10 Abstract

11 **Background:** Periods of prolonged sitting impairs endothelial function in lower
12 limb conduit arteries, which is attenuated with physical activity breaks. The effect of
13 activity breaks on upper limb arteries has not been examined. This study assessed
14 changes in brachial artery endothelial function following either a prolonged sitting
15 period or breaking up this sedentary time by performing sets of calisthenics
16 exercises. **Methods:** Ten healthy participants (6 men) completed two conditions in a
17 counterbalanced order: a) 1-hr 26-min sitting, or b) breaking up this period every 20-
18 min by performing a set of five calisthenics exercises. Brachial artery endothelial
19 function was assessed via ultrasound using the flow-mediated dilation (FMD)
20 technique prior to and following each condition, while brachial shear rate (SR) was
21 acquired after each set of calisthenics. **Results:** There was no significant change in
22 FMD over time ($p=0.09$) or between conditions ($p=0.12$). Compared to sitting,
23 brachial SR increased following each set of calisthenics, with a significant difference
24 after the third break (Sit: $33.94 \pm 12.79 \text{ s}^{-1}$; Calisthenics: $57.16 \pm 30.48 \text{ s}^{-1}$, $p=0.02$).
25 **Conclusion:** Alterations in SR in the upper limbs suggest calisthenics may be an
26 effective intervention to break up sedentary time and attenuate the potentially
27 deleterious effects of prolonged sitting on cardiovascular health.

28

29 Introduction

30 Sitting is the most prevalent sedentary behaviour (Dunstan et al., 2012a; Owen et al.,
31 2010), particularly in workplaces (Parry et al., 2013), and is emerging as an
32 independent health risk factor (Dunstan et al., 2012a; Healy et al., 2008). Periods of
33 prolonged sitting impairs cardiometabolic health, however this is attenuated by
34 frequently breaking up this time (Dunstan et al., 2012b; Henson et al., 2015; Peddie
35 et al., 2013). Research is emerging to suggest that vascular health is also negatively
36 influenced by prolonged sedentary periods. Sitting for three (Thosar et al., 2014;
37 2015; McManus et al., 2015) and six (Restaino et al., 2015) hours caused superficial
38 femoral and popliteal artery endothelial function to decrease respectively. Whether
39 upper limb vascular function is also negatively influenced by sitting is less clear, as
40 over these time periods no decline in brachial artery endothelial function was
41 observed (Thosar et al., 2014; Restaino et al., 2015).

42
43 Reductions in shear stress appear to strongly mediate sitting-induced impairments in
44 vascular function. Shear stress is a key physiological mechanism in the regulation of
45 endothelial function (Carter et al., 2013; Padilla et al., 2011; Tinken et al., 2009),
46 chronic reductions of which augments the atherosclerotic process (Malek et al.,
47 1999). Prolonged sitting causes shear rate (SR) to decline in the superficial femoral
48 (Thosar et al., 2014; 2015), popliteal (Restaino et al., 2015, 2016) and brachial
49 (Thosar et al., 2014; Restaino et al., 2015) arteries. As brachial artery endothelial
50 function is maintained despite reductions in SR it suggests this vessel may be more
51 resistant to this negative effect of sitting (Restaino et al., 2015).

52

1
2
3 53 Using activity breaks to disrupt prolonged sitting periods appears to contribute to the
4
5 54 preservation of endothelial function by increasing shear stress. Frequently breaking
6
7 55 up prolonged sitting with walking bouts prevents the decline in femoral artery
8
9 56 endothelial function that is otherwise observed (Thosar et al., 2015). Physical
10
11 57 activity enhances endothelial function (Di Francescomarino et al., 2009) via
12
13 58 increased blood flow and shear stress (Tinken et al., 2009; 2010), but this
14
15 59 improvement is abolished if shear stress is attenuated using cuff inflation methods
16
17
18 60 (Birk et al., 2013; Tinken et al., 2009; 2010). Moreover, Exercise training increases
19
20
21 61 endothelial function due to exposing the vasculature to repeated episodic elevations
22
23 62 in shear stress (Green et al., 2011; Tinken et al., 2009). Consequently, this pattern of
24
25 63 repeated increases in shear stress is replicated using activity breaks, which may
26
27 64 explain their protective role. However, in their study Thosar et al., (2015) assessed
28
29 65 SR 25 minutes after the activity breaks therefore any immediate changes were not
30
31 66 recorded, which may explain the lack of difference observed between the activity
32
33 67 and sitting conditions. Moreover, changes to upper limb endothelial function were
34
35 68 not considered.

36
37
38 69
39
40 70 Upper limb vascular function was assessed when a single ten minute walking bout
41
42 71 was completed following an extended sitting period (Restaino et al., 2015). This
43
44 72 intervention restored the decrease in popliteal but not brachial microvascular
45
46 73 function, possibly due to the lack of increased blood flow to the upper limbs
47
48 74 (Restaino et al., 2015). Consequently, a whole body exercise modality such as
49
50 75 calisthenics exercises (using body weight as a resistance) may be more effective in
51
52 76 enhancing vascular function as this activates both upper and lower limb musculature.
53
54
55 77 Additionally, calisthenics make an ideal workplace intervention as individuals are

1
2
3 78 not required to leave their working environment, purchase equipment or make
4
5 79 workplace adaptations (Carr et al., 2012; Carter et al., 2015).
6
7
8
9

80

10 81 The purpose of this study was to determine changes in brachial artery endothelial
11
12 82 function following either a prolonged sitting period or breaking up this sedentary
13
14 83 time performing sets of calisthenics exercises. We also aimed to assess the changes
15
16 84 in SR over this time period, to provide a greater mechanistic understanding of the
17
18 85 effects of sitting with or without activity breaks on upper limb vascular function.

87 **Methods**

88 **Study population**

89 Ten healthy participants (6 men) were screened prior to testing (PAR-Q) and
90 exclusion criteria included: smoker, current medication and presence of apparent
91 cardio-metabolic disease. The experimental procedures and potential risks were
92 explained to participants prior to testing and written informed consent obtained. The
93 University of Essex ethics committee approved the experimental protocol, which
94 conformed to the Declaration of Helsinki.

96 **Study design and procedures**

97 Participants attended the temperature controlled (20-22°C) laboratory at the same
98 time of day (between 9.00-9.30 am) on two separate occasions. Prior to testing
99 participants avoided strenuous exercise for 48-hr and any exercise for 12-hr prior,
100 and completed an overnight fast and abstinence from caffeine. Women were assessed
101 in days 1–7 of the menstrual cycle. Participants randomly completed either 1-hr 26-
102 min of: a) uninterrupted sitting (Sit) or b) disrupting this sitting every 20-min
103 performing a set of calisthenics (Calisthenics). This time period was chosen as
104 previous work has shown changes in SR occur within the first two hours of sitting
105 (Restaino et al., 2015; Thosar et al., 2015). Moreover, due to the novelty of the
106 calisthenics, it was important to assess the feasibility of participants completing this
107 intervention without too much participant burden.

109 After arrival, participants were fitted with a 3-lead electrocardiogram and separate
110 heart rate (HR) monitor, to assess HR during endothelial function measures and
111 during the physical activity breaks respectively. Participants rested in a supine

1
2
3 112 position for 20-min followed by baseline assessment of right brachial artery
4
5 113 endothelial function (Pre Condition) using the noninvasive flow mediated-dilation
6
7 114 (FMD) technique. Participants then moved to a seated position and baseline right
8
9 115 brachial artery mean SR was acquired, with SR used as an estimation of shear stress
10
11 116 (Johnson et al., 2011). Following this, participants completed one of the
12
13 117 experimental conditions. In the Calisthenics condition, mean brachial artery SR was
14
15 118 acquired following each activity break (Post Break). Time points were matched in
16
17 119 the Sit condition. After the condition baseline FMD and SR measures were repeated
18
19 120 (Post Condition) (Figure 1). The same researcher completed all measures.
20
21
22
23

121

122 Condition 1: Sit

123 Participants remained seated in a chair at a desk for 1-hr 26-min. During this time,
124 non-vigorous arm and leg movements were permitted, enabling participants to
125 complete desk-based activities such as reading and working on a computer (Figure
126 1a).
127

128

129 Condition 2: Calisthenics

130 The sedentary period was broken up every 20-min with a 2-min set of calisthenics.
131 This was repeated three times (Break 1, Break 2 and Break 3), followed by a final 20-
132 min sitting period, therefore totalling 1-hr 26-min (Figure 1b).
133

134

135 Five different exercises were performed: squats, arm circles, calf raises, knees to
136 elbows and forward lunges. Exercises alternatively activated upper and lower body
muscles groups to minimise fatigue. Participants performed 8 repetitions of each
exercise across a 3 second cycle (24 seconds per exercise) in time to an audible and

1
2
3 137 visual metronome. Prior to testing written and verbal instructions and demonstrations
4
5 138 for each exercise were given, and participants were provided the opportunity to
6
7 139 practise any unfamiliar exercises. Participants were instructed to keep exercise
8
9 140 technique consistent for each set of exercises.
10
11
12 141

13
14 142 To ensure consistent duration of break, a standardised transition time between sitting
15
16 143 to starting each activity bout and then returning to sitting was included of 25 and 15
17
18 144 seconds respectively.
19

20
21 145

22 146 **Vascular endothelial function testing**

23
24
25 147 Assessment of brachial artery FMD was performed according to published
26
27 148 guidelines (Harris et al., 2010; Stoner et al., 2012; Thijssen et al., 2011) using M-
28
29 149 mode imaging. Arterial blood flow and SRs were assessed using a linear array 10
30
31 150 Mhz Doppler ultrasound in triplex mode (Prosound Alpha 6, Hitachi Aloka Medical,
32
33 151 Tokyo, Japan), with an insonation angle of 60°. The ultrasound had built in software
34
35 152 enabling automated edge detection for diameter analysis in real time and fast Fourier
36
37 153 transform of raw audio data to determine mean blood velocity. Testing procedures
38
39 154 were completed as previously described (Carter et al., 2014).
40
41
42 155

43
44
45 156 For data analysis, basal arterial diameter was determined as the average of 30 heart
46
47 157 cycles prior to cuff inflation; while peak vessel dilation was calculated from the
48
49 158 highest average diameter of three consecutive heart cycles after cuff deflation. FMD
50
51 159 was calculated as: $\frac{([Peak\ post-occlusion\ arterial\ diameter - Baseline\ mean\ arterial\ diameter])}{Baseline\ mean\ arterial\ diameter} \times 100\ %$. SR area under the curve
52
53 160
54
55
56
57
58
59
60

1
2
3 161 (AUC) was calculated from post cuff deflation until the point of peak vessel
4
5 162 diameter and formulated using the trapezoid rule (Harris et al., 2010).
6

7 163

10 164 **Shear rate measurements**

11 165 Brachial artery mean SR measurements were acquired at the same location as FMD
12
13 166 measures, as indicated by an indelible marking at the site. SRs were measured at Pre
14
15 167 Condition, Post Condition and Post each Break (at 22, 44 and 66-min during each
16
17 168 condition). Measures were collected at 1.5 minutes following each set of
18
19 169 calisthenics, providing time for probe positioning and imaging. Time points were
20
21 170 replicated in the Sit condition (Time 1, Time 2 and Time 3; Figure 1).
22
23
24

25 171

26
27 172 For each SR measurement 20 heart cycles of blood velocity and arterial diameter
28
29 173 data were collected. From this mean SR ($4 \times [\text{mean blood velocity}/\text{arterial diameter}$
30
31 174 at the measurement time]) could be calculated in accordance to published guidelines
32
33 175 (Harris et al., 2010).
34
35

36 176

38 177 **Heart rate and blood pressure**

39
40 178 HR was continually monitored (S610i, Polar Electro Oy, Kempele, Finland) with
41
42 179 measures taken at 5 second intervals. Blood pressure (BP) was measured at left
43
44 180 brachial artery (MX3 plus, Omron, USA) at the same time points as SR measures
45
46 181 and mean arterial pressure (MAP) subsequently calculated.
47
48

49 182

51 183 **Physical activity and sedentary behaviour assessment**

1
2
3 184 Participants completed the International Physical Activity Questionnaire (Long form,
4
5 185 IPAQ) (Booth, 2000), a validated and reliable measure of adult physical activity
6
7 186 (Craig et al., 2003) and sedentary behaviour (Rosenberg et al., 2008).
8
9

10 187

11 188 **Statistical analyses**

12
13
14 189 ~~All data are presented as mean \pm standard deviation (SD).~~ Data were normally
15
16 190 distributed, assessed using Shapiro-Wilk test. Technical reasons during data
17
18 191 collection meant ten data sets for endothelial function and eight sets for brachial SR
19
20 192 were analysed.
21
22

23 193

24
25 194 Two-way repeated measures ANOVA were used to compare the effect of condition
26
27 195 on relative FMD, basal arterial diameters, mean SR and MAP. All post hoc analyses
28
29 196 were performed via paired samples t-test with Bonferroni adjustment. Data are
30
31 197 presented as means \pm standard deviation (SD) from which effects sizes were
32
33 198 calculated (partial eta squared η^2). These were interpreted as: $\eta^2=0.01$ considered
34
35 199 small, $\eta^2=0.06$ considered medium and $\eta^2=0.14$ considered large (Cohen, 1988).
36
37
38 200 Data was analysed using statistical software (SPSS Version 18.0, IBM Corporation,
39
40 201 Somers, NY, USA), with significance accepted as $p \leq 0.05$.

202 Results

203 Descriptive statistics

204 Descriptive statistics are shown in Table 1. Participants were classified as
205 highly active but spent over 6.5 hours per day seated (Table 1).

206

207 Endothelial function

208 For relative FMD, no significant interaction ($F(1,9)= 0.9, p=0.37, \eta^2=0.09$),
209 condition ($F(1,9)= 3.6, p=0.12, \eta^2=0.29$) or time ($F(1,9)= 2.9, p=0.09, \eta^2=0.25$)
210 effects were observed (Pre Sit: $4.58 \pm 5.20 \%$; Post Sit: $5.33 \pm 5.81 \%$; Pre
211 Calisthenics: $5.36 \pm 4.07 \%$; Post Calisthenics: $8.32 \pm 6.10 \%$; Figure 2). For SR AUC
212 there were no significant effects for interaction ($F(1,9)= 0.9, p=0.36, \eta^2=0.14$),
213 condition ($F(1,9)= 0.5, p=0.48, \eta^2=0.10$) or time ($F(1,9)= 0.8, p=0.40, \eta^2=0.12$) (Pre
214 Sit: $3261.6 \pm 2887.8 \text{ s}^{-1}$; Post Sit: $3191.3 \pm 2619.4 \text{ s}^{-1}$; Pre Calisthenics: 3903.9
215 $\pm 1948.5 \text{ s}^{-1}$; Post Calisthenics: $3249.8 \pm 1893.3 \text{ s}^{-1}$). Normalising FMD for SR AUC
216 (dividing the percentage of FMD by SR AUC) resulted in no significant interaction
217 ($F(1,9)= 1.2, p=0.31, \eta^2=0.16$), condition ($F(1,9)= 0.7, p=0.44, \eta^2=0.11$) or time
218 ($F(1,9)= 2.9, p=0.12, \eta^2=0.33$) effects (Pre Sit: $0.001 \pm 0.004 \%/s^{-1}$; Post Sit: 0.001
219 $\pm 0.002 \%/s^{-1}$; Pre Calisthenics: $0.001 \pm 0.001 \%/s^{-1}$; Post Calisthenics: 0.003 ± 0.002
220 $\%/s^{-1}$). There was no main effect for time ($F(1,9)= 2.5, p=0.15, \eta^2=0.21$) or condition
221 ($F(1,9)= 3.9, p=0.52, \eta^2=0.05$) for basal arterial diameters (Pre Sit: $3.72 \pm 0.69 \text{ mm}$;
222 Post Sit: $3.55 \pm 0.76 \text{ mm}$; Pre Calisthenics: $3.60 \pm 0.66 \text{ mm}$; Post Calisthenics: 3.57
223 $\pm 0.79 \text{ mm}$).

224

225 Shear rate

1
2
3 226 A significant interaction effect was observed for brachial SR ($F(4,32)=2.0$ $p=0.02$,
4
5 227 $\eta^2=0.12$). Post Break SRs were increased in the Calisthenics condition compared to
6
7 228 the same time points in the Sit condition, however post-hoc analysis revealed this
8
9 229 difference was only statistically significant following Break 3 with Calisthenics
10
11 230 elevating SR by 23.22 s^{-1} more compared to Sit at Time 3 ($p=0.02$, $\eta^2=0.51$; Table
12
13 231 2). Post Condition, Sit SR remained depressed compared to Calisthenics ($p=0.07$,
14
15 232 $\eta^2=0.36$). Finally, Pre Condition SRs were not significantly different between
16
17 233 conditions ($p=0.88$, $\eta^2=0.01$).
18
19
20
21
22

234

235 **Cardiovascular response**

236 For MAP no significant interaction ($F(5,45)= 0.8$, $p=0.56$, $\eta^2=0.08$), time ($F(5,45)=$
237 1.2 , $p=0.33$, $\eta^2=0.12$) or condition ($F(1,9)= 0.8$, $p=0.41$, $\eta^2=0.08$) effects were
238 observed (Sit Pre: 91.1 ± 10.2 mmHg, Post: 88.1 ± 8.2 mmHg; Calisthenics Pre: 90.0
239 ± 9.9 mmHg, Post: 90.9 ± 7.4 mmHg). HR in the Calisthenics condition showed a
240 significant main effect for time ($F(11,88)= 23.3$, $p=0.001$, $\eta^2=1.0$). Post hoc analysis
241 revealed calisthenics significantly increased HR (Break 1: $90.05 \pm 8.26\text{ b}\cdot\text{min}^{-1}$;
242 Break 2: $92.24 \pm 6.16\text{ b}\cdot\text{min}^{-1}$; Break 3: $92.51 \pm 7.24\text{ b}\cdot\text{min}^{-1}$; Figure 3) compared to
243 Baseline-Pre Condition ($68.90 \pm 9.10\text{ b}\cdot\text{min}^{-1}$; $p=0.001$) and HR remained elevated
244 above Baseline-Pre Condition at 30 seconds following each break ($p=0.001$). In the
245 Sit condition, no main effect for time was observed ($F(4,36)= 1.2$, $p=0.34$, $\eta^2=0.33$)
246 with HR only slightly reduced over time (Pre: $70.25 \pm 8.92\text{ b}\cdot\text{min}^{-1}$; Post: 66.21
247 $\pm 8.72\text{ b}\cdot\text{min}^{-1}$).
248

249

249 Discussion

250 This study investigated changes in brachial artery endothelial function and SR in
251 response to a prolonged sitting period or breaking up this sedentary time. Sitting did
252 not attenuate brachial SR or FMD. Using calisthenics to disrupt this sitting time
253 caused significant transient increases in HR and brachial mean SR, however this did
254 not significantly increase brachial FMD. Results indicate that brachial artery
255 endothelial function is resistant to the negative effects of one hour of sitting. Data
256 also suggests that over a longer time period using calisthenics to break up sedentary
257 time may improve vascular function.

258

259 Calisthenics activity breaks and endothelial function

260 Using calisthenics to break up sedentary time did not significantly increase brachial
261 endothelial function. Despite what is known about activity-related improvements in
262 endothelial function (Di Francescomarino et al., 2009), this current result is in
263 support of existing research. Although in previous work, short walking bouts to
264 break up sitting attenuated the decline in FMD that otherwise occurred, FMD in the
265 activity condition was also not significantly increased compared to baseline (Thosar
266 et al., 2015). Whilst the FMD results from this current study were not significantly
267 different between conditions, unlike in Thosar et al. (2015) study, FMD was not
268 attenuated in the sitting condition. There are currently no guidelines as to clinically
269 meaningful changes in FMD and consequently, the 2.99 % greater increase in the
270 calisthenics condition compared to the sit condition ~~difference between the~~
271 ~~conditions~~ may have important vascular health implications; especially considering
272 the relative acute nature of this study.

1
2
3 273

4
5 274 For the first time, changes in SR immediately after activity breaks to sitting have
6
7 275 been characterised. Brachial SR was elevated following each set of calisthenics and,
8
9 276 of particular interest, the increase in SR was greater after break three than break one,
10
11 277 suggesting a possible accumulative effect of the calisthenics interventions.
12
13 278 Moreover, SR measured 20 minutes after the final activity break had returned to a
14
15 279 value similar to baseline; highlighting the need to frequently disrupt sedentary
16
17 280 periods in order to maintain elevated SR.
18
19

20
21 281

22
23 282 Repeated episodic increases in SR are a suggested mechanism underlying exercise
24
25 283 related improvements in endothelial function (Padilla et al., 2008; Tinken et al.,
26
27 284 2010). In the current study, although over a short time period, each break replicated
28
29 285 this repetitive stimulus, suggesting that SR alterations could be a mechanism to
30
31 286 explain the slight increase brachial FMD observed. Indeed, this has previously been
32
33 287 proposed as an explanation for the maintenance of femoral artery endothelial
34
35 288 function when sedentary time was broken up with walking bouts (Thosar et al.,
36
37 289 2015). However, in the study by Thosar et al. (2015) SR measures were taken over
38
39 290 20 minutes after each walk, consequently assessing SR immediately post-activity
40
41 291 allows a clearer mechanistic explanation to describe the effects activity breaks
42
43 292 during sitting have on the vascular system. Future work should seek to characterise
44
45 293 the SR response following an activity break at more regular intervals to determine
46
47 294 the length of time over which elevations in SR persist.
48
49

50
51 295

52
53 296 Despite calisthenics not significantly changing brachial FMD, this does not imply it
54
55 297 is not an effective intervention choice to break up sedentary time. Results show that
56
57
58

1
2
3 298 mean brachial SR can be acutely increased using this intervention and, as the
4
5 299 calisthenics routine employed was a whole body exercise, such elevations may also
6
7 300 have been present in the lower limbs. Previous work (Thosar et al., 2015; Restaino et
8
9 301 al., 2015; 2016) has shown this vasculature is more susceptible to decreases in
10
11 302 endothelial function following prolonged sitting periods. Consequently, future
12
13 303 research should use calisthenics and investigate changes in lower limb vascular
14
15 304 function.
16
17
18
19

305

306 **Sitting did not attenuate endothelial function**

307 In agreement with existing literature (Thosar et al., 2014; Restaino et al., 2015)
308 continuous sitting did not decrease brachial FMD compared to baseline values.
309 Additionally, no significant reductions in brachial SR were observed. This may
310 provide an explanation for this outcome, as decreased SR is a proposed mechanism
311 for the reduction in lower limb endothelial function following sitting (Thosar et al.,
312 2014; 2015; Restaino et al., 2016). Importantly during these studies participants'
313 lower limbs remained motionless (Restaino et al., 2015; Thosar et al., 2015) whereas
314 in this current study participants were permitted to move their upper limbs to
315 complete desk-based tasks. This may have resulted in low level muscular
316 contractions, maintaining blood flow and SR. In support of this, upper limb
317 movement during bed rest enhanced brachial FMD (Hamburg et al., 2007), whilst
318 reducing daily step count attenuated femoral but not brachial FMD, related to a
319 larger reduction in lower limb perfusion compared to the upper limbs (Boyle et al.,
320 2013).

321

1
2
3 322 The absence of a decline in mean brachial SR after one hour and six minutes of
4
5 323 sitting is in line with existing research, as SR was not significantly reduced after the
6
7 324 first hour of a three hour sedentary period (Thosar et al., 2014). However, mean
8
9 325 brachial SR was significantly attenuated after two hours of sitting and remained
10
11 326 depressed for the further five hours of assessment (Restaino et al., 2015). This
12
13 327 indicates that the brachial artery is susceptible to SR reductions, however the results
14
15 328 from this current study and Thosar et al. (2014) suggest within an hour of sitting this
16
17 329 is not apparent. In the current study, the measure taken after one hour and six
18
19 330 minutes resulted in the largest reduction in SR which then remained slightly
20
21 331 depressed for the post-condition measure, indicating that reductions may have
22
23 332 continued if the time period was extended, in line with existing research (Restaino et
24
25 333 al., 2015). Taken together these results support the idea that the brachial artery is
26
27 334 more ~~resistance-resistive~~ to the negative effects of sitting (Restaino et al., 2015), as
28
29 335 popliteal and femoral mean SR are reduced within the first hour of sitting (Thosar et
30
31 336 al., 2015; Restaino et al., 2015). Moreover, even when reductions in brachial SR
32
33 337 have been observed the magnitude of decline was less than that in the lower limbs
34
35 338 and only microvascular function was attenuated (Restaino et al., 2015).
36
37
38
39
40
41 339

42 43 340 **Limitations and future research**

44
45 341 As aforementioned, it is likely that the continuous sitting condition duration was not
46
47 342 long enough for significant changes to endothelial function and SR to occur. As there
48
49 343 is no definition as to what is considered prolonged sitting (Dunstan et al., 2012a) the
50
51 344 current design was chosen to provide initial data on calisthenics and endothelial
52
53 345 function without excessive participant demands. Previous research considering
54
55 346 metabolic health and changes to endothelial function has utilised longer assessment
56
57
58
59
60

1
2
3 347 periods of up to nine hours (Dunstan et al., 2012b; Peddie et al., 2013; Thosar et al.,
4
5 348 2014; 2015; Restaino et al., 2015). Additionally, the population assessed were
6
7 349 young, healthy and had high levels of physical activity. Larger changes to
8
9 350 endothelial function may have occurred with an older or less active population.
10
11 351 Indeed, exercise status and age are known to influence endothelial responses (Black
12
13
14 352 et al., 2009). Furthermore, participants' transport to the laboratory was not
15
16 353 standardised, therefore pre-testing physical activity may have varied between
17
18 354 participants. However, based on the location of the university campus, it is assumed
19
20 355 participants would have used car or bus transportation; moreover participants were
21
22 356 asked to use the same form of transport for each test visit. Finally, due to the pilot
23
24 357 nature of this research, it is possible that the study was underpowered to detect
25
26 358 changes in FMD. Although as previous work has shown significant differences with
27
28 359 a sample size of 12 (Thosar et al., 2015) a power calculation using our data suggests
29
30 360 our study may be underpowered and that 30 participants might be needed to detect a
31
32 361 significant change in relative -FMD. This ~~As this~~ study shows that calisthenics are
33
34 362 feasible for participants to complete ~~therefore~~ future work should therefore use a
35
36 363 larger sample size.
37
38
39
40
41 364

42
43 365 This study presents results following a single sitting period, however of greater
44
45 366 ecological interest is the influence of repeatedly performing either the calisthenics
46
47 367 intervention or prolonged sitting over several days or weeks. This would determine
48
49 368 if, as in exercise training studies, the repeated exposure of the vasculature to
50
51 369 increases in SR can lead to longer term improvements in endothelial function.
52
53 370 Furthermore, if repeated prolonged sitting periods does decrease endothelial function
54
55 371 it would further support the need for a reduction of this behaviour in the population.
56
57
58
59
60

1
2
3 372 In practical terms, longer term research within a workplace environment would
4
5 373 determine the feasibility of individuals carrying out multiple breaks to their daily
6
7 374 routine, alongside assessing behavioural change and adherence.
8
9

10 375

11 376 **Conclusions**

12
13
14 377 For the first time, this study demonstrates breaking up sedentary time with
15
16 378 calisthenics can lead to transient increases in HR and brachial artery mean SR. This
17
18 379 did not significantly increase brachial artery endothelial function, however a longer
19
20 380 assessment period more representative of a working day may be needed to result in a
21
22 381 significant improvement. Additionally results show that brachial artery endothelial
23
24 382 function is not negatively affected by an acute sitting period, when upper limb
25
26 383 movement typical of daily living is permitted. Overall, the SR results from this study
27
28 384 present calisthenics as a potential intervention to break up sedentary time and
29
30 385 enhance or maintain cardiovascular health. Longer term research, assessing upper
31
32 386 and lower limb endothelial function is required to assess whether repeatedly
33
34 387 exposing the vascular system to increases in SR can lead to larger improvements in
35
36 388 endothelial function.

514 **Table 1:** Descriptive characteristics, self-reported physical activity scores and total
515 sitting time of participants (n= 10)

516

Variable	Mean	SD
Age (years)	27.3	8.1
Body Mass (kg)	82.6	19.7
Height (cm)	172.3	10.4
Physical Activity Score (MET-minutes/week)	3844.0	3271.8
Sitting Time Per Day (Hours)	6.6	2.3
Sitting Time Per Week (Hours)	46.2	16.3

518 **Table 2:** Brachial artery shear rate (SR) at baseline (Pre) and after (Post) two experimental conditions: a) uninterrupted sitting for 1-hr 26-min
519 (Sit) or b) disrupting this sitting every 20-min performing a set of calisthenics (Calisthenics). In Calisthenics SR was measured after each break
520 (Break 1, Break 2 and Break 3) and these time points were matched in Sit condition (Time 1, Time 2 and Time 3).

Measurement	Sit					Calisthenics				
	Pre	Time 1	Time 2	Time 3	Post	Pre	Break 1	Break 2	Break 3	Post
Brachial SR (s ⁻¹)	40.95 ±14.67	42.17 ±17.31	46.22 ±14.20	33.94 ±12.79	36.32 ±10.73	40.13 ±16.19	47.26 ±19.37	65.86 ±36.43	57.16 ±30.48*	46.41 ±20.22

521
522 * Indicates Calisthenics was significantly greater than Sit at Break 3 (p<0.05).

523 **Figure Legends**

524 **Figure 1:** The experimental design and measurement time points for the two
525 conditions, completed in a randomised order on separate days. (a) Sitting for 1-hr 26-
526 min, or (b) breaking up this period every 20-min with a 2-min set of calisthenics
527 exercises. FMD- flow mediated dilation; SR- shear rate.

528
529 **Figure 2:** Brachial artery flow mediated dilation (FMD) before (Pre) and following
530 (Post) either 1-hr 26-min uninterrupted sitting (Sit) or, breaking up this period every
531 20-min with 2-min of performing calisthenics exercises (Calisthenics). (Error bars=
532 \pm SD)

533
534 **Figure 3:** Mean heart rate (HR) prior to each condition (Pre), during each
535 calisthenics activity break (Break 1, Break 2 and Break 3), and during the 5-min of
536 recovery following this intervention. * indicates a significantly greater HR than Pre
537 ($p=0.001$). (Error bars= \pm SD)

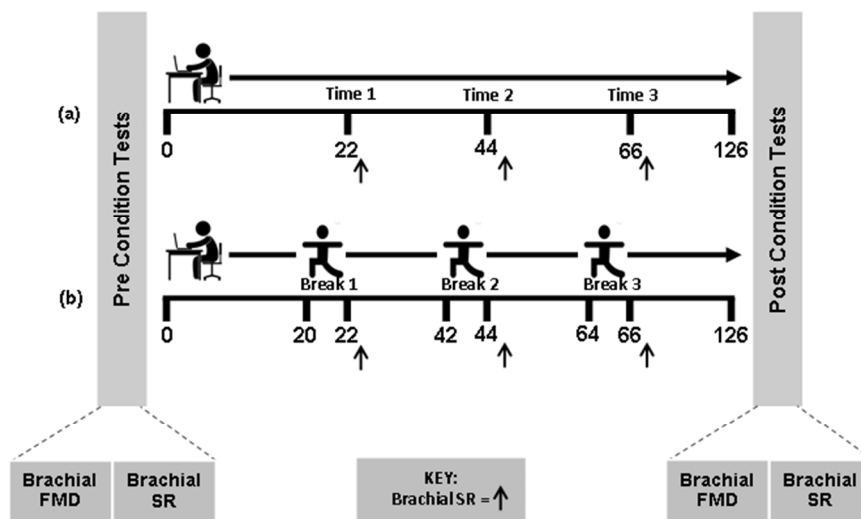

Figure 1: The experimental design and measurement time points for the two conditions, completed in a randomised order on separate days. (a) Sitting for 1-hr 26-min, or (b) breaking up this period every 20-min with a 2-min set of calisthenics exercises. FMD- flow mediated dilation; SR- shear rate.
162x84mm (120 x 120 DPI)

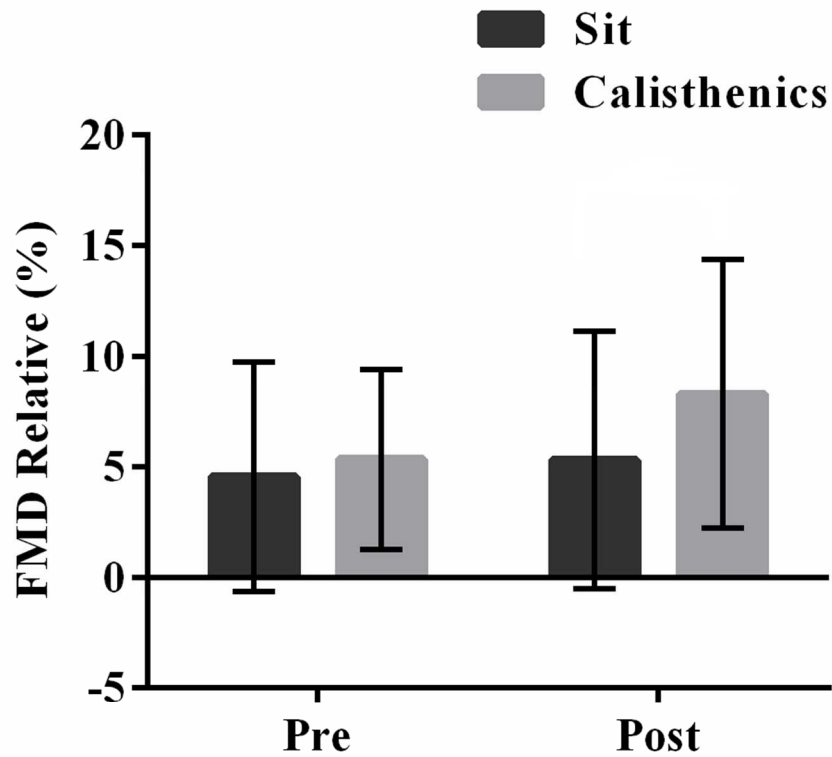

Figure 2: Brachial artery flow mediated dilation (FMD) before (Pre) and following (Post) either 1-hr 26-min uninterrupted sitting (Sit) or, breaking up this period every 20-min with 2-min of performing calisthenics exercises (Calisthenics). (Error bars= \pm SD)
91x77mm (300 x 300 DPI)

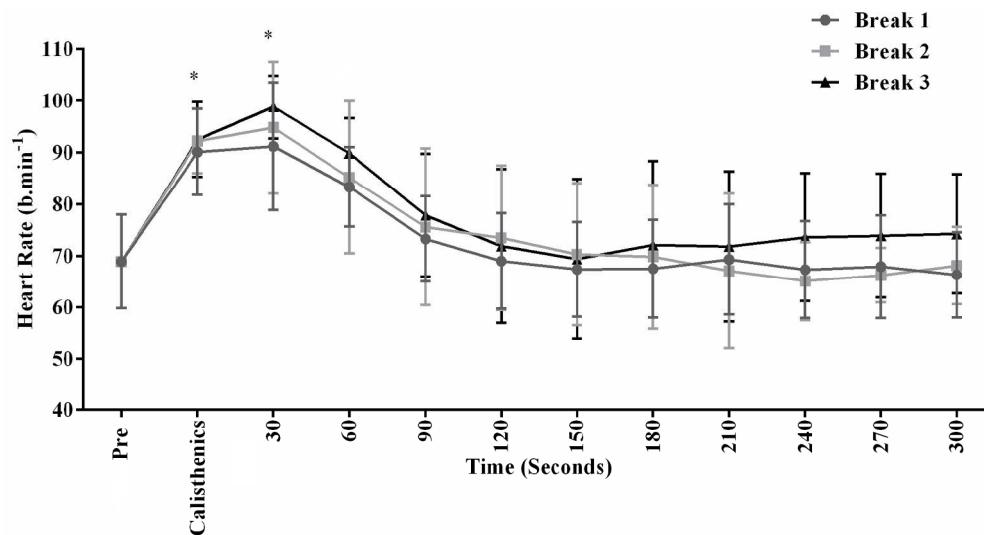

Figure 3: Mean heart rate (HR) prior to each condition (Pre), during each calisthenics activity break (Break 1, Break 2 and Break 3), and during the 5-min of recovery following this intervention * indicates a significantly greater HR than Pre ($p=0.001$). (Error bars= \pm SD)
