Just Accepted

“Just Accepted” manuscripts have been peer-reviewed and accepted for publication. They are posted online prior to technical editing, formatting for publication and author proofing. The American Chemical Society provides “Just Accepted” as a free service to the research community to expedite the dissemination of scientific material as soon as possible after acceptance. “Just Accepted” manuscripts appear in full in PDF format accompanied by an HTML abstract. “Just Accepted” manuscripts have been fully peer reviewed, but should not be considered the official version of record. They are accessible to all readers and citable by the Digital Object Identifier (DOI®). “Just Accepted” is an optional service offered to authors. Therefore, the “Just Accepted” Web site may not include all articles that will be published in the journal. After a manuscript is technically edited and formatted, it will be removed from the “Just Accepted” Web site and published as an ASAP article. Note that technical editing may introduce minor changes to the manuscript text and/or graphics which could affect content, and all legal disclaimers and ethical guidelines that apply to the journal pertain. ACS cannot be held responsible for errors or consequences arising from the use of information contained in these “Just Accepted” manuscripts.

1 **ABSTRACT**

2 Milk powder is an important ingredient in the confectionary industry but its variable nature
3 has consequences for the quality of the final confectionary product. This paper demonstrates
4 that skim milk powders (SMP) produced using different (but typical) manufacturing
5 processes, when used as ingredients in the manufacture of model white chocolates, had a
6 significant impact on the sensory and volatile profiles of the chocolate. SMP was produced
7 from raw bovine milk using either low or high heat treatment, and a model white chocolate
8 was prepared from each SMP. A directional discrimination test with naïve panellists showed
9 that the chocolate prepared from the high heat SMP had more caramel/fudge character
10 ($p < 0.0001$), and sensory profiling with an expert panel showed an increase in both fudge
11 ($p < 0.05$) and condensed milk ($p < 0.05$) flavor. GC-MS and GC-Olfactometry of both the
12 SMPs and the model chocolates showed a concomitant increase in Maillard-derived volatiles
13 which are likely to account for this change in flavor.

22 INTRODUCTION

23 Milk powder is an important confectionery ingredient, used in products such as toffees,
24 caramels and fudges, as well as in white and milk chocolate. However, the role of milk
25 powder in flavor formation during confectionery manufacture remains poorly understood.
26 The aroma profile of milk chocolate has been thoroughly investigated^{1,2} and since many of
27 the desirable flavor characteristics are derived from cocoa solids, comparisons have been
28 made with the aroma profiles of other cocoa-containing products such as dark chocolate,^{2,4}
29 cocoa powder⁵, roasted cocoa^{6,7} and cocoa liquor.² The aroma profile of white chocolate has
30 not previously been investigated and it provides an ideal base in which to investigate the
31 aroma compounds present in chocolate which are derived from the milk powder, excluding
32 those which are derived from the cocoa solids.

33 Milk powder is used in confectionery production where a low moisture environment is
34 required. For example, the moisture content of chocolate must remain below 1.5% to prevent
35 interactions between water and sugar which increase the viscosity of the product.⁸ The quality
36 of milk powder available, and the processing conditions applied during production, are highly
37 variable and heat treatment in particular can vary from pasteurization alone (15 s at 72 °C) to
38 more severe processing, depending on the final properties required. For example, high heat
39 milk powder can be produced by applying a heat treatment of 120-135 °C for 2-3 min.⁹

40 Turner et al.¹⁰ studied the effect of heating on the aroma of SMP, showing that a number of
41 Maillard-derived compounds, such as 2,3-butanedione and 2-furfural, were produced at
42 90 °C. Karagül-Yüceer et al.¹¹ used aroma extract dilution analysis (AEDA) to compare the
43 aroma of commercial SMP samples prepared with different heat treatments (low, medium
44 and high). They concluded that volatile compounds derived from thermal reactions were
45 fundamental to SMP aroma, with compounds such as 3-hydroxy-2-methyl-4H-pyran-4-one

46 (maltol), 4-hydroxy-2,5-dimethyl-3(2*H*)-furanone (furanol) and free fatty acids perceived to
47 have higher flavor dilution factors in high-heat SMP. Similarly, Kobayashi et al.¹² used
48 AEDA and sensory evaluation to compare the characteristic odorants of high-heat SMP and
49 UHT milk. Whereas UHT milk was scored more highly for milky attributes, resulting from
50 higher levels of lactones, brothy notes were given higher scores in high heat SMP, attributed
51 to the presence of sulfur compounds. In both studies, the heating conditions used to produce
52 the different powders were not specified, as the powders were obtained from commercial
53 sources.

54 Pistokoulou et al.¹³ used solvent assisted flavor evaporation (SAFE) and AEDA to identify
55 aroma compounds responsible for a cooked-milk note present in milk after mild heat
56 treatment more typical of domestic processing. Fatty acids were present in all samples and
57 showed some of the highest odor activity values. Shiratsuchi et al.¹⁴ also found these
58 compounds to be the major contributors to the flavor of spray-dried SMP, and also identified
59 lactones in skim milk powder, whereas Pistokoulou et al. identified lactones in whole milk
60 samples only. Thermally-derived compounds are considered as off-flavors in milk powder
61 consumed as a final product (as a milk substitute), but compounds such as 2,3-butanedione
62 (creamy/buttery odor) have the potential to contribute positively to the flavor profile of
63 confectionery.¹

64 The aim of this work was to determine whether SMP manufactured under different
65 conditions, when used as an ingredient in the manufacture of a model white chocolate, had a
66 significant impact on the sensory and volatile profile of the final product. The impact of the
67 standard thermal processes used during the manufacture of milk powder has not been
68 previously investigated. Two batches of SMP were prepared from the same batch of raw milk
69 and the process carefully controlled to ensure that the only difference between the batches

70 was in the heating step traditionally applied prior to spray drying. A model white chocolate
71 was selected for this study because of its relative simplicity compared to milk chocolate,
72 where the incorporation of cocoa solids influences both the chemistry and the sensory
73 properties of the product. Two batches of white chocolate were prepared and compared using
74 discrimination tests, sensory profiling, GC-Olfactometry and GC-MS.

75 MATERIALS AND METHODS

76 **Chemicals.** Aroma chemical were obtained from the following suppliers: 2,3-diethyl-5-
77 methylpyrazine and 2-furfural from Acros (Fisher Scientific, Loughborough, UK); 2-acetyl-
78 1-pyrroline and maltol (methyl d3) from AromaLab (Planegg, Germany); 1-octen-3-one from
79 Danisco (Kettering, UK), γ -decalactone, δ -decalactone, δ -dodecalactone, benzaldehyde,
80 butanoic acid, hexanoic acid and 4-hydroxy-5-methyl-3(2H)-furanone (norfuranol) from
81 Givaudan (Milton Keynes, UK); (*E,E*)-2,4-decadienal from Lancaster Synthesis (Heysham,
82 UK); 2-furanmethanol from Oxford Organics (Hartlepool, UK); (*E,E*)-2,4-nonadienal, 2,3,5-
83 trimethylpyrazine, 2,3-butanedione, 2-methylbutanoic acid, 3-methylbutanoic acid, 2-
84 methyl-3-(methyldithio)furan, acetic acid, decanal, dimethyl trisulfide, 4-hydroxy-2,5-
85 dimethyl-3(2H)-furanone (furanol), heptanal, hexanal, 3-hydroxy-2-methyl-4H-pyran-4-one
86 (maltol), 3-methylsulfanylpropanal (methional), 3-hydroxy-4,5-dimethyl-2(5H)-furanone
87 (sotolon), undecanal, (*Z*)-4-heptenal, 2H-furan-5-one, 2-methylpropanoic acid, 5-
88 (hydroxymethyl)furfural, nonanoic acid, nonanal, (*E*)-2-nonenal, (*E*)-2-octenal, (*E*)-2-
89 undecenal, (*E,E*)-2,4-octadienal, decanoic acid, γ -dodecalactone, 2-nonanone, dimethyl
90 sulfone, tetramethylpyrazine, 2-isobutyl-3-methoxy-pyrazine and 2-methyl-3-heptanone from
91 Sigma Aldrich Ltd. (Gillingham, UK); 1-octen-3-ol, γ -octalactone, δ -octalactone, octanoic
92 acid, pentanoic acid and propanoic acid from Synergy (High Wycombe, UK). Repurified
93 diethyl ether (DEE) was prepared by distilling 99% purity anhydrous DEE (Sigma) through a

94 Vigreux column (30 cm, 4 mm glass beads, distilled at 40 °C). HPLC-grade water was
95 obtained from Fisher Scientific (Loughborough, UK). Alkane standard C₅-C₃₀ (100 µg/µL in
96 diethyl ether) was also obtained from Sigma-Aldrich Co. Ltd.

97 **Production of SMP.** The process is summarised in Figure 1. Raw bovine milk (113 kg)
98 supplied by The University of Reading CEDAR Dairy Farm (CEDAR, Reading RG2 9HX,
99 UK) was pasteurized at 72 °C for 15 s and separated using a disc bowl centrifuge to produce
100 skim milk.

101 Concentration of skim milk. Skim milk was concentrated to ~20 % (w/w) solids using a
102 rising film evaporator (T = 54 – 55 °C). The concentrated milk was divided into two batches
103 of equal size. One batch was subjected to heat treatment (see below) to produce a high heat
104 skim milk powder while the other batch was used directly (no additional heat treatment) to
105 produce a low heat skim milk powder.

106 Heat treatment. One batch of concentrated milk was sealed into metal cans (3 L per can) and
107 heated in a vertical retort at 125 °C for 5 min. It took approximately 10 min to reach a
108 temperature of 125 °C inside the retort, from which time the 5 min heating period was
109 measured. After heating it took approximately 5 min to reduce the pressure and remove the
110 cans from the retort, after which the sealed cans were placed in cold water. These conditions
111 were selected based on previous literature.⁹

112 Spray drying. Both batches of concentrated milk (one with a heat treatment, one without a
113 heat treatment) were spray-dried to ~5% moisture using a NIRO spray dryer (Copenhagen,
114 Denmark) with an A/S NIRO atomizer. The inlet air temperature was fixed at 200 °C and the
115 feed flow rate was adjusted to give an outlet air temperature of 80 – 90 °C. The wet bulb
116 temperature during spray drying was 45 – 50 °C. These two batches of milk powder (low heat

117 skim milk powder (LHSMP) and a high heat skim milk powder (HHSMP)) were used to
118 prepare two corresponding batches of model white chocolate, LHCHOC and HHCHOC
119 respectively.

120 Measurement of milk components. The protein, fat, lactose and total solids content were
121 measured throughout processing using a Lactoscope (Quadrachem Laboratories Ltd. London,
122 UK), and the results are shown in Table 1.

123 **Production of White Chocolate.** The milk powders, prepared as described above, were used
124 to manufacture two different model white chocolates. Sugar (4.57 kg), deodorized cocoa
125 butter (1.89 kg), pasteurized milk fat (0.75 kg) and skim milk powder (LHSMP or HHSMP,
126 2.79 kg) were mixed thoroughly using a mixer with a beater attachment (Model K175, Crypto
127 Peerless Ltd., Birmingham, UK) and refined to a particle size of 25 – 35 μm using a 3-roll
128 refiner (Model SDX 600, Buehler, Uzwil, Switzerland) in two passes. The majority of the
129 refined mix (7.47 kg) was transferred to a 10 kg Conche (Model IMC-E10, Lipp, Mannheim,
130 Germany) and cocoa butter (0.25 kg) was added to make the mixture into a paste. The white
131 chocolate was conched for 4 h at 50 °C, adding lecithin (0.032 kg) and the remaining cocoa
132 butter (0.26 kg) for the final 30 min. After conching, the molten model chocolate was sieved
133 and tempered by heating to 45 °C, cooling to 26.5 °C and finally bringing the temperature up
134 to 27.5 °C. The tempered chocolate was moulded into 100 g bars and allowed to cool
135 completely. The bars were sealed in metallic foil bags and stored at room temperature until
136 use.

137 **Discrimination testing.** A panel of naïve volunteers (n = 50) was recruited from university
138 staff and students who were willing to evaluate white chocolate, had no relevant food
139 allergies and who provided written consent. Testing took place in individual sensory booths,
140 at a controlled room temperature of 23 \pm 0.5 °C, and data were collected using Compusense 5

141 software (Compusense Inc., Guelph, Ontario, Canada). Assessors were provided with a glass
142 of warm water for palate cleansing between samples. Samples were labelled with random 3-
143 digit codes and presented in a balanced order under red lights, to minimize any color
144 difference between products. Two forced choice discrimination tests were performed; a non-
145 directional triangle test and, separately, a directional two-alternative forced choice (2-AFC)
146 test. During the non-directional triangle test, assessors were presented with three samples of
147 white chocolate. Two of the samples were identical and the other one different. Assessors
148 were asked to taste the samples and state which product they believed to be the odd one out.
149 During the directional 2-AFC test, assessors were presented with one sample of white
150 chocolate prepared from low heat milk powder (LHCHOC) and one sample of white
151 chocolate prepared from high heat milk powder (HHCHOC). Assessors were asked to taste
152 both samples and state which sample they perceived to have “more caramel flavor”.

153 **Sensory profiling.** A panel of nine trained assessors, each with a minimum of six months
154 experience, was used to develop a quantitative descriptive analysis (QDA) sensory profile
155 describing the sensory characteristics of different white chocolate samples. A sample of each
156 model white chocolate (LHCHOC and HHCHOC) was presented to each assessor labelled
157 with a random symbol. To develop the vocabulary for the sensory profiling, assessors were
158 asked to smell, taste and finally swallow the samples to produce a list of descriptive terms for
159 the appearance, odor, taste, flavor and mouthfeel of the samples and also for the attributes
160 which lingered in the mouth after 60 s. Following this initial collection of terms, reference
161 materials (Table S1) were provided. These terms were discussed by the panel of assessors as
162 a group, assisted by a panel leader, to agree a final profile consisting of 2 appearance terms, 7
163 odor terms, 9 taste/flavor terms, 11 mouthfeel terms and 5 after-effect terms. A full list of
164 terms is given in Table S2. The quantitative sensory assessment took place in individual
165 sensory booths under red light and at room temperature controlled to 23 ± 0.5 °C. Assessors

166 were provided with a glass of warm water and unsalted crackers for palate cleansing between
167 samples. Samples were presented to the assessors in a balanced order and assessors were
168 asked to smell, taste and swallow the samples and score them on appearance, odor, taste,
169 flavor and mouthfeel attributes. There was a 60 s pause after scoring the mouthfeel attributes,
170 after which the assessors scored the samples for after-effects. The intensity of each attribute
171 was recorded on an unstructured line scale (scaled 0-100) and all data were collected using
172 Compusense 5 software (Compusense Inc., Guelph, Ontario, Canada). A duplicate
173 assessment was carried out in a separate session.

174 **Preparation of Extracts for GC-MS, GC-O and AEDA.** Milk powders (15 g) were
175 reconstituted using 100 mL HPLC-grade water, and 30 μ L 2-methyl-3-heptanone (6.18 μ g/25
176 mL) in methanol was added as an internal standard, before samples were stirred for 30 min.
177 Reconstituted milk samples were added to 250 mL wide mouth Teflon screw cap bottles with
178 9 g solid NaCl to break the emulsion during extraction. Repurified DEE (99% purity, 100
179 mL) was used to extract the volatiles. Bottles were shaken every 10 min for 60 min, and then
180 centrifuged at 4 $^{\circ}$ C for 20 min at $2990 \times g$. After centrifugation, the organic supernatant was
181 carefully removed. The solvent-assisted flavor evaporation (SAFE) technique described by
182 Engel *et al.*¹⁵ was used to separate the volatile fraction of the milk (distillate) from any non-
183 volatile residue

184 White chocolate (200 g) was cut into pieces, frozen in liquid nitrogen, and ground to a fine
185 powder using a coffee grinder (DeLonghi KG49, Hampshire, UK). The powder was
186 combined with DEE (800 mL), 2-methyl-3-heptanone (30 μ L, 6.18 μ g/25 mL methanol) was
187 added as an internal standard, and maltol-(*methyl-d*₃) (17 μ L, 2g/L in ethyl acetate) was
188 added in order to quantify the maltol using stable isotope dilution analysis. The mixture was

189 stirred well and left overnight. After filtering (Whatman No. 1 filter paper) to remove any
190 solid material, the extract was distilled by SAFE, using the same method as for milk powder.

191 Extracts were dried over anhydrous sodium sulfate and then concentrated to 500 μL using a
192 Vigreux column (50 cm \times 1 cm internal diameter; VMR International, UK). The extracts
193 were divided into two equal parts, and concentrated further to 100 μL . Each extract was
194 prepared in triplicate, to give twelve samples in total, and stored at $-80\text{ }^\circ\text{C}$ before analysis.

195 **GC-Olfactometry and Aroma Extract Dilution Analysis (AEDA).** The extracts (1 μL) of
196 the four samples (LHSMP, HHSMP, LHCHOC, HHCHOC) were injected in splitless mode
197 into the injection port of an Agilent HP5890 gas chromatograph fitted with an ODO II odor
198 port (SGE) and a polar ZB-wax column (Phenomenex, UK) (30 m \times 0.25 mm i.d. \times 0.25
199 μm). The carrier gas was helium at 2 ml/min with a 50:50 split between the odorport and the
200 FID. After injection, the GC oven was held at $40\text{ }^\circ\text{C}$ for 5 min, ramped at $5\text{ }^\circ\text{C}/\text{min}$ to $250\text{ }^\circ\text{C}$
201 and then held for 15 min. The effluent from the column was split 1:1, v/v, to an FID and a
202 humidified sniffing port. Three experienced assessors evaluated each sample in duplicate,
203 describing odors in their own words and recording the description alongside the retention
204 time. Assessors were also asked to score the overall intensity of each odor using a 1-10 scale
205 (where 1 = barely perceptible and 10 = overpoweringly strong). The modified frequency
206 (%MF) was calculated according to Dravnieks.¹⁶ All odors reported were detected by at least
207 two assessors.

208 The flavor dilution (FD) factors of the odorants in the four samples were determined by
209 AEDA. Extracts were diluted stepwise with diethyl ether (1: 2, v/v), and aliquots of the
210 dilutions (1 μL) were evaluated by one assessor. A homologous series of *n*-alkanes $\text{C}_5\text{--C}_{30}$
211 was analyzed under the same conditions to obtain linear retention index (LRI) values.
212 Volatiles were identified by comparing the LRI value and odor description to those of an

213 authentic standard, analyzed by GC-O under the same experimental conditions. In addition,
214 the extract was sniffed on a DB5 column under similar conditions and the LRIs compared to
215 those of authentic standards.

216 **Gas Chromatography-Mass Spectrometry (GC-MS).** SAFE extracts (1 μ L) were
217 analyzed in splitless mode on a DB-Wax column (Agilent) (30 m \times 0.25 mm i.d. \times 0.25 μ m
218 film thickness) using an Agilent 6890/5975 GC-MS system. The carrier gas was helium with
219 a flow rate of 1 ml/min. The GC oven was held at 40 $^{\circ}$ C for 5 min, ramped at 5 $^{\circ}$ C/min to 250
220 $^{\circ}$ C and held for 15 min.

221 Mass spectra were recorded in electron impact mode at an ionization voltage of 70 eV and
222 source temperature of 230 $^{\circ}$ C. A scan range of m/z 29-400 with a scan time of 0.69 s was
223 employed and the data were controlled and stored by the ChemStation system. A homologous
224 series of *n*-alkanes (C₅-C₃₀) was analyzed under the same experimental conditions to obtain
225 LRI values. Volatiles were identified by comparing the mass spectrum and LRI value with
226 those of authentic samples run under the same conditions. Each sample was analyzed in
227 triplicate. Approximate relative concentrations were calculated by comparison of the peak
228 areas against those of the internal standard, using a response factor of 1 for each compound.

229 **Statistical analysis.** SENPAQ version 3.2 (Qi Statistics, Reading, UK) was used to carry out
230 two-way ANOVA on sensory profiling data where main effects were tested against the
231 sample by assessor interaction. Multiple pairwise comparisons were done using the Fisher's
232 least significant difference (LSD) test with the significance level set at $p < 0.05$. The binomial
233 test for probability was used to analyze the discrimination test data (Diff test version 2.1,
234 StatBasics, Birmingham, UK). XLSTAT was used to carry our ANOVA on the GC-MS data.

235 **RESULTS**

236 **Sensory Analysis.** Two discrimination tests were carried out with an untrained panel of 50
237 assessors, to establish whether a difference was perceived between the two types of white
238 chocolate. Using a triangle test, a significant difference between the samples was established
239 where 26 out of 50 assessors correctly identified the different sample ($p = 0.005$). The 2-AFC
240 test showed that HHCHOC was perceived to have “more caramel flavor” than LHCHOC,
241 with 42 out of 50 assessors selecting the sample prepared with HHSMP ($p < 0.0001$).

242 Having used discrimination testing to establish a significant difference between the model
243 white chocolates produced using low and high heat SMP, sensory profiling was carried out
244 with a trained panel to identify the specific attributes responsible for this difference.

245 Of 34 attributes describing the samples, five were found to be significantly different between
246 LHCHOC and HHCHOC (Figure 2, see Table S2 for all attributes). Yellow color ($p < 0.001$),
247 overall flavor intensity ($p < 0.01$), fudge flavor ($p < 0.05$) and condensed-milk flavor ($p < 0.05$)
248 were rated significantly higher in HHCHOC, whereas hardness of bite was significantly
249 higher ($p < 0.05$) in LHCHOC. The yellow color of the HHCHOC reflected the fact that the
250 HHSMP was also slightly yellow compared to the LHSMP, consistent with a greater thermal
251 process and indicative of Maillard browning. The flavor attributes that were scored higher in
252 HHCHOC were both heated notes, fudge and condensed-milk, which are generally associated
253 with the Maillard reaction. Both the color change and the differences in flavor attributes are
254 consistent with the fact that the SMP used to prepare the HHCHOC had received more
255 thermal processing than that used for the LHCHOC.

256 **Volatile compounds: GC-Olfactometry.** Having established a sensory difference between
257 LHCHOC and HHCHOC, the volatile profiles of the SMP and model white chocolate
258 samples were analyzed and compared to determine the key compounds responsible for this
259 difference. GC-Olfactometry (GC-O) analysis of the four extracts yielded 42 odor-active

260 regions which were described by at least two out of three assessors (Table 2). Of these 42
261 odor-active regions, 34 were attributed to the corresponding odorant by running authentic
262 reference compounds under the same analytical conditions, and matching both the LRI and
263 odor description to those obtained during GC-O analysis. Short chain fatty acids were the
264 major compounds identified in all samples, with butanoic acid showing the highest modified
265 frequency (MF) overall. Other compounds with a high MF ($\geq 40\%$) were furaneol (burnt
266 sugar, candy floss), maltol (burnt sugar, sweet), 2-acetyl-1-pyrroline (popcorn, toasted),
267 dimethyl trisulfide (pickled onions, cabbage), (*Z*)-4-heptenal (lamb fat, potato), 1-octen-3-one
268 (mushroom, earthy), (*E,E*)-2,4-nonadienal (fried, hazelnut) and (*E,E*)-2,4-decadienal (nutty,
269 fried). These compounds have all been previously identified in both SMP¹⁷ and milk
270 chocolate^{1,2} by GC-O.

271 Short chain fatty acids have previously been identified as the most abundant volatile
272 components in SMP.¹⁴ This is consistent with our GC-O findings, as short chain fatty acids
273 were detected in all four samples. Butanoic acid in particular was the only compound that
274 was detected by all the assessors in all the extracts and the MF was $> 80\%$ for all samples. In
275 milk, free fatty acids can be released through the hydrolysis of fat by lipases,^{11,14} but high
276 temperature will also enhance the hydrolysis of free fatty acids from the glycerol backbone.¹⁸
277 Short-chain free fatty acids contribute cheesy, sweaty notes to the flavor profile, which can
278 lead to rancid off-notes at high concentrations. However, the chocolate samples in this study
279 did not receive high scores for cheesy odor or flavor attributes during sensory profiling
280 (Table S2) and, although HHCHOC was scored higher than LHCHOC, the difference was not
281 significant. This is consistent with the work on boiled milk reported by Pistokoulou et al.¹³
282 who found several acids to have relatively high FD factors by GC-O, but they were present in
283 the milk at concentrations below the reported odor threshold.

284 Products of lipid oxidation and degradation, such as aldehydes and ketones, were described
285 as having green, mushroom, waxy, fatty and fried aromas. These compounds are often
286 present at concentrations below the detection limit of the mass spectrometer, but can
287 nevertheless be detected by assessors during GC-O because of their very low odor thresholds
288 (e.g. the odor threshold of 1-octen-3-one in oil is 0.0001 mg/kg¹⁹). Of these compounds, 1-
289 octen-3-one, (*Z*)-4-heptenal, (*E,E*)-2,4-nonadienal and (*E,E*)-2,4-decadienal had the highest
290 MF. Identified previously as a primary odorant in milk products,²⁰ (*E,E*)-2,4-decadienal
291 (nutty, fried) has also been shown to be an important odorant in milk chocolate.² Vazquez-
292 Landaverde et al.²¹ demonstrated a large increase in the total concentration of both aldehydes
293 and ketones after UHT treatment of milk. Our results support these findings: the general trend
294 within this group was for an increase in the high heat products. However, for some
295 compounds, these differences decreased after processing into model white chocolate.

296 Sulfur-containing compounds, such as methional and dimethyl trisulfide, also have low odor
297 thresholds. They were identified in all samples and had a higher MF in HHSMP and
298 HHCHOC, compared to LHSMP and LHCHOC respectively. Al-Attabi et al. identified sulfur
299 compounds as significant contributors to the cooked flavor of UHT milk.²² During thermal
300 processing of milk, the Strecker degradation of methionine forms methional,²³ which explains
301 the higher scores for this compound in HHSMP. With further heating, methional is degraded
302 to dimethyl disulfide²⁴ (via methanethiol), which is further converted to dimethyl trisulfide.
303 During sensory profiling, the HHCHOC was scored significantly more highly than LHCHOC
304 for “condensed-milk” flavor, and it is likely that methional and dimethyl trisulfide were
305 contributors to this cooked flavor. Koyabashi et al.¹² reported that 2-methyl-2-furyl methyl
306 disulfide and bis(2-methyl-3-furyl) disulfide contributed to brothy notes in HHSMP. The
307 former was detected by GC-O in all four extracts with MF<30%, but this is one of few
308 compounds where the MF was greater in the LHSMP compared to the HHSMP. Although

309 present in the white chocolate extracts, no brothy notes were identified in the chocolate by the
310 sensory panel and, in this case, these compounds are unlikely to be contributing to the
311 difference in flavor of the two chocolates.

312 Maillard reaction products contributing cooked and caramel notes are the most likely cause of
313 the flavor differences between LHCHOC and HHCHOC. Maltol, furaneol and 2-acetyl-1-
314 pyrroline all had MF>40% and were detected in all four samples. Maltol and furaneol
315 received higher MF scores in HHSMP compared to LHSMP and the same trend was observed
316 in the corresponding chocolates. They both impart a sweet, caramel odor and this is
317 consistent with the sensory results which showed a significant increase in fudge flavor and
318 caramel flavor in the sensory profiling and discrimination tests respectively.

319 2-Acetyl-1-pyrroline (popcorn, toasted) is a potent aroma compound, which can be formed by
320 the Maillard reaction of proline,²⁵ and has been identified extensively in basmati rice²⁶ as well
321 as in UHT milk²⁷ and SMP.¹¹ There was a small difference in MF scores for 2-acetyl-1-
322 pyrroline between heat treatments for SMP.

323 Other thermally-derived compounds, such as 2,3-butanedione (butter, creamy) and 3-
324 hydroxy-4,5-dimethyl-2(5*H*)-furanone (sotolon) (curry, maple, burnt rubber), were also
325 detected but showed much lower MF. In a study by Vasquez-Landaverde et al.,²¹ 2,3-
326 butanedione was one of the ketones that increased significantly between raw and UHT milk.
327 In this study, it was difficult to draw conclusions about the levels of 2,3-butanedione as it is a
328 highly volatile (boiling point 88 °C) and low molecular weight (86 g/mol) compound that is
329 easily lost during concentration.

330 **Volatile compounds: Aroma extract dilution analysis.** AEDA is another technique which
331 can be used to compare the relative intensity of aroma compounds within and between
332 extracts. A single assessor was used for AEDA to compare the low and high heat samples

333 (Table 3) and confirm differences between products which had already been identified by
334 three assessors using the GC-O technique discussed above. Although Ferreira et al.²⁸ have
335 recommended the use of a larger pool of assessors and fewer dilutions (1:10) for AEDA, it
336 was more practical to use small dilutions and a single assessor.

337 In general, the most persistent odor compounds in the milk powder extracts (FD 81) were
338 those which also had a high MF. They included three fatty acids, acetic acid, maltol and
339 furaneol as well as two unidentified compounds - one with a minty aroma (LRI 1704) and the
340 other with a milky nutty aroma (LRI 1639). The lipid degradation products and the sulfur
341 compounds tended to be less persistent by 1 or 2 FD factors. However those that persisted the
342 longest in the chocolate extracts (FD 27), in addition to the acids, were the lipid degradation
343 products ((*Z*)-4-heptenal and 1-octen-3-one), pyrazines and furaneol as well as one tentatively
344 identified compound which eluted at the correct LRI (1509) for 2-(1-methylpropyl)-3-
345 methoxypyrazine and imparted the green, potato and green pepper aroma typical of this
346 compound. This may have been introduced into the system from the cocoa butter.

347 It is the difference between HH and LH which is important when accounting for the flavor
348 differences between LHCHOC and HHCHOC. In the milk powder extracts, there were six
349 compounds which were detected in the HHSMP but not in the LHSMP. Furthermore, there
350 were 13 compounds that showed a difference in FD factor of at least 2 (representing at least a
351 1 in 9 dilution), nine of which were higher in HHSMP, confirming differences in MF
352 discussed above.

353 A similar trend was found in the chocolate extracts, with nine compounds showing a
354 difference in FD factor of 2 or more, all of which were higher in HHCHOC compared to
355 LHCHOC. The difference between the furaneol FD factors for LHCHOC and HCHOC was 3
356 (1 in 27 dilution), consistent with the differences found in the GC-O and the increase in

357 caramel and fudge notes detected in the HHCHOC by the sensory panels. Maltol showed a
358 difference of 2 FD factors and was overall less persistent than furaneol. Trimethylpyrazine
359 and 2,3-diethyl-5-methylpyrazine also had FD factors of 27 in the HHCHOC and persisted
360 for two more FD factors compared to LHCHOC. Interestingly, these pyrazines had relatively
361 low MF scores in the GC-O study, whereas 2-acetyl-1-pyrroline had MF>40% in the
362 chocolate extracts, but was barely detected by AEDA. These could be due to assessor
363 differences or could be indicative of the differences between the two GC-O techniques.
364 Otherwise the results are fairly consistent between the two techniques. It is interesting that
365 the unidentified aroma with a nutty, cooked milk, toasted and biscuit character which was
366 prominent in the SMP, was barely detected in the chocolate and therefore unlikely to
367 contribute to the flavor change.

368 Lipid degradation products are significant contributors to off-flavor in milk powder.²⁹ FD
369 factors for these compounds were generally low in the chocolate extracts, except for (*E,E*)-
370 2,4-decadienal, (*Z*)-4-heptenal and 1-octen-3-one (FD 27), which also had high MF scores
371 during GC-O analysis. 1-Octen-3-one (earthy, mushroom) was identified in previous studies
372 as one of the most significant off-flavors in skim milk powder,¹⁷ formed as a result of light-
373 induced oxidation, often during long-term storage of milk powder.³⁰ However the sensory
374 profiling of the chocolate showed relatively low mean scores for cardboard odor (<9), which
375 is a common descriptor for the oxidized off-flavor in milk caused by these compounds.¹⁷

376 **Volatile compounds: GC-MS.** Gas chromatography-mass spectrometry (GC-MS) was used
377 to aid identification of compounds present in the samples and Table 4 lists the compounds
378 identified. Fewer compounds were identified by GC-MS, compared to the GC-O. This
379 demonstrates that many of the odor-active compounds were present at levels above the GC-
380 odor detection threshold but below the detection limit of the instrument. Conversely, it was

381 possible to identify some compounds that were not detected by GC-O analysis, were unlikely
382 to be odor-active but provide additional evidence of, for example, greater Maillard activity in
383 the more thermally processed samples.

384 Maillard-derived compounds were found in both low and high heat samples, but were shown
385 to be consistently higher in the high heat samples, for both SMP and chocolate. Sugar
386 degradation products, such as 2-furfural, 2-furanmethanol and 2,3-dihydro-3,4-dihydroxy-6-
387 methyl-4*H*-pyran-4-one were all significantly higher in the HHSMP compared to the
388 LHSMP, and although not all of these were detected in the chocolate, the same trend was
389 observed for those that were. 5-(Hydroxymethyl)furfural (HMF) is often used as a marker of
390 thermal processing in milk,³¹ however there was not a significant difference in the amount of
391 HMF between the two SMPs and therefore it cannot be considered to be a good marker of
392 heat treatment in this case. This supports previous work by Berg and van Boekel,³² which
393 demonstrated that HMF is not formed in significant concentrations in milk (<400 µmol/L)
394 after 10 min heating at 150 °C or 20 min at 140 °C.

395 2-Furfural can be formed via the formation of Amadori compounds, from the reaction of
396 lactose and lysine, or as a result of the isomerization of lactose to lactulose.³³ Similarly, 2-
397 furanmethanol is likely to be formed from the thermal breakdown of lactose. Although
398 described as having a sweet, nutty odor, the odor detection thresholds of 2-furfural and 2-
399 furanmethanol in water are 2000 and 3000 µg/kg respectively.³⁴ As a result, the
400 concentrations were likely to be too low to contribute to the aroma profile of these samples,
401 but the increase in the high heat samples is further evidence of enhanced Maillard activity.
402 These compounds have not been identified before as odour-active in milk chocolate.^{1,2}

403 **DISCUSSION**

404 The directional discrimination test with naïve panellists showed that the chocolate prepared
405 from the HHSMP had more caramel/fudge character ($p < 0.0001$), and sensory profiling with
406 an expert panel confirmed the increase in the intensity of both the fudge flavor ($p < 0.05$) and
407 the condensed milk flavor ($p < 0.05$). GC-MS and GC-Olfactometry were carried out in order
408 to understand what was driving these differences in perception. The aroma of the white
409 chocolate undoubtedly results from the combination of many of the compounds identified.
410 However, those most likely to compounds to contribute to the change in aroma when
411 HHSMP was used are likely to be those that were detected consistently by GC-O, had
412 relatively high %MF scores (Table 2) and high FD factors (Table 3). More importantly, they
413 are those where there was a significant difference observed between the HHCHOC and the
414 LHCHOC, either in %MF, FD or both. Finally, the compounds responsible are likely to have
415 aroma characteristics similar to those described by the panellists. On these grounds, the acids,
416 which were amongst the highest scoring compounds, were ruled out as they tended not to
417 increase substantially in the HH products, the cheesy notes were not detected by the panel
418 and previous work has shown that despite the high FD values, they are usually present at
419 concentrations below their odour threshold¹³. The high scoring lipid-derived compounds were
420 discounted on the grounds that the aroma characters were uncharacteristic of the perceived
421 sensory difference. The sulfur compounds (methional and dimethyl trisulfide) scored very
422 highly and, although their aroma is also uncharacteristic of those used by the panellists, they
423 have been shown to contribute to the cooked notes in UHT milk,²² and could be contributing
424 to the condensed-milk flavor which was significantly higher in HHCHOC. The group of
425 Maillard-derived compounds are those which are likely to be contributing to the increase in
426 fudge and caramel aroma. Maltol, furaneol, 2-acetyl-1-pyrroline all had high %MF and high
427 FD factors particularly in the HH products. Maltol and furaneol impart sweet and burnt sugar
428 notes which both persisted for two or more FD factors in HHSMP or HHCHOC, compared to

429 LHSMP and LHCHOC respectively. They are likely to contribute to the perceived increase in
430 fudge and caramel notes as well as providing some sweet character to the condensed milk
431 notes. 2-Acetyl-1-pyrroline imparts a more roasted popcorn note which might contribute to
432 the toasted character in the fudge notes. Trimethylpyrazine and 2,3-diethyl-5-methylpyrazine
433 did not have high %MF scores, but had high FD factors which were higher in the HH
434 products. It is a combination of these Maillard-derived compounds which is likely to be
435 driving the difference between the HHCHOC and the LHCHOC. This is entirely consistent
436 with the fact that the difference between them is a 5 min heat treatment of the milk at 125 °C
437 prior to spray-drying, conditions which will promote the Maillard reaction in the HH
438 products. The sensory results demonstrate that this difference carries through to the white
439 chocolate where significant differences in flavor were perceived.

440 Furaneol has a low odor detection threshold of 10 µg/kg,³⁵ but was not detected by GC-MS in
441 the chocolate extracts. On the other hand, the odor detection threshold of maltol is much
442 higher and reported values vary from 9000 µg/kg³⁶ to 35000 µg/kg.³⁷ From addition of a
443 known amount of maltol-(*methyl-d*₃) to the DEE extracts prior to SAFE extraction, the
444 concentration of maltol in the model white chocolate prepared from low and high heat SMP
445 was found to be 122 and 315 µg/kg respectively. These concentrations are well below the
446 reported thresholds, but the reported threshold values were determined in water whereas
447 chocolate has a continuous fat-phase and a very low water content. The threshold and flavor
448 release of maltol from the chocolate matrix will be very different to that of water, as maltol is
449 relatively hydrophilic (Log P = 0.07±0.282 calculated from Advanced Chemistry
450 Development (ACD/Labs) Software V11.02). Without more appropriate threshold data, the
451 relative contribution of maltol and furaneol to the caramel note cannot be determined.

452 Maltol is formed from the Maillard reaction of lactose^{38, 39} and it has been suggested that it
453 can be formed during the conching of chocolate. Counet et al.³ found much higher
454 concentrations of maltol in conched dark chocolate (4.2 and 28.4 mg/kg) and demonstrated a
455 six fold increase during conching. However, typical conching temperatures for dark chocolate
456 are higher than that used for the white chocolate in this study (70 - 80 °C compared to 50 °C)
457 as there is less need to avoid browning in milk chocolate and dark chocolate. Liu et al.² found
458 similar a concentration in dark chocolate (1.9 mg/kg) but less in milk chocolate (715 µg/kg),
459 more in line with the quantities found in white chocolate. Previous work in our laboratory⁴⁰
460 showed no significant difference in maltol concentration between the model white chocolate
461 analyzed before and after conching. This confirmed that these key Maillard-derived
462 compounds were formed during the production of the milk powder, and not during chocolate
463 processing.

464 Overall, results from this study demonstrate that the SMP manufacturing process can
465 influence the flavor profile of model white chocolate. Many thermally-derived compounds
466 were present at significantly higher concentrations in HHSMP, and were shown to be formed
467 during the heating step traditionally carried out before the concentrated milk is spray-dried.
468 This flavor difference carries over into the white chocolate which was prepared from the
469 corresponding SMPs. The most significant flavor differences between white chocolate
470 produced from LHSMP or HHSMP are likely to be attributed to the Maillard-derived
471 compounds (maltol, furaneol, 2-acetyl-1-pyrroline, trimethylpyrazine and 2,3-diethyl-5-
472 methylpyrazine) and sulfur compounds (methional and dimethyl trisulfide). This
473 understanding of flavor generation in SMP is important for confectionery manufacturers to
474 maintain, or manipulate, the flavor of their products.

1986	-	nd	-	hot, dry, waxy	unknown	8	11	13	26	18
2070	2032	nd	1171	acidic, sweat, cheese	octanoic acid	14	43	52	14	22

^aLinear retention index of aroma by GC-O (expt) or of authentic aroma compounds by GC-O (au) determined on either a ZB-Wax or DB5 column, calculated from a linear equation between each pair of straight chain alkanes C₅-C₃₀

^bDetection Frequency (freq): total number of times odorant was detected (maximum = 24)

^cModified frequency (%MF) was calculated with the formula proposed by Dravnieks¹⁶: $MF(\%) = \sqrt{F(\%) \times I(\%)}$, where $F(\%)$ is the detection frequency expressed as a percentage and $I(\%)$ is the average intensity expressed as a percentage of the maximum intensity. nd = not detected

Table 3 Aroma extract dilution analysis (AEDA) of extracts of high heat skim milk powder (HHSMP), low heat skim milk powder (LHSMP), high heat white chocolate (HHCHOC) and low heat white chocolate (LHCHOC)

odorant	LRI ^a	FD factor ^b			
		LH SMP	HH SMP	LH CHOC	HH CHOC

^a Linear retention index on ZB-Wax column (30m), calculated from a linear equation between each pair of straight chain alkanes C₅–C₃₀.

^b Identity of compounds: A = confirmed by comparison of mass spectrum and LRI with those of authentic compounds, B = comparison of mass spectrum with NIST11 library

^c Relative concentration = peak area of compound \times concentration of internal standard (ISTD) / peak area of ISTD, nd = not detected. ISTD: 30 μ L 2-methyl-3-heptanone (6.18 μ g/25 mL) in methanol

^dS: Significance of samples; Probability, obtained from ANOVA, that there is a difference between means; ns = no significant difference between means ($p > 0.05$); * significant at the 5% level; ** significant at the 1% level; *** significant at the 0.1% level.
