3 **1. Abstract:** This paper offers an explanation for the wide spatial variations in choice of  
4  
5 insolvency route by personal debtors across local authorities in England and Wales. It is  
6  
7 argued that formal bankruptcy has a more negative impact on social capital through  
8  
9 stigma effects than the alternative of Individual Voluntary Arrangements. Consequently,  
10  
11 spatial variations in choices are related to variations in social capital. The hypotheses  
12  
13 derived from this approach are tested through the use of spatial econometric models  
14  
15 utilising data from England and Wales. The results provide support for a positive link  
16  
17 between variables related to social capital (age, mobility and home ownership) and choice  
18  
19 of IVAs. It is argued that avoidance of stigma costs provides an explanation for the  
20  
21 apparent paradox of the significant growth of IVAs despite their high cost to debtors  
22  
23 compared to bankruptcy. Whilst there is only limited support for impacts directly related  
24  
25 to the urban-rural environment, significant spatial interdependencies in choices across  
26  
27 neighbouring areas are also uncovered.

## 36 **2. Introduction**

37  
38 In recent decades, there has been a dramatic rise in the number of personal insolvencies in  
39  
40 many leading economies (Bishop and Gripaios, 2010). The rise has been particularly striking  
41  
42 in England and Wales, where the insolvency rate increased fifteen-fold in the quarter of a  
43  
44 century following the mid-1980s, with particularly rapid growth occurring from 2003 to  
45  
46 2006. One notable development has been the rise in the number of Individual Voluntary  
47  
48 Arrangements (IVAs) which, since their introduction in 1986, have grown to account for over  
49  
50 50% of personal insolvencies. This growth has attracted critical attention as the  
51  
52 administration fees for IVAs can be substantial, potentially providing an incentive for  
53  
54  
55  
56  
57  
58  
59  
60

1  
2  
3 providers to recommend this option rather than the alternative of bankruptcy (Walters,  
4  
5 2009).  
6  
7

8  
9  
10 One interesting feature of the growth of IVAs is the existence of wide regional variations in  
11  
12 their usage. Whilst several studies have attempted to explain spatial variations in  
13  
14 insolvency choices, most have utilised data from the USA and focused on differences in laws  
15  
16 across states (McIntyre et al, 2010). Such an approach is of limited value for England and  
17  
18 Wales and other countries in which there is a common legal system. This paper fills this gap  
19  
20 by developing an explanation based on spatial aspects of stigma and social capital. It is  
21  
22 argued that bankruptcy attracts considerable social stigma and has a more negative impact  
23  
24 on social capital than IVAs. Consequently, spatial variations in insolvency choices are  
25  
26 related to spatial variations in social capital; these may, in turn, be influenced by the  
27  
28 composition of an area's population, the impact of the urban-rural environment and spatial  
29  
30 spillover effects across neighbouring locations.  
31  
32  
33  
34  
35  
36  
37  
38  
39

40 The analysis begins with an overview of current legal arrangements governing insolvency  
41  
42 and recent trends in insolvency choices. This is followed by an examination of alternative  
43  
44 explanations for insolvency choice, including a discussion of the role of stigma, social capital,  
45  
46 the urban-rural environment and spillover effects. The derived hypotheses are then tested  
47  
48 through the estimation of spatial econometric models for sub-regions of England and Wales.  
49  
50 The results provide support for a positive link between variables associated with social  
51  
52 capital (age, homeownership and mobility) and choice of IVAs. Whilst there is limited  
53  
54 support for a direct influence of the urban-rural environment, significant spatial  
55  
56  
57  
58  
59  
60

1  
2  
3 interdependencies are uncovered. The final section discusses the implications of the  
4  
5 research findings.  
6

8  
9

### 10 11 **3. Personal Insolvency in England and Wales** 12

13  
14 Personal Insolvency arises if an individual is unable to pay their debts as payments fall due.  
15  
16 The legal process prior to the 1986 Insolvency Act primarily involved bankruptcy - a form of  
17  
18 *liquidation insolvency* in which the debtor surrenders non-exempt assets to creditors in  
19  
20 return for a discharge of unsecured debts and retention of future income. Asset exemptions  
21  
22 are relatively sparse, encompassing only the tools of trade that enable pursuit of  
23  
24 employment and items necessary for basic needs. If debts are secured on an asset such as a  
25  
26 house, the secured creditor may acquire the asset and any shortfall can be included within  
27  
28 the bankruptcy as an unsecured debt. Un-discharged bankrupts are subject to certain job  
29  
30 restrictions and disclosure of bankruptcy is required for credit applications. After a defined  
31  
32 period most unsecured debts are discharged and the individual is free to have a fresh start.  
33  
34  
35  
36  
37  
38  
39  
40  
41  
42

43 Prior to the 1986 Insolvency Act, a second option was technically available - a Deed of  
44  
45 Arrangement. This procedure embodied a *payment plan* approach in which individuals  
46  
47 retained their assets but made payments out of ongoing income (Di Martino, 2005).  
48  
49 However, Deeds accounted for less than 1% of insolvencies by the mid-1980s (Pond, 2002).  
50  
51 IVAs sought to provide an updated and more attractive payment plan. Under an IVA, the  
52  
53 debtor proposes a plan for partial debt repayment under the guidance of a licensed  
54  
55 Insolvency Practitioner (IP); creditors may then accept, reject or propose changes to the  
56  
57  
58  
59  
60

1  
2  
3 plan. If 75% or more of creditors accept, the agreement becomes binding and typically lasts  
4  
5 for five years. Although there may be a requirement to release some equity in an owned  
6  
7 property by re-mortgaging, an IVA enables an individual to retain their property. The IP  
8  
9 supervises the arrangement and pays creditors in return for a fee paid by the debtor. A  
10  
11 fundamental aspect of IVAs is that they require the mutual agreement of debtors and  
12  
13 creditors; this differs from bankruptcy where either party may petition the court without  
14  
15 the agreement of the other party.  
16  
17  
18  
19  
20  
21  
22  
23

24 Initially the growth of IVAs was relatively modest, reaching 4-5,000 per annum by the mid-  
25  
26 1990s. However, the popularity of the arrangements grew markedly in the mid-2000s and,  
27  
28 by 2014 the annual number of IVAs had reached 51,000 representing 52% of individual  
29  
30 insolvencies. Statistics on insolvencies at the sub-regional level are only available from 2000  
31  
32 onwards. A recent analysis by Bishop (2013) concludes that there were significant spatial  
33  
34 variations in total insolvencies per capita over the period 2000 to 2007. Similar variations  
35  
36 are evident for IVAs. In 2011, for example, the average rate of IVAs per ten thousand adults  
37  
38 was 11.08; however, at the sub-regional level, rates varied from 2.97 to 23.17. The data also  
39  
40 suggest that the spatial distribution of choices is non-random. Figure 1, for example, shows  
41  
42 areas with above or below average rates of IVAs to bankruptcies in 2011. One obvious  
43  
44 feature is the cluster of low IVA areas across South West England and much of central and  
45  
46 northern Wales, whilst higher rates of IVAs are evident across the central spine of England.  
47  
48 This pattern suggests that interdependencies across neighbouring areas may be an  
49  
50 important issue.

#### 8 **4. Determinants of Insolvency choice**

9

10  
11  
12 Theoretical approaches to explaining insolvency choices have typically adopted a  
13 perspective in which rational economic agents make decisions on the basis of utility  
14 maximisation (White, 2005; McIntyre et al, 2010). These approaches are invariably based on  
15 the system in the USA and the analysis of spatial variations in insolvency choices has focused  
16 on differences in laws across states. However, these legal variations are not relevant in  
17 England and Wales where there is a common legal system. Nevertheless, there is one  
18 feature of the system in England and Wales that suggests an alternative explanation for  
19 spatial variations in choices. In the USA, creditors do not have to agree to a payment plan  
20 proposed by the debtor for the plan to be approved: the final authority is vested in the  
21 court. This contrasts with England and Wales where IVAs are only established through  
22 agreement between debtors and creditors. From a rational choice perspective, this implies  
23 that both parties must perceive additional net benefits compared to bankruptcy to co-  
24 operate on the establishment of an IVA. If these net benefits differ across space, then this  
25 may result in spatial variations in insolvency choices.  
26

43  
44  
45  
46  
47

48 On the surface, the need for co-operation creates a paradox. IVAs impose a greater financial  
49 burden on debtors than bankruptcy due to higher payments to creditors (Pond, 2002) and  
50 substantially greater fees (Business, Innovation and Skills Committee, 2013). However,  
51 debtors have opted for IVAs in increasingly greater numbers. This suggests that there must  
52 be other factors that motivate the choice of IVAs. One possible explanation is the influence  
53  
54  
55  
56  
57  
58  
59  
60

1  
2  
3 of IPs who provide advice to consumers but have a financial interest in IVAs due to the fees  
4  
5 involved. A piece of evidence that might support this is the rise in IVA failure rates during  
6  
7 the period in which IVA growth surged in the mid-2000s. However, this resulted in a dispute  
8  
9 between creditor institutions and IVA suppliers; as a consequence, IVA providers agreed to a  
10  
11 new protocol and failure rates have since fallen (Walters, 2009). Whilst poor advice may  
12  
13 have led to a high failure rate, the undermining of the reputation of providers prompted  
14  
15 countervailing mechanisms to regulate the industry. Indeed, a survey by R3 (2010) found  
16  
17 that two thirds of those undertaking IVAs had discussed alternatives with advisors and only  
18  
19 12% felt that they had been pushed towards IVAs. An alternative explanation for the rise of  
20  
21 IVAs proposed in this paper is that debtors derive additional benefits from IVAs in terms of  
22  
23 reduced stigma costs compared to bankruptcy. Debtors can induce creditors to opt for IVAs  
24  
25 by offering greater financial payments and hence both parties benefit from co-operation. A  
26  
27 spatial dimension arises through a recognition that the incentive to avoid stigma costs may  
28  
29 vary across space due to the links between stigma and social capital.  
30  
31  
32  
33  
34  
35  
36  
37  
38  
39

40 The concept of stigma refers to the social devaluation of an individual who deviates from a  
41  
42 social norm. A theoretical basis for stigma can be grounded within the concept of social  
43  
44 capital, which can be broadly defined as the social networks, norms, reciprocity and trust  
45  
46 that arise from human interactions in a community (Muir, 2011). Different theoretical  
47  
48 perspectives conceptualise social capital in diverse ways. This paper adopts an approach  
49  
50 which views social capital in terms of the assets produced by network interactions which  
51  
52 yield potential benefits (or costs) to those involved (Hansen and Hansen, 2008). This allows  
53  
54 the incorporation of social capital within a rational choice perspective in which individuals  
55  
56  
57  
58  
59  
60

1  
2  
3 invest in accumulating capital to acquire the benefits from such investments (Rutten and  
4  
5 Boekema, 2007).  
6  
7  
8  
9

10  
11 Social capital is a concept that has attracted interest amongst spatial analysts due to a  
12  
13 recognition that network interactions may have an important spatial dimension. One  
14  
15 approach argues that spatial variations in the impact of network interactions arises from the  
16  
17 differing nature of the environments within which individuals live. Lannoo et al (2011) note  
18  
19 two strands to this argument. First, a "traditional view" that urban locations foster lower  
20  
21 levels of individual social capital due to the diverse social nature of urban settlements and  
22  
23 the greater anonymity and ephemeral nature of relationships. More homogenous, rural  
24  
25 communities in which individuals share common backgrounds, find it easier to build the  
26  
27 trust upon which effective network ties are based (Vermuelen et al, 2012). Second, urban  
28  
29 environments create different types of social capital to rural areas (Debertin and Goetz,  
30  
31 2013). The heterogeneity, size and density of urban environments increases the range of  
32  
33 choices available in forming network ties. Individuals living in rural communities have fewer  
34  
35 options and are characterised by more 'bonding' social capital involving family and friends  
36  
37 in contrast to urban locations where 'bridging' or between group social capital dominates  
38  
39 (Roskruge et al, 2013).  
40  
41  
42  
43  
44  
45  
46  
47  
48  
49  
50

51 An alternative view is that urban-rural differences arise from the different characteristics of  
52  
53 the population who live in these environments (Debertin and Goetz, 2013). If social capital  
54  
55 varies with individual characteristics, then areas with different demographic and social  
56  
57  
58  
59  
60

1  
2  
3 structures will exhibit variations in social capital. It is the demographic and social  
4  
5 composition of an area rather than the environment *per se* that creates differences in social  
6  
7 capital. Finally, there is a view that urban-rural differences have been eroded due to the  
8  
9 widespread availability of communication and transport technologies, which have reduced  
10  
11 the costs of interaction across space. Thus, even if, historically, the urban-rural distinction  
12  
13 did impact on social capital, it is no longer of significance. However, it is important to  
14  
15 recognise that this approach does not imply that spatial factors are unimportant. If  
16  
17 neighbouring urban and rural areas are linked together due to commuting and transport  
18  
19 linkages, they may form spatial clusters distinct from more remote areas where transport  
20  
21 costs still limit face to face interactions.  
22  
23  
24  
25  
26  
27  
28  
29  
30

31 The norms, values and trust that characterise networks may have a spatial dimension as  
32  
33 they are related to the specific context within which interactions occur. Such trust and  
34  
35 norms can be regarded as intangible assets that facilitate co-operation and create positive  
36  
37 externalities by strengthening social networks and attitudes towards certain types of  
38  
39 behaviour (Rutten and Boekema, 2007). However, individuals who violate norms may lose  
40  
41 social status, adversely affecting the benefits they obtain from co-operation and this may  
42  
43 affect job prospects and earning potential. In this regard, there is a clear link from social  
44  
45 capital to the concept of stigma: the threat of stigmatization provides an incentive to  
46  
47 conform to norms.  
48  
49  
50  
51  
52  
53  
54  
55  
56  
57  
58  
59  
60

1  
2  
3 Modern approaches emphasise that stigma is related to the context in which it occurs (Bos  
4  
5 et al, 2013). Individuals who benefit from significant investments in social capital suffer  
6  
7 potentially greater costs from violating social norms than those with fewer investments, as a  
8  
9 greater range of network ties may be adversely affected. Consequently, spatial variations in  
10  
11 social capital create spatial variations in the impact of violating social norms and this affects  
12  
13 the incentives to engage in certain types of behaviour. There is support for such effects  
14  
15 from studies that have found that that the incentives to engage in criminal behaviour are  
16  
17 affected by the extent to which local networks informally punish (i.e. stigmatise) behaviour  
18  
19 that violates social norms (Akçomak and ter Weel, 2012).  
20  
21  
22  
23  
24  
25  
26  
27  
28

29 If stigma effects are to explain insolvency choices, there must be substantive differences  
30  
31 between the stigma attached to bankruptcy and IVAs. Efrat (2006a) argues that a strong  
32  
33 stigma has historically been attached to bankruptcy as it has been associated with *wilful*  
34  
35 conduct that violates significant social norms such as trust, honour and thrift. Bankrupts are  
36  
37 regarded as having violated the trust of their creditors, failed to honour the terms of their  
38  
39 legal agreements and managed their financial affairs in a profligate manner. The view that  
40  
41 the conduct is wilful reflects an underlying view that the individual is autonomous and  
42  
43 responsible for their own decisions (Mols, 2012). The breaking of these norms involves the  
44  
45 individual's own deliberate conduct, in terms of fraudulent behaviour or financial  
46  
47 mismanagement, rather than the impact of unavoidable external events.  
48  
49  
50  
51  
52  
53  
54  
55  
56  
57  
58  
59  
60

1  
2  
3 The view that bankruptcy attracts a strong social stigma has deep historical and cultural  
4 roots as illustrated by the social condemnation of bankrupts in British bankruptcy law. Early  
5 laws regarded debtors as criminals who were deliberately dishonest and fraudulent (Di  
6 Martino, 2005). The legal system gradually developed a more nuanced approach and  
7 modern law primarily seeks the restitution of debts through financial means. Additional  
8 stigma arises as a consequence of restrictions that may be imposed by the court including  
9 the prohibition from certain professions and the requirement to disclose bankruptcy in  
10 credit applications (Maroto, 2012). Those deemed culpable or dishonest may face a  
11 Bankruptcy Restriction Order (BRO) which extends some of these restrictions for between 2  
12 and 15 years. These extended restrictions vary from case to case but typically include a  
13 prohibition on becoming a company director and the necessity to reveal the bankruptcy in  
14 applications for credit of over £500. The breaching of a BRO is a criminal offence; this  
15 reflects a continuation of the view that wilful bankrupts deserve significant punishment.  
16 This may affect access to credit markets, the price of credit and employment prospects,  
17 leading to cumulative financial disadvantage. Public shaming in the local community has also  
18 been a consistent feature of the bankruptcy process. Until 2009, the names and addresses  
19 of bankrupts were published in the local press and, whilst this is no longer routinely done,  
20 details are published in the London Gazette and the Insolvency Register both of which can  
21 be searched on-line.

48  
49  
50  
51

52 Information on contemporary attitudes to bankruptcy is scarce. A review of the 2002  
53 Enterprise Act concluded that bankruptcy stigma remains as it was prior to the Act (The  
54 Insolvency Service, 2007). Another recent study found that a majority of an advice firms'  
55  
56  
57  
58  
59  
60

1  
2  
3 clients whom were advised that bankruptcy was the best option did not pursue it, primarily  
4  
5 due to the perceived stigma (Credit Counselling Services, 2007). The Insolvency Service have  
6  
7 also tracked attitudes in several surveys which have shown that, whilst there has been a  
8  
9 small fall in the proportion of individuals thinking that stigma is attached to bankruptcy, a  
10  
11 strong stigma still remains (The Insolvency Service, 2009). This stigma is associated primarily  
12  
13 with the difficulty of accessing future credit, social embarrassment and the potential loss of  
14  
15 the home.  
16  
17  
18  
19  
20

21  
22 There are a number of reasons why IVAs might involve lower stigma costs than bankruptcy.  
23  
24 First, by avoiding usage of the term bankruptcy an individual avoids the historical, cultural  
25  
26 opprobrium attached to the term. The payment plan approach is considered a new, modern  
27  
28 form of debt management, whereas bankruptcy is a term associated with wrong-doing. The  
29  
30 provision of IVAs by many reputable financial institutions lends credence to the notion that  
31  
32 an IVA is a standard financial product. Indeed, there are numerous debt advice and IP web-  
33  
34 sites which explicitly state that IVAs have less of a social stigma than bankruptcy.  
35  
36  
37  
38  
39  
40

41  
42 Second, IVAs embody the concept of an 'earned fresh start' in which individuals make  
43  
44 restitution for their violation of trust by partially paying off their debts. This is in contrast to  
45  
46 bankruptcy which typically involves individuals being discharged from most debts, with  
47  
48 creditors receiving minimal recompense (Pond, 2002). Third, until 2009, an IVA permitted a  
49  
50 higher level of confidentiality than bankruptcy as the arrangement was not advertised in the  
51  
52 local press (Walters, 2009). Finally, in principle, an IVA permits retention of the home and  
53  
54 avoids the loss of social capital and sentiment attached to the home.  
55  
56  
57  
58  
59  
60

1  
2  
3 Some direct evidence that IVAs attract a lower stigma is available from a recent survey  
4  
5 which found that that avoiding formal bankruptcy was the prime reason (70% of those  
6  
7 surveyed) given for taking out an IVA (R3, 2010). In addition, The Insolvency Service (2008)  
8  
9 conducted a survey of a sample of debtors who were asked to give the primary reason for  
10  
11 taking out an IVA. The three main reasons were: wanting to pay back creditors, maintaining  
12  
13 control of finances and avoiding the stigma of bankruptcy. Thus, in addition to directly  
14  
15 avoiding the stigma of bankruptcy, debtors view IVAs as a mechanism to re-establish  
16  
17 financial management of their affairs and make restitution to debtors, which may also  
18  
19 indirectly help to reduce stigma.

## 27 **5. Analytical framework, data and hypotheses**

28  
29  
30  
31 The analytical framework proposed in this article can be summarised as follows: individuals  
32  
33 invest in social capital to acquire the benefits of assets produced by network interactions  
34  
35 within their local community. These interactions are characterised by certain norms, values  
36  
37 and trust; individuals who violate these norms may be stigmatised, adversely affecting the  
38  
39 benefits they obtain from these networks. The greater the scale of an individual's stock of  
40  
41 social capital, the greater will be the negative impacts arising from stigma as a greater range  
42  
43 of network ties are affected. As bankruptcy attracts a greater stigma than IVAs, those with  
44  
45 high stocks of social capital have an incentive to choose IVAs. Consequently, spatial  
46  
47 variations in average levels of local social capital create spatial variations in insolvency  
48  
49 choices.  
50  
51

55  
56  
57  
58  
59  
60

1  
2  
3 Direct empirical testing of the impact of stigma on insolvency is problematic as it is  
4  
5 intrinsically difficult to measure. However, the linking of stigma to social capital offers a  
6  
7 mechanism for measuring these effects by utilising variables related to local social capital.  
8  
9 Of course, measuring social capital is not an easy task as data on either the accumulation of  
10  
11 local social capital (e.g. through participation in community activities) or direct measures of  
12  
13 local social capital (e.g. trust) is often not readily available. One approach that offers  
14  
15 potential has been adopted by Agwaral et al (2011) based on Glaeser et al's (2002)  
16  
17 framework in which rational individuals invest in social capital on the basis of the relevant  
18  
19 benefits and costs, which vary according to individual characteristics. Thus, variations in  
20  
21 insolvency choices across communities can be related to the factors that influence location-  
22  
23 specific social capital investment decisions, together with a range of control variables that  
24  
25 reflect different economic, social and geographic conditions.  
26  
27  
28  
29  
30  
31  
32  
33  
34  
35

36 The remainder of this paper focuses upon an analysis of the impact of stigma on the choice  
37  
38 between IVAs and bankruptcy (including Debt Relief Orders – a fast-track bankruptcy  
39  
40 arrangement) across the 348 local administrative units in England and Wales in 2011. All  
41  
42 data were derived from the 2011 population census apart from insolvencies which were  
43  
44 obtained from The Insolvency Service and migration and earnings which were sourced from  
45  
46 the Office of National Statistics (ONS). The units of observation vary in nature and include  
47  
48 rural areas, towns, cities and suburbs of urban agglomerations, facilitating an examination  
49  
50 of the impact of these factors. Whilst there are limitations to a cross-section approach,  
51  
52 these are mitigated through the use of spatial regression techniques that account for spatial  
53  
54 dependencies and omitted regionally correlated variables. Given that insolvent individuals  
55  
56  
57  
58  
59  
60

1  
2  
3 face a choice between IVAs and Bankruptcy, the dependent variable was defined in logit  
4  
5 form as  $IVABANK = \ln(q/1-q)$ , where  $q$  is the probability of choosing an IVA in a region and  
6  
7  $(1-q)$  the probability of choosing bankruptcy.  
8  
9

10  
11  
12 Three variables identified as being of particular relevance to the social capital investment  
13  
14 decision in the Glaeser et al (2002) model were utilised. First, age: individuals have a strong  
15  
16 incentive to invest in social capital at early stages of their life cycle as lifetime returns are  
17  
18 significant. However, the incentive falls in later years as the expected returns fall. Thus, the  
19  
20 model predicts an inverted-U shaped relationship between age and social capital, with the  
21  
22 stock of individual social capital accumulated by past investments peaking in mid-age where  
23  
24 there is, consequently, the greatest incentive to avoid stigma. In the reported results, age  
25  
26 effects are measured by the proportion of the local population in the 30-44 age groups  
27  
28 (AGE3044) when the incentive to invest in social capital should be highest. A positive  
29  
30 relationship is expected between this variable and the choice of IVAs. However, it is  
31  
32 important to note that age may reflect factors other than social capital. For example, those  
33  
34 in the mid-age group may be individuals who have relatively stable careers and employment  
35  
36 opportunities in contrast to younger people who may be at the start of their working life  
37  
38 without a clear career path. Creditors may be more willing to agree to IVAs with the mid-age  
39  
40 group as the risks of IVA failure may be perceived as lower.  
41  
42  
43  
44  
45  
46  
47  
48  
49

50 The second variable is labour mobility. Social capital arises from the network benefits of  
51  
52 belonging to a community, unlike human capital which moves with an individual, social  
53  
54 capital is relatively immobile (Buckley and Brinig, 1998). Individuals who are mobile have  
55  
56 less incentive to invest in local social capital due to lower expected benefits. They may also  
57  
58  
59  
60

1  
2  
3 have reduced reputational concerns arising from behaviour that violates norms and imposes  
4 stigma costs. Thus, sub-regions characterised by high levels of labour mobility may have  
5 lower average levels of social capital and relatively higher rates of bankruptcy. The impact of  
6 mobility is measured by the turnover of population via internal migration, represented by  
7 MOB – (out-migrants plus in-migrants per 1000 resident population). (In initial runs of the  
8 model, inward and outward migration were included as separate variables; however, these  
9 variables are highly correlated and including both raises issues of multicollinearity. Running  
10 the model with either individually yields similar results to those for the combined variable  
11 and hence MOB was used for the final analysis.)  
12  
13  
14  
15  
16  
17  
18  
19  
20  
21  
22  
23  
24  
25

26 The third social capital variable is home ownership, measured by OWN - the proportion of  
27 the population owning their own property. The high transaction costs involved in selling  
28 property tends to reduce mobility, thereby increasing the incentive to invest in location-  
29 specific social capital (Roskrug et al, 2013). Moreover, homeowners have an incentive to  
30 invest in social capital that increases local property values, whilst the sentiment attached to  
31 the home may raise its value above the market value making the owner reluctant to  
32 liquidate the asset through bankruptcy. Thus, high rates of home ownership should imply a  
33 higher average level of social capital and have a positive impact on the choice of IVAs. Of  
34 course, it is plausible that the possibility of realising the value of an owned home may make  
35 bankruptcy an attractive option for creditors and this may partially offset this positive  
36 impact on IVA choice.  
37  
38  
39  
40  
41  
42  
43  
44  
45  
46  
47  
48  
49  
50  
51  
52  
53  
54

55 In addition to the social capital variables, a number of control variables were included. First,  
56 less opprobrium has historically been attached to bankrupt entrepreneurs than to consumer  
57  
58  
59  
60

1  
2  
3 debtors as business failure is partly regarded as a result of risk-taking entrepreneurship  
4  
5 rather than a deliberate violation of social norms. Consequently, it is plausible that there are  
6  
7 lower stigma costs for self-employed insolvents. This was taken into account by the  
8  
9 inclusion of SELF, defined as the proportion of the population who were full time self-  
10  
11 employed. It is hypothesised that there will be a negative relationship between SELF and IVA  
12  
13 choice. Second, it is necessary to control for variations in economic circumstances across  
14  
15 areas. A recent survey of individuals with debt problems concluded that those on average  
16  
17 incomes were more likely to opt for IVAs (R3, 2010). In order to measure the impact of  
18  
19 differences in incomes, the (squared) difference between median average earnings in a sub-  
20  
21 region and average median earnings across the sample as a whole (WMED) was included in  
22  
23 the analysis. The hypothesis is that the choice of IVAs will be greatest in those sub-regions  
24  
25 with a median income closest to the sample median and negatively related to deviations  
26  
27 from this median.  
28  
29  
30  
31  
32  
33  
34  
35

36 Third, attitudes to insolvency might be affected by knowledge of the insolvency system. In  
37  
38 areas with a high rate of insolvency, knowledge concerning insolvency procedures, personal  
39  
40 knowledge of insolvents and the merits of alternative options may become widespread.  
41  
42 Gathergood (2005) found a strong relationship between the likelihood an individual would  
43  
44 consider bankruptcy and personal association with a bankrupt, suggesting a relationship  
45  
46 between past levels of bankruptcy and current rates. The impact on the choice between  
47  
48 insolvency routes is less clear. However, if information promotes better decision making and  
49  
50 knowledge concerning the high cost of IVAs, high rates of insolvency might lead to lower  
51  
52 rates of IVAs. This was taken into account by including the average rate of total insolvencies  
53  
54 over the previous three year period (INSOL) as an explanatory variable.  
55  
56  
57  
58  
59  
60

1  
2  
3  
4  
5 Other control variables reflecting socio-economic status that might plausibly affect choices  
6  
7 (e.g. occupation) were also included as control variables but proved to be insignificant; for  
8  
9 parsimony these are not reported in the subsequent analysis. The final aspect of the  
10  
11 modelling process was the incorporation of spatial effects. The previous discussion has  
12  
13 noted that social capital may vary across rural and urban areas. However, there are differing  
14  
15 views as to whether the impact arises from the nature of the rural-urban environment or  
16  
17 compositional effects. In the latter case, the incorporation of social capital and control  
18  
19 variables related to demographic and social characteristics will account for many of these  
20  
21 factors. However, if environmental effects are important, it is necessary to include direct  
22  
23 measures. Preliminary analysis experimented with a number of measures including the  
24  
25 percentage of population living in urban areas, population density and dummy variables  
26  
27 related to rural-urban classification schemes. The results were weak, with all measures (bar  
28  
29 one dummy variable) having an insignificant impact. These negative results (and the  
30  
31 significance of other variables) might lend some support to the view that it is compositional  
32  
33 effects rather than the urban-rural environment that impacts on social capital and  
34  
35 insolvency choices.  
36  
37  
38  
39  
40  
41  
42  
43  
44

45 For the sake of parsimony, the reported results omit the urban-rural variables with the  
46  
47 exception of the significant dummy variable SUBDUM, coded as 1 for areas defined as  
48  
49 having suburban traits in the official 2011 area classification scheme and 0 otherwise. This  
50  
51 scheme classifies areas into broad groupings on the basis of a cluster analysis of a range of  
52  
53 variables. SUBDUM contains 39 local authorities which are typically characterised by  
54  
55 populations concentrated in urban conurbations in the transitional areas between urban  
56  
57  
58  
59  
60

1  
2  
3 centres and suburbia. These areas are primarily but not exclusively located in the South East  
4  
5 of England and, in particular, in Outer London boroughs.  
6  
7

## 8 9 10 **6. Method and Results**

11  
12  
13  
14  
15 Table 1 presents the descriptive statistics of the variables (for ease of interpretation, MED  
16  
17 refers to median earnings rather than the squared deviation WMED). The correlation matrix  
18  
19 (Table 2) shows that correlations between independent variables are generally low (all  
20  
21 below 0.5 apart from age and ownership) providing no initial indication of collinearity issues.  
22  
23  
24 The mapping data presented earlier suggest that the dependent variable may not be  
25  
26 distributed randomly across space. This creates problems for OLS regression and hence it is  
27  
28 essential to test for spatial autocorrelation. This requires specification of a spatial weight  
29  
30 matrix ( $W$ ) indicating the nature of the interaction across areas. With  $i = 1 \dots N$  locations,  $W$   
31  
32 is an  $N \times N$  matrix with non-zero elements in the  $i$ th row for locations which are  
33  
34 “neighbours” to  $i$ . Neighbours may be defined on the basis of geographical contiguity or  
35  
36 distance. Using a contiguity weight matrix (with neighbours defined as areas having  
37  
38 contiguous boundaries and row weights standardised to sum to 1), the Moran test for  
39  
40 spatial autocorrelation was significant (Moran  $I = 0.1038$ ,  $p$ -value = 0.0009). This conclusion  
41  
42 was robust to alternative specifications of  $W$  based on a variety of distance measures. This  
43  
44 suggests evidence of positive global spatial autocorrelation involving geographical clustering  
45  
46 of areas with similar values of the dependent variable.  
47  
48  
49  
50  
51

52  
53  
54  
55 *Insert Tables 1 and 2 approximately here*  
56  
57  
58  
59  
60

1  
2  
3 There are three types of interdependencies that might lead to spatial autocorrelation  
4  
5 (Elhorst, 2014). First, endogenous interactions, whereby the dependent variable in one  
6  
7 region directly affects the dependent variable in other regions. Second, exogenous  
8  
9 interactions, where the independent variables in one region affect the dependent variable  
10  
11 in neighbouring regions. Both of these effects may arise from economic and social  
12  
13 interactions across boundaries arising, for example, through commuting, retail spending or  
14  
15 interactions with family and friends. Of particular importance for the current paper is the  
16  
17 potential for information flows across boundaries that might spread knowledge concerning  
18  
19 insolvency choices. Third, error dependencies, through interactions amongst the error terms  
20  
21 across neighbours which may arise from omitted variables that are spatially correlated or  
22  
23 unobserved shocks that follow a regional pattern. Ignoring the first two effects can lead to  
24  
25 bias in OLS estimates, whereas neglecting error dependence violates the assumption of  
26  
27 independent errors and results in a loss of efficiency.  
28  
29  
30  
31  
32  
33  
34  
35  
36  
37

38 In the present paper, there is no particular reason to rule out any type of interaction effect.  
39  
40 However, as Elhorst notes (2014), there are problems involved in identifying the parameters  
41  
42 in models including all three effects. Consequently, the strategy followed is to estimate a  
43  
44 Spatial Durbin Model (SDM) which incorporates endogenous and exogenous interactions.  
45  
46 This model has the advantage that by imposing various restrictions it nests three other  
47  
48 models: the spatial lag model (SAR) which only includes endogenous interaction effects, the  
49  
50 SLX (spatial lag of independent variables) model which only includes exogenous interaction  
51  
52 effects and the spatial error model (SEM) which only includes error dependence.  
53  
54  
55  
56  
57  
58  
59  
60

1  
2  
3  
4  
5  
6  
7 The SDM model takes the form  $y = \rho W y + X \beta + W X \theta + e$ , where  $y$  is an  $N \times 1$  vector of the  
8 observations on the dependent variable,  $X$  an  $N \times K$  matrix of the observations on  $K$   
9 independent variables,  $W$  the weight matrix,  $\beta$  and  $\theta$  are vectors of parameters to be  
10 estimated,  $\rho$  is a spatial lag coefficient, and  $e$  the vector of error terms.  $W y$  denotes the  
11 endogenous interaction effects and can be interpreted as the average of the dependent  
12 variable in neighbouring regions.  $W X$  denotes the exogenous interaction effects. Restricting  
13  $\theta = 0$  yields the SAR model,  $\rho = 0$  the SLX model and  $\theta = \rho \beta$  the SEM model (Elhorst, 2014).  
14  
15 The SLX model can be estimated by standard OLS, whilst maximum likelihood is used for the  
16 other spatial models. A second version of the SEM model (SEM2) was also estimated using a  
17 GMM estimator with robust standard errors (Kelejian and Prucha, 2010). (The relative  
18 advantages of alternative estimation techniques for spatial modelling are discussed in  
19 Elhorst (2014)).

32  
33  
34  
35  
36  
37  
38

39 Table 3 presents the results for the OLS and spatial models. For ease of interpretation  
40 WMED is expressed in units of £1000 (WMED1000). All coefficients were significant and of  
41 the expected sign in all models (apart from WMED1000 in SEM2 and AGE3044 in the SDM  
42 and SLX models). The spatial models were compared to the OLS model using Likelihood  
43 Ratio (LR) tests. In three cases (SAR: test statistic = 10.11,  $p = 0.001$ ; SEM: 9.25,  $p = 0.002$ ;  
44 SDM: 8.64,  $p = 0.003$ ), the test rejected the hypothesis that the spatial effects were zero,  
45 suggesting a preference for the spatial models. In the SLX model, the hypothesis that the  
46 WX effects were zero could not be rejected (4.33,  $p = 0.74$ ). An examination of this model  
47  
48  
49  
50  
51  
52  
53  
54  
55  
56  
57  
58  
59  
60

1  
2  
3 shows that all the exogenous interaction effects were insignificant. The lack of importance  
4  
5 of these effects is also highlighted in the SDM model. Further LR tests revealed a preference  
6  
7 for both the SEM and SAR models over the SDM model (test statistic = 3.728 and 2.668  
8  
9 compared to a critical value of 14.067).  
10  
11  
12  
13  
14  
15  
16

17 The above results suggest that the spatial effects arise from either endogenous or error  
18  
19 forms of dependence. The SEM and SAR models are not nested and so cannot be compared  
20  
21 using LR tests, whilst the Akaike Information Criteria (AIC) values are very similar. It is  
22  
23 possible to compare the models using Lagrangean Multiplier (LM) tests but these tests  
24  
25 revealed no clear preference. As the coefficient estimates from the two models are similar,  
26  
27 the substantive conclusions are not affected by model choice. However, the two models  
28  
29 imply different underlying spatial processes. The error model implies the omission of  
30  
31 variables that are spatially correlated or unobserved shocks that follow a regional pattern,  
32  
33 whilst the SAR model implies that insolvency choices in one region directly affect those in  
34  
35 neighbours. It is relatively straightforward to envisage the small sub-regions used in the  
36  
37 present analysis suffering spatially correlated shocks; hence, the error interpretation is  
38  
39 plausible and the remaining discussion focuses on this model. However, endogeneity effects  
40  
41 are also possible: for example, as already noted, there is evidence of a strong relationship  
42  
43 between the likelihood an individual would consider bankruptcy and personal association  
44  
45 with a bankrupt (Gathergood, 2005). Personal relationships involving family, friends and  
46  
47 colleagues are likely to spillover across adjacent area boundaries potentially creating  
48  
49 information spillovers in which high rates of insolvency in one area raise awareness in  
50  
51 neighbouring areas.  
52  
53  
54  
55  
56  
57  
58  
59  
60

1  
2  
3 *Insert Table 4 approximately here*  
4  
5  
6  
7

8 Specification tests of the SEM model revealed the presence of hetero-scedasticity and the  
9 model was re-estimated using robust standard errors (SEM2). The only difference to emerge  
10 was the insignificance of the WMED1000 control variable, casting doubt on the importance  
11 of controlling for income effects. However, the other control variables were significant and  
12 of the expected signs. Thus, self-employed individuals are less likely to choose IVAs,  
13 consistent with the view that bankruptcy imposes a lower level of stigma on such  
14 individuals. INSOL is also significant and negative suggesting support for the view that high  
15 rates of insolvency improve information flows making IVAs less attractive. The significance  
16 of SUBDUM suggest that those areas with suburban traits are more likely to choose IVAs.  
17 Debertin and Goetz (2013) suggest that suburban locations are often characterised by a  
18 strong desire for neighbourhood stability, safety, increasing property values and  
19 geographically-based neighbourhood associations. It might be hypothesised that they are  
20 characterised by relatively high levels of social capital and norm enforcement having a  
21 positive impact on the choice of IVAs.  
22

38  
39  
40  
41  
42  
43  
44

45 The results confirm the importance of the social capital variables which are significant and  
46 of the expected sign in all equations. The choice of IVAs is positively associated with a high  
47 rate of home ownership, low levels of labour mobility and a high proportion of the  
48 population in the 30-44 years age group. This lends support to the contention that  
49 individuals with greater social capital have a stronger preference for IVAs in order to avoid  
50 the stigma effects associated with bankruptcy. Spatial effects arise as a consequence of  
51  
52  
53  
54  
55  
56  
57  
58  
59  
60

1  
2  
3 variations in social capital associated with spatial variations in these factors. Hence, the role  
4  
5 of social capital is of considerable importance to the analysis of individual financial decisions  
6  
7 across spatial areas.  
8  
9

10  
11  
12 It is, of course, important to recognise that the variables utilised in the study are only  
13  
14 proxies for social capital and other interpretations of the results are possible. In particular,  
15  
16 some of the effects identified may, at least partially, reflect the impact of creditor  
17  
18 behaviour. Creditors may be more willing to agree to IVAs with individuals in mid-career,  
19  
20 who own their own homes and are relatively immobile as these individuals may be seen as  
21  
22 having a relatively low risk of failing to meet the payments required during an IVA. However,  
23  
24 even if these effects are of some importance, debtors must have an incentive to agree to an  
25  
26 IVA and the social capital approach provides a coherent explanation for debtor behaviour  
27  
28 that is consistent with the empirical results.  
29  
30  
31  
32  
33  
34  
35

36 A more detailed inspection of the results offers insights into the regional clusters of low IVA  
37  
38 take-up in the South West (comprising most of Devon, Cornwall, Dorset, Somerset and  
39  
40 Wiltshire) and central and northern Wales. Both clusters have a proportion of the  
41  
42 population in the 30-44 age group that is significantly lower than the rest of the sample  
43  
44 suggesting that demographic factors may be important in explaining IVA take-up rates. The  
45  
46 two clusters also have above average rates of home ownership (although the difference is  
47  
48 not statistically significant). However, the impact of labour mobility differs, with the South  
49  
50 West cluster having significantly above average rates of labour mobility whilst the opposite  
51  
52 is true for Wales, suggesting that the impact of the social capital factors is not of uniform  
53  
54 importance. In addition, both clusters have an above average rate of self-employment and  
55  
56  
57  
58  
59  
60

1  
2  
3 median incomes below the sample average. The former factor implies that the clusters  
4  
5 contain a greater proportion of the population who suffer less from the stigma attached to  
6  
7 bankruptcy, whilst the latter implies a higher proportion of debtors for whom IVAs are  
8  
9 unaffordable or unattractive to creditors.  
10  
11

## 12 13 14 15 **7. Conclusion** 16

17  
18  
19 Whilst the dramatic increase in insolvency in England and Wales during the 2000s has  
20  
21 attracted some interest, the spatial aspects have remained under-researched. This paper  
22  
23 has sought to fill this gap by focusing on the factors determining insolvency choices across  
24  
25 sub-regions of England and Wales. At a theoretical level, the analysis has proposed an  
26  
27 explanation for spatial choices rooted in the geography of social capital, extending this  
28  
29 analytical framework to a new area of enquiry. The linking of stigma to social capital  
30  
31 integrates the literature on consumer insolvency with the wider literature concerning social  
32  
33 capital. This offers a theoretical basis for the importance of stigma costs and their variation  
34  
35 across space. It also demonstrates how the incentives created by a common legal system  
36  
37 may vary across space due to variations in factors associated with social capital.  
38  
39  
40  
41  
42  
43  
44  
45  
46  
47

48 The study has argued that bankruptcy has a greater impact on social capital through stigma  
49  
50 effects than IVAs. This reflects the long historical association of bankruptcy with wilful  
51  
52 wrongdoing as evidenced by social condemnation, punishment and public shaming. This  
53  
54 contrasts with IVAs which are regarded as a modern method of debt management  
55  
56 promoted by reputable institutions. IVAs constitute a mechanism for both avoiding stigma  
57  
58  
59  
60

1  
2  
3 and re-establishing control over a debtor's financial affairs. Hence, whilst the cost of IVAs  
4  
5 has attracted considerable criticism, from the individual's point of view they may be an  
6  
7 option that yields substantial non-pecuniary benefits.  
8  
9

10  
11  
12 From an empirical point of view, the analysis examined the relationship between stigma and  
13  
14 choice of insolvency route by utilising a modelling approach accounting for spatial  
15  
16 autocorrelation. The model builds upon the Glaeser et al (2002) approach to social capital  
17  
18 which offers a useful mechanism for tackling the dilemma of measuring stigma effects. The  
19  
20 significance of the spatial coefficients also emphasises the importance of taking into account  
21  
22 spatial autocorrelation. Treating spatial areas as independent entities risks ignoring the  
23  
24 importance of spatial dependencies and clusters. This is highlighted by the existence of a  
25  
26 cluster of areas with a low take-up of IVAs in the South West region and much of Wales. The  
27  
28 lack of significance of most direct measures of the urban-rural environment suggests that, at  
29  
30 least in the case of insolvency choices, social capital effects associated with compositional  
31  
32 effects may be of more importance. Further research into alternative facets of differing  
33  
34 environmental and compositional effects would be useful to explore this in more detail.  
35  
36  
37  
38  
39  
40  
41  
42  
43  
44

45  
46 Finally, the paper offers a potential explanation for the apparent paradox concerning the  
47  
48 significant growth of IVAs despite their high cost to debtors. Existing explanations have  
49  
50 focused on the supply side impact of the rise of mass IVA providers, suggesting that these  
51  
52 providers have a financial incentive to recommend IVAs rather than bankruptcy. The present  
53  
54 paper suggests an alternative demand side explanation by arguing that the rise IVAs is  
55  
56 related to the desire of insolvents to avoid the stigma associated with bankruptcy. It is also  
57  
58  
59  
60

1  
2  
3 plausible that the results may partially reflect the behaviour of creditors who may be more  
4  
5 willing to agree to IVAs with individuals having certain desirable characteristics. Future  
6  
7 research might usefully attempt to ascertain the relative importance of debtors, creditors  
8  
9 and IPs within an integrated explanation of insolvency choice.

<b>R<sup>2</sup>(Adj)</b>	0.261			0.255		
<b>Log Likelihood</b>	-59.575	-54.522	-54.953	-57.408	-53.088	-54.953
<b>AIC</b>	135.15	127.045	125.905	144.82	138.177	125.905

Note: R<sup>2</sup> is the standard adjusted R<sup>2</sup> for OLS and SLX models; although a variety of pseudo-R<sup>2</sup>'s are available for maximum likelihood estimation there is no directly comparable measure and hence the models are compared using the log-likelihoods and AIC values; the number of observations is 348 in all cases. \*\* signifies that p<0.05.
