28 **Abstract-** High reliability water quality guideline values (GVs) have been derived for four
29 pharmaceuticals, carbamazepine, diclofenac, fluoxetine and propranolol in fresh waters using
30 a Burr Type III distribution applied to species sensitivity distributions (SSDs) of chronic
31 toxicity data. Data were quality assured and had to meet acceptability criteria for ‘chronic’
32 NOEC or EC10 endpoints including population relevance (namely, effect endpoints based on
33 development, growth, reproduction and survival). Biomarker response data (e.g. biochemical,
34 histological or molecular responses) were excluded from the derivation as they are typically
35 not directly relevant to population-related impacts. The derived GVs for 95% species
36 protection were 4.3, 770, 1.6 and 14 µg/L for carbamazepine, diclofenac, fluoxetine and
37 propranolol, respectively. These values significantly higher than the low reliability values
38 derived for the European Commission, Switzerland or Germany that are based on the
39 application of assessment factors to the most sensitive experimental endpoint (which may
40 include biochemical, histological or molecular biomarker responses). The GVs derived in this
41 exercise were not exceeded in recent data for Australian rivers and streams receiving
42 pharmaceutical containing effluents from WWTPs.

INTRODUCTION

Our growing dependence on pharmaceuticals, and their increased availability to consumers, means that a number of the commonly used products are becoming detectable constituents of wastewaters [1, 2]. Depending on the effectiveness of the wastewater treatment process, there are real prospects for these products to reach natural water systems, with the potential for effects on aquatic ecosystem health. Ecotoxicological investigations have been carried out for many of the popularly used pharmaceuticals, however, there have been limited attempts to derive water quality guidelines that enable regulatory agencies to determine whether measured environmental concentrations pose a concern.

This paper collates the available data for four pharmaceuticals, carbamazepine, diclofenac, fluoxetine and propranolol, and derives high reliability guideline values for ecosystem protection of 99, 95 and 90% of species using species sensitivity distributions (SSDs) [3]. The latest revisions to the guideline derivation protocols [4] were applied. These involve:

- (i) Using effects endpoints for development, growth, reproduction or survival and focussing on chronic EC10 data, where available, rather than NOEC data and excluding biomarker responses (e.g. biochemical, histological or molecular responses);
- (ii) Ensuring that all toxicity data meet the required definitions of chronic tests, in particular, for juvenile fish tests, exposure duration should be ≥ 21 days and ≥ 7 days for fish embryo tests;
- (iii) High reliability guideline values require 8 or more data points for chronic exposure (no conversions of acute data to chronic) representing at least 4 taxonomic groups;
- (iv) The goodness of fit of data to the Burr Type III distribution used in the SSD being acceptable; and

73 (v) Careful evaluation of all data to ensure they meet acceptability criteria (Batley et al.,
74 2013).

75 The basic data for each of the pharmaceuticals are summarised in Table 1.

76

77

EXPERIMENTAL

78 A thorough review of the literature was undertaken for all toxicity data relating to
79 carbamazepine, diclofenac, fluoxetine and propranolol and added to a new dataset determined
80 in our laboratories [5]. Since our priority is ecological protection based on population-
81 relevant endpoints, adverse effects on development, growth, reproduction and survival were
82 used to derive NOEC or EC10 values, as per the recommendation by Hutchinson et al. [6].
83 This approach recognizes that biomarkers responses based on biochemical, histological and
84 molecular endpoints may be highly useful for exposure monitoring [7, 8] and also in
85 developing adverse outcome pathways to help prioritize appropriate testing strategies for
86 ecotoxicology research and risk assessment [9]. Data were sorted into acute and chronic tests,
87 with the objective of obtaining at least 8 chronic NOEC or EC10 data points for species from
88 4 or more taxonomic groups. If this was achieved, acute data and chronic data having other
89 endpoints (e.g. EC50 or LOECs) were discarded, otherwise lower reliability guidelines could
90 be generated using a combination of converted acute data (using an ACR or default value of
91 10) and chronic data. A quality check of the data as described by Hobbs et al. [10] was then
92 undertaken and only data of high or acceptable quality were retained as recommended for
93 guideline derivation in Australia and New Zealand [4].

94 Data were then screened to ensure that the endpoints reported were acceptable as
95 chronic tests according to agreed criteria [4, 10]. An SSD was then obtained from the data set

96 using the BurrliOz Version 2 software to derive guideline values (GVs) that were protective
97 of 99, 95 and 90% of species (PC99, PC95 and PC90) with 50% confidence.

98

99

RESULTS AND DISCUSSION

100 *Carbamazepine*

101 A review of the literature found acute toxicity data reported for 6 species, and chronic
102 toxicity for 17 species. Of these, acceptable chronic toxicity data were available for 11
103 species (2 cladocerans, 2 green algae, 1 blue-green algae, 1 diatom, 1 midge, 1 rotifer, 1
104 cnidarian and 2 fish) representing 8 taxonomic groups (Table 2). The cladoceran,
105 *Ceriodaphnia dubia*, was the most sensitive, with an EC10 of 25 µg/L [11]. The data
106 distribution using a Burr Type III fit in the SSD was such that it had a long tail (Figure 1),
107 which meant that a 99% protection GV could not be determined. The 95% protection GV was
108 4.3 µg/L (Table 6).

109 Carbamazepine enters the environment largely through discharges from wastewater
110 treatment plants, in which it is not effectively removed [12, 13]. It has been detected in
111 discharges from German plants at concentrations up to 6.3 µg/L [14]. Loos et al. [15]
112 reported a mean concentration of 250 ng/L (maximum 12 µg/L) in studies of 122 European
113 river waters. Indian rivers contained 6-128 ng/L [16] while in Spanish rivers 80-3090 ng/L
114 [17] and in the Pearl River in China, 43 ng/L [18]. It has a relative long half-life of 38 days in
115 natural waters in the presence of sunlight, with photolysis being the major degradation
116 pathway [12]. Tixier et al. [19] reported a half-life of 63 days in Lake Greifensee in
117 Germany, indicating that it was relatively persistent.

118 In all cases, detected concentrations in receiving waters were below the derived GV.
119 The guidelines recommended in Switzerland and Germany [20, 21] are considerably lower

120 (Table 7). The Swiss environmental quality standard (EQS) of 0.5 µg/L was derived by
121 applying an assessment factor of 50 to the most sensitive reliable endpoint, that for
122 reproduction of *Ceriodaphnia dubia* (25 µg/L) [22]. The available fish data were only for a
123 10-d exposure and considered not acceptable for a chronic test, although in Australia and
124 New Zealand, the 7-d test is acceptable for fish embryos and a 21-d test required for juvenile
125 fish [4]. In the Swiss study, the scope of the data analysis included both adverse effects data
126 and biomarker responses in contrast to our focus solely on population-relevant effects [22].
127 Their GV is clearly of low reliability compared to that derived in this paper. Ferrari et al.
128 [23] using a limited dataset and a log-normal distribution in a SSD, determined 95%
129 protection value (reported as a hazardous concentration to 5% of species, HC5) of 2.1 µg/L.
130 (Table 7), comparable to our value of 4.3 µg/L with a large dataset.

131

132 *Diclofenac*

133 Of 13 chronic data for diclofenac, 11 had EC10 or NOEC values suitable for GV
134 derivation. These comprised 2 cladocerans, 1 diatom, 2 green algae, 1 blue-green algae, 1
135 rotifer, 1 angiosperm, 1 arthropod and 2 fish, representing 8 taxonomic groups. The most
136 sensitive species was the midge, *Chironomus tepperi* with an EC10 of 760 µg/L [5].

137

138 Schmitt-Jansen et al. [24] exposed the green alga *Scenedesmus vacuolatus* to
139 diclofenac in ultrapure water to sunlight and noted an increase in toxicity measured as growth
140 inhibition, with time over 6 days, with the EC50 decreasing from 46.3 mg/L to 23 µg/L after
141 6 days. There was a rapid decrease in diclofenac concentrations due to photodegradation and
142 the enhanced toxicity was clearly due to the presence of degradation products. These data
143 were not included as the tests were not conducted in natural waters and the pH was not

144 recorded, nor EC10 values calculated. It is unclear how the results relate to actual field
145 conditions.

146 Concentrations in the range 310-930 ng/L have been detected in the effluents from a
147 Swiss wastewater treatment plant, with concentrations only marginally reduced during
148 passage through the plant [25]. Diclofenac has been detected at <1-12 ng/L in Swiss lakes
149 and 11-310 ng/L in a nearby river [25] and from 110-220 ng/L in the Hölje River in Sweden
150 downstream of a WWTP [26]. Photolysis is the major degradation pathway with half-lives
151 near 3 h at summer temperatures [24] (Buser et al. [25] reported 0.9 h), but up to 2 days in
152 winter in some locations [27]. Diclofenac is ionised at the pH of most waters ($pK_a=4.2$), so is
153 not readily volatilised, nor does it readily attach to particulates [25].

154 The measured concentrations are below the GV derived in this study (Table 6), but
155 would exceed the proposed EQS for the European Commission (reported in Europe (Johnson
156 et al., 2013) (Table 7). A discussion paper on the EU guidelines [28] indicated that these
157 values are derived by applying an assessment factor of 10 to the lowest acceptable NOEC, for
158 a fish. For rainbow trout, both Schwaiger et al. [29] and Triebkorn [30] reported a LOEC of
159 1 $\mu\text{g/L}$ for a histopathological effect, while the latter referred to a threshold of 5 $\mu\text{g/L}$ for
160 histopathological lesions. A NOEC of 0.5 $\mu\text{g/L}$ was reported by Hoeger et al. [31] for
161 monocyte infiltration/accumulation in livers of brown trout exposed to diclofenac for 21
162 days. They concluded that the adverse effects in various organs could 'possibly compromise
163 fish health'. The EQS of 0.05 $\mu\text{g/L}$ proposed by the Swiss Ecotox Centre [32] was based on
164 the application of an assessment factor of 10 to the above NOEC for brown trout.

165 The current Australian and New Zealand approach to biomarker endpoints of this type
166 is that they should not be used in the derivation of water quality guidelines, unless their
167 ecological relevance can be demonstrated [4]. This approach is consistent with that of
168 Hutchinson et al. [33] who advocated that biomarker responses or signals (such as

169 vitellogenin, secondary sexual characteristics, gonadosomatic index, gonad histology, plasma
170 steroids, enzyme induction and gene expression) may provide valuable mechanistic signals to
171 guide chronic testing for adverse effects and, at present, should not be used to directly derive
172 water quality guidelines. Moreover, it is recognized that interpretation of many biomarkers
173 responses in aquatic organisms is highly complex [33-35]. Acceptable population-relevant
174 effects endpoints include survival, length, weight, development, fecundity, fertilisation rate,
175 hatching success and sex ratios. The focus on population-relevant endpoints for setting GVs
176 for pharmaceuticals is also proposed by Caldwell et al. [36, 37].

177 The use of an assessment factor results in a conservative, very low reliability GV. By
178 contrast, the GV derived in this study would be classified as high reliability based on the
179 criteria being adopted for Australian and New Zealand water quality guideline derivation [4].
180 Using a limited data set, Ferrari et al. [23] applied a log normal distribution in an SSD to
181 derive an HC5 that protected 95% of species that was of the same order of magnitude as our
182 value of 770 µg/L.

183 SCHER [28] raised a concern regarding the solubility of diclofenac being exceeded in
184 some of the toxicity tests, however, data from Llinas et al. [38] suggest that this would only
185 be an issue in mildly acidic solutions below the diclofenac pKa. At the pH of natural waters,
186 solubility limitations would not be an issue.

187

188 *Fluoxetine*

189 There is a large toxicity database for fluoxetine, comprising both acute and chronic
190 tests as well as others based on behavioural and biomarker endpoints. Of these only 13
191 reported chronic NOEC or EC/IC10 endpoints, comprising 6 green algae, 1 arthropod, 1
192 angiosperm, 3 crustaceans, 1 gastropod and 1 fish, representing 6 taxonomic groups (Table
193 4). Oakes et al. [39] found that the green alga *Desmodesmus subspicatus* was the most

194 sensitive species to fluoxetine with a NOEC was $\leq 0.6 \mu\text{g/L}$. Given that NOECs are not a
195 reliable endpoint, most jurisdictions, including Australia and New Zealand, recommend the
196 use of EC/IC10 values as a more defensible alternative [4]. In the supplementary information
197 to Oakes et al. [39], the plotted dose response curve showed an IC10 of $1 \mu\text{g/L}$ and so this
198 was included in the database used in this study. Along with this species, the New Zealand
199 mud snail, *Potamopygus antipodarum* was also very sensitive (Table 4) [40, 41].

200 The malformation endpoint for the African clawed frog, *Xenopus laevis* [42] (Table 4)
201 was deemed unacceptable for use in GV derivation as many non-contaminant factors can lead
202 to malformations. The 7-d juvenile fish data for fathead minnow [43] were considered acute
203 and not chronic according to the Australian and New Zealand data selection criteria [4] which
204 require a 21-d test, so this too was not included.

205

206 Fluoxetine is a racemate, a mixture of two stereoisomers with mirror-image structures
207 [4]. The (*R*)-enantiomer is known as dextro-propranolol. The (*S*)-enantiomer is known as
208 levo-fluoxetine. The most common form is as a racemic mixture (1:1) of the stereoisomers,
209 supplied as the hydrochloride. To date only one study has examined the chronic toxicity of
210 the stereoisomers and found that (*S*)-fluoxetine was more toxic than (*R*)-fluoxetine to fathead
211 minnow, *Pimephales promelas*, while there was no significant difference in the responses of
212 *Daphnia magna* [4]. Fluoxetine photodegradation has a relatively long half-life (160 days)
213 [44] and its relatively high K_{ow} means that it binds preferentially to particulate organic matter.

214 Measured concentrations of fluoxetine in natural waters are typically in the ng/L
215 range. Kolpin et al. [45] reported a median concentration of 12 ng/L for a range of US
216 streams, and similar values have been reported for waters in Canada and the UK [39]. WWTP
217 effluent concentrations are typically $<500 \text{ ng/L}$ [46-48].

218 The high reliability GV for fluoxetine derived in this study was 1.6 µg/L for 95%
219 species protection. No reported EQS values could be found, however, a number of studies
220 reported predicted no effects concentrations (PNECs) for fluoxetine in surface waters. These
221 were all obtained by applying assessment factors to the most sensitive data (Table 7). Thus
222 Oakes et al. [39] obtained a PNEC of 0.012 µg/L by applying a factor of 50 to the *D.*
223 *subspicatus* data. Montforts [49] reported a PNEC of 0.031 µg/L using a factor of 1000 with
224 algal toxicity data. Grung et al. [50] reported a PNEC of 0.004 µg/L, while Verlicchi et al.
225 [2] reported a PNEC of 0.05 µg/L. All of these values are conservative and of very low
226 reliability.

227 Sumpter et al. [51] have discussed the fact that both vertebrates and invertebrates use
228 serotonin as a neurotransmitter and, as such, fluoxetine as a serotonin reuptake inhibitor, may
229 have effects on fish (and invertebrate) behaviour (e.g. swimming speed, schooling
230 behaviour). Such non-standard endpoints have not been considered on our GV derivation.

231

232 *Propranolol*

233 Although there are published results for over 20 chronic toxicity tests, only 12
234 reported chronic NOEC or EC10 values, with the remainder only giving EC50 or LOEC
235 values. Although both an EC10 and an EC5 were available for the green algae, *Desmodesmus*
236 *subspicatus*, because of the greater errors around the EC5, the EC10 value was used for
237 guideline derivation [52].

238 Data were obtained for 2 cladocerans, 1 diatom, 2 green algae, 1 blue-green algae, 1
239 rotifer, 1 angiosperm, 1 arthropod and 3 fish, representing 8 taxonomic groups. Of these, the
240 fathead minnow, *Pimephales promelas* [53] and the cladoceran, *Ceriodaphnia dubia*, were

241 the most sensitive [54]. Like fluoxetine, propranolol is a racemate [55], with the most
242 common form a racemic mixture (1:1) of the stereoisomers, supplied as the hydrochloride.

243 Propranolol has been detected in WWTP effluents in Germany at a median
244 concentration of 170 ng/L (290 ng/L maximum) [14] and in Sweden near 30 ng/L [26].
245 Downstream river water concentrations were closer to 12 ng/L (590 ng/L maximum) and 10
246 ng/L respectively. High concentrations are unlikely to persist as the laboratory-determined
247 half-life for photolytic decomposition was 1.1 h [56]. For sunlight exposure, Liu et al. [57]
248 extrapolating from laboratory studies calculated a half-life closer to 1 day in summer and 8
249 days in winter, with photodegradation being up to 19 times faster than biodegradation.

250 Our study yielded a high reliability guideline value for propranolol of 14 µg/L. This is
251 almost 100-fold higher than the value recommended for Switzerland [32]. Their low
252 reliability EQS of 0.16 µg/L (Ecotox Centre, 2013d) used an assessment factor of 50 applied
253 to a NOEC of 8 µg/L for *Ceriodaphnia dubia* reproduction [54] (although the value reported
254 in Ferrari et al. was actually 9 µg/L).

255

256

CONCLUSIONS

257 High reliability GVs have been derived for carbamazepine, diclofenac, fluoxetine and
258 propranolol in fresh waters applying a Burr Type III distribution in SSDs of chronic toxicity
259 data (NOECs or EC10s). Data were quality assured and had to meet acceptability criteria for
260 ‘chronic’ endpoints. Sub-chronic biomarker data were excluded from the derivation and only
261 data for ecologically relevant, population-related effects were included. The derived GVs for
262 95% species protection were 4.3, 770, 1.6 and 14 µg/L respectively, for the four
263 pharmaceuticals. These values significantly higher than the low reliability values derived for
264 the European Commission, Switzerland or Germany that are based on the application of

265 assessment factors to the most sensitive endpoint. They are not exceeded in recent data for
266 rivers and streams receiving pharmaceutical containing effluents from WWTPs.

Table 1. Key properties of the studied pharmaceuticals

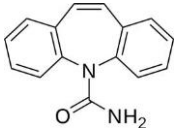

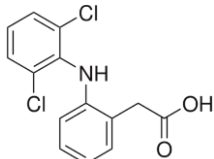

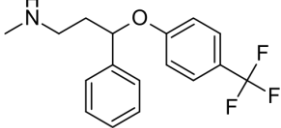

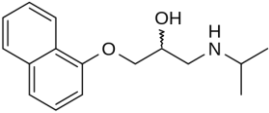

Pharmaceutical	Chemical Structure	Common name	Log K_{ow}	Solubility, mg/L	pKa	Reference
Carbamazepine (anti-convulsant and mood stabiliser)	 MW =236.3	Tegretol	2.45	112	13.9	[54]
Diclofenac (non-steroidal anti-inflammatory)	 MW=296.1	Voltarin	4.51	2,430	4.2	[54]
Fluoxetine (anti-depressant)	 MW=309.3	Prozac, Sarafem	4.05	10,800	9.4	[39, 44, 58]
Propranolol (beta-blocker)	 MW=259.3	Inderal	3.12	609	9.5	[54, 59]

Table 2. Chronic data used in carbamazepine guideline derivation

Taxonomic group	Common name	Scientific name	Life stage	Exposure duration (d)	Test medium	Test endpoint	Toxicity estimate	Toxicity value (mg/L)	pH	Temp (°C)	Reference
Blue-green algae	Blue-green algae	<i>Synechococcus leopolensis</i>	-	4	Moderately hard water	Growth inhibition	NOEC	17.5			[54]
Green algae	Green algae	<i>Pseudokirchneriella subcapitata</i>	-	4	Freshwater	Growth inhibition	NOEC	0.52			[60]
Green algae	Green algae	<i>Chlorella vulgaris</i>	-	2	Freshwater	Growth inhibition	EC10	13^a		22	[61]
Arthropoda	Midge	<i>Chironomus tepperi</i>	Embryo	7	Freshwater	Larval survival	EC10	4.0			[5]
Diatom	Diatom	<i>Cyclotella meneghiniana</i>	-	4	Freshwater	Growth inhibition	NOEC	10.0			[54]
Rotifer	Rotifer	<i>Brachionus calyciflorus</i>	-	2	Freshwater	Reproduction	NOEC	0.38			[54]
Cnidarian	Cnidarian	<i>Hydra attenuate</i>		3	Freshwater	Morphology changes	NOEC	1	7	20	[62]
Crustacean	Water flea	<i>Ceriodaphnia dubia</i>	-	7	Freshwater	Reproduction	NOEC	0.025			[54]
Crustacean	Water flea	<i>Daphnia magna</i>		21	Freshwater	Reproduction	NOEC	0.4			[22, 63]
Fish	Zebrafish	<i>Danio rerio</i>	Embryo	10		Mortality	NOEC	25		23	[54]
Fish	Golden perch	<i>Macquaria ambigua</i>	Embryo	7	Freshwater	Larval survival	EC10	1.1			[5]

^a Estimated from dose-response curve

Table 3. Chronic data used to derive diclofenac guideline

Taxonomic group	Common name	Scientific name	Life stage	Exposure duration (d)	Test medium	Test endpoint	Toxicity estimate	Toxicity value (mg/L)	pH	Temp (°C)	Reference
Blue-green algae	Blue-green algae	<i>Synechococcus leopolensis</i>	-	4	Moderately hard water	Growth inhibition	NOEC	10			[54]
Green algae	Green algae	<i>Pseudokirchneriella subcapitata</i>	-	4	Moderately hard water	Growth inhibition	NOEC	10			[54]
Green algae	Green algae	<i>Desmodesmus subspicatus</i>	-	3	Freshwater	Growth inhibition	NOEC	50			[64]
Arthropod	Midge	<i>Chironomus tepperi</i>	Embryo	7	Freshwater	Larval survival	EC10	0.76			[5]
Angiosperm	Duckweed	<i>Lemna minor</i>	-			Growth inhibition	NOEC	3.5			[5]
Diatom	Diatom	<i>Cyclotella meneghiniana</i>	-	4	Freshwater	Growth inhibition	NOEC	10.0			[54]
Rotifer	Rotifer	<i>Brachionus calyciflorus</i>	-	2	Freshwater	Reproduction	NOEC	12.5			[54]
Crustacean	Water flea	<i>Ceriodaphnia dubia</i>	-	7	Freshwater	Reproduction	NOEC	1.0			[54]
Crustacean	Water flea	<i>Daphnia magna</i>	-	21	Reconstituted hard water	Reproduction	NOEC	10	7.8	25	[65]
Fish	Zebrafish	<i>Danio rerio</i>	Embryo	10	Freshwater	Mortality	NOEC	4.0		23	[54]
Fish	Golden perch	<i>Macquaria ambigua</i>	Embryo	7	Freshwater	Larval survival	EC10	5.92			[5]

Table 4. Chronic data used to derive the fluoxetine guideline

Taxonomic group	Common name	Scientific name	Life stage	Exposure duration (d)	Test medium	Test endpoint	Toxicity estimate	Toxicity value (µg/L)	pH	Temp (°C)	Reference
