. NASC values were allocated to blue whiting and other acoustic targets based on the composition of the trawl catches and the appearance of the echotraces. To estimate the abundance, the allocated NASC values were averaged for 1° latitude by 2° longitude strata (4 ICES rectangles). For each strata, the unit area density of fish ( $S_A$ ) in number per square nautical mile ( $N \cdot nmi^{-2}$ ) was calculated using standard equations (Foote *et al.* 1987, Toresen *et al.* 1998).

For blue whiting a target strength (TS) of  $= 20 \log_{10} - 65.2$  dB was applied based on Pedersen *et al.*, 2011.

To estimate the total abundance of fish, the unit area abundance for each statistical rectangle was multiplied by the number of square nautical miles in each statistical square and then summed for all statistical rectangles within defined sub areas and for the total area. Biomass estimation was calculated by multiplying abundance in numbers by the average weight of the fish in each statistical rectangle and then sum of all squares within defined sub areas and the total area.

## 2.5 Marine mammal and seabirds

### 2.5.1 Marine mammals

A dedicated marine mammal visual survey was conducted during daylight hours during the survey. The ships crow's nest, located 17m above sea-level, formed the primary survey platform, with the monkey island (14m) and the bridge (11m) were used as secondary platforms during rough weather conditions. The observer surveyed 180 degrees in front of the line of the vessel track (90 degrees starboard to 90 degrees port), with the emphasis on the

middle 120 degrees in front of the survey vessel. Visual effort included scanning with the use of 7x30 binoculars (7x30 ruggedized Steiner Navigator with built-in compass) and with the naked eye. Binoculars were used to conduct systematic scans and to aid with species identification, the estimation of group size and group composition for distant sightings.

Visual survey effort and sightings data were recorded using Logger 2000 software (IFAW) running on a ruggedized laptop (Panasonic Toughbook CF18 with GPS receiver (Globalsat BU353)). Logger 2000 was set to automatically store GPS metadata including the vessel position, vessel speed and vessel course. Environmental conditions were recorded every 15 minutes in a customised effort form in Logger, and included: Beaufort sea state, wind speed (Bft), wind direction, swell height, cloud cover, visibility (km) and glare (%).

For each sighting, the species, group size, group composition and behavioural characteristics were recorded, along with distance and angle from the ship, used to determine the geographical location and direction of movement. The distance of the sightings was estimated using a distance stick or estimated visually by the observer.

### 2.5.2 Seabirds

Surveys of seabirds at sea were conducted from R.V. *Celtic Explorer* between 25<sup>th</sup> March and 7<sup>th</sup> April 2014. A standardised line transect method with sub-bands to allow correction for species detection bias and 'snapshots' to account for flying birds was used (following the recommendations of Tasker et al. 1984; Komdeur et al. 1992; Camphuysen et al. 2004).

Two observers (a primary observer and a scribe, who also acted as a secondary observer) worked in rotating one hour shifts, surveying between 08:00 and 18:00 hours. Environmental conditions, including wind force and direction, sea state, swell height, visibility and cloud cover, and the ship's speed and heading were noted at regular intervals during surveys. No surveys were conducted in conditions greater than sea state 6, when high swell made working on deck unsafe, or when visibility was reduced to less than 300m.

Seabird surveys were conducted from the platform of the bridge deck. The platform for observation was changed to either the port or starboard side on the basis of suitable viewing conditions at the time (e.g. presence of glare). The platform height was 10.5m above the waterline, providing an uninterrupted view of the survey area. The survey area was defined as a 300m wide band operated on one side (in a 90° arc from the bow) and ahead of the ship. This survey band was sub-divided (A = 0-50m from the ship, B = 50-100m, C = 100-200m, D = 200-300m, E = >300m) to subsequently allow correction of species differences in detection probability with distance from the observer. A fixed-interval range finder (Heinemann 1981) was used to periodically check distance estimates. The area was scanned by eye, with binoculars used only to confirm species identification. All birds seen within the survey area were counted, and those recorded on the water noted as 'in transect'. All flying birds within the survey area were also noted, but only those recorded during a 'snapshot' were regarded as 'in transect'. This method avoids overestimating bird numbers in flight (Tasker et al. 1984). The frequency of the snapshot scan was ship-speed dependent, such that they were timed to occur at the moment the ship passed from one survey area (300m long x 300m wide) to the next. Any bird recorded within the survey area that was regarded as being in association with the survey vessel was noted as such (to be excluded from abundance and density calculations). Survey time intervals were set at 1 minute.

Additional bird species observed outside the survey area or during periods of casual observations were also recorded and added to the species list for the duration of the survey. In this report we present our daily total count data for each species across all days along with the daily survey effort.

### 3 Results

#### 3.1 Blue whiting abundance and distribution

A total of 11 directed blue whiting trawls were carried out during the survey (Figure 1, Table 2).

In total 702 echotraces were positively identified as blue whiting over the 22 strata surveyed (Table 9). Blue whiting aggregations were most frequently encountered between 350-550m with a range extending from 250 to 650m.

The second most frequently encountered group of species were the Myctophidae present in 7 of 11 survey hauls (Table 9). High density mesopelagic echotraces were observed in a number of areas during daylight hours. The presence of mesopelagic species in trawl catches is generally regarded as by-catch due to the passage of the trawl through the mesopelagic layer (70-200 m) to the target blue whiting layer (250-650 m).

##### 3.1.2 Blue whiting biomass and abundance

The table below shows the estimated abundance and biomass of each category of blue whiting across the entire survey area. A full breakdown of the survey estimate is presented by distribution, age, length, biomass, abundance and area in Figures 2 & 4 and Tables 3-9.

<b>Blue whiting</b>	<b>Millions</b>	<b>Biomass (t)</b>	<b>% contribution</b>
<i>Total estimate</i>			
<b>Definitely</b>	13,666	1,574,804	100.0
<b>Mixture</b>	0	0	0.0
<b>Probably</b>	0	0	0.0
<b>Total estimate</b>	13,666	1,574,804	100
<i>SSB Estimate</i>			
<b>Definitely</b>	12716	1,509,815	100.0
<b>Probably</b>	0	0	0.0
<b>Mixture</b>	0	0	0.0
<b>SSB estimate</b>	12716	1,509,815	100

##### 3.1.3 Blue whiting distribution

For the purposes of the international survey, spawning areas are broken into target areas ranked according to historic core abundance (Figure 1).

Four target areas were surveyed with varying degrees of coverage as part of the agreed component of international effort allocation. Two target areas; south Porcupine and Rockall were only partly covered by this survey and combined accounted for less than 14% (7,800nmi<sup>2</sup>) of the total area. As a result they are not considered representative outside of the international survey effort. Blue whiting distribution within the south Porcupine area was dominated by a small number of high density echotraces (Table 9, Figure 3a). The Hebrides and north Porcupine areas were comprehensively covered using 66% (38,500nmi<sup>2</sup>) and 21% (12,000nmi<sup>2</sup>) of survey effort respectively and are thus considered representative.

Overall high density echotraces dominated near shelf regions (c.15nmi) from south to north at depths of between 250-650m (Figure 3b). This year the centre of gravity of the stock was located further to the south than observed in 2013. Western extension of high density echotraces into the Rockall Trough was similar to last year latitudinally but with increased westward spread. This spread of echotraces was centred on the northern edge of the Porcupine Bank (54°N) to 56°N and extended to up to 100nmi (60nmi in 2013) from the shelf

edge (Figure 2 & 3d). This area contained the highest single blue whiting echotrace recorded during the survey (Figure 3b). North of 56°N the distribution of high density echotraces were observed in close proximity out to 15nmi from the shelf edge.

The distribution of biomass within target areas is broken down as follows (detailed in Tables 5 & 6):

South Porcupine Bank represented 3.5% (2033nmi<sup>2</sup>) of survey effort and contained 2.0% of TSB (c.30,000t) and 25.7 million individuals.

North Porcupine Bank represented 20.6% (12,031nmi<sup>2</sup>) of survey effort and contained 25.6% TSB (c.403,000t) and 3,515.5 million individuals.

The Rockall area represented 9.8% (5,700nmi<sup>2</sup>) of survey effort and contained 8.1% of TSB (c.128,200t) and 941.7million individuals.

The Hebrides area represented 66.1% (38,600nmi<sup>2</sup>) of survey effort and contained 66.1% of TSB (c.1,041,000t) and 9,183.4 million individuals.

### 3.1.4 Blue whiting stock structure

During the survey 550 fish were aged with length, weight, sex, maturity and stomach fullness data recorded. A further 1,100 fish were measured and weighed. Age analyses of otoliths showed individuals from 1 to 14-years old from trawl samples (Figure 4).

The age structure of survey stock was dominated by 3 strong year classes; the 4 (2010 yr class), 5 (2009 yr class) and 3-year old fish (2011 yr class) respectively. Together these year classes represented 65.4% of the TSB and 73% of the TSN.

In terms of biomass the breakdown is as follows: 4-year old fish 29.3% (462,200t), 5-year old fish 20.7% (326,100t) and 3-year old fish 15.4% (242,400t). In terms of abundance: 4-year old fish 33% (4,509 million individuals), 5-year old fish 20.7% (2,822 million individuals) and 3-year old fish 19.3% (2,642 million individuals).

Maturity analysis (international data) indicates 14% of 1-year old, 56% of 2-year old and 90% of 3-year old fish were mature. Of the mature fish sampled, most were spent and a smaller proportion was actively spawning. Over 97% of the surveyed stock was found to be mature with less than 3% immature. Immature fish were found in all strata surveyed (n=22) with the highest concentrations in the Faroe/Shetland area as observed previously

## 3.2 Oceanography

Overall 29 CTD casts were carried out during the survey. Open water stations were conducted to a maximum of 1,000m. Horizontal profiles of temperature and salinity from 10m subsurface to 600m are shown in Figures 8-11.

Surface water conditions (10m) indicate relatively stable conditions south of 60°N in terms of temperature and salinity.

At 200m the influence of warmer Atlantic water is evident to the north of the Porcupine Bank and southeast of Rockall (Figure 9). For profiles at depths at 400m and 600m both temperature and salinity profiles appear relatively uniform for the main body of the survey area to the south of 59°N (Figures 10 & 11). Uniform temperatures and salinity regions are the preferred spawning habitat for blue whiting and are often observed when the sub polar gyre is weak allowing the influence of Atlantic water to dominate on the spawning grounds (Monstad 2004). During weak gyre cycles the distribution of spawning aggregations of blue whiting occurs further west into the Rockall Trough and on the Rockall Bank than during strong cycles where spawning is limited predominantly to shelf edge (Hatun *et al* 2009).

### 3.3 Marine mammal and seabirds

#### 3.3.1 Marine mammals

##### 3.3.1.1 Effort

In total 120 hours of visual survey were conducted, of which 50.47 hours (42%) were conducted in Beaufort sea state three or less (Figures 6 & 7). Of this 106.1 hours (88%) of visual effort were conducted from the primary platform, followed by the bridge (11.5 hours) and Monkey Island (2.1 hours). Despite relatively calm sea conditions, visual effort was often constrained due to limited visibility resulting from sea fog.

##### 3.3.2.1 Sightings

In total 31 sightings of five marine mammal species were recorded, totalling 138 individuals (Table 12 and Figure 6). Long-finned pilot whales (*Globicephala melas*) were the most observed species with 16 confirmed sightings of 97 individuals, which include seven calves and six juveniles / sub-adults. The long-finned pilot whale sightings were recorded in areas with steep bathymetry along the continental shelf edge and near the Rosemary seamount (Figure 6). The sperm whale (*Physeter macrocephalus*) was the second most observed species with six sightings of seven individuals. Sperm whale sightings were confined to deep waters (>1000m depth) in the northern section of the Rockall trough, west of the Hebrides, Scotland (Figure 6). Small groups of common dolphins (*Delphinus delphis*) were observed bow-riding the survey vessel on two occasions, and a single sighting of a group of six individuals including two calves, was recorded inside Dunmanus Bay. One group of bottlenose dolphins (*Tursiops truncatus*) was observed in close proximity to a number of long-finned pilot whale groups, located within the shelf edge waters Northwest of Co. Donegal. A single breaching event of an unidentified beaked whale was observed by Niall Keogh while conducting a seabird survey from the bridge deck. The animal, observed in the deep waters of the Rockall trough, was not resighted despite its close distance to the vessel. Two groups of unidentified dolphins and a single unidentified small whale, possibly a minke whale (*Balaenoptera acutorostrata*), were sighted in deep water of the Rockall trough. Finally, a single grey seal was observed in the coastal waters west of Dunmanus Bay.

#### 3.3.2 Seabirds

##### 3.3.2.1 Effort

A total of 4,003 minutes (66 hours and 43 minutes) of dedicated seabird surveying was conducted between 25<sup>th</sup> March and 7<sup>th</sup> April 2014 with an average of 286 minutes (4 hours and 46 minutes) surveyed per day (range of 180 minutes to 360 hours). A total of 240 minutes was conducted from inside the Bridge on 25<sup>th</sup> March with the remaining 3,763 minutes being conducted from the Bridge Deck between 26<sup>th</sup> March and 7<sup>th</sup> April (Table 13).

##### 3.3.2.2 Sightings

An uncorrected, cumulative total of 7749 individual seabirds of 15 species were recorded (Table 14). A total of 1442 seabirds were noted as 'off survey', outside of dedicated survey time or associating with the vessel and as such will be excluded from future analysis of abundance and density. Thus, the corrected total of seabird recorded during dedicated survey time was 6307. A synopsis of daily totals for all seabird species recorded is presented in Table 14.

More detail and information can be found in the species accounts, in which taxonomy and nomenclature follows Irish Rare Birds Committee (2012).

## 4 Discussion and Conclusions

### 4.1 Discussion

Overall, the survey objectives were carried out as planned with the exception of one transect that was dropped from the original plan (southern most transect 51°30N) due to poor weather at the start of the survey. In total poor weather accounted for 36 hrs of lost survey time and the track plan was adjusted to ensure continuity of coverage with participant vessels. Good weather conditions dominated the remainder of the survey. At the mid point 3 planned CTD stations were dropped to allow the Explorer to catch up with Russian and Dutch vessels and maintain pace.

Communication between vessels was very good and this allowed for close spatio-temporal alignment and adaptive changes to the survey design to be implemented quickly and efficiently.

The abundance estimate is considered robust as the stock was well contained within the survey area (international coverage) and good trawl sampling was undertaken in core as well as peripheral abundance areas.

The distribution of the bulk of the stock in the mid latitudes indicated that the timing of the survey was good and post spawning migration was not fully underway.

### 4.2 Conclusions

As this survey is part of a cooperative survey covering the larger spawning range of the stock it is difficult to take the results from the Irish survey as an indicator of the state of the stock over the entire area and this should be considered when reviewing the results.

The distribution of the bulk of the stock within the Hebrides target area is consistent with previous years. Although the stock was located in the southern end on the border with the Porcupine target area indicating spawning occurred later than in 2013. During recent surveys the bulk of the stock was located further north to the west of the Hebrides. The westward continuation of spawning/post spawning aggregations extending into the Rockall Trough, which was more pronounced in 2014 than in 2013, would indicate favourable spawning habitat in the mid Rockall Trough. Hydrographic data indicates a stable water mass dominating the main body of the survey area in terms of temperature and salinity. Such conditions are indicative of a weaker sub polar gyre which allow for more stable conditions to develop on the Rockall Bank and through the Rockall Trough. During strong gyre conditions spawning aggregation are most often observed in close proximity to the shelf edge.

The stock appears to be in the fourth year of positive recruitment after a prolonged period of poor recruitment. Although episodic, periods of positive recruitment can have a strong influence on the stock within a relatively short time frame. The 3 and 4-year old fish (strong 2010 & 2011 year classes) continue to be observed within the survey and are now considered fully recruited to the spawning stock. A sign of a potentially strong emerging 2013 year class was observed during the international survey. However, it is too early to predict the magnitude of that year class yet with any degree of accuracy until it can be confirmed in the coming 2-3 years.

## **Acknowledgements**

We would like to express our thanks and gratitude to Dennis Rowan (Captain) and crew of the Celtic Explorer for their good will and professionalism during the survey.

Our thanks goes to our visiting scientists from the University of Liverpool, BirdWatch Ireland and National Parks and Wildlife service and to Jan Pederssen (DTU Aqua, Denmark) for their help and expertise during the survey.

## Echo Sounder System Calibration

Vessel : RV Celtic Explorer	Date : 23.03.14
Echo sounder : EK60 PC	Locality : Dunmnaus Bay
Type of Sphere : Cu-60.1mm	TS <sub>Sphere</sub> : -33.50 dB (Corrected for soundvelocity)
	Depth(Sea floor) 31 m

Calibration Version 2.1.0.11

<b>Comments:</b> CE14005.BWAS. Dunmanus Bay			
<b>Reference Target:</b>			
TS	-33.5 dB	Min. Distance	16.00 m
TS Deviation	5.0 dB	Max. Distance	20.00 m
<b>Transducer: ES38B Serial No. 30227</b>			
Frequency	38000 Hz	Beamtype	Split
Gain	26.5 dB	Two Way Beam Angle	-20.6 dB
Athw. Angle Sens.	21.90	Along. Angle Sens.	21.90
Athw. Beam Angle	7.10 deg	Along. Beam Angle	7.10 deg
Athw. Offset Angle	-0.00 deg	Along. Offset Angl	-0.00 deg
SaCorrection	-0.00 dB	Depth	8.8 m
<b>Transceiver: GPT 38 kHz 009072033933 1 ES38B</b>			
Pulse Duration	1.024 ms	Sample Interval	0.191 m
Power	2000 W	Receiver Bandwidth	2.43 kHz
<b>Sounder Type:</b> ER60 Version 2.4.3			
<b>TS Detection:</b>			
Min. Value	-50.0 dB	Min. Spacing	100 %
Max. Beam Comp.	6.0 dB	Min. Echolength	80 %
Max. Phase Dev.	8.0	Max. Echolength	180 %
<b>Environment:</b>			
Absorption Coeff.	9.8 dB/km	Sound Velocity	1486.4 m/s
<b>Beam Model results:</b>			
Transducer Gain =	25.98 dB	SaCorrection =	-0.69 dB
Athw. Beam Angle =	7.00 deg	Along. Beam Angle =	6.93 deg
Athw. Offset Angle =	-0.03 deg	Along. Offset Angle =	-0.06 deg
<b>Data deviation from beam model:</b>			
RMS = 0.10 dB			
Max = 0.27 dB No. = 31 Athw. = -3.1 deg Along = -1.9 deg			
Min = -0.26 dB No. = 123 Athw. = -3.6 deg Along = 2.4 deg			
<b>Data deviation from polynomial model:</b>			
RMS = 0.05 dB			
Max = 0.13 dB No. = 128 Athw. = -2.2 deg Along = 2.8 deg			
Min = -0.21 dB No. = 123 Athw. = -3.6 deg Along = 2.4 deg

**Figure 7.** Summary of the environmental conditions and survey effort recorded between 22 March and 10 April 2014. A) swell height (m); B) Beaufort sea state; C) visibility (km); and D), visual survey effort (hr).

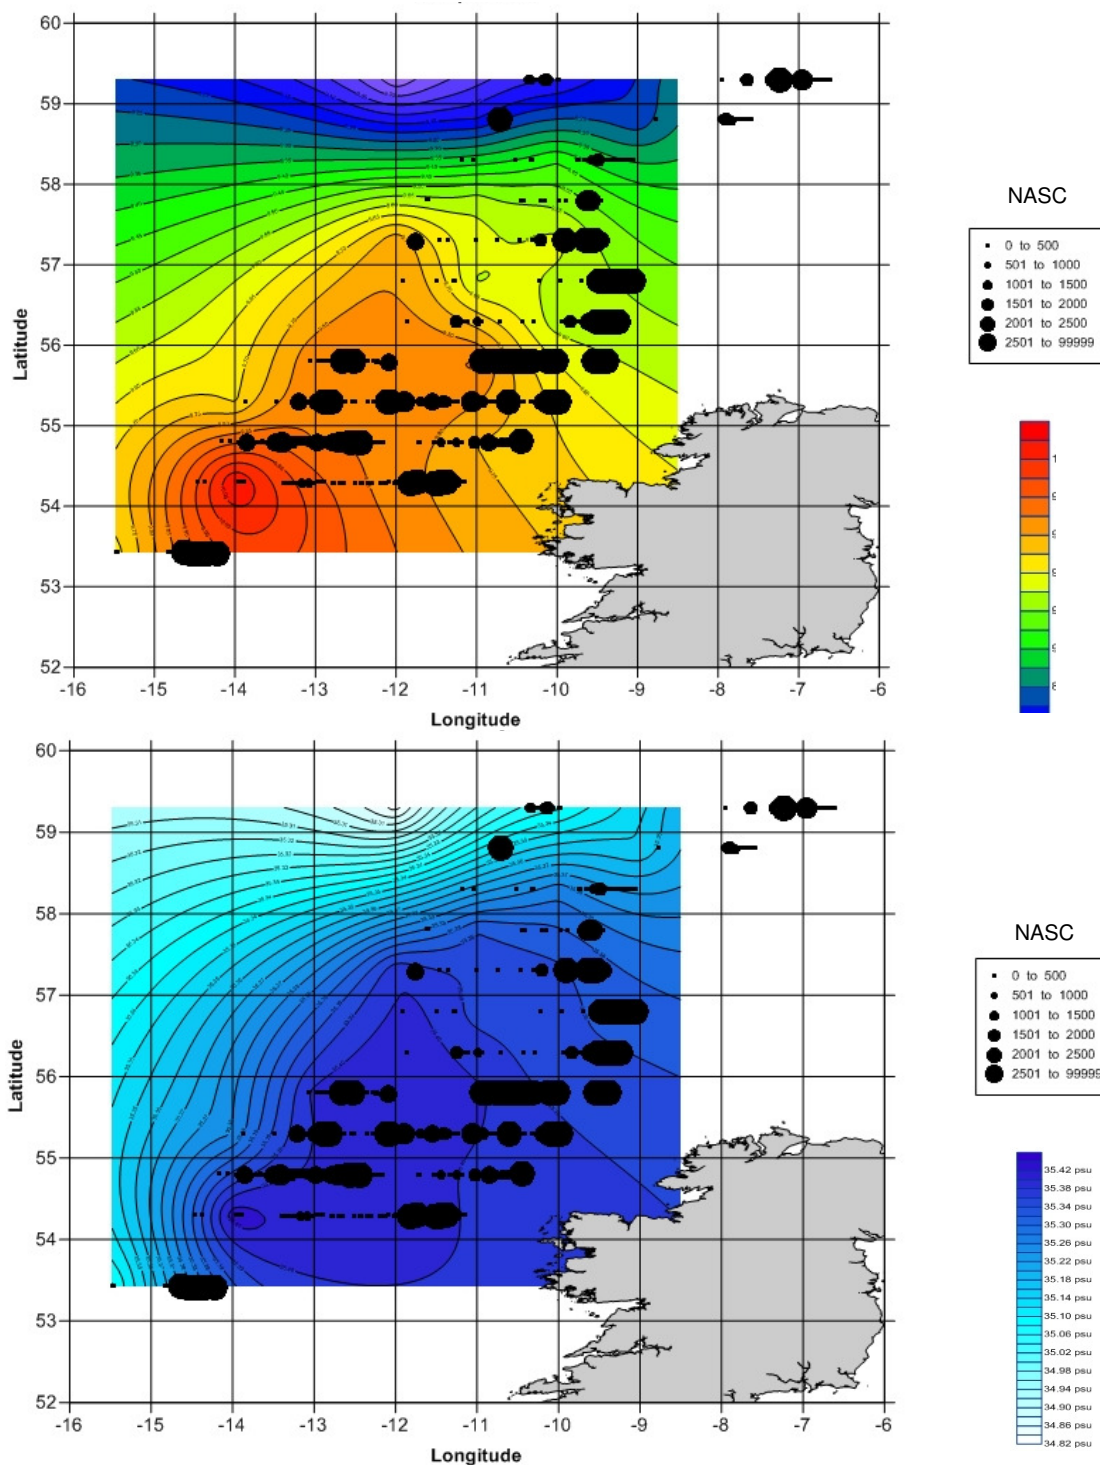

**Figure 8.** Horizontal temperature (top) and salinity (bottom) at 10m as compiled from Irish CTD stations (black dots).

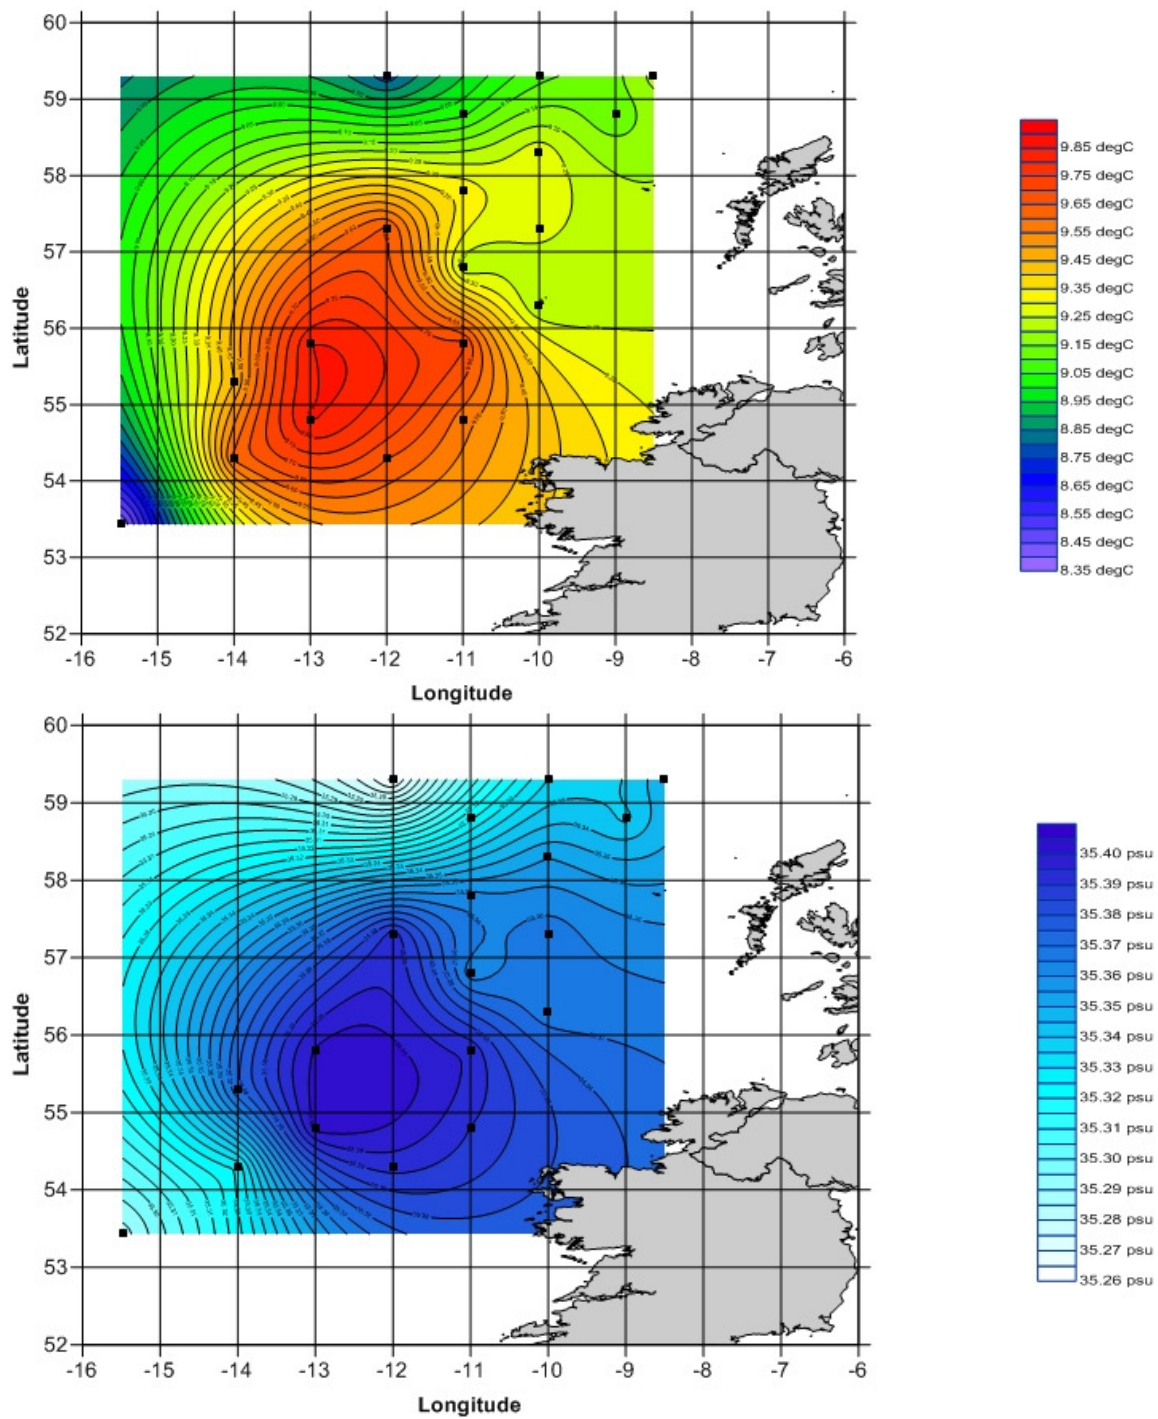

**Figure 9.** Horizontal temperature (top) and salinity (bottom) at 200m as compiled from Irish CTD stations (black dots).

**Figure 10.** Habitat plot of horizontal temperature (top) and salinity (bottom) at 400m overlaid proportional NASC values from acoustic observations (black circles). NASC observations outside of temp/sal profiles are due to rejected/compromised CTD data.

**Figure 11.** Horizontal temperature (top) and salinity (bottom) at 600m as compiled from Irish CTD stations (black dots).

<b>Net specifics</b>	
Clump weights:	1000 Kg per side
Trawl doors:	Polyice pelagic 6m <sup>2</sup> (750Kg weight in air)
Bridle length:	80m
Door spread:	170m
Vertical net opening:	50m

**Figure 12.** Pelagic midwater trawl employed during the survey.

## Appendix

### SEABIRD SPECIES ACCOUNT

#### **Fulmar** (*Fulmarus glacialis*)

The most abundant seabird observed with a corrected total of 3656 individuals recorded during survey periods. The highest single day total relates to 901 birds on 29<sup>th</sup> March over the Rockall Trough, West of Malin More, Co. Donegal. Over 360 birds were recorded in association with the survey vessel during sample trawls for fish on 2<sup>nd</sup> April.

A maximum, uncorrected total of 53 'blue' fulmars were recorded throughout the survey period. These darker colour morphs represent individuals from the High Arctic breeding range of the species. The majority of 'blue' fulmars recorded were of the 'Light' (L) or 'Dark' (D) type. A single 'Double Dark' (DD) bird was noted on 29<sup>th</sup> March.

*'Blue' fulmar © Machiel Oudejans*

#### **Sooty Shearwater** (*Puffinus griseus*)

Two seen. Singles noted on the Porcupine Bank shelf edge, West of Co. Mayo on 27<sup>th</sup> March and near the Flannan Isles, Outer Hebrides on 6<sup>th</sup> April.

#### **Manx Shearwater** (*Puffinus puffinus*)

Seen infrequently and in small numbers during the survey with a maximum, uncorrected total of 42 birds recorded, 25 of which were on 25<sup>th</sup> March along inshore waters off West Cork. The most Northerly record of manx shearwater during the survey related to a single bird seen on 5<sup>th</sup> April, approximately 80 nautical miles West-Northwest of Sula Sgeir, Outer Hebrides.

#### **Gannet** (*Morus bassanus*)

Gannet was the second most frequently observed species during the survey, with a corrected total of 1656 individuals recorded during survey periods. Up to 500 gannets were sometimes found in association with the survey vessel during sample trawls for fish. The large majority of birds observed were adults or 5<sup>th</sup> calendar year birds. Only of handful of immature birds were noted.

*Gannets foraging during a sample trawl © Machiel Oudejans*

**Shag** (*Phalacrocorax aristotelis*)

A single shag was seen near the Flannan Isles, Outer Hebrides on 6<sup>th</sup> April.

**Great Skua** (*Stercorarius skua*)

Present throughout the survey period with small numbers of birds regularly recorded following the survey vessel. A maximum, uncorrected total of 91 birds were recorded. The highest single day count of 37 was noted over the Southern end of the Porcupine Bank on 26<sup>th</sup> March.

*Great skua © Macheil Oudejans*

**Puffin** (*Fratercula arctica*)

A total of 5 birds were seen on three dates during the survey.

**Razorbill** (*Alca torda*)

A maximum, uncorrected total of 26 razorbills were recorded along inshore waters or over the top of the Eastern Rockall Trough shelf edge break closest to land.

**Guillemot** (*Uria aalge*)

A maximum, uncorrected total of 162 guillemots were recorded along inshore waters or over the top of the Eastern Rockall Trough shelf edge break closest to land. Individuals showing plumage characteristics of Northern (*aalge*) and Southern (*albionis*) populations were identified.

**Kittiwake** (*Rissa tridactyla*)

Kittiwake was the third most frequently observed species during the survey, with a corrected total of 626 individuals recorded. The single highest day total was of 150 birds seen over the Western edge of the Porcupine Bank on 27<sup>th</sup> March.

**Black-headed Gull** (*Chroicocephalus ridibundus*)

A total of three single adult birds were recorded migrating North, far out to sea over the Rockall Trough on 3<sup>rd</sup>, 4<sup>th</sup> and 6<sup>th</sup> April respectively. It is likely that these birds were on their way to breeding grounds in Iceland.

*Black-headed Gull © Machiel Oudejans*

**Lesser Black-backed Gull** (*Larus fuscus graellsii*)

Present throughout the survey, with a maximum, uncorrected total of 133 birds recorded, most often associating with the survey vessel. The majority of birds observed were adults, with only a small number of near-adult or immature birds seen.

**Herring Gull** (*Larus argentatus*)

Seen infrequently in small numbers, associating with the survey vessel. A maximum, uncorrected total of 26 birds were recorded along inshore waters.

**Yellow-legged Gull** (*Larus michaellis*)

A single adult was identified on 4<sup>th</sup> April, approximately 60 nautical miles Northwest of St. Kilda, Outer Hebrides, associating with the survey vessel during sample trawls for fish. Yellow-legged gull is classified as a rarity in Scotland by the Scottish Rare Birds Committee. As such, a full description and series of pictures has been submitted for assessment.

*Yellow-legged gull © Machiel Oudejans*

**Glaucous Gull (*Larus hyperboreus*)**

A single 1<sup>st</sup> winter bird was noted in association with the survey vessel on 29<sup>th</sup> March.

*Glaucous gull © Machiel Oudejans*

**Great Black-backed Gull (*Larus marinus*)**

Seen frequently throughout the survey period in small numbers, associating with the survey vessel. A maximum, uncorrected total of 53 birds was recorded with the highest single day count of 25 on 4<sup>th</sup> April.

**SPECIES ACCOUNTS: TERRESTRIAL AND COASTAL BIRDS**

**Oystercatcher (*Haematopus ostralegus*)**

Two records of single birds flying around the survey vessel, each on 1<sup>st</sup> and 4<sup>th</sup> April.

**Collared Dove (*Streptopelia decaocto*)**

A single bird landed on the deck of the survey vessel on 6<sup>th</sup> April, approximately 33 nautical miles West of the Butt of Lewis, Outer Hebrides.

*Collared Dove © Machiel Oudejans*

**Skylark** (*Alauda arvensis*)

A single bird circling the survey vessel early on the morning of 1<sup>st</sup> April associated with a period of heavy sea mist and light South-easterly winds, approximately 80 nautical miles West of Tiree, Outer Hebrides.

**Redwing** (*Turdus iliacus*)

A single flock of c.500 birds circling the survey vessel early on the morning of 1<sup>st</sup> April associated with a period of heavy sea mist and light South-easterly winds, approximately 80 nautical miles West of Tiree, Inner Hebrides. Followed by records of 9 on 2<sup>nd</sup> April, 5 on 3<sup>rd</sup> April and 1 on 4<sup>th</sup> April.

*Redwing © Niall Keogh*

**Robin** (*Erithacus rubecula*)

One caught inside the dry laboratory of the survey vessel early on the morning of 1<sup>st</sup> April associated with a period of heavy sea mist and light South-easterly winds, approximately 80 nautical miles West of Tiree, Outer Hebrides.

*Robin © Niall Keogh*

**Wheatear** (*Oenanthe oenanthe*)

A male and female seen circling and landing on the survey vessel early on the morning of 1<sup>st</sup> April associated with a period of heavy sea mist and light South-easterly winds, approximately 80 nautical miles West of Tiree, Outer Hebrides.

*Wheatear © Niall Keogh*

**Meadow Pipit** (*Anthus pratensis*)

A single bird flying around the survey vessel on 28<sup>th</sup> March, approximately 150km West the Mullet Peninsula, Co. Mayo.
