STEPHEN F. AUSTIN STATE UNIVERSITY
NACOGOOCHES, TEXAS 75962

This is the seventh in a continuing series of reports describing results from the East Texas Pine Plantation Research Project.

Subject and content of each ETPPRP report is regional in scope and of particular interest to loblolly and slash pine plantation owners in East Texas.

Any suggestions, ideas or comments will always be welcomed.

Professor, School of Forestry, SFASU

ABSTRACT. Equations are presented to estimate the dry weight in pounds of the wood in the stem and branches of individual loblolly pine trees planted on site-prepared land in East Texas.

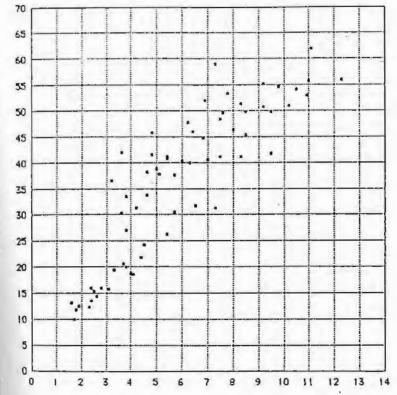

The estimation of the content of individual trees is a principal component in the measurement process to determine per acre yields. In particular, the content of individual trees is a value needed in the last stages of the diameter distribution yield prediction method. Also, tree content information is useful in timber cruising.

In this report, we present equations to estimate the dry weight in pounds of individual planted loblolly pines on non-old-fields in East Texas as:

- 1. Complete Tree Dry Weight Wood, Bark and Needles: CTDWW.
- 2. Complete Tree Dry Weight only: CTDWW.
- 3. <u>Total Stem Dry Weight Wood only:</u> TSDWW.
- 4. Partial Stem Dry Weight Wood only: PSDWW.

By appropriate subtraction, the dry weight of wood in the branches can be determined. In addition, differences between total stem and partial stem values can be obtained for various multiple-product computations.

DBH - INCHES

NUMBER OF LOBLOLLY PINE SAMPLE TREES BY DBH AND HEIGHT. n = 65 trees.

LOBLOLLY

n = 55 trees

Number of sample trees by species and county in Texas.

### COMPLETE TREE DRY WEIGHT ESTIMATION

Plottings of CTDWW over dbh (D) and total tree height (H) indicated a model originally suggested by Schumacher and Hall (1933) as

Tree content = 
$$b_0 D^{b_1} H^{b_2}$$
 (1)

represented the relationships seen in the plottings.

Non-linear regression analysis of the data set produced the following prediction equations as

CTDWW = 
$$0.060286D^2.126861H^{0.970500}$$
, (2)

with  $R^2 = 99\%$ .

$$R^2 = ((n-1)(\text{std dev dep ver})^2 - \text{Residual SS})/((n-1)(\text{std dev dep ver})^2)(100)$$

 $<sup>^{\</sup>star}$  All R<sup>2</sup> values in this report were calculated using non-linear regression results as:

### PARTIAL AND TOTAL STEM DRY WEIGHT ESTIMATION

In a dissertation by McTague (1985), a new tree content estimation model was presented, that has several desireable properties as

- Treats total stem content as a special case of partial stem content.
- Predicts partial stem content between stump and any upper stem diameter limit.
- 3. Convertible to a well-behaved taper function.
- Suitable for estimating green or dry weight of the total or partial stem.

Subsequently, Pienaar and others (1985) developed a variation of the original McTague model as

Content wood only in the stem =  $b_0D^{b_1}H^{b_2}$ 

$$-b_3(d^{b4}/D^{b4}-2)(h-4.5),$$
 (3)

where a = upper stem diameter o. b.

TABLE 1. ESTIMATED DRY WEIGHT OF WOOD ONLY IN THE STEM TO SPECIFIED UPPER DIAMETER LIMITS FOR INDIVIDUAL LOBLOLLY PINE TREES ON NON-OLD-FIELD PLANTATIONS IN EAST TEXAS.

UPPER STEM DBH DIAMETER		TOTAL TREE HEIGHT (FEET)						
		20	30	40	50	60	70	80
