# Bifurcation of equilibrium forms of an elastic rod on a two-parameter Winkler foundation

Marek Izydorek, Joanna Janczewska, Nils Waterstraat  
& Anita Zgorzelska

February 3, 2017

## Abstract

We consider two-parameter bifurcation of equilibrium states of an elastic rod on a deformable foundation. Our main theorem shows that bifurcation occurs if and only if the linearization of our problem has nontrivial solutions. In fact our proof, based on the concept of the Brouwer degree, gives more, namely that from each bifurcation point there branches off a continuum of solutions.

**key words:** Bifurcation, buckling, Winkler foundation.

**AMS Subject Classification:** Primary 58E07; Secondary 47J15, 74G60.

**running head:** Bifurcation of equilibrium forms.

## 1 Introduction

Bifurcation theory is one of the most powerful tools in studying deformations of elastic beams, plates and shells. Numerous works have been devoted to the study of bifurcation in elasticity theory (see for instance [8], [12] and the references therein).

A familiar example from beam theory is the problem of stability of an isotropic elastic rod lying on a deformable foundation which is being compressed by forces at the ends (see Fig. 1). For small forces the rod maintains its shape, however, as the forces increase they reach a first critical value beyond which the rod may buckle.

In this work, we consider mixed boundary conditions which are as follows. The beam is free at the left end, and so it may move as in figure 2 below. However, we require the shear force at the left end to vanish. At the right end, we assume the beam to be simply supported.

As we will show later, equilibrium forms of the rod under these boundary conditions satisfy the boundary value problem

$$\begin{cases} x^{(4)} + \alpha x'' + \beta x - f(x, x', \dots, x^{(4)}) = 0, & \text{in } [-r, r], \\ x'(-r) = x'''(-r) = 0, \\ x(r) = x''(r) = 0, \end{cases} \quad (1)$$

where  $\alpha$  is a parameter of the compressive force,  $\beta$  is a parameter of the elastic foundation, and  $f$  is a nonlinear term which we define in (9) below. It follows

Figure 1: An elastic beam on an elastic foundation

from the definition of  $f$  that for small forces the only solution of (1) is the trivial one, i.e.  $x_0(s) = 0$ ,  $s \in [-r, r]$ , which corresponds to the straight rod in our bifurcation model.

However, as the forces increase the rod may buckle and it is desirable to know for which positive parameter values  $(\alpha, \beta)$  this might happen.

In order to answer this question, we associate with (1) the linear boundary value problem

$$\begin{cases} x^{(4)} + \alpha x'' + \beta x = 0, & \text{in } [-r, r], \\ x'(-r) = x'''(-r) = 0, \\ x(r) = x''(r) = 0 \end{cases} \quad (2)$$

and we denote by  $N(\alpha, \beta)$  its space of solutions.

The main theorem of this paper shows that a necessary and sufficient condition for bifurcation, and so for the possibility of a buckling of the rod, is that  $\dim N(\alpha, \beta) \neq 0$ .

Let us point out that a similar model was investigated by A. Borisovich, Yu. Morozov and Cz. Szymczak in [7], where the authors assumed that the rod is simply supported at both ends. They proved the existence of simple bifurcation points (meaning that  $\dim N(\alpha, \beta) = 1$ ) by applying a variational version of the Crandall-Rabinowitz theorem (compare Thm. 3.4 below). Later, in [6], A. Borisovich and J. Dymkowska showed a corresponding result under our boundary conditions, however, to the best of our knowledge the existence of multiple bifurcation points in the solution set of (1) is new. Note that here we prove even more, namely the existence of multiple branching points.

Figure 2: A buckling of an elastic beam

Finally, let us mention that other models for buckling are described for example in [1–5, 9, 12].

Our paper is composed of three sections. In Section 2 we derive the equation of equilibrium forms of the rod and state our main theorem. Section 3 is devoted to the proof of this result.

### Acknowledgments.

Our research was supported by the Grant PPP-PL no. 57217076 of the Deutscher Akademischer Austauschdienst - DAAD and the Ministry of Science and Higher Education of Poland - MNiSW.

The authors wish to express their thanks to Professor Czesław Szymczak from the Faculty of Ocean Engineering and Ship Technology of Gdańsk University of Technology for several helpful comments concerning the model.

The authors are greatly indebted to Professor Józef E. Sienkiewicz, the physicist from the Faculty of Applied Physics and Mathematics of Gdańsk University of Technology, for pointing out a mistake in the formula for  $E_2$  in [6].

Our special thanks go to a student of mathematics at Gdańsk University of Technology, Aleksander Rogiński, for the preparation of pictures for the article.

## 2 Mathematical model

In this section we derive the equation (1) of equilibrium forms of the rod by a variational approach along the lines of [6]. The following formulas for  $E_1$  and  $E_3$  are as in [6], but as a result of conversations with J.E. Sienkiewicz and Cz.

Szymczak, the formula for  $E_2$  has been improved. The authors of [6] assumed that the rod under the action of the compressing force became longer, and so their assumption does not agree with experiments. Our refinement leads to a different nonlinear term in the equation (1), however the system (2), obtained by linearizing (1), is not changed.

Due to the fact that the work of A. Borisovich and J. Dymkowska contains a mistake, and moreover, it appeared only in Polish and in a limited number of copies, we do not restrict the discussion to explain the improvement, but for the convenience of the reader we provide a detailed exposition of the mathematical model.

The total potential energy  $E_t$  of the system composed of the rod and the foundation is equal to:

$$E_t = E_1 - E_2 + E_3,$$

where

- $E_1$  is the energy of the compressed rod,
- $E_2$  is the work of the compressing force,
- $E_3$  is the energy of the Winkler foundation (i.e. of the springs).

The energy  $E_1$  is given by

$$E_1(x) = \mathcal{E}I \int_{-r}^r \frac{\kappa^2(s)}{2} ds,$$

where

$$\kappa(s) = \frac{x''(s)}{(1 + x'(s)^2)^{\frac{3}{2}}}$$

is the curvature of the rod at a point  $s \in [-r, r]$ ,  $\mathcal{E}$  is Young's modulus and  $I$  is the moment of inertia of the cross section of the rod. The second energy  $E_2$  is defined as

$$E_2(x, \lambda) = \lambda \int_{-r}^r \left(1 - \sqrt{1 - x'(s)^2}\right) ds,$$

where

$$\int_{-r}^r \left(1 - \sqrt{1 - x'(s)^2}\right) ds$$

is the horizontal displacement of the left end of the rod and  $\lambda > 0$  is the value of the compressing force. Finally, the energy  $E_3$  is defined by

$$E_3(x, \mu, \nu) = \int_{-r}^r U(x(s), \mu, \nu) ds,$$

where

$$U(x, \mu, \nu) = \frac{1}{2}\mu x^2 - \frac{1}{4}\nu x^4 + o(x^4)$$

is determined experimentally, and  $\mu > 0$  and  $\nu > 0$  are parameters of the elastic foundation.

Expanding  $(1+x)^{-3}$  and  $\sqrt{1+x}$  as Maclaurin series, we get

$$\frac{1}{(1+x)^3} = 1 - 3x + 6x^2 - 10x^3 + o(x^3) \quad (3)$$

and

$$\sqrt{1+x} = 1 + \frac{x}{2} - \frac{x^2}{8} + \frac{x^3}{16} + o(x^3), \quad (4)$$

respectively. If we omit the terms of order higher than 4, we obtain

$$E_1(x) \approx \mathcal{E}I \int_{-r}^r \left( \frac{1}{2}x''(s)^2 - \frac{3}{2}x'(s)^2x''(s)^2 \right) ds$$

and

$$E_2(x, \lambda) \approx \lambda \int_{-r}^r \left( \frac{1}{2}x'(s)^2 + \frac{1}{8}x'(s)^4 \right) ds.$$

Hence the approximative formula for the total potential energy has the form

$$\begin{aligned} E_t(x, \lambda, \mu, \nu) \approx & \mathcal{E}I \int_{-r}^r \left( \frac{1}{2}x''(s)^2 - \frac{3}{2}x'(s)^2x''(s)^2 \right) ds \\ & - \lambda \int_{-r}^r \left( \frac{1}{2}x'(s)^2 + \frac{1}{8}x'(s)^4 \right) ds \\ & + \int_{-r}^r \left( \frac{1}{2}\mu x(s)^2 - \frac{1}{4}\nu x(s)^4 \right) ds. \end{aligned} \quad (5)$$

We now define

$$X = \{x \in C^4[-r, r]: x'(-r) = x'''(-r) = 0, \quad x(r) = x''(r) = 0\}$$

which is a Banach space with respect to the standard norm

$$\|x\|_X = \sum_{k=0}^4 \max_{s \in [-r, r]} |x^{(k)}(s)|.$$

Note that the boundary conditions in the definition of  $X$  describe the behaviour of the rod at its ends (see Fig. 2).

Setting

$$\alpha = \frac{\lambda}{\mathcal{E}I}, \quad \beta = \frac{\mu}{\mathcal{E}I}, \quad \gamma = \frac{\nu}{\mathcal{E}I}.$$

and dividing the formula (5) by  $2r\mathcal{E}I$ , we obtain a functional  $E: X \times \mathbb{R}_+^3 \rightarrow \mathbb{R}$  defined by

$$\begin{aligned}
E(x, \alpha, \beta, \gamma) &= \frac{1}{4r} \int_{-r}^r (x''(s)^2 - 3x'(s)^2 x''(s)^2) ds \\
&\quad - \frac{1}{4r} \int_{-r}^r \left( \alpha x'(s)^2 + \frac{\alpha}{4} x'(s)^4 \right) ds \\
&\quad + \frac{1}{4r} \int_{-r}^r \left( \beta x(s)^2 - \frac{\gamma}{2} x(s)^4 \right) ds.
\end{aligned} \tag{6}$$

In what follows we refer to  $E$  as *the energy functional*, and we note for later reference that its derivative with respect to the space variable  $x$  is

$$\begin{aligned}
E'_x(x, \alpha, \beta, \gamma)h &= \frac{1}{2r} \int_{-r}^r (\beta x(s) - \gamma x(s)^3) h(s) ds \\
&\quad - \frac{1}{2r} \int_{-r}^r \left( \alpha x'(s) + \frac{\alpha}{2} x'(s)^3 + 3x'(s)x''(s)^2 \right) h'(s) ds \\
&\quad + \frac{1}{2r} \int_{-r}^r (x''(s) - 3x'(s)^2 x''(s)) h''(s) ds
\end{aligned} \tag{7}$$

for all  $x, h \in X$  and  $\alpha, \beta, \gamma \in \mathbb{R}_+$ . Let us now denote by  $Y$  the space  $C[-r, r]$  with the standard norm

$$\|y\|_Y = \max_{s \in [-r, r]} |y(s)|,$$

and let us consider the map  $F: X \times \mathbb{R}_+^3 \rightarrow Y$  defined by

$$\begin{aligned}
F(x, \alpha, \beta, \gamma) &= x^{(4)} + \alpha x'' + \beta x \\
&\quad - \gamma x^3 - 3x''^3 - 12x'x''x''' \\
&\quad - 3x'^2 \left( x^{(4)} - \frac{\alpha}{2} x'' \right).
\end{aligned} \tag{8}$$

If we set

$$f(x, x', \dots, x^{(4)}) = \gamma x^3 + 3x''^3 + 12x'x''x''' + 3x'^2 \left( x^{(4)} - \frac{\alpha}{2} x'' \right) \tag{9}$$

for each  $x \in X$ , then the operator equation

$$F(x, \alpha, \beta, \gamma) = 0 \tag{10}$$

is equivalent to our previously introduced boundary value problem (1). Clearly, the trivial function  $x_0 \equiv 0$  satisfies the equation (10) for all values of parameters  $\alpha, \beta$  and  $\gamma$ . We call the set  $\Gamma \subset X \times \mathbb{R}_+^3$  given by

$$\Gamma = \{(0, \alpha, \beta, \gamma) : \alpha, \beta, \gamma \in \mathbb{R}_+\}$$

*the trivial family* of solutions of the equation (10). Naturally, a solution of (10) is said to be *nontrivial* if it does not belong to  $\Gamma$ .

An interesting phenomenon is when there is a "branching" of the equation (10) in correspondence with some value of the multiparameter  $(\alpha, \beta, \gamma)$ . This is the object of bifurcation theory.

**Definition 2.1** A point  $(0, \alpha_0, \beta_0, \gamma_0) \in \Gamma$  is called a bifurcation point of (10) if in every neighbourhood of it in  $X \times \mathbb{R}_+^3$  there is a nontrivial solution of (10), in other words,  $(0, \alpha_0, \beta_0, \gamma_0)$  belongs to the closure in  $X \times \mathbb{R}_+^3$  of the set of nontrivial solutions of the equation (10).

In particular, a bifurcation point  $(0, \alpha_0, \beta_0, \gamma_0) \in \Gamma$  of the equation (10) is said to be a branching point if there is a continuum (namely a closed connected set) of nontrivial solutions of (10) which contains  $(0, \alpha_0, \beta_0, \gamma_0)$ .

Integrating by parts in (7), we have

$$\begin{aligned} E'_x(x, \alpha, \beta, \gamma)h &= \frac{1}{2r} \int_{-r}^r \left( x^{(4)}(s) + \alpha x''(s) + \beta x(s) \right) h(s) ds \\ &\quad - \frac{1}{2r} \int_{-r}^r \left( \gamma x(s)^3 + 3x''(s)^3 + 12x'(s)x''(s)x'''(s) \right) h(s) ds \\ &\quad - \frac{1}{2r} \int_{-r}^r 3x'(s)^2 \left( x^{(4)}(s) - \frac{\alpha}{2} x''(s) \right) h(s) ds. \end{aligned} \tag{11}$$

If we denote by  $\langle \cdot, \cdot \rangle$  the standard inner product in  $L^2(-r, r)$ , i.e.

$$\langle g, h \rangle = \frac{1}{2r} \int_{-r}^r g(s)h(s) ds, \quad g, h \in L^2(-r, r),$$

then

$$E'_x(x, \alpha, \beta, \gamma)h = \langle F(x, \alpha, \beta, \gamma), h \rangle \tag{12}$$

for all  $x, h \in X$  and  $\alpha, \beta, \gamma \in \mathbb{R}_+$ . Therefore, we call  $F$  the variational gradient of  $E$ , and we see from (12) that solutions of (10) are critical points of (6).

Differentiating the map  $F$  with respect to the space variable  $x$  at  $x_0 \equiv 0$  we get

$$F'_x(0, \alpha, \beta, \gamma)h = h^{(4)} + \alpha h'' + \beta h \tag{13}$$

for every  $h \in X$  and  $\alpha, \beta, \gamma \in \mathbb{R}_+$ , and so

$$N(\alpha, \beta) = \ker F'_x(0, \alpha, \beta, \gamma).$$

We can now state the main result of this paper.

**Theorem 2.1** A point  $(0, \alpha_0, \beta_0, \gamma_0) \in \Gamma$  is a branching point of the equation (10) if and only if  $\dim N(\alpha_0, \beta_0) \neq 0$ .

□

Our theorem extends Theorem 5.3.2 of [6], which states that  $\dim N(\alpha_0, \beta_0) \neq 0$  is a necessary condition for bifurcation in the solution set of the equation (10) at a point  $(0, \alpha_0, \beta_0, \gamma_0)$ .

It is worth pointing out that the theorem shows that the parameter  $\gamma$  has no influence on the occurrence of bifurcation.

### 3 Proof of Theorem 2.1

In order to prove Theorem 2.1, we first discuss some properties of the nonlinear map  $F$ .

**Proposition 3.1** *For all values of parameters  $\alpha, \beta, \gamma \in \mathbb{R}_+$  the linear operator  $F'_x(0, \alpha, \beta, \gamma): X \rightarrow Y$  is Fredholm of index zero.*

**Proof.** The linear operator  $A: C^4[-r, r] \rightarrow Y$ ,  $Ah = h^{(4)}$  is surjective and its kernel consists of all polynomials of degree at most 3. Hence  $A$  is Fredholm of index 4. As  $X$  has codimension 4 in  $C^4[-r, r]$ , the restriction of  $A$  to  $X$  is Fredholm of index 0 (cf. [10, Lemma XI.3.1]). Since the embeddings of  $C^2[-r, r]$  and  $C^4[-r, r]$  into  $C[-r, r]$  are compact, it follows that  $F'_x(0, \alpha, \beta, \gamma)$  is a compact perturbation of the restriction of  $A$  to  $X$  and so a Fredholm operator of index zero. □

The following proposition is an immediate consequence of the equality (12).

**Proposition 3.2** *For all  $\alpha, \beta, \gamma \in \mathbb{R}_+$  the map  $F'_x(0, \alpha, \beta, \gamma): X \rightarrow Y$  is self-adjoint with respect to the inner product  $\langle \cdot, \cdot \rangle$ , i.e.*

$$\langle F'_x(0, \alpha, \beta, \gamma)h, g \rangle = \langle h, F'_x(0, \alpha, \beta, \gamma)g \rangle$$

for all  $h, g \in X$ . □

We now denote by  $Z$  the set of all points  $(\alpha, \beta) \in \mathbb{R}_+^2$  satisfying the inequality  $4\beta \leq \alpha^2$ . Let us consider in  $Z$  the family of rays  $l_m$  for  $m \in \mathbb{N}$  given by

$$\beta = -c_m\alpha - c_m^2,$$

where

$$c_m = -\left(\frac{\pi}{r}\right)^2 \left(\frac{2m-1}{4}\right)^2. \quad (14)$$

**Theorem 3.3 ( [6] )** *For  $(\alpha, \beta) \in \mathbb{R}_+^2$  one of the following three cases hold:*

(i) *If the point  $(\alpha, \beta)$  does not belong to any ray  $l_m$ , then*

$$\dim N(\alpha, \beta) = 0$$

*and the linear boundary value problem (2) possesses only the trivial solution.*

(ii) *If the point  $(\alpha, \beta)$  belongs to one and only one ray  $l_m$ , then*

$$\dim N(\alpha, \beta) = 1$$

*and  $N(\alpha, \beta)$  is generated by*

$$e_m(s) = 2 \cos \sqrt{-c_m}(s+r).$$

(iii) If the point  $(\alpha, \beta)$  belongs to the intersection of two rays  $l_{m_1}$  and  $l_{m_2}$  then

$$\dim N(\alpha, \beta) = 2$$

and the two linearly independent functions

$$e_{m_1}(s) = 2 \cos \sqrt{-c_{m_1}}(s + r)$$

and

$$e_{m_2}(s) = 2 \cos \sqrt{-c_{m_2}}(s + r)$$

are a basis of  $N(\alpha, \beta)$ .

□

It follows from the implicit function theorem and Proposition 3.1 that there is no bifurcation at points  $(0, \alpha_0, \beta_0, \gamma_0) \in \Gamma$  if  $\dim N(\alpha_0, \beta_0) = 0$ . Hence Theorem 3.3 shows that bifurcation can only occur at multiparameters  $(\alpha, \beta, \gamma)$  where  $(\alpha, \beta) \in l_m$  for some  $m$ .

Now, the rest of the proof of Theorem 2.1 splits into two cases, where we distinguish between simple and multiple branching points, i.e. whether the dimension of  $N(\alpha, \beta)$  is 1 or greater.

#### Case 1.: Simple branching points.

In [6], A. Borisovich and J. Dymkowska proved the existence of bifurcation at a point  $(0, \alpha_0, \beta_0, \gamma_0) \in \Gamma$  in the case  $\dim N(\alpha_0, \beta_0) = 1$  by applying the key function method due to Saprnov (see [13]).

For the convenience of the reader we present our own proof that is based on a variational version of the Crandall-Rabinowitz theorem on simple bifurcation points from [11], thus making our exposition self-contained.

It will cause no confusion if we use the same letters  $X, Y, \Gamma, F$  and  $E$  in the abstract result as in our issue.

**Theorem 3.4 (see [11])** *Let  $X$  and  $Y$  be real Banach spaces that are continuously embedded in a real Hilbert space  $H$  with inner product  $\langle \cdot, \cdot \rangle$ .*

*Suppose that a  $C^r$ -smooth map  $F: X \times \mathbb{R} \rightarrow Y$  and a  $C^{r+1}$ -smooth functional  $E: X \times \mathbb{R} \rightarrow \mathbb{R}$  satisfy the conditions below:*

$$(C_1) \quad F(0, p) = 0 \text{ for all } p \in \mathbb{R},$$

$$(C_2) \quad \dim \ker F'_x(0, p_0) = 1,$$

$$(C_3) \quad \text{codim im } F'_x(0, p_0) = 1,$$

$$(C_4) \quad E'_x(x, p)h = \langle F(x, p), h \rangle \text{ for all } x, h \in X \text{ and } p \in \mathbb{R},$$

$$(C_5) \quad E'''_{x^2 p}(0, p_0)(e, e, 1) \neq 0, \text{ where } e \in X \text{ is such that } F'_x(0, p_0)e = 0, \langle e, e \rangle = 1.$$

*Then the set of solutions of the equation*

$$F(x, p) = 0$$

*in a small neighbourhood of  $(0, p_0)$  is composed of two curves:  $\Gamma$  and  $\Lambda$ , intersecting only at  $(0, p_0)$ , where  $\Gamma$  is the trivial branch*

$$\Gamma = \{(0, p) \in X \times \mathbb{R} : p \in \mathbb{R}\},$$

and  $\Lambda$  is a  $C^{r+1}$ -smooth curve that can be parametrized for some  $\delta > 0$  as

$$\Lambda = \{(x(t), p(t)) : t \in (-\delta, \delta)\},$$

where  $x(0) = 0$ ,  $p(0) = p_0$  and  $x'(0) = e$ .

□

Combining (12) with Proposition 3.1, the proof of Theorem 2.1 in the first case will be completed by showing that at least one of the partial derivatives  $E'''_{xx\alpha}(0, \alpha_0, \beta_0, \gamma_0)(e_m, e_m, 1)$  or  $E'''_{xx\beta}(0, \alpha_0, \beta_0, \gamma_0)(e_m, e_m, 1)$  is not trivial, where  $e_m$  is the function introduced in Theorem 3.3.

An easy computation shows that

$$E'''_{xx\alpha}(0, \alpha_0, \beta_0, \gamma_0)(e_m, e_m, 1) = -\langle e'_m, e'_m \rangle = c_m < 0 \quad (15)$$

and

$$E'''_{xx\beta}(0, \alpha_0, \beta_0, \gamma_0)(e_m, e_m, 1) = \langle e_m, e_m \rangle = 1 > 0. \quad (16)$$

By Theorem 3.4,  $(0, \alpha_0, \beta_0, \gamma_0)$  is a branching point of the equation (10) both with respect to the parameter of compressive force  $\alpha$  and with respect to the parameter of the elastic foundation  $\beta$ . Moreover, the solution set of (10) in a small neighbourhood of  $(0, \alpha_0, \beta_0, \gamma_0)$  contains the trivial family  $\Gamma$  and two  $C^\infty$ -smooth curves  $\Lambda_1, \Lambda_2$  of the form

$$\Lambda_1 = \{(x_1(t), \alpha(t)) : |t| < \delta_1\} \subset X \times \mathbb{R}_+ \times \{(\beta_0, \gamma_0)\},$$

where  $x_1(0) = 0$ ,  $\alpha(0) = \alpha_0$ ,  $x'_1(0) = e_m$ , and

$$\Lambda_2 = \{(x_2(t), \beta(t)) : |t| < \delta_2\} \subset X \times \mathbb{R}_+ \times \{(\alpha_0, \gamma_0)\},$$

where  $x_2(0) = 0$ ,  $\beta(0) = \beta_0$ ,  $x'_2(0) = e_m$ . Hence  $(0, \alpha_0, \beta_0, \gamma_0)$  is a branching point.

### Case 2.: Multiple branching points.

We now turn to multiple branching points.

Here the method based on the Crandall-Rabinowitz theorem does not work anymore. In order to prove the existence of branching points also in this case, we will make a finite-dimensional reduction of Lyapunov-Schmidt type.

Let  $\alpha_0, \beta_0, \gamma_0 \in \mathbb{R}_+$  be such that

$$\dim N(\alpha_0, \beta_0) = 2,$$

and let  $e_{m_1}$  and  $e_{m_2}$  be the corresponding functions in Theorem 3.3. Since

$$(\alpha_0, \beta_0) \in \overline{\{(\alpha, \beta) \in \mathbb{R}_+^2 : \dim N(\alpha, \beta) = 1\}},$$

we see that  $(0, \alpha_0, \beta_0, \gamma_0)$  is a bifurcation point, and we shall now show that it is a branching point. We define a map  $G: X \times \mathbb{R}^2 \times \mathbb{R}_+ \times \mathbb{R}_+ \rightarrow Y$  by

$$G(x, \xi, \alpha, \beta) = F(x, \alpha, \beta, \gamma_0) + \sum_{i=1}^2 (\xi_i - \langle x, e_{m_i} \rangle) e_{m_i},$$

where  $x \in X$ ,  $\xi = (\xi_1, \xi_2) \in \mathbb{R}^2$  and  $\alpha, \beta \in \mathbb{R}_+$ .

It is easily seen that

$$G'_x(0, 0, \alpha_0, \beta_0)h = F'_x(0, \alpha_0, \beta_0, \gamma_0)h - \sum_{i=1}^2 \langle h, e_{m_i} \rangle e_{m_i},$$

where  $h \in X$ , is an isomorphism of  $X$  onto  $Y$ .

By the implicit function theorem there exist open subsets  $U \subset X$  and  $S \subset \mathbb{R}^2 \times \mathbb{R}_+ \times \mathbb{R}_+$  such that  $0 \in U$ ,  $(0, \alpha_0, \beta_0) \in S$ , and the set

$$\{(x, \xi, \alpha, \beta) \in U \times S : G(x, \xi, \alpha, \beta) = 0\}$$

is the graph of a smooth function  $\tilde{x}: S \rightarrow U$  satisfying  $\tilde{x}(0, \alpha_0, \beta_0) = 0$ . Moreover, since  $G(0, 0, \alpha, \beta) = 0$  for all  $\alpha, \beta \in \mathbb{R}_+$ , it follows that  $\tilde{x}(0, \alpha, \beta) = 0$  for all  $(0, \alpha, \beta) \in S$ .

We now introduce a function  $\varphi = (\varphi_1, \varphi_2): S \rightarrow \mathbb{R}^2$  by

$$\varphi_i(\xi, \alpha, \beta) = \xi_i - \langle \tilde{x}(\xi, \alpha, \beta), e_{m_i} \rangle, \quad i = 1, 2, \quad (17)$$

and we note that  $\varphi$  is smooth and  $\varphi(0, \alpha, \beta) = 0$  for all  $(0, \alpha, \beta) \in S$ .

**Theorem 3.5 (see [11])** *The point  $(0, \alpha_0, \beta_0, \gamma_0) \in X \times \mathbb{R}_+^3$  is a bifurcation point (a branching point) of (10) if and only if the point  $(0, \alpha_0, \beta_0) \in \mathbb{R}^2 \times \mathbb{R}_+ \times \mathbb{R}_+$  is a bifurcation point (a branching point) of the equation*

$$\varphi(\xi, \alpha, \beta) = 0. \quad (18)$$

□

The rest of the argument is based on the concept of topological degree due to Brouwer. To be more precise, we will apply a theorem of Krasnosielski, which we recall for the convenience of the reader.

**Theorem 3.6 (see [11])** *If  $(0, \lambda_0, \beta_0) \in S$  is not a bifurcation point of equation (18) then there exist open sets  $V_1 \subset \mathbb{R}^2$  and  $V_2 \subset \mathbb{R}_+ \times \mathbb{R}_+$  satisfying:*

- (i)  $(0, \alpha_0, \beta_0) \in V_1 \times V_2 \subset S$ .
- (ii) *For each open subset  $V \subset V_1$  such that  $0 \in V$  and for all  $(\alpha, \beta), (\tilde{\alpha}, \tilde{\beta}) \in V_2$  the mappings  $\varphi(\cdot, \alpha, \beta)$  and  $\varphi(\cdot, \tilde{\alpha}, \tilde{\beta})$  have no zeros on the boundary of  $V$  and*

$$\deg(\varphi(\cdot, \alpha, \beta), V, 0) = \deg(\varphi(\cdot, \tilde{\alpha}, \tilde{\beta}), V, 0). \quad (19)$$

□

Here and subsequently,  $\deg(\varphi(\cdot, \alpha, \beta), V, 0)$  stands for the Brouwer degree of the map  $\varphi(\cdot, \alpha, \beta)$  on the set  $V$  with respect to 0.

We do not want to recapitulate degree theory here, however, let us point out the important fact that in our case for each  $(\alpha, \beta) \in V_2$  there is a neighbourhood  $V \subset V_1$  of 0 such that

$$\deg(\varphi(\cdot, \alpha, \beta), V, 0) = \text{sgn det}[\varphi'_\xi(0, \alpha, \beta)].$$

We now proceed to show that  $(0, \alpha_0, \beta_0) \in \mathbb{R}^2 \times \mathbb{R}_+ \times \mathbb{R}_+$  is a branching point of (18). It is well-known from bifurcation theory and degree theory that it is sufficient to prove that the equality (19) does not hold.

Differentiating

$$G(\tilde{x}(\xi, \alpha, \beta), \xi, \alpha, \beta) = 0$$

with respect to  $\xi$  we get

$$\begin{aligned} F'_x(\tilde{x}(\xi, \alpha, \beta), \alpha, \beta, \gamma_0) \sum_{j=1}^2 \frac{\partial \tilde{x}}{\partial \xi_j}(\xi, \alpha, \beta) t_j + \sum_{j=1}^2 t_j e_{m_j} \\ - \sum_{i=1}^2 \sum_{j=1}^2 \left\langle \frac{\partial \tilde{x}}{\partial \xi_j}(\xi, \alpha, \beta) t_j, e_{m_i} \right\rangle e_{m_i} = 0, \end{aligned}$$

for all  $t = (t_1, t_2) \in \mathbb{R}^2$ . Hence

$$\begin{aligned} F'_x(0, \alpha, \beta, \gamma_0) \sum_{j=1}^2 \frac{\partial \tilde{x}}{\partial \xi_j}(0, \alpha, \beta) t_j + \sum_{j=1}^2 t_j e_{m_j} \\ - \sum_{i=1}^2 \sum_{j=1}^2 \left\langle \frac{\partial \tilde{x}}{\partial \xi_j}(0, \alpha, \beta) t_j, e_{m_i} \right\rangle e_{m_i} = 0, \end{aligned} \quad (20)$$

and combining (20) and (8) we have

$$\begin{aligned} \frac{d^4}{ds^4} \sum_{j=1}^2 \frac{\partial \tilde{x}}{\partial \xi_j}(0, \alpha, \beta) t_j + \alpha \frac{d^2}{ds^2} \sum_{j=1}^2 \frac{\partial \tilde{x}}{\partial \xi_j}(0, \alpha, \beta) t_j + \beta \sum_{j=1}^2 \frac{\partial \tilde{x}}{\partial \xi_j}(0, \alpha, \beta) t_j \\ + \sum_{j=1}^2 t_j e_{m_j} - \sum_{i=1}^2 \sum_{j=1}^2 \left\langle \frac{\partial \tilde{x}}{\partial \xi_j}(0, \alpha, \beta) t_j, e_{m_i} \right\rangle e_{m_i} = 0. \end{aligned} \quad (21)$$

If we now substitute into  $t = (t_1, t_2)$  the vectors  $(1, 0)$  and  $(0, 1)$  subsequently, we obtain

$$\begin{aligned} \frac{d^4}{ds^4} \frac{\partial \tilde{x}}{\partial \xi_j}(0, \alpha, \beta) + \alpha \frac{d^2}{ds^2} \frac{\partial \tilde{x}}{\partial \xi_j}(0, \alpha, \beta) + \beta \frac{\partial \tilde{x}}{\partial \xi_j}(0, \alpha, \beta) \\ + e_{m_j} - \sum_{i=1}^2 \left\langle \frac{\partial \tilde{x}}{\partial \xi_j}(0, \alpha, \beta), e_{m_i} \right\rangle e_{m_i} = 0 \end{aligned} \quad (22)$$

for  $j = 1, 2$ . Therefore

$$\begin{aligned} & \left\langle \frac{d^4}{ds^4} \frac{\partial \tilde{x}}{\partial \xi_j}(0, \alpha, \beta), e_{m_k} \right\rangle + \left\langle \alpha \frac{d^2}{ds^2} \frac{\partial \tilde{x}}{\partial \xi_j}(0, \alpha, \beta), e_{m_k} \right\rangle + \left\langle \beta \frac{\partial \tilde{x}}{\partial \xi_j}(0, \alpha, \beta), e_{m_k} \right\rangle \\ & + \langle e_{m_j}, e_{m_k} \rangle - \left\langle \frac{\partial \tilde{x}}{\partial \xi_j}(0, \alpha, \beta), e_{m_k} \right\rangle = 0 \end{aligned}$$

for  $j = 1, 2$  and  $k = 1, 2$ . Applying Proposition 3.2 we see that

$$\left\langle \frac{\partial \tilde{x}}{\partial \xi_j}(0, \alpha, \beta), e_{m_k}^{(4)} + \alpha e_{m_k}'' + \beta e_{m_k} - e_{m_k} \right\rangle = -\langle e_{m_j}, e_{m_k} \rangle \quad (23)$$

for  $j = 1, 2$  and  $k = 1, 2$ . Since  $e_{m_k}'' = c_{m_k} e_{m_k}$  and  $e_{m_k}^{(4)} = c_{m_k}^2 e_{m_k}$  for  $k = 1, 2$ , we obtain

$$\left\langle \frac{\partial \tilde{x}}{\partial \xi_j}(0, \alpha, \beta), e_{m_k} \right\rangle = \begin{cases} -\frac{1}{c_{m_k}^2 + \alpha c_{m_k} + \beta - 1} & \text{if } j = k \\ 0 & \text{if } j \neq k \end{cases},$$

by (23). Now (17) yields

$$\frac{\partial \varphi_k}{\partial \xi_j}(0, \alpha, \beta) = \begin{cases} \frac{c_{m_k}^2 + \alpha c_{m_k} + \beta}{c_{m_k}^2 + \alpha c_{m_k} + \beta - 1} & \text{if } j = k \\ 0 & \text{if } j \neq k \end{cases}$$

and so

$$[\varphi'_\xi(0, \alpha, \beta)] = \begin{bmatrix} \frac{c_{m_1}^2 + \alpha c_{m_1} + \beta}{c_{m_1}^2 + \alpha c_{m_1} + \beta - 1} & 0 \\ 0 & \frac{c_{m_2}^2 + \alpha c_{m_2} + \beta}{c_{m_2}^2 + \alpha c_{m_2} + \beta - 1} \end{bmatrix}. \quad (24)$$

Furthermore, it follows from Theorem 3.3 that

$$\beta_0 = -c_{m_1} \alpha_0 - c_{m_1}^2 \quad \text{and} \quad \beta_0 = -c_{m_2} \alpha_0 - c_{m_2}^2,$$

and so

$$c_{m_1}^2 = -c_{m_1} \alpha_0 - \beta_0 \quad \text{and} \quad c_{m_2}^2 = -c_{m_2} \alpha_0 - \beta_0.$$

Hence (24) now becomes

$$[\varphi'_\xi(0, \alpha, \beta)] = \begin{bmatrix} \frac{(\alpha - \alpha_0)c_{m_1} + \beta - \beta_0}{(\alpha - \alpha_0)c_{m_1}^2 + \beta - \beta_0 - 1} & 0 \\ 0 & \frac{(\alpha - \alpha_0)c_{m_2} + \beta - \beta_0}{(\alpha - \alpha_0)c_{m_2}^2 + \beta - \beta_0 - 1} \end{bmatrix},$$

and in consequence,

$$\det[\varphi'_\xi(0, \alpha, \beta)] = \frac{(\alpha - \alpha_0)c_{m_1} + \beta - \beta_0}{(\alpha - \alpha_0)c_{m_1}^2 + \beta - \beta_0 - 1} \cdot \frac{(\alpha - \alpha_0)c_{m_2} + \beta - \beta_0}{(\alpha - \alpha_0)c_{m_2}^2 + \beta - \beta_0 - 1}. \quad (25)$$

Our aim is now to determine the sign of (25) at points in a small neighbourhood of  $(0, \alpha_0, \beta_0)$ .

We first note that there exists  $\varepsilon > 0$  such that the denominator of (25) is positive for every  $(\alpha, \beta) \in (\alpha_0 - \varepsilon, \alpha_0 + \varepsilon) \times (\beta_0 - \varepsilon, \beta_0 + \varepsilon)$ .

Let  $n(\alpha, \beta)$  denote the numerator of (25), i.e.

$$n(\alpha, \beta) = ((\alpha - \alpha_0)c_{m_1} + \beta - \beta_0) \cdot ((\alpha - \alpha_0)c_{m_2} + \beta - \beta_0).$$

For  $\alpha \neq \alpha_0$  we have

$$n(\alpha, \beta) = (\alpha - \alpha_0)^2 \left( c_{m_1} + \frac{\beta - \beta_0}{\alpha - \alpha_0} \right) \left( c_{m_2} + \frac{\beta - \beta_0}{\alpha - \alpha_0} \right).$$

We can assume without loss of generality that  $m_1 < m_2$ . Then  $c_{m_1} > c_{m_2}$  by (14), and we can check at once that

$$\text{sign det}[\varphi'_\xi(0, \alpha, \beta)] = \begin{cases} 1 & \text{if } \frac{\beta - \beta_0}{\alpha - \alpha_0} \in (-\infty, -c_{m_1}) \cup (-c_{m_2}, \infty) \\ -1 & \text{if } \frac{\beta - \beta_0}{\alpha - \alpha_0} \in (-c_{m_1}, -c_{m_2}) \end{cases}.$$

Now let us suppose, contrary to our claim, that  $(0, \alpha_0, \beta_0)$  is not a bifurcation point of the equation (18). Let  $V_1 \subset \mathbb{R}^2$  and  $V_2 \subset \mathbb{R}_+ \times \mathbb{R}_+$  be the open sets as in Theorem 3.6. Clearly, there are  $(\alpha, \beta)$  and  $(\tilde{\alpha}, \tilde{\beta})$  in  $V_2 \cap (\alpha_0 - \varepsilon, \alpha_0 + \varepsilon) \times (\beta_0 - \varepsilon, \beta_0 + \varepsilon)$  such that

$$\frac{\beta - \beta_0}{\alpha - \alpha_0} \in (-\infty, -c_{m_1}) \cup (-c_{m_2}, \infty)$$

and

$$\frac{\tilde{\beta} - \beta_0}{\tilde{\alpha} - \alpha_0} \in (-c_{m_1}, -c_{m_2}).$$

We now take a neighbourhood  $V \subset V_1$  of 0 such that the Brouwer degrees of  $\varphi(\cdot, \alpha, \beta)$  and  $\varphi(\cdot, \tilde{\alpha}, \tilde{\beta})$  on  $V$  with respect to 0 are the same as the signs of  $\text{det}[\varphi'_\xi(0, \alpha, \beta)]$  and  $\text{det}[\varphi'_\xi(0, \tilde{\alpha}, \tilde{\beta})]$  respectively. We get

$$\text{deg}(\varphi(\cdot, \alpha, \beta), V, 0) = \text{sgn det}[\varphi'_\xi(0, \alpha, \beta)] = 1$$

and

$$\text{deg}(\varphi(\cdot, \tilde{\alpha}, \tilde{\beta}), V, 0) = \text{sgn det}[\varphi'_\xi(0, \tilde{\alpha}, \tilde{\beta})] = -1,$$

which contradicts the equality (19). Hence  $(0, \alpha_0, \beta_0, \gamma_0)$  is a branching point of the equation (10).
