

Detection of bacterial tRNA and rRNA gene clusters hidden in long DNA sequences: Prediction of a putative tRNA (Glu) (TTC) -tRNA (Asp) (GTC) -tRNA (Phe) (GAA) gene cluster of the Gram-positive bacterium *Mycobacterium leprae*

Abstract

From the genomic DNA sequences of Archeobacteria, Gram-negative and Gram-positive bacteria, Mycoplasmas, and other bacteria accumulated by the GenBank/EMBL/DBJ (Release 19), records of only the tRNA and rRNA gene clusters were extracted, and arranged in a KWIC index-like list of gene clusters. In the genomic 40123-base DNA fragment (Locus ML15182) of the Gram-positive bacterium *Mycobacterium lepre*, we found two putative genes, tRNA^{Glu}(TTC) (37225 to 37296, 72bp) and tRNA^{Asp}(GTC) (37328 to 37400, 73 bp). The gene cluster list currently has only two entries whose headwords begin with [ED] (i.e., the tRNA^{Glu}(TTC) -tRNA^{Asp}(GTC) popular gene cluster) : (1) the 5S rRNA - tRNA^{Gly}(GCC) -tRNA^{Arg}(ACG) -tRNA^{Val}(TAC) - [ED], and (2) the tRNA^{Lys}(TTT) - [ED] -tRNA^{Phe}(GAA) of the Gram-positive bacteria *Bacillus subtilis* and *Lactobacillus delbruecki*, respectively. Therefore we tried to find corresponding tRNA^{Val}(TAC), tRNA^{Lys}(TTT), and/or tRNA^{Phe}(GAA) genes also in *M. lepre*, and found a tRNA^{Phe}(GAA) (37432 to 37509, 73bp). The resulted new putative tRNA^{Glu}(TTC) -tRNA^{Asp}(GTC) -tRNA^{Phe}(GAA) gene cluster overlaps the known tRNA^{Asp}(ATC) -tRNA^{Phe}(GGC). Also one more putative tRNA^{Lys}(TTT) (37101 to 37029, complement, 73 bp) came into sight, which overlaps the known tRNA^{Lys}(TTT) (37095 to 37023, complement, 73 bp). They are separated from the known coding regions.

1. Notation

Since the present paper describes the tRNA and rRNA gene clusters in terms of bacteria, their categories, and their tRNA and rRNA genes, some important notations for representing them are defined here in advance.

[RNA gene] The present paper represents either a

tRNA gene with its relevant amino acid 1-letter code with codon in lower letters and RNA-mode, or an amino acid 3-letter code with ANTICODON in CAPITAL letters and DNA-mode, e.g. M^{au}, MetCAT, a tRNA^{M^{et}}(aug) gene and a tRNA^{M^{et}}(CAT) gene are perfectly equivalent. A special kind of methionine,

so-called fM, is given not M but X if and only if it is identified. Ribosomal RNAs are represented with 16S, 23S, 5S, 7S and so on.

[Category code] Each bacterium is classified into the five categories as follows: Archaeobacteria (Code A), Gram-negative (N) and Gram-positive (P) bacteria, Mycoplasmas (M), and a group of members of other categories and bacteria whose categories are unknown (O).

[Bacterial species] Each bacterium is represented with a category code, a hyphen mark, and 5-letter abbreviation of its name: e.g. N-escoco for Gram-negative bacterium *Escherichia coli*, and P-bacsu for the Gram-positive one *Bacillus subtilis*.

[A gene cluster] A gene cluster is defined as a string of two or more tRNA and rRNA genes whose spacer sequences are, in principle, shorter than 100 bp. Some of gene clusters which appeared more than one time are treated as popular gene clusters, and are given short names: e. g., [GRV] for GggcRcguVgua.

2. Introduction

It is known that the archaeobacteria has several consensus gene clusters, e.g., "16S-23S.....5S" in some species of the crenarchaeota, and "16S-Ala-23S-5S" in many species of the eutyarchaeota [1]. Phylogenetical relationship among *B. Subtilis* (P-bacsu) and some *Mycoplasmas* species was discussed using several consensus gene clusters such as "AgcaIaugI (or M)augSuca" [2]. In fact, *Mycoplasmas* bacteria are sometimes treated as Gram-positive ones. We collected as many records of bacterial tRNA and

rRNA gene clusters as possible, and found, in addition that there were many consensus gene clusters, that some of them could be often related to the same respective categories. For example, so far the Glu-Cys-Val and the 16S-Glu-23S gene clusters belong to only Gram-positive (*Micrococcus luteus* and *Streptomyces lividans*) and Gram-negative bacteria (*E. coli* and *Plesiomonas shigelloides*), respectively. Moreover, we confirmed not only that the above mentioned AgcaIaugI (or M) augSuca gene cluster has been found in Gram-positive bacteria and Mycoplasmas [2], but also that it had not been found in Gram-negative bacteria and Archaeobacteria as yet [3]. The present paper mainly reports that we deductively found a new putative EgaaDgacFuuc gene cluster of the Gram-positive bacterium *Mycobacterium leprae* (P-mycele).

3. Data source and the basic tool for analysis.

All data were extracted from the international database of DNA sequences accumulated by the GenBank/EMBL/DDBJ (Release 19) with annotation by original authors. We collected as many records of tRNA (and rRNA) gene clusters as possible, and edited a KWIC index-like gene cluster list. Each entry is added a unique code indicating its relevant bacterium such as N-escoco for *Escherichia coli*. Table 1 lists the bacteria concerned and their name codes. Figure 1 exemplifies gene clusters of some of the bacteria. Table 2 is the current list of the popular gene clusters. Figure 2 denotes all entries of the current gene cluster list, where the mark '# ' is the indicator of each headword.

Table I . List of relevant bacteria and their codes

A Archaeobacteria; N Gram-Negative bacteria; P Gram-positive bacteria; M Mycoplasmas; O Others

Figure 2 . The current KWIC index-like gene cluster list (# : a heading)

4. Results

Figure 3 shows three parts of the 40123-base pair DNA fragment (Locus ML15182, Accession No. U15182) of *M. leprae* (P-myce) : (a) the heading part, (b) two parts covering the four tRNA genes, and (c) the relevant regions of the DNA sequence. As shown in Figure 3 (b), the four known tRNA genes are "Asp (ATC) [or Dcau]" (37219 to 37291, 73 bp),

"Phe (GGC) [or Fgcc]" (37322 to 37395, 74 b), Lys (TTT) [or Kaaa] (complement, 37095 to 37023, 73 bp), and "Glu (ATT) [or Eaau]" (complement, 3315 to 3233, 83 bp). Attempting to confirm their cloverleaf structures, we found two new putative genes, Egaa (37225 to 37296, 72 bp) and Dgac (37328 to 37400, 73bp), which can form one of the popular gene clusters [ED].

(Figure 3) (c) Two parts of the DNA sequences covering the four known tRNA genes.

The gene cluster list currently has only two entries whose headwords are [ED] as follows:
 Kaaa #[ED] Fuuc (P-bacu)D26185 X00889 K00968
 5S- [GRV] #[ED] (P-lacde)X15246.
 Because *M. leprae* (P-myce) also is Gram-positive, we searched sequences near this putative [ED] for new putative Kaaa (upstream), Fuus (downstream), and/or Vgua (upstream), and fortunately found Fuuc (37432 to 37509, 78 bp). Moreover, one more putative gene, Laaa (37101 to 37029, complement, 73 bp), came in sight. Figure 4 shows some data on the known and the putative tRNA genes: (a) DNA sequences, (b) their proposed cloverleaf structures, and (c) relationship of positions.

```

(c) Relationship of positions

Figure 4 . Relationship between the three known and the four new putative tRNA genes.

In order to reveal one more relevant fact, Figure 5 shows the 9-tRNA gene cluster of the 1120-bp DNA fragment (Locus BSTG9168, Accession No. M87888) of *B. subtilis* (P-bacsu) consisting of

Taca (75 to 250, 176 bp), Vgua (95 to 170, 76 bp) and other seven ones. The most upstream part (75 to 174) of the Taca perfectly covers the Vgua (95 to 170).

(b) The DNA sequence.

(c) The cloverleaf structures of Thr (75-250) and Val (95-170), which is included in the Thr.

5. Discussion

Our examples may be too few to be used for reliable deductive inference. Nevertheless, the few examples appear to demonstrate that this approach is useful as a means of finding some clue for the detection of tRNA gene clusters. We hope that this suggestion is supported with much more cases. When we began this study, we found this rule of thumb on the relation of bacterial categories and tRNA gene clusters [3], and correctly predicted classes, which were unknown for us at that time, of three Gram-negative bacteria *Rhodobacter sphaeroides* (N-rhosp), *Thermotoga maritima* (N-thema), and *Thermas thermophilus* (N-theth). Addition of information on codon/ANTICODON [4] enhanced the resolution with few exceptions. For example, Ser-Leu of Archaeobacterium was decomposed into SagcLcug from *Halobacterium marismortui* (A-halma) and SucgLcug from *Salfolobus solfataricus* (A-sulso). But at the same time, this kind of enhancement of the resolution resulted in advantageous division of Leu-Leu into LcugLcug from *E. coli* (N-escoco) and LuuaLuug from *B. subtilis* (P-bacscu) [5]. Characteristic analysis of tRNA and rRNA gene clusters is on going from a viewpoint of phylogenetic relationship. This concept also can lead to the chance detection of erroneous operations as exemplified with the description of Thr (75 to 250) - Val (90 to 170). The gene cluster list keeps many entries whose headwords are [VT] (i. e. , VguaTaca), but there is no entry of Thr-Val because we revised even this only one entry itself to [VT].

According to e-mail from the DDBJ (kfukami@genes.nig.ac.jp) dated on 22 Oct 1995, they informed

GenBank and EMBL of our questions on the facts described here and some other topics which were sent to the DDBJ through e-mail dated on 10 Oct 1995. According to GenomeNet (Kyoto center), the description of the Thr (Locus BACTG9168, Accession No. M87888) has been updated on 060-FEB-1997, and the data of the Thr has been revised from (75 to 250) to (175 to 250) as described in the original paper [6] without any comment.
