REVIEW OF PARTICLE PHYSICS*

Particle Data Group

Abstract

The *Review* summarizes much of particle physics and cosmology. Using data from previous editions, plus 3,062 new measurements from 721 papers, we list, evaluate, and average measured properties of gauge bosons and the recently discovered Higgs boson, leptons, quarks, mesons, and baryons. We summarize searches for hypothetical particles such as supersymmetric particles, heavy bosons, axions, dark photons, etc. All the particle properties and search limits are listed in Summary Tables. We also give numerous tables, figures, formulae, and reviews of topics such as Higgs Boson Physics, Supersymmetry, Grand Unified Theories, Neutrino Mixing, Dark Energy, Dark Matter, Cosmology, Particle Detectors, Colliders, Probability and Statistics. Among the 117 reviews are many that are new or heavily revised, including new reviews on Pentaquarks and Inflation.

The complete *Review* is published online in a journal and on the website of the Particle Data Group (`http://pdg.lbl.gov`). The printed *PDG Book* contains the Summary Tables and all review articles but no longer includes the detailed tables from the Particle Listings. A *Booklet* with the Summary Tables and abbreviated versions of some of the review articles is also available.

DOI: 10.1088/1674-1137/40/10/100001

The 2016 edition of *Review of Particle Physics* should be cited as:
C. Patrignani et al. (Particle Data Group), Chinese Physics C, **40**, 100001 (2016)

*The publication of the *Review of Particle Physics* is supported by the Director, Office of Science, Office of High Energy Physics of the U.S. Department of Energy under Contract No. DE–AC02–05CH11231; by the European Laboratory for Particle Physics (CERN); by an implementing arrangement between the governments of Japan (MEXT: Ministry of Education, Culture, Sports, Science and Technology) and the United States (DOE) on cooperative research and development; by the Institute of High Energy Physics, Chinese Academy of Sciences; and by the Italian National Institute of Nuclear Physics (INFN).

HIGHLIGHTS OF THE 2016 EDITION OF THE REVIEW OF PARTICLE PHYSICS

721 new papers with 3062 new measurements

- Over 332 new papers from **LHC** experiments (ATLAS, CMS, and LHCb).
- Extensive up-to-date **Higgs boson** coverage from 79 new papers with 172 measurements.
- **Supersymmetry**: 82 new papers with major exclusions.
- **Top quark**: 55 new papers.
- Latest from ***B*-meson** physics: 133 papers with 542 measurements.
- New τ **branching fractions** fit in collaboration with the HFAG-Tau group.
- New limits on neutrinoless **double-β decays**.
- Updated and new results in **neutrino mixing** on Δm^2 and mixing angle measurements.
- Experimental Tests of Gravitational Theory review includes LIGO observation of **gravitational waves**.
- Cosmology reviews updated to include **2015 Planck** results.
- **Periodic Table** 7th row completed; significantly revised Atomic-Nuclear Properties website.

117 reviews (most are revised)

- **New reviews** on:
  - Inflation
  - Pentaquarks
  - Pole Structure of the $\Lambda(1405)$ Region
- **Significant update/revision** to reviews on:
  - Higgs Boson Physics
  - Grand Unified Theories
  - Dark Energy, Dark Matter and CMB
  - Cosmological Parameters, Astrophysical Constants and Parameters
  - Neutrino Mass, Mixing, and Flavor Change
  - Neutrino Cross Section Measurements
  - W' and Z' bosons searches
  - Searches for Quark and Lepton Compositeness
  - Leptonic Decays of Charged Pseudoscalar Mesons
  - Particle Detectors for accelerator and non-accelerator physics, including new section on Accelerator Neutrino Detectors
  - High-Energy Collider Parameters

See **pdgLive.lbl.gov** for online access to PDG database.

See **pdg.lbl.gov/AtomicNuclearProperties** for Atomic Properties of Materials.

INTRODUCTION

ONLINE PARTICLE PHYSICS INFORMATION

INTRODUCTION

1. Overview

The *Review of Particle Physics* is a review of the field of Particle Physics and of related areas in Cosmology. It consists of "Summary Tables", "Particle Listings", and "Reviews, Tables, and Plots". The latter covers a wide variety of theoretical and experimental topics and provides a quick reference for the practicing particle physicist.

The Summary Tables give our best values and limits for particle properties such as masses, widths or lifetimes, and branching fractions, as well as an extensive summary of searches for hypothetical particles and a summary of experimental tests of conservation laws.

The Particle Listings are a compilation/evaluation of data on particle properties. They contain all the data used to get the values given in the Summary Tables. The Particle Listings also give information on unconfirmed particles and on particle searches, as well as reviews on subjects of particular interest or controversy. In this edition, the Particle Listings include 3,062 new measurements from 721 papers, in addition to the 35,436 measurements from 9,843 papers that first appeared in previous editions [1]. Because of the large quantity of data, the Particle Listings are not an archive of all published data on particle properties. We refer interested readers to earlier editions for data now considered to be obsolete.

The book version of the *Review* is published in even-numbered years. This edition is an updating through January 2016 (and, in some areas, well into 2016). The content of this *Review* is available on the web and is updated between printed editions.

We organize the particles into six categories:

Gauge and Higgs bosons
Leptons
Quarks
Mesons
Baryons
Searches for monopoles, supersymmetry, compositeness, extra dimensions, *etc.*

The last category only includes searches for particles that do not belong to the previous groups; searches for heavy charged leptons and massive neutrinos, by contrast, are with the leptons.

In Sec. 2 of this Introduction, we list the main areas of responsibility of the authors of the Particle Listings. Our many consultants, without whom we would not have been able to produce this *Review*, are acknowledged in Sec. 3. In Sec. 4, we mention briefly the naming scheme for hadrons. In Sec. 5, we discuss our procedures for choosing among measurements of particle properties and for obtaining best values of the properties from the measurements.

The accuracy and usefulness of this *Review* depend in large part on interaction between its users and the authors. We appreciate comments, criticisms, and suggestions for improvements of any kind. Please send them to the appropriate author, according to the list of responsibilities in Sec. 2 below, or to `pdg@lbl.gov`.

The complete *Review* is published online in a journal and on the PDG website (`http://pdg.lbl.gov`). In addition to the online publication, the Review is available in different formats:

- The printed *PDG Book* contains the Summary Tables and all review articles. In contrast to previous editions, the detailed tables from the Particle Listings are no longer printed.
- The *Particle Physics Booklet* includes the Summary Tables and abbreviated versions of some of the review articles in a pocket format.
- *pdgLive* (`http://pdgLive.lbl.gov`) is a web application for online access to the PDG database.
- Files that can be downloaded from the PDG website include a table of masses, widths, and PDG Monte Carlo particle ID numbers; PDF files of the entire PDG Book and Booklet; individual review articles; all figures; and an archive file containing the complete PDG website (except for pdgLive).

Copies of the *PDG Book* or the *Particle Physics Booklet* can be ordered from our website or directly at `http://pdg.lbl.gov/order`. For special requests only, please email `pdg@lbl.gov` in North and South America, Australia, and the Far East, and `pdg-products@cern.ch` in all other areas.

2. Particle Listings responsibilities

* Asterisk indicates the people to contact with questions or comments about Particle Listings sections.

Gauge and Higgs bosons

γ	C. Grab, D.E. Groom*
Gluons	R.M. Barnett,* A.V. Manohar
Graviton	D.E. Groom*
W, Z	A. Gurtu,* M. Grünewald*
Higgs bosons	K. Hikasa, G. Weiglein*
Heavy bosons	S. Pagan Griso,* M. Tanabashi
Axions	K.A. Olive, F. Takahashi, G. Raffelt*

Leptons

Neutrinos	M. Goodman, C.-J. Lin,* K. Nakamura, K.A. Olive, A. Piepke, P. Vogel
e, μ	C. Grab, C.-J. Lin*
τ	K.G. Hayes, K. Mönig*

Quarks

Quarks	R.M. Barnett,* A.V. Manohar
Top quark	R.M. Barnett,* Y. Sumino
b', t'	R.M. Barnett,* Y. Sumino
Free quark	S. Pagan Griso*

Mesons

π, η	D.A. Dwyer,* C. Grab
Unstable mesons	C. Amsler, M. Doser,* S. Eidelman,* T. Gutsche, C. Hanhart, B. Heltsley, J.J. Hernández-Rey, A. Masoni, R.E. Mitchell, S. Navas, C. Patrignani, S. Spanier, N.A. Törnqvist, G. Venanzoni
K (stable)	G. D'Ambrosio, C.-J. Lin*
D (stable, no mix.)	J. Rademacker, C.G. Wohl*
D^0 mixing	D.M. Asner, W.-M. Yao*

Baryons

B (stable)	A. Cerri,* P. Eerola, M. Kreps, Y. Kwon, W.-M. Yao*
Stable baryons	C. Grab, C.G. Wohl*
Unstable baryons	V. Burkert, E. Klempt, M. Pennington, L. Tiator, R.L. Workman*
Charmed baryons	J. Rademacker, C.G. Wohl*
Bottom baryons	A. Cerri,* P. Eerola, M. Kreps, Y. Kwon, W.-M. Yao*

Miscellaneous searches

Monopole	D. Milstead*
Supersymmetry	H.K. Dreiner,* A. de Gouvêa, M. D'Onofrio, F. Moortgat, K.A. Olive
Technicolor	K. Agashe,* M. Tanabashi
Compositeness	M. Tanabashi, J. Terning*
Extra Dimensions	D.A. Dwyer,* T. Gherghetta
WIMPs and Other	K. Hikasa*

3. Consultants

The Particle Data Group benefits greatly from the assistance of some 700 physicists who are asked to verify every piece of data entered into this *Review*. Of special value is the advice of the PDG Advisory Committee which meets biennially and thoroughly reviews all aspects of our operation. The members of the 2016 committee are:

A. Seiden (UCSC)
T. Carli (CERN)
L. Hall (UC Berkeley/LBNL)
J. Olson (Princeton)
A. Slosar (BNL)
J. Tanaka (Tokyo)

We have especially relied on the expertise of the following people for advice on particular topics:

- E. Accomando (Southampton University)
- D. Akerib (SLAC)
- J. Alcaraz (Madrid)
- A. Ali (DESY)
- B. Allanach (University of Cambridge)
- L. Althaus (La Plata University)
- V. Anisovich (Petersburg Nuclear Physics Institute)
- F. Anulli (INFN, Rome)
- S. Aoki (Kyoto University)
- S. Arceo Diaz (Colima University)
- M. Artuso (Syracuse University)
- S. Arzumanov (Moscow)
- H. Bachacou (IRFU, Saclay)
- H. Band (Yale)
- A. Barabash (ITEP Moscow)
- W. Barletta (MIT)
- R. Battye (Manchester University)
- J. Beatty (Ohio State University)
- C. Beck (Queen Mary University of London)
- R. Beck (University of Bonn)
- Y. Bedfer (CEA, Saclay)
- M. Beneke (Aachen)
- J. Bernauer (MIT)
- M. Bertolami (MPI, Garching)
- V. Bezerra (Paraiba University)
- E. Bloom (SLAC)
- J. Blümlein (DESY)
- D. Boscherini (INFN, Bologna)
- T. Bose (Boston University)
- C. Bozzi(INFN, Ferrara)
- A. Bressan (Triese University)
- R. Briere (Hawaii University)
- P. Brun (DAPNIA, Saclay)
- O. Bruning (CERN)
- D. Bryman (TRIUMF)
- M. Buckley (Rutgers University)
- A. Cabrera (APC, Paris)
- J. Cao (IHEP, Beijing)
- J. Carlstrom (Chicago University)
- M. Casolino (INFN, Tor Vergata)
- D. Cassel (Cornell University)
- F. Cerutti (LBNL)
- J. Chou (Rutgers University, Piscataway)
- W. Chou (Fermilab)
- M. Chrzaszcz (H. Niewodniczanski Inst.; U. Zurich)
- D. Cinabro (Wayne State University)
- G. Colangelo (University of Bern)
- J. Collar (Chicago University)
- J. Conrad (Stockholm University)
- J. Conway (UC Davis)
- N. Craig (UCSB)
- K. Cranmer (NYU)
- O. Cremonesi (INFN, Milan Bicocca)
- M. Crisler (FNAL)
- C. Csaki (Cornell University)
- P. Cushman (Minnesota University)
- G. Cvetic (Santa Maria U., Valparaiso)
- M. Czakon (RWTH Aachen)
- T. Dafni (Zaratoga University)
- S. Davidson (IPN, Lyon)
- C. Davies (University of Glasgow)
- D. Denisov (FNAL)
- A.V. Derbin (INP St. Petersburg)
- S. Derenzo (LBNL)
- G. De Rijk (CERN)
- P. De Simone (Frascati)
- A. Di Canto (CERN)
- S. Dobbs (Northwester University)
- A. Dolgov (INFN, Ferrara)
- J. Donini (Clermont-Ferrand University)
- T. Dorigo (INFN, Padova)
- V.P. Druzhinin (BINP SB RAS, Novosibirsk)
- V.A. Duk (INR RAS, Moscow)
- G. Edda (University of Geneva)
- G. Efstathiou (Cambridge University)
- G. Eigen (University of Bergen)
- D. Ejlli (Gran Sasso)

4. Naming scheme for hadrons

We introduced in the 1986 edition [2] a new naming scheme for the hadrons. Changes from older terminology affected mainly the heavier mesons made of u, d, and s quarks. Otherwise, the only important change to known hadrons was that the $F^{\pm}$ became the $D_s^{\pm}$. None of the lightest pseudoscalar or vector mesons changed names, nor did the $c\overline{c}$ or $b\overline{b}$ mesons (we do, however, now use χ_c for the $c\overline{c}$ χ states), nor did any of the established baryons. The Summary Tables give both the new and old names whenever a change has occurred.

The scheme is described in "Naming Scheme for Hadrons" (p. 130) of this *Review*.

We give here our conventions on type-setting style. Particle symbols are italic (or slanted) characters: e^-, p, Λ, π^0, K_L, D_s^+, b. Charge is indicated by a superscript: B^-, Δ^{++}. Charge is not normally indicated for p, n, or the quarks, and is optional for neutral isosinglets: η or η^0. Antiparticles and particles are distinguished by charge for charged leptons and mesons: τ^+, K^-. Otherwise, distinct antiparticles are indicated by a bar (overline): $\overline{\nu}_\mu$, $\overline{t}$, $\overline{p}$, $\overline{K}^0$, and $\overline{\Sigma}^+$ (the antiparticle of the Σ^-).

5. Procedures

5.1. ***Selection and treatment of data*** : The Particle Listings contain all relevant data known to us that are published in journals. With very few exceptions, we do not include results from preprints or conference reports. Nor do we include data that are of historical importance only (the Listings are not an archival record). We search every volume of 20 journals through our cutoff date for relevant data. We also include later published papers that are sent to us by the authors (or others).

In the Particle Listings, we clearly separate measurements that are used to calculate or estimate values given in the Summary Tables from measurements that are not used. We give explanatory comments in many such cases. Among the reasons a measurement might be excluded are the following:

- It is superseded by or included in later results.
- No error is given.
- It involves assumptions we question.
- It has a poor signal-to-noise ratio, low statistical significance, or is otherwise of poorer quality than other data available.
- It is clearly inconsistent with other results that appear to be more reliable. Usually we then state the criterion, which sometimes is quite subjective, for selecting "more reliable" data for averaging. See Sec. 5.4.
- It is not independent of other results.
- It is not the best limit (see below).
- It is quoted from a preprint or a conference report.

In some cases, *none* of the measurements is entirely reliable and no average is calculated. For example, the masses of many of the baryon resonances, obtained from partial-wave analyses, are quoted as estimated ranges thought to probably include the true values, rather than as averages with errors. This is discussed in the Baryon Particle Listings.

For upper limits, we normally quote in the Summary Tables the strongest limit. We do not average or combine upper limits except in a very few cases where they may be re-expressed as measured numbers with Gaussian errors.

As is customary, we assume that particle and antiparticle share the same spin, mass, and mean life. The Tests of Conservation Laws table, following the Summary Tables, lists tests of CPT as well as other conservation laws.

We use the following indicators in the Particle Listings to tell how we get values from the tabulated measurements:

- OUR AVERAGE—From a weighted average of selected data.
- OUR FIT—From a constrained or overdetermined multi-parameter fit of selected data.
- OUR EVALUATION—Not from a direct measurement, but evaluated from measurements of related quantities.
- OUR ESTIMATE—Based on the observed range of the data. Not from a formal statistical procedure.
- OUR LIMIT—For special cases where the limit is evaluated by us from measured ratios or other data. Not from a direct measurement.

An experimentalist who sees indications of a particle will of course want to know what has been seen in that region in the past. Hence we include in the Particle Listings all reported states that, in our opinion, have sufficient statistical merit and that have not been disproved by more reliable data. However, we promote to the Summary Tables only those states that we feel are well established. This judgment is, of course, somewhat subjective and no precise criteria can be given. For more detailed discussions, see the minireviews in the Particle Listings.

5.2. ***Averages and fits*** : We divide this discussion on obtaining averages and errors into three sections: (1) treatment of errors; (2) unconstrained averaging; (3) constrained fits.

5.2.1. *Treatment of errors:* In what follows, the "error" δx means that the range $x \pm \delta x$ is intended to be a 68.3% confidence interval about the central value x. We treat this error as if it were Gaussian. Thus when the error *is* Gaussian, δx is the usual one standard deviation (1σ). Many experimenters now give statistical and systematic errors separately, in which case we usually quote both errors, with the statistical error first. For averages and fits, we then add the the two errors in quadrature and use this combined error for δx.

When experimenters quote asymmetric errors $(\delta x)^+$ and $(\delta x)^-$ for a measurement x, the error that we use for that measurement in making an average or a fit with other measurements is a continuous function of these three quantities. When the resultant average or fit $\overline{x}$ is less than $x-(\delta x)^-$, we use $(\delta x)^-$; when it is greater than $x+(\delta x)^+$, we use $(\delta x)^+$. In between, the error we use is a linear function of x. Since the errors we use are functions of the result, we iterate to get the final result. Asymmetric output errors are determined from the input errors assuming a linear relation between the input and output quantities.

In fitting or averaging, we usually do not include correlations between different measurements, but we try to select data in such a way as to reduce correlations. Correlated errors are, however, treated explicitly when there are a number of results of the form $A_i \pm \sigma_i \pm \Delta$ that have identical systematic errors Δ. In this case, one can first average the $A_i \pm \sigma_i$ and then combine the resulting statistical error with Δ. One obtains, however, the same result by averaging $A_i \pm (\sigma_i^2 + \Delta_i^2)^{1/2}$, where $\Delta_i = \sigma_i \Delta [\sum (1/\sigma_j^2)]^{1/2}$. This procedure has the advantage that, with the modified systematic errors Δ_i, each measurement may be treated as independent and averaged in the usual way with other data. Therefore, when appropriate, we adopt this procedure. We tabulate Δ and invoke an automated procedure that computes Δ_i before averaging and we include a note saying that there are common systematic errors.

Another common case of correlated errors occurs when experimenters measure two quantities and then quote the two and their difference, *e.g.*, m_1, m_2, and $\Delta = m_2 - m_1$. We cannot enter all of m_1, m_2 and Δ into a constrained fit because they are not independent. In some cases, it is a good approximation to ignore the quantity with the largest error and put the other two into the fit. However, in some cases correlations are such that the errors on m_1, m_2 and Δ are comparable and none of the three values can be ignored. In this case, we put all three values into the fit and invoke an automated procedure to increase the errors prior to fitting such that the three quantities can be treated as independent measurements in the constrained fit. We include a note saying that this has been done.

5.2.2. *Unconstrained averaging:* To average data, we use a standard weighted least-squares procedure and in some cases, discussed below, increase the errors with a "scale factor." We begin by assuming that measurements of a given quantity are uncorrelated, and calculate a weighted average and error as

$$\overline{x} \pm \delta\overline{x} = \frac{\sum_i w_i\, x_i}{\sum_i w_i} \pm \left(\sum_i w_i\right)^{-1/2} , \qquad (1)$$

where

$$w_i = 1/(\delta x_i)^2 .$$

Here x_i and δx_i are the value and error reported by the ith experiment, and the sums run over the N experiments. We then calculate $\chi^2 = \sum w_i(\overline{x} - x_i)^2$ and compare it with $N-1$, which is the expectation value of χ^2 if the measurements are from a Gaussian distribution.

If $\chi^2/(N-1)$ is less than or equal to 1, and there are no known problems with the data, we accept the results.

If $\chi^2/(N-1)$ is very large, we may choose not to use the average at all. Alternatively, we may quote the calculated average, but then make an educated guess of the error, a conservative estimate designed to take into account known problems with the data.

Finally, if $\chi^2/(N-1)$ is greater than 1, but not greatly so, we still average the data, but then also do the following:

(a) We increase our quoted error, $\delta\overline{x}$ in Eq. (1), by a scale factor S defined as

$$S = \left[\chi^2/(N-1)\right]^{1/2} . \qquad (2)$$

Our reasoning is as follows. The large value of the χ^2 is likely to be due to underestimation of errors in at least one of the experiments. Not knowing which of the errors are underestimated, we assume they are all underestimated by the same factor S. If we scale up all the input errors by this factor, the χ^2 becomes $N-1$, and of course the output error $\delta\overline{x}$ scales up by the same factor. See Ref. 3.

When combining data with widely varying errors, we modify this procedure slightly. We evaluate S using only the experiments with smaller errors. Our cutoff or ceiling on δx_i is arbitrarily chosen to be

$$\delta_0 = 3N^{1/2}\,\delta\overline{x}\ ,$$

where $\delta\overline{x}$ is the unscaled error of the mean of all the experiments. Our reasoning is that although the low-precision experiments have little influence on the values $\overline{x}$ and $\delta\overline{x}$, they can make significant contributions to the χ^2, and the contribution of the high-precision experiments thus tends to be obscured. Note that if each experiment has the same error δx_i, then $\delta\overline{x}$ is $\delta x_i/N^{1/2}$, so each δx_i is well below the cutoff. (More often, however, we simply exclude measurements with relatively large errors from averages and fits: new, precise data chase out old, imprecise data.)

Our scaling procedure has the property that if there are two values with comparable errors separated by much more than their stated errors (with or without a number of other values of lower accuracy), the scaled-up error $\delta\,\overline{x}$ is approximately half the interval between the two discrepant values.

We emphasize that our scaling procedure for *errors* in no way affects central values. And if you wish to recover the unscaled error $\delta\overline{x}$, simply divide the quoted error by S.

(b) If the number M of experiments with an error smaller than δ_0 is at least three, and if $\chi^2/(M-1)$ is greater than 1.25, we show in the Particle Listings an ideogram of the data. Figure 1 is an example. Sometimes one or two data points lie apart from the main body; other times the data split into two or more groups. We extract no numbers from these ideograms; they are simply visual aids, which the reader may use as he or she sees fit.

Each measurement in an ideogram is represented by a Gaussian with a central value x_i, error δx_i, and area proportional to $1/\delta x_i$. The choice of $1/\delta x_i$ for the area is somewhat arbitrary. With this choice, the center of gravity of the ideogram corresponds to an average that uses weights $1/\delta x_i$ rather than the $(1/\delta x_i)^2$ actually used in the averages. This may be appropriate when some of the experiments have seriously underestimated systematic errors. However, since for this choice of area the height of the Gaussian for each measurement is proportional to $(1/\delta\, x_i)^2$, the peak position of the ideogram will often favor the high-precision measurements at least as much as does the least-squares average. See our 1986 edition [2] for a detailed discussion of the use of ideograms.

5.2.3. *Constrained fits:* In some cases, such as branching ratios or masses and mass differences, a constrained fit may be needed to obtain the best values of a set of parameters. For example, most branching ratios and rate measurements are analyzed by making a simultaneous least-squares fit to all the data and extracting the partial decay fractions P_i, the partial widths Γ_i, the full width Γ (or mean life), and the associated error matrix.

Assume, for example, that a state has m partial decay fractions P_i, where $\sum P_i = 1$. These have been measured in N_r different ratios R_r, where, e.g., $R_1 = P_1/P_2$, $R_2 = P_1/P_3$, *etc.* [We can handle any ratio R of the form $\sum \alpha_i\, P_i/\sum \beta_i\, P_i$, where α_i and β_i are constants, usually 1 or 0. The forms $R = P_iP_j$ and $R = (P_iP_j)^{1/2}$ are also allowed.] Further assume that *each* ratio R has been measured by N_k experiments (we designate each experiment with a subscript k, e.g., R_{1k}). We then find the best values of the fractions P_i by minimizing the χ^2 as a function of the $m-1$ independent parameters:

$$\chi^2 = \sum_{r=1}^{N_r}\sum_{k=1}^{N_k}\left(\frac{R_{rk}-R_r}{\delta R_{rk}}\right)^2\ , \qquad (3)$$

where the R_{rk} are the measured values and R_r are the fitted values of the branching ratios.

In addition to the fitted values $\overline{P}_i$, we calculate an error matrix $\langle\delta\overline{P}_i\ \delta\overline{P}_j\rangle$. We tabulate the diagonal elements of $\delta\,\overline{P}_i = \langle\delta\,\overline{P}_i\ \delta\,\overline{P}_i\rangle^{1/2}$ (except that some errors are scaled as discussed below). In the Particle Listings, we give the complete correlation matrix; we also calculate the fitted value of each ratio, for comparison with the input data, and list it above the relevant input, along with a simple unconstrained average of the same input.

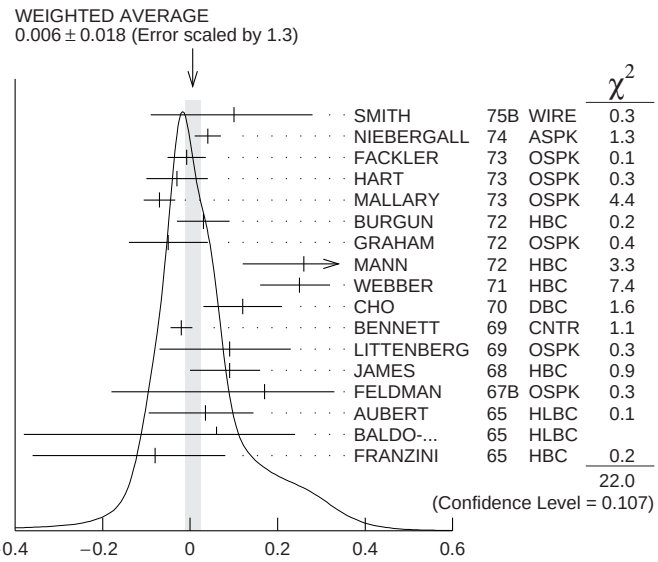

Figure 1: A typical ideogram. The arrow at the top shows the position of the weighted average, while the width of the shaded pattern shows the error in the average after scaling by the factor S. The column on the right gives the χ^2 contribution of each of the experiments. Note that the next-to-last experiment, denoted by the incomplete error flag ($\perp$), is not used in the calculation of S (see the text).

Three comments on the example above:

(1) There was no connection assumed between measurements of the full width and the branching ratios. But often we also have information on partial widths Γ_i as well as the total width Γ. In this case we must introduce Γ as a parameter in the fit, along with the P_i, and we give correlation matrices for the widths in the Particle Listings.

(2) We try to pick those ratios and widths that are as independent and as close to the original data as possible. When one experiment measures all the branching fractions and constrains their sum to be one, we leave one of them (usually the least well-determined one) out of the fit to make the set of input data more nearly independent. We now do allow for correlations between input data.

(3) We calculate scale factors for both the R_r and P_i when the measurements for any R give a larger-than-expected contribution to the χ^2. According to Eq. (3), the double sum for χ^2 is first summed over experiments $k = 1$ to N_k, leaving a single sum over ratios $\chi^2 = \sum \chi^2_r$. One is tempted to define a scale factor for the ratio r as $S_r^2 = \chi^2_r/\langle\chi^2_r\rangle$. However, since $\langle\chi^2_r\rangle$ is not a fixed quantity (it is somewhere between N_k and N_{k-1}), we do not know how to evaluate this expression. Instead we define

$$S_r^2 = \frac{1}{N_k}\sum_{k=1}^{N_k}\frac{\left(R_{rk} - \overline{R}_r\right)^2}{\langle(R_{rk} - \overline{R}_r)^2\rangle}. \qquad (4)$$

With this definition the expected value of S_r^2 is one. We can show that

$$\langle(R_{rk} - \overline{R}_r)^2\rangle = \langle(\delta R_{rk})^2\rangle - (\delta\overline{R}_r)^2\ , \qquad (5)$$

where $\delta\overline{R}_r$ is the fitted error for ratio r.

The fit is redone using errors for the branching ratios that are scaled by the larger of S_r and unity, from which new and often larger errors $\delta\overline{P}_i'$ are obtained. The scale factors we finally list in such cases are defined by $S_i = \delta\overline{P}_i'/\delta\overline{P}_i$. However, in line with our policy of not letting S affect the central values, we give the values of $\overline{P}_i$ obtained from the original (unscaled) fit.

There is one special case in which the errors that are obtained by the preceding procedure may be changed. When a fitted branching ratio (or rate) $\overline{P}_i$ turns out to be less than three standard deviations ($\delta\overline{P}_i'$) from zero, a new smaller error $(\delta\overline{P}_i'')^-$ is calculated on the low side by requiring the area under the Gaussian between $\overline{P}_i - (\delta\overline{P}_i'')^-$ and $\overline{P}_i$ to be 68.3% of the area between zero and $\overline{P}_i$. A similar correction is made for branching fractions that are within three standard deviations of one. This keeps the quoted errors from overlapping the boundary of the physical region.

5.3. ***Rounding*** : While the results shown in the Particle Listings are usually exactly those published by the experiments, the numbers that appear in the Summary Tables (means, averages and limits) are subject to a set of rounding rules.

The basic rule states that if the three highest order digits of the error lie between 100 and 354, we round to two significant digits. If they lie between 355 and 949, we round to one significant digit. Finally, if they lie between 950 and 999, we round up to 1000 and keep two significant digits. In all cases, the central value is given with a precision that matches that of the error. So, for example, the result (coming from an average) 0.827 ± 0.119 would appear as 0.83 ± 0.12, while 0.827 ± 0.367 would turn into 0.8 ± 0.4.

Rounding is not performed if a result in a Summary Table comes from a single measurement, without any averaging. In that case, the number of digits published in the original paper is kept, unless we feel it inappropriate. Note that, even for a single measurement, when we combine statistical and systematic errors in quadrature, rounding rules apply to the result of the combination. It should be noted also that most of the limits in the Summary Tables come from a single source (the best limit) and, therefore, are not subject to rounding.

Finally, we should point out that in several instances, when a group of results come from a single fit to a set of data, we have chosen to keep two significant digits for all the results. This happens, for instance, for several properties of the W and Z bosons and the τ lepton.

5.4. ***Discussion*** : The problem of averaging data containing discrepant values is nicely discussed by Taylor in Ref. 4. He considers a number of algorithms that attempt to incorporate inconsistent data into a meaningful average. However, it is difficult to develop a procedure that handles simultaneously in a reasonable way two basic types of situations: (a) data that lie apart from the main body of the data are incorrect (contain unreported errors); and (b) the opposite—it is the main body of data that is incorrect. Unfortunately, as Taylor shows, case (b) is not infrequent. He concludes that the choice of procedure is less significant than the initial choice of data to include or exclude.

We place much emphasis on this choice of data. Often we solicit the help of outside experts (consultants). Sometimes, however, it is simply impossible to determine which of a set of discrepant measurements are correct. Our scale-factor technique is an attempt to address this ignorance by increasing the error. In effect, we are saying that present experiments do not allow a precise determination of this quantity because of unresolvable discrepancies, and one must await further measurements. The reader is warned of this situation by the size of the scale factor, and if he or she desires can go back to the literature (via the Particle Listings) and redo the average with a different choice of data.

Our situation is less severe than most of the cases Taylor considers, such as estimates of the fundamental constants like $\hbar$, *etc.* Most of the errors in his case are dominated by systematic effects. For our data, statistical errors are often at least as large as systematic errors, and statistical errors are usually easier to estimate. A notable exception occurs in partial-wave analyses, where different techniques applied to the same data yield different results. In this case, as stated earlier, we often do not make an average but just quote a range of values.

A brief history of early Particle Data Group averages is given in Ref. 3. Figure 2 shows some histories of our values of a few particle properties. Sometimes large changes occur. These usually reflect the introduction of significant new data or the discarding of older data. Older data are discarded in favor of newer data when it is felt that the newer data have smaller systematic errors, or have more checks on systematic errors, or have made corrections unknown at the time of the older experiments, or simply have much smaller errors. Sometimes, the scale factor becomes large near the time at which a large jump takes place, reflecting

the uncertainty introduced by the new and inconsistent data. By and large, however, a full scan of our history plots shows a dull progression toward greater precision at central values quite consistent with the first data points shown.

We conclude that the reliability of the combination of experimental data and our averaging procedures is usually good, but it is important to be aware that fluctuations outside of the quoted errors can and do occur.

ACKNOWLEDGMENTS

The publication of the *Review of Particle Physics* is supported by the Director, Office of Science, Office of High Energy Physics of the U.S. Department of Energy under Contract No. DE–AC02–05CH11231; by the European Laboratory for Particle Physics (CERN); by an implementing arrangement between the governments of Japan (MEXT: Ministry of Education, Culture, Sports, Science and Technology) and the United States (DOE) on cooperative research and development; by the Institute of High Energy Physics, Chinese Academy of Sciences; and by the Italian National Institute of Nuclear Physics (INFN).

We thank all those who have assisted in the many phases of preparing this *Review*. We particularly thank the many who have responded to our requests for verification of data entered in the Listings, and those who have made suggestions or pointed out errors.

ONLINE PARTICLE PHYSICS INFORMATION

Updated Nov. 2015 by T. Basaglia (CERN), A. Holtkamp (CERN).†

1. Introduction

The collection of online information resources in particle physics and related areas presented in this chapter is of necessity incomplete. An expanded and regularly updated online version can be found at:

`http://library.web.cern.ch/particle_physics_information`

Suggestions for additions and updates are very welcome.†

2. Particle Data Group (PDG) resources

- **Review of Particle Physics (RPP)** A comprehensive report on the fields of particle physics and related areas of cosmology and astrophysics, including both review articles and a compilation/evaluation of data on particle properties. The review section includes articles, tables and plots on a wide variety of theoretical and experimental topics of interest to particle physicists and astrophysicists. The particle properties section provides tables of published measurements as well as the Particle Data Groups best values and limits for particle properties such as masses, widths, lifetimes, and branching fractions, and an extensive summary of searches for hypothetical particles. RPP is published as a 1500-page book every two years, with partial updates made available once each year on the web.

  All the contents of the book version of RPP are available online:

  `http://pdg.lbl.gov`

  The printed book can be ordered:

  `http://pdg.lbl.gov/2015/html/receive_our_products.html`

  Of historical interest is the complete RPP collection which can be found online:

  `http://library.web.cern.ch/PDG_publications/review_particle_physics`

- **Particle Physics booklet:** An abridged version of the Review of Particle Physics available as a pocket-sized 300-page booklet. Although produced in print and available online only as a PDF file, the booklet is included in this guide because it is one of the most useful summaries of physics data. The booklet contains an abbreviated set of reviews and the summary tables from the most recent edition of the Review of Particle Physics.

  The PDF file of the booklet can be downloaded:

  `http://pdg.lbl.gov/current/booklet.pdf`

  The printed booklet can be ordered:

  `http://pdg.lbl.gov/2015/html/receive_our_products.html`

- **PDGLive:** A web application for browsing the contents of the PDG database that contains the information published in the Review of Particle Physics. It allows one to navigate to a particle of interest, see a summary of the information available, and then proceed to the detailed information published in the Review of Particle Physics. Data entries are directly linked to the corresponding bibliographic information in INSPIRE.

  `http://pdglive.lbl.gov`

- **Computer-readable files:** Data files that can be downloaded from PDG include tables of particle masses and widths, PDG Monte Carlo particle numbers, and cross-section data. The files are updated with each new edition of the Review of Particle Physics.

  `http://pdg.lbl.gov/current/html/computer_read.html`

3. Particle Physics Information Platforms

- **INSPIRE:** The time-honored SPIRES database suite has in November 2011 been replaced by INSPIRE, which combines the most successful aspects of SPIRES - like comprehensive content and high-quality metadata - with the modern technology of Invenio, the CERN open-source digital-library software, offering major improvements like increased speed and Google-like free-text search syntax. INSPIRE serves as one-stop information platform for the particle physics community, comprising 8 interlinked databases on literature, conferences, institutions, journals, researchers, experiments, jobs and data. INSPIRE is jointly developed and maintained by CERN, DESY, Fermilab, IHEP and SLAC. Close interaction with the user community and with arXiv, ADS, HepData, PDG and publishers is the backbone of INSPIRE's evolution.

  `http://inspirehep.net/`

  INSPIRE is integrated with ORCID (Open Researcher and Contributor ID), a persistent identifier that enables researchers to connect services and get credit for their works.

  `http://orcid.org/`

  INSPIRE is currently developing a new version of the portal, maintaining its quality standards and introducing new functionality. The INSPIRE Labs site is available at:

  `http://labs.inspirehep.net`

  `blog: http://blog.inspirehep.net/`

  `twitter:` @inspirehep

4. Literature Databases

- **ADS:** The SAO/NASA Astrophysics Data System is a Digital Library portal offering access to 11 million bibliographic records in Astronomy and Physics. The ADS's search engine also indexes the full-text for approximately four million publications in this collection and tracks citations, which now amount to over 80 million links. The system also provides access and links to a wealth of external resources, including electronic articles hosted by publishers and arXiv, data catalogs and a variety of data products hosted by the astronomy archives worldwide. The ADS can be accessed at

  `http://ads.harvard.edu/`

- **arXiv.org:** A repository of full text papers in physics, mathematics, computer science, statistics, nonlinear sciences, quantitative finance and quantitative biology interlinked with ADS and INSPIRE. Papers are usually submitted by their authors to arXiv in advance of submission to a journal for publication. Primarily covers 1991 to the present but authors are encouraged to post older papers retroactively. Permits searching by author, title, and words in abstract and experimentally also in the fulltext. Allows limiting by subfield archive or by date. Daily update alerts by subfield are available by email and RSS.

† Please send comments and corrections to `Annette.Holtkamp@cern.ch`.

http://arXiv.org

- **CDS:** The CERN Document Server contains records of more than 1,000,000 CERN and non-CERN articles, preprints, theses. It includes records for internal and technical notes, official CERN committee documents, and multimedia objects. CDS is going to focus on its role as institutional repository covering all CERN material from the early 50s and reflecting the holdings of the CERN library. Non-CERN particle and accelerator physics content is in the process of being exported to INSPIRE.

  http://cds.cern.ch

- **INSPIRE HEP:** The HEP collection, the flagship of the INSPIRE suite, serves more than 1.1 million bibliographic records with a growing number of fulltexts attached and metadata including author affiliations, abstracts, references, experiments, keywords as well as links to arXiv, ADS, PDG, HepData and publisher platforms. It provides fast metadata and fulltext searches, plots extracted from fulltext, author disambiguation, author profile pages and citation analysis and is expanding its content to, e.g., experimental notes.

  http://inspirehep.net

- **JACoW:** The Joint Accelerator Conference Website publishes the proceedings of APAC, EPAC, PAC, IPAC, ABDW, BIW, COOL, CYCLOTRONS, DIPAC, ECRIS, FEL, HIAT, ICALEPCS, IBIC, ICAP, LINAC, North American PAC, PCaPAC, RuPAC, SRF. A custom interface allows searching on keywords, titles, authors, and in the fulltext.

  http://www.jacow.org/

- **KISS (KEK Information Service System) for preprints:** The KEK Library preprint and technical report database contains bibliographic records of preprints and technical reports held in the KEK library with links to the full text images of more than 100,000 papers scanned from their worldwide collection of preprints. Particularly useful for older scanned preprints. KISS links are included in INSPIRE HEP.

  http://www-lib.kek.jp/KISS/kiss_prepri.html

- **MathSciNet:** This database of almost 3 million items provides reviews, abstracts and bibliographic information for much of the mathematical sciences literature. Over 100,000 new items are added each year, most of them classified according to the Mathematics Subject Classification. Authors are uniquely identified, enabling a search for publications by individual author. Over 80,000 reviews on the current published literature are added each year. Citation data allows to track the history and influence of research publications.

  http://www.ams.org/mathscinet

- **OSTI SciTech Connect:** A portal to free, publicly available DOE-sponsored R&D results including technical reports, bibliographic citations, journal articles, conference papers, books, multimedia and data information. SciTech Connect is a consolidation of two core DOE search engines, the Information Bridge and the Energy Citations Database. SciTech Connect incorporates all of the R&D information from these two products into one search interface. It includes over 2.7 million citations, including citations to 1.5 million journal articles. SciTech Connect also has over 400,000 full-text DOE sponsored STI reports; most of these are post-1991, but over 140,000 of the reports were published prior to 1990.

  http://www.osti.gov/scitech/

5. Particle Physics Journals and Conference Proceedings Series

- **CERN Journals List:** This list of journals and conference series publishing particle physics content provides information on Open Access, copyright policies and terms of use.

  http://library.web.cern.ch/oa/where_publish

- **INSPIRE Journals:** The database covers more than 3,400 journals publishing HEP-related articles.

  http://inspirehep.net/collection/journals

6. Conference Databases

- **INSPIRE Conferences:** The database of more than 20,600 past, present and future conferences, schools, and meetings of interest to high-energy physics and related fields is searchable by title, acronym, series, date, location. Included are information about published proceedings, links to conference contributions in the INSPIRE HEP database, and links to the conference Web site when available. New conferences can be submitted from the entry page.

  http://inspirehep.net/conferences

7. Research Institutions

- **INSPIRE Institutions:** The database of more than 10,800 institutes, laboratories, and university departments in which research on particle physics and astrophysics is performed covers six continents and over a hundred countries. Included are address and Web links where available as well as links to the papers from each institution in the HEP database, to scientists listed in HEPNames affiliated to this institution in the past or present and to experiments performed at this institution. Searches can be performed by name, acronym, location, etc. The site offers an alphabetical list by country as well as a list of the top 500 HEP and astrophysics institutions sorted by country.

  http://inspirehep.net/institutions

8. People

- **INSPIRE HEPNames:** Searchable worldwide database of over 112,000 people associated with particle physics and related fields. The affiliation history of these researchers, their e-mail addresses, web pages, experiments they participated in, PhD advisor, information on their graduate students and links to their papers in the INSPIRE HEP, arXiv and ADS databases are provided as well as a user interface to update these informations.

  http://inspirehep.net/hepnames

9. Experiments

- **INSPIRE Experiments:** Contains more than 2,700 past, present, and future experiments in particle physics. Lists both accelerator and non-accelerator experiments. Includes official experiment name and number, location, and collaboration lists. Simple searches by participant, title, experiment number, institution, date approved, accelerator, or detector, return a description of the experiment, including a complete list of authors, title, overview of the experiment's goals and methods, and a link to the experiment's web page if available. Publication lists distinguish articles in refereed journals, theses, technical or instrumentation papers and those which rank among Topcite at 50 or more citations.

  http://inspirehep.net/Experiments

- **Cosmic ray/Gamma ray/Neutrino and similar experiments:** This extensive collection of experimental web sites is organized by focus of study and also by location. Additional sections link to educational materials, organizations, related Web sites, etc. The site is maintained at the Max Planck Institute for Nuclear Physics, Heidelberg.

  http://www.mpi-hd.mpg.de/hfm/CosmicRay/
  CosmicRaySites.html

10. Jobs

- **AAS Job Register:** The American Astronomical Society publishes once a month graduate, postgraduate, faculty and other positions mainly in astronomy and astrophysics.

  http://jobregister.aas.org/

- **APS Careers:** A gateway for physicists, students, and physics enthusiasts to information about physics jobs and careers. Physics job listings, career advice, upcoming workshops and meetings, and career and job related resources provided by the American Physical Society.

  http://www.aps.org/careers/employment

- **brightrecruits.com:** A recruitment service run by IOP Publishing that connects employers from different industry sectors with jobseekers who have a background in physics and engineering.
  `http://brightrecruits.com/`

- **IOP Careers:** Careers information and resources primarily aimed at university students are provided by the UK Institute of Physics.
  `http://www.iop.org/careers/`

- **INSPIRE HEPJobs:** Lists academic and research jobs in high energy physics, nuclear physics, accelerator physics and astrophysics with the option to post a job or to receive email notices of new job listings. About 500 jobs are currently listed.
  `http://inspirehep.net/jobs`

- **Physics Today Jobs:** Online recruitment advertising website for Physics Today magazine, published by the American Institute of Physics. Physics Today Jobs is the managing partner of the AIP Career Network, an online job board network for the physical science, engineering, and computing disciplines. 8,000 resumes are currently available, and more than 2,500 jobs were posted in 2012.
  `http://www.physicstoday.org/jobs`

11. Software Repositories

Particle Physics

- **FastJet:** FastJet is a software package for jet finding in pp and e+e- collisions. It includes fast native implementations of many sequential recombination clustering algorithms, plugins for access to a range of cone jet finders and tools for advanced jet manipulation.
  `http://fastjet.fr/`

- **FermiTools:** Fermilab's software tools program provides a repository of Fermilab - developed software packages of value to the HEP community. Permits searching for packages by title or subject category.
  `http://www.fnal.gov/fermitools/`

- **FreeHEP:** A collection of software and information about software useful in high-energy physics and adjacent disciplines, focusing on open-source software for data analysis and visualization. Searching can be done by title, subject, date acquired, date updated, or by browsing an alphabetical list of all packages.
  `http://www.freehep.org/`

- **Geant4:** Geant4 is a toolkit for the simulation of the passage of particles through matter. Its areas of application include high energy, nuclear and accelerator physics, as well as studies in medical and space science.
  `http://geant4.web.cern.ch/geant4/`

- **GenSer:** The Generator Services project collaborates with Monte Carlo (MC) generators authors and with LHC experiments in order to prepare validated LCG compliant code for both the theoretical and experimental communities at the LHC, sharing the user support duties, providing assistance for the development of the new object-oriented generators and guaranteeing the maintenance of the older packages on the LCG supported platforms. The project consists of the generators repository, validation, HepMC record and MCDB event databases.
  `http://ph-dep-sft.web.cern.ch/project/generator-service-project-genser`

- **Hepforge:** A development environment for high-energy physics software development projects, in particular housing many event-generator related projects, that offers a ready-made, easy-to-use set of Web based tools, including shell account with up to date development tools, web page hosting, subversion and CVS code management systems, mailing lists, bug tracker and wiki system.
  `http://www.hepforge.org/`

- **QUDA:** Library for performing calculations in lattice QCD on GPUs using NVIDIA's "C for CUDA" API. The current release includes optimized solvers for Wilson, Clover-improved Wilson,Twisted mass, Improved staggered (asqtad or HISQ), Domain wall and Mobius fermion actions.
  `http://lattice.github.com/quda/`

- **ROOT:** This framework for data processing in high-energy physics, born at CERN, offers applications to store, access, process, analyze and represent data or perform simulations.
  `http://root.cern.ch`

- **tmLQCD:** This freely available software suite provides a set of tools to be used in lattice QCD simulations, mainly a HMC implementation for Wilson and Wilson twisted mass fermions and inverter for different versions of the Dirac operator.
  `https://github.com/etmc/tmLQCD`

- **USQCD:** The software suite enables lattice QCD computations to be performed with high performance across a variety of architectures. The page contains links to the project web pages of the individual software modules, as well as to complete lattice QCD application packages which use them.
  `http://usqcd-software.github.io`

Astrophysics

- **ASCL:** The Astrophysics Source Code Library (ASCL) is a free online registry for source codes of interest to astronomers and astrophysicists and lists codes that have been used in research that has appeared in, or been submitted to, peer-reviewed publications.
  `http://ascl.net`

- **Astropy:** The Astropy Project is a community effort to develop a single core package for Astronomy in Python and foster interoperability between Python astronomy packages
  `http://www.astropy.org`

- **IRAF:** The Image Reduction and Analysis Facility is a general purpose software system for the reduction and analysis of astronomical data. IRAF is written and supported by the National Optical Astronomy Observatories (NOAO) in Tucson, Arizona.
  `http://iraf.noao.edu/`

- **Starlink:** Starlink was a UK Project supporting astronomical data processing. It was shut down in 2005 but its open-source software continued to be developed at the Joint Astronomy Centre until March 2015. It is currently maintained by the East Asian Observatory. The open-source software products are a collection of applications and libraries, usually focused on a specific aspect of data reduction or analysis.
  `http://starlink.eao.hawaii.edu/starlink`

- Links to a large number of astronomy software archives are listed at:
  `http://heasarc.nasa.gov/docs/heasarc/astro-update/`

Apps

- **arXiv mobile:** Android app for browsing and searching arXiv.org, and for reading, saving and sharing articles.
  `play.google.com/store/apps/details?id=com.commonsware.android.arXiv`

- **arXiv scanner:** Scans downloads folder for pdf files from arXiv. Adds title, authors and summary and makes all this information easily searchable from inside the application.
  `https://play.google.com/store/apps/details?id=com.agio.arxiv.scaner`

- **aNarXiv:** arXiv viewer.
  `http://github.com/nephoapp/anarxiv`

- **Collider:** This mobile app allows to see data from the ATLAS experiment at the LHC.
  `http://collider.physics.ox.ac.uk/`

- **LHSee:** This smartphone app allows to see collisions from the Large Hadron Collider.

  `http://www2.physics.ox.ac.uk/about-us/outreach/public/lhsee`

- **The Particles:** App for Apple iPad, Windows 8 and Microsoft Surface. Allows to browse a wealth of real event images and videos, read popular biographies of each of the particles and explore the A-Z of particle physics with its details and definitions of key concepts, laboratories and physicists. Developed by Science Photo Library in partnership with Prof. Frank Close.

  `http://www.sciencephoto.com/apps/particles.html`

12. Data repositories

Particle Physics

- **HepData:** The HepData Project, funded by the STFC (UK) and based at Durham University, has been built up over the past four decades as a unique repository for scattering data from experimental particle physics. It currently comprises the data points from plots and tables related to several thousand publications including those from the LHC.

  `http://hepdata.cedar.ac.uk/`

  The data from HEPData can also be accessed through INSPIRE. A new enhanced service, rebranded as HEPData, is under development and will be available at:

  `http://hepdata.net`

- **CERN Open Data:** The CERN Open Data portal provides data from real collision events, produced by the experiments at the LHC; virtual machines to reproduce the analysis environment; and software to process them. It serves almost 30 TB of data and encourages use both for educational and research purposes.

  `http://opendata.cern.ch`

- **ILDG:** The International Lattice Data Grid is an international organization which provides standards, services, methods and tools that facilitate the sharing and interchange of lattice QCD gauge configurations among scientific collaborations, by uniting their regional data grids. It offers semantic access with local tools to worldwide distributed data.

  `http://www.usqcd.org/ildg/`

- **MCDB - Monte Carlo Database:** This central database of MC events aims to facilitate communication between Monte-Carlo experts and users of event samples in LHC collaborations. Having these events stored in a public place along with the corresponding documentation allows for direct cross checks of the performances on reference samples.

  `http://mcdb.cern.ch/`

- **MCPLOTS:** mcplots is a repository of Monte Carlo plots comparing High Energy Physics event generators to a wide variety of available experimental data. The site is supported by the LHC Physics Centre at CERN.

  `http://mcplots.cern.ch/`

Astrophysics

- **CfA Dataverse:** This astronomy data repository at Harvard is open to all scientific data from astronomical institutions worldwide.

  `https://dataverse.harvard.edu/dataverse/cfa`

- **NASA's HEASARC:** The High Energy Astrophysics Science Archive Research Center (HEASARC) is the primary archive for NASA's (and other space agencies') missions dealing with electromagnetic radiation from extremely energetic phenomena ranging from black holes to the Big Bang.

  `http://heasarc.gsfc.nasa.gov/`

- **LAMBDA @ HEASARC:** This data center for Cosmic Microwave Background research, a merger of the High Energy Astrophysics Science Archive Research Center (HEASARC) and the Legacy Archive for Microwave Background Data Analysis (LAMBDA), provides archive data from NASA missions, software tools, and links to other sites of interest.

  `http://lambda.gsfc.nasa.gov/`

- The NASA archives provide access to raw and processed datasets from numerous NASA missions.

  Mikulski Archive for Space Telescopes (MAST): Hubble telescope, other missions (UV, optical):

  `http://archive.stsci.edu/`

  NASA/IPAC Infrared Science Archive: Spitzer, Herschel, Planck telescope, other missions:

  `http://irsa.ipac.caltech.edu/`

- **NASA/IPAC Extragalactic Database (NED):** An astronomical database that collates and cross-correlates information on extragalactic objects. It contains their positions, basic data, and names as well as bibliographic references to published papers, and notes from catalogs and other publications. NED supports searches for objects and references, and offers browsing capabilities for abstracts of articles of extragalactic interest.

  `http://ned.ipac.caltech.edu/`

- **SIMBAD:** The SIMBAD astronomical database provides basic data, cross-identifications, bibliography and measurements for astronomical objects outside the solar system. It can be queried by object name, coordinates and various criteria. Lists of objects and scripts can be submitted.

  `http://simbad.u-strasbg.fr/simbad/`

- **Virtual Observatory:** The Virtual Observatory (VO) provides a suite of resources to query for original data from a large number of archives. Two main tools are provided. One runs queries across multiple databases (such as the SDSS database) and combines the results. The other queries hundreds of archives for all datasets that fall on a particular piece of sky.

  `http://www.us-vo.org/`

General Physics

- **NIST Physical Measurement Laboratory:** The National Institute of Standards and Technology provides access to physical reference data (physical constants, atomic spectroscopy data, x-ray and gamma-ray data, radiation dosimetry data, nuclear physics data and more) and measurements and calibrations data (dimensional and electromagnetic measurements). The site points to a general interest page, linking to exhibits of the Physical Measurement Laboratory in the NIST Virtual Museum.

  `http://physics.nist.gov/`

- **Springer Materials - The Landolt-Börnstein Database:** Landolt-Börnstein is a data collection in all areas of physical sciences and engineering, among others particle physics, electronic structure and transport, magnetism, superconductivity. International experts scan the primary literature in more than 8,000 peer-reviewed journals and evaluate and select the most valid information to be included in the database. It includes more than 100,000 online documents, 1,2 million references, and covers 250,000 chemical substances. The search functionality is freely accessible and the search results are displayed in their context, whereas the full text is secured to subscribers.

  `http://materials.springer.com/`

13. Data preservation activities

Particle Physics

- **DASPOS:** A collective effort to explore the realisation of a viable data, software and computation preservation architecture in High Energy Physics

  `https://daspos.crc.nd.edu`

- **DPHEP:** The efforts to define and coordinate Data Preservation and Long Term Analysis in HEP are coordinated by a study group formed to investigate the issues associated with these activities.

The group, DPHEP, was initiated during 2008-2009 and includes all HEP major experiments and labs.

Details of the organizational structure, the objectives, workshops and publications can be found on the website.

The group is endorsed by the International Committee for Future Accelerators (ICFA).

In July 2014 the DPHEP collaboration was formed as a result of the signature of the Collaboration Agreement by seven large funding agencies (others have since joined or are in the process of acquisition) and in June 2015 the first DPHEP Collaboration Workshop and Collaboration Board meeting took place.

`http://dphep.org`

Astrophysics

More formal and advanced data preservation activity is ongoing in the field of Experimental Astrophysics, including:

- SDSS (Sloan Digital Sky Survey)
  `http://sdss.org`
- Fermi Data
  `http://fermi.gsfc.nasa.gov/ssc/data`
- IVOA (International Virtual Observatory Alliance)
  `http://www.ivoa.net/`

14. Particle Physics Education and Outreach Sites

Science Educators' Networks:

- **IPPOG:** The International Particle Physics Outreach Group is a network of particle physicists, researchers, informal science educators and science explainers aiming to raise awareness, understanding and standards of global outreach efforts in particle physics and general science by providing discussion forums and regular information exchange for science institutions, proposing and implementing strategies to share lessons learned and best practices and promoting current outreach efforts of network members.
  `http://ippog.web.cern.ch`
- **Interactions.org:** Designed to serve as a central resource for communicators of particle physics. The daily updated site provides links to current particle physics news from the world's press, high-resolution photos and graphics from the particle physics laboratories of the world; links to education and outreach programs; information about science policy and funding; a glossary; and links to many educational sites.
  `http://www.interactions.org`
- **I2U2 (Interactions in Understanding the Universe):** The I2U2 e-Labs use the Internet and distributed computing in high-school classes and provide an opportunity for students to organise and conduct authentic research; experience the environment of scientific collaborations; make real scientific contributions. It is supported by QuarkNet, NSF and DOE.
  `http://www.i2u2.org`

Master Classes

- **CMS physics masterclass:** Lectures from active scientists give insight into methods of basic research, enabling the students to perform measurements on real data from the CMS experiment at the LHC. Like in an international research collaboration, the participants then discuss their results and compare with expectations.
  `http://cms.web.cern.ch/content/cms-physics-masterclass`
- **International Masterclasses:** Each year about 10000 high school students in 42 countries come to one of about 200 nearby universities or research centres for one day in order to unravel the mysteries of particle physics. Lectures from active scientists give insight in topics and methods of basic research at the fundaments of matter and forces, enabling the students to perform measurements on real data from particle physics experiments themselves. At the end of each day, like in an international research collaboration, the participants join in a video conference for discussion and combination of their results.
  `http://physicsmasterclasses.org/`
- **MINERVA:** MINERVA (Masterclass INvolving Event recognition visualised with Atlantis) is a masterclass tool for students to learn more about the ATLAS experiment at CERN, based on a simplified setup of the ATLAS event display, Atlantis.
  `http://atlas-minerva.web.cern.ch/atlas-minerva/`

General Sites

- **Contemporary Physics Education Project (CPEP):** Provides charts, brochures, Web links, and classroom activities. Online interactive courses include: Fundamental Particles and Interactions; Plasma Physics and Fusion; History and Fate of the Universe; and Nuclear Science.
  `http://www.cpepweb.org/`

Particle Physics Lessons & Activities

- **Angels and Demons:** With the aim of looking at the myth versus the reality of antimatter and science at CERN this site offers teacher resources, slide shows and videos of talks given to teachers visiting CERN.
  `http://angelsanddemons.web.cern.ch/`
- **ATLAS @ Home** A research project that uses volunteer computing to run simulations of the ATLAS experiment at CERN.
  `http://atlasathome.cern.ch`
- **Big Bang Science: Exploring the origins of matter:** This Web site, produced by the Particle Physics and Astronomy Research Council of the UK (PPARC), explains what physicists are looking for with their giant instruments. It focuses on CERN particle detectors and on United Kingdom scientists' contribution to the search for the fundamental building blocks of matter.
  `http://hepwww.rl.ac.uk/pub/bigbang/part1.html`
- **Cambridge Relativity and Cosmology:**
  `http://www.damtp.cam.ac.uk/research/gr/public/index.html`
- **CAMELIA:** CAMELIA (Cross-platform Atlas Multimedia Educational Lab for Interactive Analysis) is a discovery tool for the general public, based on computer gaming technology.
  `http://www.atlas.ch/camelia.html`
- **CERNland:** With a range of games, multimedia applications and films CERNland is a virtual theme park developed to bring the excitement of CERN's research to a young audience aged between 7 and 12. CERNland is designed to show children what is being done at CERN and inspire them with some physics at the same time.
  `http://www.cernland.net/`
- **CollidingParticles:** A series of films following a team of physicists involved in research at the LHC.
  `http://www.collidingparticles.com/`
- **Hands-On Universe:** This educational program enables students to investigate the Universe while applying tools and cocncepts from science, math and technology.
  `http://handsonuniverse.org/`
- **Higgs Hunters:** A web-based citizen science project to help search for unknown exotic particles in the LHC data.
  `http://HiggsHunters.org`
- **HYPATIA:** HYPATIA (Hybrid Pupil's Analysis Tool for Interactions in Atlas) is a tool for high school students to inspect the graphic visualizaton of products of particle collisions in the ATLAS detector at CERN.
  `http://hypatia.phys.uoa.gr/`

- **Imagine the Universe:** This NASA site is intended for students age 14 and up and for anyone interested in learning about the universe.

  `http://imagine.gsfc.nasa.gov/home.html`

- **In particular:** Podcast about physics and the process of discovering physics at the ATLAS experiment.

  `https://itunes.apple.com/us/podcast/in-particular/id1001131655?mt=2`

- **Lancaster Particle Physics:** This site, suitable for 16+ students, offers a number of simulations and explanations of particle physics, including a section on the LHC.

  `http://www.lppp.lancs.ac.uk/`

- **LHC @ home:** Volunteer computing platform to help physicists compare theory with experiment, in the search for new fundamental particles and answers to questions about the Universe.

  `http://lhcathome.web.cern.ch`

  The Test4Theory allows allows volunteers to run simulations of high-energy particle physics on their home computers. The results are submitted to a database which is used as a common resource by both experimental and theoretical scientists working on the Large Hadron Collider at CERN.

  `http://lhcathome.web.cern.ch/projects/test4theory`

  The SIXTRACK project allows users with Internet-connected computers to participate in advancing Accelerator Physics.

  `http://lhcathome.web.cern.ch/projects/sixtrack`

- **Particle Adventure:** One of the most popular Web sites for learning the fundamentals of matter and force. An award-winning interactive tour of quarks, neutrinos, antimatter, extra dimensions, dark matter, accelerators and particle detectors from the Particle Data Group of Lawrence Berkeley National Laboratory. Simple elegant graphics and translations into 16 languages.

  `http://particleadventure.org/`

- **Quarked! - Adventures in the Subatomic Universe:** This project, targeted to kids aged 7-12 (and their families), brings subatomic physics to life through a multimedia project including an interactive website, a facilitated program for museums and schools, and an educational outreach program.

  `http://www.quarked.org/`

- **QuarkNet:** Brings the excitement of particle physics research to high school teachers and their students. Teachers join research groups at about 50 universities and labs across the country. These research groups are part of particle physics experiments at CERN or Fermilab. About 100,000 students from 500+ US high schools learn fundamental physics as they participate in inquiry-oriented investigations and analyze real data online. QuarkNet is supported in part by the National Science Foundation and the U.S. Department of Energy.

  `https://quarknet.i2u2.org/`

- **Rewarding Learning videos about CERN:** The three videos based on interviews with scientists and engineers at CERN introduce pupils to CERN and the type of research and work undertaken there and are accompanied by teachers' notes.

  `http://www.nicurriculum.org.uk/STEMWorks/resources/cern/index.asp`

Lab Education Offices

- **Argonne National Laboratory (ANL) Educational Programs:**

  `http://www.anl.gov/education/`

- **Brookhaven National Laboratory (BNL) Educational Programs:** The Office of Educational Programs mission is to design, develop, implement, and facilitate workforce development and education initiatives that support the scientific mission at Brookhaven National Laboratory and the Department of Energy.

  `http://www.bnl.gov/education/`

- **CERN:** The CERN education website offers informations about teacher programmes and educational resources for schools.

  `http://education.web.cern.ch/education/`

- **DESY:** Offers courses for pupils and teachers as well as information for the general public, mostly in German.

  `http://www.desy.de/information_services/education/`

- **FermiLab Education Office:** Provides education resources and information about activities for educators, physicists, students and visitors to the Lab. In addition to information on 25 programs, the site provides online data-based investigations for high school students, online versions of exhibits in the Lederman Science Center, links to particle physics discovery resources, web-based instructional resources, what works for education and outreach, and links to the Lederman Science Center and the Teacher Resource Center.

  `http://ed.fnal.gov/`

- **Science Education at Jefferson Lab:**

  `http://education.jlab.org/`

- **LBL Workforce Development and Education:** This group carries out Berkeley Labs mission to inspire and prepare the next generation of scientists, engineers, and technicians.

  `http://csee.lbl.gov/`

Educational Programs of Experiments

- **ATLAS Discovery Quest:** One of several access points to ATLAS education and outreach pages. This page gives access to explanations of physical concepts, blogs, ATLAS facts, news, and information for students and teachers.

  `http://www.atlas.ch/physics.html`

- **ATLAS eTours:** Give a description of the Large Hadron Collider, explain how the ATLAS detector at the LHC works and give an overview over the experiments and their physics goals.

  `http://www.atlas.ch/etours.html`

- **Education and Outreach @ IceCube:**

  `http://icecube.wisc.edu/outreach`

- **LIGO Science Education Center:** The LIGO (Laser Interferometer Gravitational-wave Observatory) Science Education Center has over 40 interactive, hands-on exhibits that relate to the science of LIGO. The site hosts field trips for students, teacher training programs, and tours for the general public. Visitors can explore science concepts such as light, gravity, waves, and interference; learn about LIGO's search for gravitational waves; and interact with scientists and engineers.

  `https://ligo.caltech.edu/page/educational-resources`

- **Pierre Auger Observatory's Educational Pages:** The site offers information about cosmic rays and their detection, and provides material for students and teachers.

  `https://www.auger.org/index.php/edu-outreach`

News

- **Asimmetrie:** Bimonthly magazine about particle physics published by INFN, the Istituto Nazionale di Fisica Nucleare

  `http://www.asimmetrie.it/`

- **CERN Courier:**

  `http://cerncourier.com/cws/latest/cern`

- **DESY inForm:**

  `http://www.desy.de/aktuelles/desy_inform`

- **Fermilab Today:**

  `http://www.fnal.gov/pub/today/`

- **LC Newsline:** The newsletter of the Linear Collider community

  `http://newsline.linearcollider.org/`

  `twitter: @ILCnewsline`

- **IOP News:**
  http://www.iop.org/news/
- **JINR News:**
  http://www1.jinr.ru/News/Jinrnews_index.html
- **News at Interactions.org:** The InterActions site provides news and press releases on particle physics.
  http://www.interactions.org/cms/?pid=1000680
  twitter: @particlenews
- **Symmetry:** This magazine about particle physics and its connections to other aspects of life and science, from interdisciplinary collaborations to policy to culture is published 6 times per year by Fermilab and SLAC.
  http://www.symmetrymagazine.org/
  twitter: @symmetrymag

Art in Physics

- **Arts@CERN:** The Collide@CERN residency programme brings together world-class artists and scientists in a free exchange of ideas.
  http://arts.web.cern.ch/collide/ Accelerate@CERN is a country specific one-month research award for artists who have never spent tine in a science lab before.
  http://arts.web.cern.ch/acceleratecern
- **Art of Physics Competition:** The Canadian Association of Physicists organizes this competition, the first was launched in 1992, with the aim of stimulating interest, especially among non-scientists, in some of the captivating imagery associated with physics. The challenge is to capture photographically a beautiful or unusual physics phenomenon and explain it in less than 200 words in terms that everyone can understand.
  http://www.cap.ca/aop/art.html

Blogs and Twitter

Lists of active blogs and tweets can be found on INSPIRE:

GAUGE AND HIGGS BOSONS

γ (photon)

$I(J^{PC}) = 0,1(1^{--})$

Mass $m < 1 \times 10^{-18}$ eV
Charge $q < 1 \times 10^{-35}$ e
Mean life τ = Stable

g or gluon

$I(J^{P}) = 0(1^{-})$

Mass $m = 0$ [a]
SU(3) color octet

graviton

$J = 2$

Mass $m < 6 \times 10^{-32}$ eV

W

$J = 1$

Charge $= \pm 1$ e
Mass $m = 80.385 \pm 0.015$ GeV
W/Z mass ratio $= 0.88153 \pm 0.00017$
$m_Z - m_W = 10.803 \pm 0.015$ GeV
$m_{W^+} - m_{W^-} = -0.2 \pm 0.6$ GeV
Full width $\Gamma = 2.085 \pm 0.042$ GeV
$\langle N_{\pi^\pm} \rangle = 15.70 \pm 0.35$
$\langle N_{K^\pm} \rangle = 2.20 \pm 0.19$
$\langle N_p \rangle = 0.92 \pm 0.14$
$\langle N_{\text{charged}} \rangle = 19.39 \pm 0.08$

W^- modes are charge conjugates of the modes below.

W^+ DECAY MODES		Fraction (Γ_i/Γ)		Confidence level	p (MeV/c)
$\ell^+\nu$	[b]	(10.86± 0.09)	%		–
$e^+\nu$		(10.71± 0.16)	%		40192
$\mu^+\nu$		(10.63± 0.15)	%		40192
$\tau^+\nu$		(11.38± 0.21)	%		40173
hadrons		(67.41± 0.27)	%		–
$\pi^+\gamma$		< 7	$\times 10^{-6}$	95%	40192
$D_s^+\gamma$		< 1.3	$\times 10^{-3}$	95%	40168
cX		(33.3 ± 2.6)	%		–
$c\overline{s}$		(31 $^{+13}_{-11}$)	%		–
invisible	[c]	(1.4 ± 2.9)	%		–

Z

$J = 1$

Charge $= 0$
Mass $m = 91.1876 \pm 0.0021$ GeV [d]
Full width $\Gamma = 2.4952 \pm 0.0023$ GeV
$\Gamma(\ell^+\ell^-) = 83.984 \pm 0.086$ MeV [b]
$\Gamma(\text{invisible}) = 499.0 \pm 1.5$ MeV [e]
$\Gamma(\text{hadrons}) = 1744.4 \pm 2.0$ MeV
$\Gamma(\mu^+\mu^-)/\Gamma(e^+e^-) = 1.0009 \pm 0.0028$
$\Gamma(\tau^+\tau^-)/\Gamma(e^+e^-) = 1.0019 \pm 0.0032$ [f]

Average charged multiplicity

$\langle N_{charged} \rangle = 20.76 \pm 0.16$ (S = 2.1)

Couplings to quarks and leptons

$g_V^\ell = -0.03783 \pm 0.00041$
$g_V^u = 0.25^{+0.07}_{-0.06}$
$g_V^d = -0.33^{+0.05}_{-0.06}$
$g_A^\ell = -0.50123 \pm 0.00026$
$g_A^u = 0.50^{+0.04}_{-0.06}$
$g_A^d = -0.523^{+0.050}_{-0.029}$
$g^{\nu_\ell} = 0.5008 \pm 0.0008$
$g^{\nu_e} = 0.53 \pm 0.09$
$g^{\nu_\mu} = 0.502 \pm 0.017$

Gauge & Higgs Boson Summary Table

Asymmetry parameters [g]

$A_e = 0.1515 \pm 0.0019$
$A_\mu = 0.142 \pm 0.015$
$A_\tau = 0.143 \pm 0.004$
$A_s = 0.90 \pm 0.09$
$A_c = 0.670 \pm 0.027$
$A_b = 0.923 \pm 0.020$

Charge asymmetry (%) at Z pole

$A_{FB}^{(0\ell)} = 1.71 \pm 0.10$
$A_{FB}^{(0u)} = 4 \pm 7$
$A_{FB}^{(0s)} = 9.8 \pm 1.1$
$A_{FB}^{(0c)} = 7.07 \pm 0.35$
$A_{FB}^{(0b)} = 9.92 \pm 0.16$

Z DECAY MODES			Fraction (Γ_i/Γ)		Scale factor/ Confidence level	p (MeV/c)
e^+e^-			(3.363 ±0.004) %			45594

Neutral Higgs Bosons, Searches for

Searches for a Higgs Boson with Standard Model Couplings

Mass $m > 122$ and none 128–1000 GeV, CL = 95%

The limits for H_1^0 and A^0 in supersymmetric models refer to the m_h^{max} benchmark scenario for the supersymmetric parameters.

H_1^0 in Supersymmetric Models ($m_{H_1^0} < m_{H_2^0}$)

Mass $m > 92.8$ GeV, CL = 95%

A^0 Pseudoscalar Higgs Boson in Supersymmetric Models [n]

Mass $m > 93.4$ GeV, CL = 95% $\tan\beta > 0.4$

Charged Higgs Bosons ($H^\pm$ and $H^{\pm\pm}$), Searches for

$H^\pm$ Mass $m > 80$ GeV, CL = 95%

New Heavy Bosons (W', Z', leptoquarks, etc.), Searches for

Additional W Bosons

W' with standard couplings
Mass $m > 3.710 \times 10^3$ GeV, CL = 95% ($p\overline{p}$ direct search)
W_R (Right-handed W Boson)
Mass $m > 715$ GeV, CL = 90% (electroweak fit)

Additional Z Bosons

Z'_{SM} with standard couplings
Mass $m > 2.900 \times 10^3$ GeV, CL = 95% ($p\overline{p}$ direct search)
Mass $m > 1.500 \times 10^3$ GeV, CL = 95% (electroweak fit)
Z_{LR} of $SU(2)_L \times SU(2)_R \times U(1)$ (with $g_L = g_R$)
Mass $m > 630$ GeV, CL = 95% ($p\overline{p}$ direct search)
Mass $m > 1162$ GeV, CL = 95% (electroweak fit)
Z_χ of $SO(10) \rightarrow SU(5) \times U(1)_\chi$ (with $g_\chi = e/\cos\theta_W$)
Mass $m > 2.620 \times 10^3$ GeV, CL = 95% ($p\overline{p}$ direct search)
Mass $m > 1.141 \times 10^3$ GeV, CL = 95% (electroweak fit)
Z_ψ of $E_6 \rightarrow SO(10) \times U(1)_\psi$ (with $g_\psi = e/\cos\theta_W$)
Mass $m > 2.570 \times 10^3$ GeV, CL = 95% ($p\overline{p}$ direct search)
Mass $m > 476$ GeV, CL = 95% (electroweak fit)
Z_η of $E_6 \rightarrow SU(3) \times SU(2) \times U(1) \times U(1)_\eta$ (with $g_\eta = e/\cos\theta_W$)
Mass $m > 1.870 \times 10^3$ GeV, CL = 95% ($p\overline{p}$ direct search)
Mass $m > 619$ GeV, CL = 95% (electroweak fit)

Scalar Leptoquarks

Mass $m >$ 1050 GeV, CL = 95% (1st generation, pair prod.)
Mass $m >$ 304 GeV, CL = 95% (1st generation, single prod.)
Mass $m >$ 1000 GeV, CL = 95% (2nd generation, pair prod.)
Mass $m >$ 73 GeV, CL = 95% (2nd generation, single prod.)
Mass $m >$ 740 GeV, CL = 95% (3rd generation, pair prod.)
(See the Particle Listings for assumptions on leptoquark quantum numbers and branching fractions.)

Diquarks

Mass $m >$ 4700 GeV, CL = 95% (E_6 diquark)

Axigluon

Mass $m >$ 3600 GeV, CL = 95%

Axions (A^0) and Other Very Light Bosons, Searches for

The standard Peccei-Quinn axion is ruled out. Variants with reduced couplings or much smaller masses are constrained by various data. The Particle Listings in the full *Review* contain a Note discussing axion searches.

The best limit for the half-life of neutrinoless double beta decay with Majoron emission is $> 7.2 \times 10^{24}$ years (CL = 90%).

NOTES

In this Summary Table:

When a quantity has "(S = ...)" to its right, the error on the quantity has been enlarged by the "scale factor" S, defined as $S = \sqrt{\chi^2/(N-1)}$, where N is the number of measurements used in calculating the quantity. We do this when $S > 1$, which often indicates that the measurements are inconsistent. When $S > 1.25$, we also show in the Particle Listings an ideogram of the measurements. For more about S, see the Introduction.

A decay momentum p is given for each decay mode. For a 2-body decay, p is the momentum of each decay product in the rest frame of the decaying particle. For a 3-or-more-body decay, p is the largest momentum any of the products can have in this frame.

[a] Theoretical value. A mass as large as a few MeV may not be precluded.

[b] ℓ indicates each type of lepton (e, μ, and τ), not sum over them.

[c] This represents the width for the decay of the W boson into a charged particle with momentum below detectability, p< 200 MeV.

[d] The Z-boson mass listed here corresponds to a Breit-Wigner resonance parameter. It lies approximately 34 MeV above the real part of the position of the pole (in the energy-squared plane) in the Z-boson propagator.

[e] This partial width takes into account Z decays into $\nu\overline{\nu}$ and any other possible undetected modes.

[f] This ratio has not been corrected for the τ mass.

[g] Here $A \equiv 2g_V g_A/(g_V^2+g_A^2)$.

[h] Here ℓ indicates e or μ.

[i] The value is for the sum of the charge states or particle/antiparticle states indicated.

[j] This value is updated using the product of (i) the $Z \to b\overline{b}$ fraction from this listing and (ii) the b-hadron fraction in an unbiased sample of weakly decaying b-hadrons produced in Z-decays provided by the Heavy Flavor Averaging Group (HFAG, http://www.slac.stanford.edu/xorg/hfag/osc/PDG_2009/#FRACZ).

[k] See the Z Particle Listings for the γ energy range used in this measurement.

[l] For $m_{\gamma\gamma} = (60 \pm 5)$ GeV.

[n] The limits assume no invisible decays.

Lepton Summary Table

LEPTONS

Lepton Family number (*LF*), Lepton number (*L*), or Baryon number (*B*) violating modes

L means lepton number violation (*e.g.* $\tau^- \rightarrow e^+\pi^-\pi^-$). Following common usage, *LF* means lepton family violation *and not* lepton number violation (*e.g.* $\tau^- \rightarrow e^-\pi^+\pi^-$). *B* means baryon number violation.

Heavy Charged Lepton Searches

$L^\pm$ – charged lepton

Mass $m >$ 100.8 GeV, CL = 95% [h] Decay to νW.

$L^\pm$ – stable charged heavy lepton

Mass $m >$ 102.6 GeV, CL = 95%

Neutrino Properties

See the note on "Neutrino properties listings" in the Particle Listings.

Mass $m <$ 2 eV (tritium decay)
Mean life/mass, $\tau/m >$ 300 s/eV, CL = 90% (reactor)
Mean life/mass, $\tau/m > 7 \times 10^9$ s/eV (solar)
Mean life/mass, $\tau/m >$ 15.4 s/eV, CL = 90% (accelerator)
Magnetic moment $\mu < 0.29 \times 10^{-10}\ \mu_B$, CL = 90% (reactor)

Number of Neutrino Types

Number $N = 2.984 \pm 0.008$ (Standard Model fits to LEP-SLC data)
Number $N = 2.92 \pm 0.05$ (S = 1.2) (Direct measurement of invisible Z width)

Neutrino Mixing

The following values are obtained through data analyses based on the 3-neutrino mixing scheme described in the review "Neutrino Mass, Mixing, and Oscillations" by K. Nakamura and S.T. Petcov in this *Review*.

$\sin^2(\theta_{12}) = 0.304 \pm 0.014$
$\Delta m^2_{21} = (7.53 \pm 0.18) \times 10^{-5}$ eV^2
$\sin^2(\theta_{23}) = 0.51 \pm 0.05$ (normal mass hierarchy)
$\sin^2(\theta_{23}) = 0.50 \pm 0.05$ (inverted mass hierarchy)
$\Delta m^2_{32} = (2.44 \pm 0.06) \times 10^{-3}$ eV^2 [i] (normal mass hierarchy)
$\Delta m^2_{32} = (2.51 \pm 0.06) \times 10^{-3}$ eV^2 [i] (inverted mass hierarchy)
$\sin^2(\theta_{13}) = (2.19 \pm 0.12) \times 10^{-2}$

Stable Neutral Heavy Lepton Mass Limits

Mass $m >$ 45.0 GeV, CL = 95% (Dirac)
Mass $m >$ 39.5 GeV, CL = 95% (Majorana)

Neutral Heavy Lepton Mass Limits

Mass $m >$ 90.3 GeV, CL = 95%
(Dirac ν_L coupling to e, μ, τ; conservative case(τ))
Mass $m >$ 80.5 GeV, CL = 95%
(Majorana ν_L coupling to e, μ, τ; conservative case(τ))

NOTES

In this Summary Table:

When a quantity has "(S = ...)" to its right, the error on the quantity has been enlarged by the "scale factor" S, defined as $S = \sqrt{\chi^2/(N-1)}$, where N is the number of measurements used in calculating the quantity. We do this when S > 1, which often indicates that the measurements are inconsistent. When S > 1.25, we also show in the Particle Listings an ideogram of the measurements. For more about S, see the Introduction.

A decay momentum p is given for each decay mode. For a 2-body decay, p is the momentum of each decay product in the rest frame of the decaying particle. For a 3-or-more-body decay, p is the largest momentum any of the products can have in this frame.

[a] This is the best limit for the mode $e^- \to \nu\gamma$. The best limit for "electron disappearance" is 6.4×10^{24} yr.

[b] See the "Note on Muon Decay Parameters" in the μ Particle Listings for definitions and details.

[c] P_μ is the longitudinal polarization of the muon from pion decay. In standard $V-A$ theory, $P_\mu = 1$ and $\rho = \delta = 3/4$.

[d] This only includes events with the γ energy > 10 MeV. Since the $e^-\overline{\nu}_e\nu_\mu$ and $e^-\overline{\nu}_e\nu_\mu\gamma$ modes cannot be clearly separated, we regard the latter mode as a subset of the former.

[e] See the relevant Particle Listings for the energy limits used in this measurement.

[f] A test of additive vs. multiplicative lepton family number conservation.

[g] Basis mode for the τ.

[h] $L^\pm$ mass limit depends on decay assumptions; see the Full Listings.

[i] The sign of Δm^2_{32} is not known at this time. The range quoted is for the absolute value.

Quark Summary Table

QUARKS

The u-, d-, and s-quark masses are estimates of so-called "current-quark masses," in a mass-independent subtraction scheme such as $\overline{\text{MS}}$ at a scale $\mu \approx 2$ GeV. The c- and b-quark masses are the "running" masses in the $\overline{\text{MS}}$ scheme. For the b-quark we also quote the 1S mass. These can be different from the heavy quark masses obtained in potential models.

u

$I(J^P) = \frac{1}{2}(\frac{1}{2}^+)$

$m_u = 2.2^{+0.6}_{-0.4}$ MeV Charge $= \frac{2}{3}\,e$ $I_z = +\frac{1}{2}$
$m_u/m_d = 0.38$–0.58

d

$I(J^P) = \frac{1}{2}(\frac{1}{2}^+)$

$m_d = 4.7^{+0.5}_{-0.4}$ MeV Charge $= -\frac{1}{3}\,e$ $I_z = -\frac{1}{2}$
$m_s/m_d = 17$–22
$\overline{m} = (m_u+m_d)/2 = 3.5^{+0.7}_{-0.3}$ MeV

s

$I(J^P) = 0(\frac{1}{2}^+)$

$m_s = 96^{+8}_{-4}$ MeV Charge $= -\frac{1}{3}\,e$ Strangeness $= -1$
$m_s\ /\ ((m_u + m_d)/2) = 27.3 \pm 0.7$

c

$I(J^P) = 0(\frac{1}{2}^+)$

$m_c = 1.27 \pm 0.03$ GeV Charge $= \frac{2}{3}\,e$ Charm $= +1$
$m_c/m_s = 11.72 \pm 0.25$
$m_b/m_c = 4.53 \pm 0.05$
$m_b - m_c = 3.45 \pm 0.05$ GeV

b

$I(J^P) = 0(\frac{1}{2}^+)$

Charge $= -\frac{1}{3}\,e$ Bottom $= -1$

$m_b(\overline{\text{MS}}) = 4.18^{+0.04}_{-0.03}$ GeV
$m_b(1\text{S}) = 4.66^{+0.04}_{-0.03}$ GeV

t

$I(J^P) = 0(\frac{1}{2}^+)$

Charge $= \frac{2}{3}\,e$ Top $= +1$

Mass (direct measurements) $m = 173.21 \pm 0.51 \pm 0.71$ GeV [a,b]
Mass ($\overline{\text{MS}}$ from cross-section measurements) $m = 160^{+5}_{-4}$ GeV [a]
Mass (Pole from cross-section measurements) $m = 174.2 \pm 1.4$ GeV
$m_t - m_{\overline{t}} = -0.2 \pm 0.5$ GeV (S = 1.1)
Full width $\Gamma = 1.41^{+0.19}_{-0.15}$ GeV (S = 1.4)
$\Gamma(Wb)/\Gamma(Wq(q = b, s, d)) = 0.957 \pm 0.034$ (S = 1.5)

t-quark EW Couplings

$F_0 = 0.690 \pm 0.030$
$F_- = 0.314 \pm 0.025$
$F_+ = 0.008 \pm 0.016$
$F_{V+A} < 0.29$, CL = 95%

t DECAY MODES		Fraction (Γ_i/Γ)	Confidence level	p (MeV/c)

$t \to \ell^+\overline{q}q'(q=d,s,b;\ q'=u,c)$		$< 1.6 \times 10^{-3}$	95%	–

b′ (4th Generation) Quark, Searches for

Mass $m >$ 190 GeV, CL = 95% ($p\overline{p}$, quasi-stable b')
Mass $m >$ 755 GeV, CL = 95% (pp, neutral-current decays)
Mass $m >$ 675 GeV, CL = 95% (pp, charged-current decays)
Mass $m >$ 46.0 GeV, CL = 95% (e^+e^-, all decays)

t′ (4th Generation) Quark, Searches for

$m(t'(2/3)) >$ 782 GeV, CL = 95% (neutral-current decays)
$m(t'(2/3)) >$ 700 GeV, CL = 95% (charged-current decays)
$m(t'(5/3)) >$ 800 GeV, CL = 95%

Free Quark Searches

All searches since 1977 have had negative results.

NOTES

[a] A discussion of the definition of the top quark mass in these measurements can be found in the review "The Top Quark."

[b] Based on published top mass measurements using data from Tevatron Run-I and Run-II and LHC at $\sqrt{s} = 7$ TeV. Including the most recent unpublished results from Tevatron Run-II, the Tevatron Electroweak Working Group reports a top mass of 173.2 ± 0.9 GeV. See the note "The Top Quark' in the Quark Particle Listings of this *Review*.

[c] ℓ means e or μ decay mode, not the sum over them.

[d] Assumes lepton universality and W-decay acceptance.

[e] This limit is for $\Gamma(t \to \gamma q)/\Gamma(t \to Wb)$.

[f] This limit is for $\Gamma(t \to Zq)/\Gamma(t \to Wb)$.

LIGHT UNFLAVORED MESONS ($S = C = B = 0$)

For $I = 1$ (π, b, ρ, a): $u\overline{d}$, $(u\overline{u}-d\overline{d})/\sqrt{2}$, $d\overline{u}$;
for $I = 0$ (η, η', h, h', ω, ϕ, f, f'): $c_1(u\overline{u} + d\overline{d}) + c_2(s\overline{s})$

$\pi^\pm$

$I^G(J^P) = 1^-(0^-)$

Mass $m = 139.57018 \pm 0.00035$ MeV (S = 1.2)
Mean life $\tau = (2.6033 \pm 0.0005) \times 10^{-8}$ s (S = 1.2)
$c\tau = 7.8045$ m

$\pi^\pm \to \ell^\pm\nu\gamma$ form factors [a]

$F_V = 0.0254 \pm 0.0017$
$F_A = 0.0119 \pm 0.0001$
F_V slope parameter $a = 0.10 \pm 0.06$
$R = 0.059^{+0.009}_{-0.008}$

π^- modes are charge conjugates of the modes below.

For decay limits to particles which are not established, see the section on Searches for Axions and Other Very Light Bosons.

π^+ DECAY MODES		Fraction (Γ_i/Γ)	Confidence level	p (MeV/c)

STRANGE MESONS
($S = \pm 1, C = B = 0$)

$K^+ = u\bar{s}$, $K^0 = d\bar{s}$, $\overline{K}^0 = \bar{d}s$, $K^- = \bar{u}s$, similarly for K^*'s

$K^\pm$

$I(J^P) = \frac{1}{2}(0^-)$

Mass $m = 493.677 \pm 0.016$ MeV [u] (S = 2.8)
Mean life $\tau = (1.2380 \pm 0.0020) \times 10^{-8}$ s (S = 1.8)
$c\tau = 3.711$ m

CPT violation parameters (Δ = rate difference/sum)

$\Delta(K^\pm \to \mu^\pm \nu_\mu) = (-0.27 \pm 0.21)\%$
$\Delta(K^\pm \to \pi^\pm \pi^0) = (0.4 \pm 0.6)\%$ [v]

CP violation parameters (Δ = rate difference/sum)

$\Delta(K^\pm \to \pi^\pm e^+ e^-) = (-2.2 \pm 1.6) \times 10^{-2}$
$\Delta(K^\pm \to \pi^\pm \mu^+ \mu^-) = 0.010 \pm 0.023$
$\Delta(K^\pm \to \pi^\pm \pi^0 \gamma) = (0.0 \pm 1.2) \times 10^{-3}$
$\Delta(K^\pm \to \pi^\pm \pi^+ \pi^-) = (0.04 \pm 0.06)\%$
$\Delta(K^\pm \to \pi^\pm \pi^0 \pi^0) = (-0.02 \pm 0.28)\%$

T violation parameters

$K^+ \to \pi^0 \mu^+ \nu_\mu \quad P_T = (-1.7 \pm 2.5) \times 10^{-3}$
$K^+ \to \mu^+ \nu_\mu \gamma \quad P_T = (-0.6 \pm 1.9) \times 10^{-2}$
$K^+ \to \pi^0 \mu^+ \nu_\mu \quad \mathrm{Im}(\xi) = -0.006 \pm 0.008$

Slope parameter g [x]

(See Particle Listings for quadratic coefficients and alternative parametrization related to $\pi\pi$ scattering)

$K^\pm \to \pi^\pm \pi^+ \pi^- \; g = -0.21134 \pm 0.00017$
$(g_+ - g_-) / (g_+ + g_-) = (-1.5 \pm 2.2) \times 10^{-4}$
$K^\pm \to \pi^\pm \pi^0 \pi^0 \; g = 0.626 \pm 0.007$
$(g_+ - g_-) / (g_+ + g_-) = (1.8 \pm 1.8) \times 10^{-4}$

$K^\pm$ decay form factors [a,y]

Assuming μ-e universality
$\lambda_+(K^+_{\mu 3}) = \lambda_+(K^+_{e3}) = (2.97 \pm 0.05) \times 10^{-2}$
$\lambda_0(K^+_{\mu 3}) = (1.95 \pm 0.12) \times 10^{-2}$

Not assuming μ-e universality
$\lambda_+(K^+_{e3}) = (2.98 \pm 0.05) \times 10^{-2}$
$\lambda_+(K^+_{\mu 3}) = (2.96 \pm 0.17) \times 10^{-2}$
$\lambda_0(K^+_{\mu 3}) = (1.96 \pm 0.13) \times 10^{-2}$

K_{e3} form factor quadratic fit
$\lambda'_+(K^\pm_{e3})$ linear coeff. $= (2.49 \pm 0.17) \times 10^{-2}$
$\lambda''_+(K^\pm_{e3})$ quadratic coeff. $= (0.19 \pm 0.09) \times 10^{-2}$

$K^+_{e3} \quad |f_S/f_+| = (-0.3^{+0.8}_{-0.7}) \times 10^{-2}$
$K^+_{e3} \quad |f_T/f_+| = (-1.2 \pm 2.3) \times 10^{-2}$
$K^+_{\mu 3} \quad |f_S/f_+| = (0.2 \pm 0.6) \times 10^{-2}$
$K^+_{\mu 3} \quad |f_T/f_+| = (-0.1 \pm 0.7) \times 10^{-2}$
$K^+ \to e^+ \nu_e \gamma \quad |F_A + F_V| = 0.133 \pm 0.008$ (S = 1.3)
$K^+ \to \mu^+ \nu_\mu \gamma \quad |F_A + F_V| = 0.165 \pm 0.013$
$K^+ \to e^+ \nu_e \gamma \quad |F_A - F_V| < 0.49$, CL = 90%
$K^+ \to \mu^+ \nu_\mu \gamma \quad |F_A - F_V| = -0.24$ to 0.04, CL = 90%

Charge radius

$\langle r \rangle = 0.560 \pm 0.031$ fm

Forward-backward asymmetry

$A_{FB}(K^\pm_{\pi\mu\mu}) = \frac{\Gamma(\cos(\theta_{K\mu})>0) - \Gamma(\cos(\theta_{K\mu})<0)}{\Gamma(\cos(\theta_{K\mu})>0) + \Gamma(\cos(\theta_{K\mu})<0)} < 2.3 \times 10^{-2}$, CL = 90%

K^- modes are charge conjugates of the modes below.

Γ_+/Γ_- in $\overline{K}^*(892)^0\ell^+\nu_\ell = 0.22 \pm 0.06$ (S = 1.6)

Most decay modes (other than the semileptonic modes) that involve a neutral K meson are now given as K^0_S modes, not as $\overline{K}^0$ modes. Nearly always it is a K^0_S that is measured, and interference between Cabibbo-allowed and doubly Cabibbo-suppressed modes can invalidate the assumption that $2\Gamma(K^0_S) = \Gamma(\overline{K}^0)$.

CP-even fraction in $D^0 \to \pi^+\pi^-\pi^+\pi^-$ decays $= (73.7 \pm 2.8)\%$

CP-violation asymmetry difference

$\Delta A_{CP} = A_{CP}(K^+K^-) - A_{CP}(\pi^+\pi^-) = (-0.32 \pm 0.22)\%$ (S = 1.9)

χ^2 tests of CP-violation (CPV)

Local CPV in $D^0, \overline{D}{}^0 \to \pi^+\pi^-\pi^0 = 4.9\%$
Local CPV in $D^0, \overline{D}{}^0 \to \pi^+\pi^-\pi^+\pi^- = 41\%$
Local CPV in $D^0, \overline{D}{}^0 \to K^0_S\pi^+\pi^- = 96\%$
Local CPV in $D^0, \overline{D}{}^0 \to K^+K^-\pi^0 = 16.6\%$
Local CPV in $D^0, \overline{D}{}^0 \to K^+K^-\pi^+\pi^- = 9.1\%$

T-violation decay-rate asymmetry

$A_T(K^+K^-\pi^+\pi^-) = (1.7 \pm 2.7) \times 10^{-3}$ [ss]

CPT-violation decay-rate asymmetry

$A_{CPT}(K^\mp\pi^\pm) = 0.008 \pm 0.008$

Form factors

$r_V \equiv V(0)/A_1(0)$ in $D^0 \to K^*(892)^-\ell^+\nu_\ell = 1.7 \pm 0.8$
$r_2 \equiv A_2(0)/A_1(0)$ in $D^0 \to K^*(892)^-\ell^+\nu_\ell = 0.9 \pm 0.4$
$f_+(0)$ in $D^0 \to K^-\ell^+\nu_\ell = 0.736 \pm 0.004$
$f_+(0)|V_{cs}|$ in $D^0 \to K^-\ell^+\nu_\ell = 0.719 \pm 0.004$
$r_1 \equiv a_1/a_0$ in $D^0 \to K^-\ell^+\nu_\ell = -2.40 \pm 0.16$
$r_2 \equiv a_2/a_0$ in $D^0 \to K^-\ell^+\nu_\ell = 5 \pm 4$
$f_+(0)$ in $D^0 \to \pi^-\ell^+\nu_\ell = 0.637 \pm 0.009$
$f_+(0)|V_{cd}|$ in $D^0 \to \pi^-\ell^+\nu_\ell = 0.1436 \pm 0.0026$ (S = 1.5)
$r_1 \equiv a_1/a_0$ in $D^0 \to \pi^-\ell^+\nu_\ell = -1.97 \pm 0.28$ (S = 1.4)
$r_2 \equiv a_1/a_0$ in $D^0 \to \pi^-\ell^+\nu_\ell = -0.2 \pm 2.2$ (S = 1.7)

Most decay modes (other than the semileptonic modes) that involve a neutral K meson are now given as K^0_S modes, not as $\overline{K}{}^0$ modes. Nearly always it is a K^0_S that is measured, and interference between Cabibbo-allowed and doubly Cabibbo-suppressed modes can invalidate the assumption that $2\Gamma(K^0_S) = \Gamma(\overline{K}{}^0)$.

B-particle organization

Many measurements of B decays involve admixtures of B hadrons. Previously we arbitrarily included such admixtures in the $B^\pm$ section, but because of their importance we have created two new sections: "$B^\pm/B^0$ Admixture" for $\Upsilon(4S)$ results and "$B^\pm/B^0/B^0_s$/b-baryon Admixture" for results at higher energies. Most inclusive decay branching fractions and χ_b at high energy are found in the Admixture sections. B^0-$\overline{B}^0$ mixing data are found in the B^0 section, while B^0_s-$\overline{B}^0_s$ mixing data and B-$\overline{B}$ mixing data for a B^0/B^0_s admixture are found in the B^0_s section. CP-violation data are found in the $B^\pm$, B^0, and $B^\pm$ B^0 Admixture sections. b-baryons are found near the end of the Baryon section.

The organization of the B sections is now as follows, where bullets indicate particle sections and brackets indicate reviews.

- $B^\pm$
  - mass, mean life, CP violation, branching fractions
- B^0
  - mass, mean life, B^0-$\overline{B}^0$ mixing, CP violation, branching fractions
- $B^\pm/B^0$ Admixtures
  - CP violation, branching fractions
- $B^\pm/B^0/B^0_s$/b-baryon Admixtures
  - mean life, production fractions, branching fractions
- B^*
  - mass
- $B_1(5721)^+$
  - mass
- $B_1(5721)^0$
  - mass
- $B^*_2(5747)^+$
  - mass
- $B^*_2(5747)^0$
  - mass
- $B^*_J(5970)^+$
  - mass
- $B^*_J(5970)^0$
  - mass
- B^0_s
  - mass, mean life, B^0_s-$\overline{B}^0_s$ mixing, CP violation, branching fractions
- B^*_s
  - mass
- $B_{s1}(5830)^0$
  - mass
- $B^*_{s2}(5840)^0$
  - mass
- $B^\pm_c$
  - mass, mean life, branching fractions

At the end of Baryon Listings:

- Λ_b
  - mass, mean life, branching fractions
- $\Lambda_b(5912)^0$
  - mass, mean life
- $\Lambda_b(5920)^0$
  - mass, mean life
- Σ_b
  - mass
- Σ^*_b
  - mass
- Ξ^0_b, Ξ^-_b
  - mass, mean life, branching fractions
- $\Xi'_b(5935)^-$
  - mass
- $\Xi_b(5945)^0$
  - mass
- $\Xi^*_b(5955)^-$
  - mass
- Ω^-_b
  - mass, branching fractions
- b-baryon Admixture
  - mean life, branching fractions

$B^\pm$

$I(J^P) = \frac{1}{2}(0^-)$

I, J, P need confirmation. Quantum numbers shown are quark-model predictions.

Mass $m_{B^\pm} = 5279.31 \pm 0.15$ MeV (S = 1.1)
Mean life $\tau_{B^\pm} = (1.638 \pm 0.004) \times 10^{-12}$ s
$c\tau = 491.1$ μm

CP violation

$A_{CP}(B^+ \to J/\psi(1S)K^+) = 0.003 \pm 0.006$ (S = 1.8)
$A_{CP}(B^+ \to J/\psi(1S)\pi^+) = (0.1 \pm 2.8) \times 10^{-2}$ (S = 1.2)

Meson Summary Table

B^- modes are charge conjugates of the modes below. Modes which do not identify the charge state of the B are listed in the $B^\pm/B^0$ ADMIXTURE section.

The branching fractions listed below assume 50% $B^0\overline{B}{}^0$ and 50% B^+B^- production at the $\Upsilon(4S)$. We have attempted to bring older measurements up to date by rescaling their assumed $\Upsilon(4S)$ production ratio to 50:50 and their assumed D, D_s, D^*, and ψ branching ratios to current values whenever this would affect our averages and best limits significantly.

Indentation is used to indicate a subchannel of a previous reaction. All resonant subchannels have been corrected for resonance branching fractions to the final state so the sum of the subchannel branching fractions can exceed that of the final state.

For inclusive branching fractions, *e.g.*, $B \to D^\pm$ anything, the values usually are multiplicities, not branching fractions. They can be greater than one.

B^+ DECAY MODES	Fraction (Γ_i/Γ)	Scale factor/ Confidence level	p (MeV/c)
Semileptonic and leptonic modes			
$\ell^+\nu_\ell$ anything	[ttt] (10.99 ± 0.28) %		–
$e^+\nu_e X_c$	(10.8 ± 0.4) %		–
$D\ell^+\nu_\ell$ anything	(9.8 ± 0.7) %		–

Meson Summary Table

$\overline{B}^0$ modes are charge conjugates of the modes below. Reactions indicate the weak decay vertex and do not include mixing. Modes which do not identify the charge state of the B are listed in the $B^{\pm}/B^0$ ADMIXTURE section.

The branching fractions listed below assume 50% $B^0\overline{B}^0$ and 50% B^+B^- production at the $\Upsilon(4S)$. We have attempted to bring older measurements up to date by rescaling their assumed $\Upsilon(4S)$ production ratio to 50:50 and their assumed D, D_s, D^*, and ψ branching ratios to current values whenever this would affect our averages and best limits significantly.

Indentation is used to indicate a subchannel of a previous reaction. All resonant subchannels have been corrected for resonance branching fractions to the final state so the sum of the subchannel branching fractions can exceed that of the final state.

For inclusive branching fractions, *e.g.*, $B \to D^{\pm}$ anything, the values usually are multiplicities, not branching fractions. They can be greater than one.

$\Delta A_{CP}(X_s\gamma) = A_{CP}(B^\pm \to X_s\gamma) - A_{CP}(B^0 \to X_s\gamma) =$ 0.05 ± 0.04

The branching fraction measurements are for an admixture of B mesons at the $\Upsilon(4S)$. The values quoted assume that $B(\Upsilon(4S) \to B\overline{B}) = 100\%$.

For inclusive branching fractions, *e.g.*, $B \to D^\pm$ *anything*, the treatment of multiple D's in the final state must be defined. One possibility would be to count the number of events with one-or-more D's and divide by the total number of B's. Another possibility would be to count the total number of D's and divide by the total number of B's, which is the definition of average multiplicity. The two definitions are identical if only one D is allowed in the final state. Even though the "one-or-more" definition seems sensible, for practical reasons inclusive branching fractions are almost always measured using the multiplicity definition. For heavy final state particles, authors call their results inclusive branching fractions while for light particles some authors call their results multiplicities. In the B sections, we list all results as inclusive branching fractions, adopting a multiplicity definition. This means that inclusive branching fractions can exceed 100% and that inclusive partial widths can exceed total widths, just as inclusive cross sections can exceed total cross section.

$\overline{B}$ modes are charge conjugates of the modes below. Reactions indicate the weak decay vertex and do not include mixing.

$B^\pm/B^0/B_s^0/b$-baryon ADMIXTURE

These measurements are for an admixture of bottom particles at high energy (LHC, LEP, Tevatron, S$p\overline{p}$S).

Mean life $\tau = (1.566 \pm 0.003) \times 10^{-12}$ s

Mean life $\tau = (1.72 \pm 0.10) \times 10^{-12}$ s Charged b-hadron admixture

Mean life $\tau = (1.58 \pm 0.14) \times 10^{-12}$ s Neutral b-hadron admixture

$\tau_{\text{charged } b\text{-hadron}}/\tau_{\text{neutral } b\text{-hadron}} = 1.09 \pm 0.13$

$|\Delta\tau_b|/\tau_{b,\overline{b}} = -0.001 \pm 0.014$

$\text{Re}(\epsilon_b)\ /\ (1 + |\epsilon_b|^2) = (1.2 \pm 0.4) \times 10^{-3}$

The branching fraction measurements are for an admixture of B mesons and baryons at energies above the $\Upsilon(4S)$. Only the highest energy results (LHC, LEP, Tevatron, S$p\overline{p}$S) are used in the branching fraction averages. In the following, we assume that the production fractions are the same at the LHC, LEP, and at the Tevatron.

For inclusive branching fractions, *e.g.*, $B\to\ D^\pm$anything, the values usually are multiplicities, not branching fractions. They can be greater than one.

The modes below are listed for a $\overline{b}$ initial state. b modes are their charge conjugates. Reactions indicate the weak decay vertex and do not include mixing.

$\overline{b}$ DECAY MODES	Fraction (Γ_i/Γ)	Scale factor / Confidence level	p (MeV/c)

PRODUCTION FRACTIONS

The production fractions for weakly decaying b-hadrons at high energy have been calculated from the best values of mean lives, mixing parameters, and branching fractions in this edition by the Heavy Flavor Averaging Group (HFAG) as described in the note "B^0-$\overline{B}^0$ Mixing" in the B^0 Particle Listings. The production fractions in b-hadronic Z decay or $p\overline{p}$ collisions at the Tevatron are also listed at the end of the section. Values assume

$\text{B}(\overline{b}\to\ B^+) = \text{B}(\overline{b}\to\ B^0)$

$\text{B}(\overline{b}\to\ B^+) + \text{B}(\overline{b}\to\ B^0) + \text{B}(\overline{b}\to\ B_s^0) + \text{B}(b\to\ b\text{-baryon}) = 100\%.$

The correlation coefficients between production fractions are also reported:

$cor(B_s^0,\ b\text{-baryon}) = -0.240$

$cor(B_s^0,\ B^\pm{=}B^0) = -0.161$

$cor(b\text{-baryon},\ B^\pm{=}B^0) = -0.920.$

The notation for production fractions varies in the literature (f_d, d_{B^0}, $f(b\to\ \overline{B}^0)$, $\text{Br}(b\to\ \overline{B}^0)$). We use our own branching fraction notation here, $\text{B}(\overline{b}\to\ B^0)$.

Note these production fractions are b-hadronization fractions, not the conventional branching fractions of b-quark to a B-hadron, which may have considerable dependence on the initial and final state kinematic and production environment.

$\Delta a_\perp < 1.2 \times 10^{-12}$ GeV, CL = 95%

These branching fractions all scale with $B(\overline{b} \to B_s^0)$.

The branching fraction $B(B_s^0 \to D_s^-\ell^+\nu_\ell\text{anything})$ is not a pure measurement since the measured product branching fraction $B(\overline{b} \to B_s^0) \times B(B_s^0 \to D_s^-\ell^+\nu_\ell\text{anything})$ was used to determine $B(\overline{b} \to B_s^0)$, as described in the note on "B^0-$\overline{B}^0$ Mixing"

For inclusive branching fractions, *e.g.*, $B \to D^\pm$ anything, the values usually are multiplicities, not branching fractions. They can be greater than one.

Other decays

invisible	< 1.6 %	CL=90%	–

$\psi(3770)$

$I^G(J^{PC}) = 0^-(1^{--})$

Mass $m = 3773.13 \pm 0.35$ MeV (S = 1.1)
Full width $\Gamma = 27.2 \pm 1.0$ MeV
$\Gamma_{ee} = 0.262 \pm 0.018$ keV (S = 1.4)

In addition to the dominant decay mode to $D\overline{D}$, $\psi(3770)$ was found to decay into the final states containing the J/ψ (BAI 05, ADAM 06). ADAMS 06 and HUANG 06A searched for various decay modes with light hadrons and found a statistically significant signal for the decay to $\phi\eta$ only (ADAMS 06).

Meson Summary Table

NOTES

In this Summary Table:

When a quantity has "(S = ...)" to its right, the error on the quantity has been enlarged by the "scale factor" S, defined as $S = \sqrt{\chi^2/(N-1)}$, where N is the number of measurements used in calculating the quantity. We do this when $S > 1$, which often indicates that the measurements are inconsistent. When $S > 1.25$, we also show in the Particle Listings an ideogram of the measurements. For more about S, see the Introduction.

A decay momentum p is given for each decay mode. For a 2-body decay, p is the momentum of each decay product in the rest frame of the decaying particle. For a 3-or-more-body decay, p is the largest momentum any of the products can have in this frame.

[a] See the "Note on $\pi^\pm \to \ell^\pm \nu\gamma$ and $K^\pm \to \ell^\pm \nu\gamma$ Form Factors" in the $\pi^\pm$ Particle Listings for definitions and details.

[b] Measurements of $\Gamma(e^+\nu_e)/\Gamma(\mu^+\nu_\mu)$ always include decays with γ's, and measurements of $\Gamma(e^+\nu_e\gamma)$ and $\Gamma(\mu^+\nu_\mu\gamma)$ never include low-energy γ's. Therefore, since no clean separation is possible, we consider the modes with γ's to be subreactions of the modes without them, and let $[\Gamma(e^+\nu_e) + \Gamma(\mu^+\nu_\mu)]/\Gamma_{\rm total} = 100\%$.

[c] See the $\pi^\pm$ Particle Listings for the energy limits used in this measurement; low-energy γ's are not included.

[d] Derived from an analysis of neutrino-oscillation experiments.

[e] Astrophysical and cosmological arguments give limits of order 10^{-13}; see the π^0 Particle Listings.

[f] C parity forbids this to occur as a single-photon process.

[g] See the "Note on scalar mesons" in the $f_0(500)$ Particle Listings . The interpretation of this entry as a particle is controversial.

[h] See the "Note on $\rho(770)$" in the $\rho(770)$ Particle Listings .

[i] The $\omega\rho$ interference is then due to $\omega\rho$ mixing only, and is expected to be small. If $e\mu$ universality holds, $\Gamma(\rho^0 \to \mu^+\mu^-) = \Gamma(\rho^0 \to e^+e^-) \times 0.99785$.

[j] See the "Note on scalar mesons" in the $f_0(500)$ Particle Listings .

[k] See the "Note on $a_1(1260)$" in the $a_1(1260)$ Particle Listings in PDG 06, Journal of Physics **G33** 1 (2006).

[l] This is only an educated guess; the error given is larger than the error on the average of the published values. See the Particle Listings for details.

[n] See the "Note on non-$q\overline{q}$ mesons" in the Particle Listings in PDG 06, Journal of Physics **G33** 1 (2006).

[o] See the "Note on the $\eta(1405)$" in the $\eta(1405)$ Particle Listings.

[p] See the "Note on the $f_1(1420)$" in the $\eta(1405)$ Particle Listings.

[q] See also the $\omega(1650)$ Particle Listings.

[r] See the "Note on the $\rho(1450)$ and the $\rho(1700)$" in the $\rho(1700)$ Particle Listings.

[s] See also the $\omega(1420)$ Particle Listings.

[t] See the "Note on $f_0(1710)$" in the $f_0(1710)$ Particle Listings in 2004 edition of *Review of Particle Physics*.

[u] See the note in the $K^\pm$ Particle Listings.

[v] Neglecting photon channels. See, *e.g.*, A. Pais and S.B. Treiman, Phys. Rev. **D12**, 2744 (1975).

[x] The definition of the slope parameters of the $K \to 3\pi$ Dalitz plot is as follows (see also "Note on Dalitz Plot Parameters for $K \to 3\pi$ Decays" in the $K^\pm$ Particle Listings):

$$|M|^2 = 1 + g(s_3 - s_0)/m^2_{\pi^+} + \cdots .$$

[y] For more details and definitions of parameters see the Particle Listings.

[z] See the $K^\pm$ Particle Listings for the energy limits used in this measurement.

[aa] Most of this radiative mode, the low-momentum γ part, is also included in the parent mode listed without γ's.

[bb] Structure-dependent part.

[cc] Direct-emission branching fraction.

[dd] Violates angular-momentum conservation.

[ee] Derived from measured values of ϕ_{+-}, ϕ_{00}, $|\eta|$, $|m_{K^0_L} - m_{K^0_S}|$, and $\tau_{K^0_S}$, as described in the introduction to "Tests of Conservation Laws."

[ff] The CP-violation parameters are defined as follows (see also "Note on CP Violation in $K_S \to 3\pi$" and "Note on CP Violation in K^0_L Decay" in the Particle Listings):

$$\eta_{+-} = |\eta_{+-}|e^{i\phi_{+-}} = \frac{A(K^0_L \to \pi^+\pi^-)}{A(K^0_S \to \pi^+\pi^-)} = \epsilon + \epsilon'$$

$$\eta_{00} = |\eta_{00}|e^{i\phi_{00}} = \frac{A(K^0_L \to \pi^0\pi^0)}{A(K^0_S \to \pi^0\pi^0)} = \epsilon - 2\epsilon'$$

$$\delta = \frac{\Gamma(K^0_L \to \pi^-\ell^+\nu) - \Gamma(K^0_L \to \pi^+\ell^-\nu)}{\Gamma(K^0_L \to \pi^-\ell^+\nu) + \Gamma(K^0_L \to \pi^+\ell^-\nu)} ,$$

$${\rm Im}(\eta_{+-0})^2 = \frac{\Gamma(K^0_S \to \pi^+\pi^-\pi^0)^{CP\ \rm viol.}}{\Gamma(K^0_L \to \pi^+\pi^-\pi^0)} ,$$

$${\rm Im}(\eta_{000})^2 = \frac{\Gamma(K^0_S \to \pi^0\pi^0\pi^0)}{\Gamma(K^0_L \to \pi^0\pi^0\pi^0)} .$$

where for the last two relations CPT is assumed valid, *i.e.*, ${\rm Re}(\eta_{+-0}) \simeq 0$ and ${\rm Re}(\eta_{000}) \simeq 0$.

[gg] See the K^0_S Particle Listings for the energy limits used in this measurement.

[hh] The value is for the sum of the charge states or particle/antiparticle states indicated.

[ii] ${\rm Re}(\epsilon'/\epsilon) = \epsilon'/\epsilon$ to a very good approximation provided the phases satisfy CPT invariance.

[jj] This mode includes gammas from inner bremsstrahlung but not the direct emission mode $K^0_L \to \pi^+\pi^-\gamma$(DE).

[kk] See the K^0_L Particle Listings for the energy limits used in this measurement.

[ll] Allowed by higher-order electroweak interactions.

[nn] Violates CP in leading order. Test of direct CP violation since the indirect CP-violating and CP-conserving contributions are expected to be suppressed.

[oo] See the "Note on $f_0(1370)$" in the $f_0(1370)$ Particle Listings and in the 1994 edition.

[pp] See the note in the $L(1770)$ Particle Listings in Reviews of Modern Physics **56** S1 (1984), p. S200. See also the "Note on $K_2(1770)$ and the $K_2(1820)$" in the $K_2(1770)$ Particle Listings .

[qq] See the "Note on $K_2(1770)$ and the $K_2(1820)$" in the $K_2(1770)$ Particle Listings .

[rr] This result applies to $Z^0 \to c\overline{c}$ decays only. Here ℓ^+ is an average (not a sum) of e^+ and μ^+ decays.

[ss] See the Particle Listings for the (complicated) definition of this quantity.

[tt] The branching fraction for this mode may differ from the sum of the submodes that contribute to it, due to interference effects. See the relevant papers in the Particle Listings.

[uu] These subfractions of the $K^-2\pi^+$ mode are uncertain: see the Particle Listings.

[vv] Submodes of the $D^+ \to K^-2\pi^+\pi^0$ and $K^0_S2\pi^+\pi^-$ modes were studied by ANJOS 92C and COFFMAN 92B, but with at most 142 events for the first mode and 229 for the second – not enough for precise results. With nothing new for 18 years, we refer to our 2008 edition, Physics Letters **B667** 1 (2008), for those results.

[xx] The unseen decay modes of the resonances are included.

[yy] This is *not* a test for the ΔC=1 weak neutral current, but leads to the $\pi^+\ell^+\ell^-$ final state.

[zz] This mode is not a useful test for a ΔC=1 weak neutral current because both quarks must change flavor in this decay.

[aaa] In the 2010 *Review*, the values for these quantities were given using a measure of the asymmetry that was inconsistent with the usual definition.

[bbb] This value is obtained by subtracting the branching fractions for 2-, 4- and 6-prongs from unity.

[ccc] This is the sum of our $K^-2\pi^+\pi^-$, $K^-2\pi^+\pi^-\pi^0$, $\overline{K}^0 2\pi^+2\pi^-$, $K^+2K^-\pi^+$, $2\pi^+2\pi^-$, $2\pi^+2\pi^-\pi^0$, $K^+K^-\pi^+\pi^-$, and $K^+K^-\pi^+\pi^-\pi^0$, branching fractions.

[ddd] This is the sum of our $K^-3\pi^+2\pi^-$ and $3\pi^+3\pi^-$ branching fractions.

[eee] The branching fractions for the $K^-e^+\nu_e$, $K^*(892)^-e^+\nu_e$, $\pi^-e^+\nu_e$, and $\rho^-e^+\nu_e$ modes add up to 6.19 ± 0.17 %.

[fff] This is a doubly Cabibbo-suppressed mode.

[ggg] The two experiments measuring this fraction are in serious disagreement. See the Particle Listings.

[hhh] Submodes of the $D^0 \to K^0_S\pi^+\pi^-\pi^0$ mode with a K^* and/or ρ were studied by COFFMAN 92B, but with only 140 events. With nothing new

for 18 years, we refer to our 2008 edition, Physics Letters **B667** 1 (2008), for those results.

[*iii*] This branching fraction includes all the decay modes of the resonance in the final state.

[*jjj*] This limit is for either D^0 or $\overline{D}^0$ to $p e^-$.

[*kkk*] This limit is for either D^0 or $\overline{D}^0$ to $\overline{p} e^+$.

[*lll*] This is the purely e^+ semileptonic branching fraction: the e^+ fraction from τ^+ decays has been subtracted off. The sum of our (non-τ) e^+ exclusive fractions — an $e^+\nu_e$ with an η, η', ϕ, K^0, K^{*0}, or $f_0(980)$ — is 7.0 ± 0.4 %

[*nnn*] This fraction includes η from η' decays.

[*ooo*] Two times (to include μ decays) the $\eta' e^+\nu_e$ branching fraction, plus the $\eta'\pi^+$, $\eta'\rho^+$, and $\eta' K^+$ fractions, is (18.6 ± 2.3)%, which considerably exceeds the inclusive η' fraction of (11.7 ± 1.8)%. Our best guess is that the $\eta'\rho^+$ fraction, (12.5 ± 2.2)%, is too large.

[*ppp*] This branching fraction includes all the decay modes of the final-state resonance.

[*qqq*] A test for $u\overline{u}$ or $d\overline{d}$ content in the D_s^+. Neither Cabibbo-favored nor Cabibbo-suppressed decays can contribute, and ω–ϕ mixing is an unlikely explanation for any fraction above about 2×10^{-4}.

[*rrr*] We decouple the $D_s^+ \to \phi\pi^+$ branching fraction obtained from mass projections (and used to get some of the other branching fractions) from the $D_s^+ \to \phi\pi^+$, $\phi \to K^+K^-$ branching fraction obtained from the Dalitz-plot analysis of $D_s^+ \to K^+K^-\pi^+$. That is, the ratio of these two branching fractions is not exactly the $\phi \to K^+K^-$ branching fraction 0.491.

[*sss*] This is the average of a model-independent and a K-matrix parametrization of the $\pi^+\pi^-$ S-wave and is a sum over several f_0 mesons.

[*ttt*] An ℓ indicates an e or a μ mode, not a sum over these modes.

[*uuu*] An $CP(\pm1)$ indicates the CP=+1 and CP=−1 eigenstates of the D^0-$\overline{D}^0$ system.

[*vvv*] D denotes D^0 or $\overline{D}^0$.

[*xxx*] D^{*0}_{CP+} decays into $D^0\pi^0$ with the D^0 reconstructed in CP-even eigenstates K^+K^- and $\pi^+\pi^-$.

[*yyy*] $\overline{D}^{**}$ represents an excited state with mass $2.2 < \mathrm{M} < 2.8$ GeV/c^2.

[*zzz*] $X(3872)^+$ is a hypothetical charged partner of the $X(3872)$.

[*aaaa*] $\Theta(1710)^{++}$ is a possible narrow pentaquark state and $G(2220)$ is a possible glueball resonance.

[*bbaa*] $(\overline{\Lambda}_c^- p)_s$ denotes a low-mass enhancement near 3.35 GeV/c^2.

[*ccaa*] Stands for the possible candidates of $K^*(1410)$, $K_0^*(1430)$ and $K_2^*(1430)$.

[*ddaa*] B^0 and B_s^0 contributions not separated. Limit is on weighted average of the two decay rates.

[*eeaa*] This decay refers to the coherent sum of resonant and nonresonant $J^P = 0^+$ $K\pi$ components with $1.60 < m_{K\pi} < 2.15$ GeV/c^2.

[*ffaa*] $X(214)$ is a hypothetical particle of mass 214 MeV/c^2 reported by the HyperCP experiment, Physical Review Letters **94** 021801 (2005)

[*ggaa*] $\Theta(1540)^+$ denotes a possible narrow pentaquark state.

[*hhaa*] Here S and P are the hypothetical scalar and pseudoscalar particles with masses of 2.5 GeV/c^2 and 214.3 MeV/c^2, respectively.

[*iiaa*] These values are model dependent.

[*jjaa*] Here "anything" means at least one particle observed.

[*kkaa*] This is a B($B^0 \to D^{*-}\ell^+\nu_\ell$) value.

[*llaa*] D^{**} stands for the sum of the $D(1\,^1P_1)$, $D(1\,^3P_0)$, $D(1\,^3P_1)$, $D(1\,^3P_2)$, $D(2\,^1S_0)$, and $D(2\,^1S_1)$ resonances.

[*nnaa*] $D^{(*)}\overline{D}^{(*)}$ stands for the sum of $D^*\overline{D}^*$, $D^*\overline{D}$, $D\overline{D}^*$, and $D\overline{D}$.

[*ooaa*] $X(3915)$ denotes a near-threshold enhancement in the $\omega J/\psi$ mass spectrum.

[*ppaa*] Inclusive branching fractions have a multiplicity definition and can be greater than 100%.

[*qqaa*] D_j represents an unresolved mixture of pseudoscalar and tensor D^{**} (P-wave) states.

[*rraa*] Not a pure measurement. See note at head of B_s^0 Decay Modes.

[*ssaa*] For $E_\gamma > 100$ MeV.

[*ttaa*] Includes $p\overline{p}\pi^+\pi^-\gamma$ and excludes $p\overline{p}\eta$, $p\overline{p}\omega$, $p\overline{p}\eta'$.

[*uuaa*] For a narrow state A with mass less than 960 MeV.

[*vvaa*] For a narrow scalar or pseudoscalar A^0 with mass 0.21–3.0 GeV.

[*xxaa*] For a narrow resonance in the range $2.2 < M(X) < 2.8$ GeV.

[*yyaa*] J^{PC} known by production in e^+e^- via single photon annihilation. I^G is not known; interpretation of this state as a single resonance is unclear because of the expectation of substantial threshold effects in this energy region.

[*zzaa*] $2m_\tau < \mathrm{M}(\tau^+\tau^-) < 9.2$ GeV

[*aabb*] 2 GeV $< m_{K^+K^-} <$ 3 GeV

[*bbbb*] X = scalar with $m < 8.0$ GeV

[*ccbb*] $X\overline{X}$ = vectors with $m < 3.1$ GeV

[*ddbb*] X and $\overline{X}$ = zero spin with $m < 4.5$ GeV

[*eebb*] 1.5 GeV $< m_X <$ 5.0 GeV

[*ffbb*] 201 MeV $< \mathrm{M}(\mu^+\mu^-) <$ 3565 MeV

[*ggbb*] 0.5 GeV $< m_X <$ 9.0 GeV, where m_X is the invariant mass of the hadronic final state.

[*hhbb*] Spectroscopic labeling for these states is theoretical, pending experimental information.

[*iibb*] 1.5 GeV $< m_X <$ 5.0 GeV

[*jjbb*] 1.5 GeV $< m_X <$ 5.0 GeV

[*kkbb*] For $m_{\tau^+\tau^-}$ in the ranges 4.03–9.52 and 9.61–10.10 GeV.

Meson Summary Table

See also the table of suggested $q\overline{q}$ quark-model assignments in the Quark Model section.

• Indicates particles that appear in the preceding Meson Summary Table. We do not regard the other entries as being established.

Baryon Summary Table

This short table gives the name, the quantum numbers (where known), and the status of baryons in the Review. Only the baryons with 3- or 4-star status are included in the Baryon Summary Table. Due to insufficient data or uncertain interpretation, the other entries in the table are not established baryons. The names with masses are of baryons that decay strongly. The spin-parity J^P (when known) is given with each particle. For the strongly decaying particles, the J^P values are considered to be part of the names.

**** Existence is certain, and properties are at least fairly well explored.

*** Existence ranges from very likely to certain, but further confirmation is desirable and/or quantum numbers, branching fractions, etc. are not well determined.

** Evidence of existence is only fair.

* Evidence of existence is poor.

Baryon Summary Table

N BARYONS ($S = 0$, $I = 1/2$)

p, $N^+ = uud$; n, $N^0 = udd$

p

$I(J^P) = \frac{1}{2}(\frac{1}{2}^+)$

Mass $m = 1.00727646688 \pm 0.00000000009$ u
Mass $m = 938.272081 \pm 0.000006$ MeV [a]
$|m_p - m_{\overline{p}}|/m_p < 7 \times 10^{-10}$, CL = 90% [b]
$|\frac{q_{\overline{p}}}{m_{\overline{p}}}|/(\frac{q_p}{m_p}) = 0.99999999991 \pm 0.00000000009$
$|q_p + q_{\overline{p}}|/e < 7 \times 10^{-10}$, CL = 90% [b]
$|q_p + q_e|/e < 1 \times 10^{-21}$ [c]
Magnetic moment $\mu = 2.792847351 \pm 0.000000009\ \mu_N$
$(\mu_p + \mu_{\overline{p}})\ /\ \mu_p = (0 \pm 5) \times 10^{-6}$
Electric dipole moment $d < 0.54 \times 10^{-23}$ $e$cm
Electric polarizability $\alpha = (11.2 \pm 0.4) \times 10^{-4}$ fm^3
Magnetic polarizability $\beta = (2.5 \pm 0.4) \times 10^{-4}$ fm^3 (S = 1.2)
Charge radius, μp Lamb shift = 0.84087 ± 0.00039 fm [d]
Charge radius, ep CODATA value = 0.8751 ± 0.0061 fm [d]
Magnetic radius = 0.78 ± 0.04 fm [e]
Mean life $\tau > 2.1 \times 10^{29}$ years, CL = 90% [f] ($p \rightarrow$ invisible mode)
Mean life $\tau > 10^{31}$ to 10^{33} years [f] (mode dependent)

See the "Note on Nucleon Decay" in our 1994 edition (Phys. Rev. **D50**, 1173) for a short review.

The "partial mean life" limits tabulated here are the limits on τ/B_i, where τ is the total mean life and B_i is the branching fraction for the mode in question. For N decays, p and n indicate proton and neutron partial lifetimes.

p DECAY MODES	Partial mean life (10^{30} years)	Confidence level	p (MeV/c)
Antilepton + meson			
$N \rightarrow e^+\pi$	$> 2000\ (n)$, $> 8200\ (p)$	90%	459

$\Lambda_c(2595)^+$ $I(J^P) = 0(\frac{1}{2}^-)$

The spin-parity follows from the fact that $\Sigma_c(2455)\pi$ decays, with little available phase space, are dominant. This assumes that $J^P = 1/2^+$ for the $\Sigma_c(2455)$.

Mass $m = 2592.25 \pm 0.28$ MeV
$m - m_{\Lambda_c^+} = 305.79 \pm 0.24$ MeV
Full width $\Gamma = 2.6 \pm 0.6$ MeV

$\Lambda_c^+\pi\pi$ and its submode $\Sigma_c(2455)\pi$ — the latter just barely — are the only strong decays allowed to an excited Λ_c^+ having this mass; and the submode seems to dominate.

$\Lambda_c(2595)^+$ DECAY MODES		Fraction (Γ_i/Γ)	p (MeV/c)
$\Lambda_c^+\pi^+\pi^-$	[t]	—	117
$\Sigma_c(2455)^{++}\pi^-$		24 ± 7 %	†
$\Sigma_c(2455)^0\pi^+$		24 ± 7 %	†
$\Lambda_c^+\pi^+\pi^-$ 3-body		18 ± 10 %	117
$\Lambda_c^+\pi^0$	[u]	not seen	258
$\Lambda_c^+\gamma$		not seen	288

$\Lambda_c(2625)^+$ $I(J^P) = 0(\frac{3}{2}^-)$

J^P has not been measured; $\frac{3}{2}^-$ is the quark-model prediction.

Mass $m = 2628.11 \pm 0.19$ MeV (S = 1.1)
$m - m_{\Lambda_c^+} = 341.65 \pm 0.13$ MeV (S = 1.1)
Full width $\Gamma < 0.97$ MeV, CL = 90%

$\Lambda_c^+\pi\pi$ and its submode $\Sigma(2455)\pi$ are the only strong decays allowed to an excited Λ_c^+ having this mass.

Baryon Summary Table

$\Lambda_c(2625)^+$ DECAY MODES		Fraction (Γ_i/Γ)	Confidence level	p (MeV/c)

BOTTOM BARYONS ($B = -1$)

$\Lambda_b^0 = udb$, $\Xi_b^0 = usb$, $\Xi_b^- = dsb$, $\Omega_b^- = ssb$

Λ_b^0

$I(J^P) = 0(\frac{1}{2}^+)$

$I(J^P)$ not yet measured; $0(\frac{1}{2}^+)$ is the quark model prediction.
Mass $m = 5619.51 \pm 0.23$ MeV
$m_{\Lambda_b^0} - m_{B^0} = 339.2 \pm 1.4$ MeV
$m_{\Lambda_b^0} - m_{B^+} = 339.72 \pm 0.28$ MeV
Mean life $\tau = (1.466 \pm 0.010) \times 10^{-12}$ s
$c\tau = 439.5$ μm
$A_{CP}(\Lambda_b \to p\pi^-) = 0.06 \pm 0.07$
$A_{CP}(\Lambda_b \to pK^-) = 0.00 \pm 0.19$ (S = 2.4)
$A_{CP}(\Lambda_b \to p\overline{K}^0\pi^-) = 0.22 \pm 0.13$
$\Delta A_{CP}(J/\psi p\pi^-/K^-) \equiv A_{CP}(J/\psi p\pi^-) - A_{CP}(J/\psi pK^-) = (5.7 \pm 2.7) \times 10^{-2}$
α decay parameter for $\Lambda_b \to J/\psi\Lambda = 0.18 \pm 0.13$
$A_{FB}^{\ell}(\mu\mu)$ in $\Lambda_b \to \Lambda\mu^+\mu^- = -0.05 \pm 0.09$
$A_{FB}^{h}(p\pi)$ in $\Lambda_b \to \Lambda(p\pi)\mu^+\mu^- = -0.29 \pm 0.08$
$f_L(\mu\mu)$ longitudinal polarization fraction in $\Lambda_b \to \Lambda\mu^+\mu^- = 0.61^{+0.11}_{-0.14}$

The branching fractions B(b-baryon $\to \Lambda\ell^-\overline{\nu}_\ell$ anything) and B($\Lambda_b^0 \to \Lambda_c^+\ell^-\overline{\nu}_\ell$ anything) are not pure measurements because the underlying measured products of these with B($b \to b$-baryon) were used to determine B($b \to b$-baryon), as described in the note "Production and Decay of b-Flavored Hadrons."

For inclusive branching fractions, *e.g.*, $\Lambda_b \to \overline{\Lambda}_c$ anything, the values usually are multiplicities, not branching fractions. They can be greater than one.

b-baryon ADMIXTURE (Λ_b, Ξ_b, Σ_b, Ω_b)

Mean life τ

These branching fractions are actually an average over weakly decaying b-baryons weighted by their production rates at the LHC, LEP, and Tevatron, branching ratios, and detection efficiencies. They scale with the b-baryon production fraction B($b \to b$-baryon).

The branching fractions B(b-baryon $\to \Lambda \ell^- \overline{\nu}_\ell$ anything) and B($\Lambda_b^0 \to \Lambda_c^+ \ell^- \overline{\nu}_\ell$ anything) are not pure measurements because the underlying measured products of these with B($b \to b$-baryon) were used to determine B($b \to b$-baryon), as described in the note "Production and Decay of b-Flavored Hadrons."

For inclusive branching fractions, *e.g.*, $B \to D^\pm$ anything, the values usually are multiplicities, not branching fractions. They can be greater than one.

b-baryon ADMIXTURE DECAY MODES (Λ_b,Ξ_b,Σ_b,Ω_b)	Fraction (Γ_i/Γ)	p (MeV/c)
$p \mu^- \overline{\nu}$ anything	($5.5^{+2.2}_{-1.9}$) %	–
$p \ell \overline{\nu}_\ell$ anything	(5.3± 1.2) %	–
p anything	(66 ±21) %	–
$\Lambda \ell^- \overline{\nu}_\ell$ anything	(3.6± 0.6) %	–
$\Lambda \ell^+ \nu_\ell$ anything	(3.0± 0.8) %	–
Λ anything	(37 ± 7) %	–
$\Xi^- \ell^- \overline{\nu}_\ell$ anything	(6.2± 1.6) $\times 10^{-3}$	–

EXOTIC BARYONS

$J/\psi p$	seen	820

Baryon Summary Table

NOTES

This Summary Table only includes established baryons. The Particle Listings include evidence for other baryons. The masses, widths, and branching fractions for the resonances in this Table are Breit-Wigner parameters, but pole positions are also given for most of the N and Δ resonances.

For most of the resonances, the parameters come from various partial-wave analyses of more or less the same sets of data, and it is not appropriate to treat the results of the analyses as independent or to average them together. Furthermore, the systematic errors on the results are not well understood. Thus, we usually only give ranges for the parameters. We then also give a best guess for the mass (as part of the name of the resonance) and for the width. The *Note on N and Δ Resonances* and the *Note on Λ and Σ Resonances* in the Particle Listings review the partial-wave analyses.

When a quantity has "(S = ...)" to its right, the error on the quantity has been enlarged by the "scale factor" S, defined as $S = \sqrt{\chi^2/(N-1)}$, where N is the number of measurements used in calculating the quantity. We do this when $S > 1$, which often indicates that the measurements are inconsistent. When $S > 1.25$, we also show in the Particle Listings an ideogram of the measurements. For more about S, see the Introduction.

A decay momentum p is given for each decay mode. For a 2-body decay, p is the momentum of each decay product in the rest frame of the decaying particle. For a 3-or-more-body decay, p is the largest momentum any of the products can have in this frame. For any resonance, the *nominal* mass is used in calculating p. A dagger ("†") in this column indicates that the mode is forbidden when the nominal masses of resonances are used, but is in fact allowed due to the nonzero widths of the resonances.

[a] The masses of the p and n are most precisely known in u (unified atomic mass units). The conversion factor to MeV, 1 u = 931.494061(21) MeV, is less well known than are the masses in u.

[b] The $|m_p - m_{\overline{p}}|/m_p$ and $|q_p + q_{\overline{p}}|/e$ are not independent, and both use the more precise measurement of $|q_{\overline{p}}/m_{\overline{p}}|/(q_p/m_p)$.

[c] The limit is from neutrality-of-matter experiments; it assumes $q_n = q_p + q_e$. See also the charge of the neutron.

[d] The μp and ep values for the charge radius are much too different to average them. The disagreement is not yet understood.

[e] There is a lot of disagreement about the value of the proton magnetic charge radius. See the Listings.

[f] The first limit is for $p \to$ anything or "disappearance" modes of a bound proton. The second entry, a rough range of limits, assumes the dominant decay modes are among those investigated. For antiprotons the best limit, inferred from the observation of cosmic ray $\overline{p}$'s is $\tau_{\overline{p}} > 10^7$ yr, the cosmic-ray storage time, but this limit depends on a number of assumptions. The best direct observation of stored antiprotons gives $\tau_{\overline{p}}/\mathrm{B}(\overline{p} \to e^-\gamma) > 7 \times 10^5$ yr.

[g] There is some controversy about whether nuclear physics and model dependence complicate the analysis for bound neutrons (from which the best limit comes). The first limit here is from reactor experiments with free neutrons.

[h] Lee and Yang in 1956 proposed the existence of a mirror world in an attempt to restore global parity symmetry—thus a search for oscillations between the two worlds. Oscillations between the worlds would be maximal when the magnetic fields B and B' were equal. The limit for any B' in the range 0 to 12.5 μT is >12 s (95% CL).

[i] The parameters g_A, g_V, and g_{WM} for semileptonic modes are defined by $\overline{B}_f[\gamma_\lambda(g_V + g_A\gamma_5) + i(g_{WM}/m_{B_i})\,\sigma_{\lambda\nu}\,q^\nu]B_i$, and ϕ_{AV} is defined by $g_A/g_V = |g_A/g_V|e^{i\phi_{AV}}$. See the "Note on Baryon Decay Parameters" in the neutron Particle Listings.

[j] Time-reversal invariance requires this to be 0° or 180°.

[k] This coefficient is zero if time invariance is not violated.

[l] This limit is for γ energies between 15 and 340 keV.

[n] The decay parameters γ and Δ are calculated from α and ϕ using

$$\gamma = \sqrt{1-\alpha^2}\,\cos\phi\,, \qquad \tan\Delta = -\frac{1}{\alpha}\,\sqrt{1-\alpha^2}\,\sin\phi\,.$$

See the "Note on Baryon Decay Parameters" in the neutron Particle Listings.

[o] See the Listings for the pion momentum range used in this measurement.

[p] The error given here is only an educated guess. It is larger than the error on the weighted average of the published values.

[q] A theoretical value using QED.

[r] This branching fraction includes all the decay modes of the final-state resonance.

[s] The value is for the sum of the charge states or particle/antiparticle states indicated.

[t] See AALTONEN 11H, Fig. 8, for the calculated ratio of $\Lambda_c^+\pi^0\pi^0$ and $\Lambda_c^+\pi^+\pi^-$ partial widths as a function of the $\Lambda_c(2595)^+ - \Lambda_c^+$ mass difference. At our value of the mass difference, the ratio is about 4.

[u] A test that the isospin is indeed 0, so that the particle is indeed a Λ_c^+.

[v] P_c^+ is a pentaquark-charmonium state.

[x] Not a pure measurement. See note at head of Λ_b^0 Decay Modes.

[y] Here h^- means π^- or K^-.

SEARCHES FOR MONOPOLES, SUPERSYMMETRY, TECHNICOLOR, COMPOSITENESS, EXTRA DIMENSIONS, etc.

Magnetic Monopole Searches

Isolated supermassive monopole candidate events have not been confirmed. The most sensitive experiments obtain negative results.

Best cosmic-ray supermassive monopole flux limit:

$< 1.4 \times 10^{-16}$ cm^{-2}sr^{-1}s^{-1} for $1.1 \times 10^{-4} < \beta < 1$

Supersymmetric Particle Searches

Presently all supersymmetric mass bounds are model dependent. This table contains a selection of bounds indicating the range of possibilities. For a more extensive set of cases consult the detailed listings.

The limits are based on the Minimal Supersymmetric Standard Model (MSSM) with additional assumptions as follows:

1) $\widetilde{\chi}_1^0$ is lightest supersymmetric particle; 2) R-parity is conserved;

See the Particle Listings for a Note giving details of supersymmetry.

$\widetilde{\chi}_i^0$ — neutralinos (mixtures of $\widetilde{\gamma}$, $\widetilde{Z}^0$, and $\widetilde{H}_i^0$)

Mass $m_{\widetilde{\chi}_1^0} > 0$ GeV, CL = 95%
[general MSSM, non-universal gaugino masses]

Mass $m_{\widetilde{\chi}_1^0} > 46$ GeV, CL = 95%
[all tanβ, all m_0, all $m_{\widetilde{\chi}_2^0} - m_{\widetilde{\chi}_1^0}$]

Mass $m_{\widetilde{\chi}_2^0} > 62.4$ GeV, CL = 95%
[1<tanβ <40, all m_0, all $m_{\widetilde{\chi}_2^0} - m_{\widetilde{\chi}_1^0}$]

Mass $m_{\widetilde{\chi}_2^0} > 345$ GeV, CL = 95%
[$\widetilde{\chi}_1^\pm \widetilde{\chi}_2^0 \rightarrow W \widetilde{\chi}_1^0 Z \widetilde{\chi}_1^0$, simplified model, $m_{\widetilde{\chi}_1^\pm} = m_{\widetilde{\chi}_2^0}$, $m_{\widetilde{\chi}_1^0} =$ 0 GeV]

Mass $m_{\widetilde{\chi}_3^0} > 99.9$ GeV, CL = 95%
[1<tanβ <40, all m_0, all $m_{\widetilde{\chi}_2^0} - m_{\widetilde{\chi}_1^0}$]

Mass $m_{\widetilde{\chi}_4^0} > 116$ GeV, CL = 95%
[1<tanβ <40, all m_0, all $m_{\widetilde{\chi}_2^0} - m_{\widetilde{\chi}_1^0}$]

$\widetilde{\chi}_i^\pm$ — charginos (mixtures of $\widetilde{W}^\pm$ and $\widetilde{H}_i^\pm$)

Mass $m_{\widetilde{\chi}_1^\pm} > 94$ GeV, CL = 95%
[tan$\beta < 40$, $m_{\widetilde{\chi}_1^\pm} - m_{\widetilde{\chi}_1^0} > 3$ GeV, all m_0]

Mass $m_{\widetilde{\chi}_1^\pm} > 345$ GeV, CL = 95%
[simplified model, $m_{\widetilde{\chi}_1^\pm} = m_{\widetilde{\chi}_2^0}$, $m_{\widetilde{\chi}_1^0} = 0$ GeV]

$\widetilde{\nu}$ — sneutrino

Mass $m > 94$ GeV, CL = 95%
[CMSSM, $1 \leq \tan\beta \leq 40$, $m_{\widetilde{e}_R} - m_{\widetilde{\chi}_1^0} > 10$ GeV]

$\widetilde{e}$ — scalar electron (selectron)

Mass $m(\widetilde{e}_L) > 107$ GeV, CL = 95% [all $m_{\widetilde{e}_R} - m_{\widetilde{\chi}_1^0}$]

Mass $m(\widetilde{e}_R) > 97.5$ GeV, CL = 95%
[$\Delta m > 11$ GeV, $|\mu| > 100$ GeV, tanβ=1.5]

$\widetilde{\mu}$ — scalar muon (smuon)

Mass $m > 94$ GeV, CL = 95%
[CMSSM, $1 \leq \tan\beta \leq 40$, $m_{\widetilde{\mu}_R} - m_{\widetilde{\chi}_1^0} > 10$ GeV]

$\widetilde{\tau}$ — scalar tau (stau)

Mass $m > 81.9$ GeV, CL = 95%
[$m_{\widetilde{\tau}_R} - m_{\widetilde{\chi}_1^0} > 15$ GeV, all θ_τ, B($\widetilde{\tau} \rightarrow \tau \widetilde{\chi}_1^0$) = 100%]

$\widetilde{q}$ – squarks of the first two quark generations

The first of these limits is within CMSSM with cascade decays, evaluated assuming a fixed value of the parameters μ and tanβ. The first two limits assume two-generations of mass degenerate squarks ($\widetilde{q}_L$ and $\widetilde{q}_R$) and gaugino mass parameters that are constrained by the unification condition at the grand unification scale. The third limit assumes a simplified model with a 100% branching ratio for the prompt decay $\widetilde{q} \rightarrow q \widetilde{\chi}_1^0$.

Mass $m > 1450$ GeV, CL = 95%
[CMSSM, tan$\beta = 30$, $A_0 = -2\max(m_0, m_{1/2})$, $\mu > 0$]

Mass $m > 850$ GeV, CL = 95%
[jets + $\not{E}_T$, $\widetilde{q} \rightarrow q \widetilde{\chi}_1^0$ simplified model, $m_{\widetilde{\chi}_1^0} = 0$ GeV]

Mass $m > 520$ GeV, CL = 95%
[$\widetilde{q} \rightarrow q \widetilde{\chi}_1^0$, simplified model, single light squark, $m_{\widetilde{\chi}_1^0} = 0$]

$\widetilde{b}$ — scalar bottom (sbottom)

Mass $m > 650$ GeV, CL = 95% [$\widetilde{b} \rightarrow b \widetilde{\chi}_1^0$, $m_{\widetilde{\chi}_1^0} = 0$]

Mass $m > 600$ GeV, CL = 95% [$\widetilde{b} \rightarrow b \widetilde{\chi}_1^0$, $m_{\widetilde{\chi}_1^0} < 250$ GeV]

$\widetilde{t}$ — scalar top (stop)

Mass $m > 730$ GeV, CL = 95%
[$\widetilde{t} \rightarrow t \widetilde{\chi}_1^0$, $m_{\widetilde{\chi}_1^0} = 100$ GeV, $m_{\widetilde{t}} > m_t + m_{\widetilde{\chi}_1^0}$]

Mass $m > 500$ GeV, CL = 95%
[$\ell^\pm$ + jets + $\not{E}_T$, $\widetilde{t}_1 \rightarrow b \widetilde{\chi}_1^\pm$, $m_{\widetilde{\chi}_1^\pm} = 2\, m_{\widetilde{\chi}_1^0}$, 100 GeV < $m_{\widetilde{\chi}_1^0} <$ 150 GeV]

Mass $m > 240$ GeV, CL = 95%
[$\widetilde{t}_1 \rightarrow c \widetilde{\chi}_1^0$, $m_{\widetilde{t}_1} - m_{\widetilde{\chi}_1^0} <$85 GeV]

$\widetilde{g}$ — gluino

The first limit assumes a simplified model with a 100% branching ratio for the prompt 3 body decay, independent of the squark mass. The second of these limits is within the CMSSM (for $m_{\widetilde{g}} \gtrsim 5$ GeV), and includes the effects of cascade decays, evaluated assuming a fixed value of the parameters μ and tanβ. The limit assumes GUT relations between gaugino masses and the gauge couplings. The third limit is based on a combination of searches.

Mass $m > 1225$ GeV, CL = 95% [$\widetilde{g} \rightarrow q \overline{q} \widetilde{\chi}_1^0$, $m_{\widetilde{\chi}_1^0} = 0$]

Mass $m > 1150$ GeV, CL = 95%
[CMSSM, tanβ=30, A_0=$-2\max(m_0, m_{1/2})$, $\mu > 0$]

Mass $m > 1150$ GeV, CL = 95%
[general RPC $\widetilde{g}$ decays, $m_{\widetilde{\chi}_1^0} < 100$ GeV]

Technicolor

The limits for technicolor (and top-color) particles are quite varied depending on assumptions. See the Technicolor section of the full *Review* (the data listings).

Quark and Lepton Compositeness, Searches for

Scale Limits Λ for Contact Interactions
(the lowest dimensional interactions with four fermions)

If the Lagrangian has the form

$$\pm \frac{g^2}{2\Lambda^2} \overline{\psi}_L \gamma_\mu \psi_L \overline{\psi}_L \gamma^\mu \psi_L$$

(with $g^2/4\pi$ set equal to 1), then we define $\Lambda \equiv \Lambda_{LL}^\pm$. For the full definitions and for other forms, see the Note in the Listings on Searches for Quark and Lepton Compositeness in the full *Review* and the original literature.

Excited Leptons

The limits from $\ell^{*+}\ell^{*-}$ do not depend on λ (where λ is the $\ell\ell^*$ transition coupling). The λ-dependent limits assume chiral coupling.

$e^{*\pm}$ — excited electron
Mass $m >$ 103.2 GeV, CL = 95% (from e^*e^*)
Mass $m >$ 3.000×10^3 GeV, CL = 95% (from ee^*)
Mass $m >$ 356 GeV, CL = 95% (if $\lambda_\gamma = 1$)

$\mu^{*\pm}$ — excited muon
Mass $m >$ 103.2 GeV, CL = 95% (from $\mu^*\mu^*$)
Mass $m >$ 3.000×10^3 GeV, CL = 95% (from $\mu\mu^*$)

$\tau^{*\pm}$ — excited tau
Mass $m >$ 103.2 GeV, CL = 95% (from $\tau^*\tau^*$)
Mass $m >$ 2.500×10^3 GeV, CL = 95% (from $\tau\tau^*$)

ν^* — excited neutrino
Mass $m >$ 1.600×10^3 GeV, CL = 95% (from $\nu^*\nu^*$)
Mass $m >$ 213 GeV, CL = 95% (from ν^*X)

q^* — excited quark
Mass $m >$ 338 GeV, CL = 95% (from q^*q^*)
Mass $m >$ 4.060×10^3 GeV, CL = 95% (from q^*X)

Color Sextet and Octet Particles

Color Sextet Quarks (q_6)
Mass $m >$ 84 GeV, CL = 95% (Stable q_6)

Color Octet Charged Leptons (ℓ_8)
Mass $m >$ 86 GeV, CL = 95% (Stable ℓ_8)

Color Octet Neutrinos (ν_8)
Mass $m >$ 110 GeV, CL = 90% ($\nu_8 \rightarrow \nu g$)

Extra Dimensions

Please refer to the Extra Dimensions section of the full *Review* for a discussion of the model-dependence of these bounds, and further constraints.

Constraints on the radius of the extra dimensions, for the case of two-flat dimensions of equal radii
$R <$ 30 μm, CL = 95% (direct tests of Newton's law)
$R <$ 15 μm, CL = 95% ($pp \rightarrow jG$)
$R <$ 0.16–916 nm (astrophysics; limits depend on technique and assumptions)

Constraints on the fundamental gravity scale
$M_{TT} >$ 6.3 TeV, CL = 95% ($pp \rightarrow$ dijet, angular distribution)
$M_c >$ 4.16 TeV, CL = 95% ($pp \rightarrow \ell\bar{\ell}$)

Constraints on the Kaluza-Klein graviton in warped extra dimensions
$M_G >$ 2.73 TeV, CL = 95% ($pp \rightarrow e^+e^-,\ \mu^+\mu^-$)

Constraints on the Kaluza-Klein gluon in warped extra dimensions
$M_{g_{KK}} >$ 2.5 TeV, CL = 95% ($g_{KK} \rightarrow t\bar{t}$)

TESTS OF CONSERVATION LAWS

Updated June 2016 by L. Wolfenstein (Carnegie-Mellon University) and C.-J. Lin (LBNL).

In keeping with the current interest in tests of conservation laws, we collect together a Table of experimental limits on all weak and electromagnetic decays, mass differences, and moments, and on a few reactions, whose observation would violate conservation laws. The Table is given only in the full *Review of Particle Physics*, not in the Particle Physics Booklet. For the benefit of Booklet readers, we include the best limits from the Table in the following text. Limits in this text are for CL=90% unless otherwise specified. The Table is in two parts: "Discrete Space-Time Symmetries," *i.e.*, C, P, T, CP, and CPT; and "Number Conservation Laws," *i.e.*, lepton, baryon, hadronic flavor, and charge conservation. The references for these data can be found in the the Particle Listings in the *Review*. A discussion of these tests follows.

CPT INVARIANCE

General principles of relativistic field theory require invariance under the combined transformation CPT. The simplest tests of CPT invariance are the equality of the masses and lifetimes of a particle and its antiparticle. The best test comes from the limit on the mass difference between K^0 and $\overline{K}^0$. Any such difference contributes to the CP-violating parameter ϵ. Assuming CPT invariance, ϕ_ϵ, the phase of ϵ should be very close to 44°. (See the review "CP Violation in K_L decay" in this edition.) In contrast, if the entire source of CP violation in K^0 decays were a $K^0 - \overline{K}^0$ mass difference, ϕ_ϵ would be $44° + 90°$.

Assuming that there is no other source of CPT violation than this mass difference, it is possible to deduce that [1]

$$m_{\overline{K}^0} - m_{K^0} \approx \frac{2(m_{K_L^0} - m_{K_S^0})\,|\eta|\,(\frac{2}{3}\phi_{+-} + \frac{1}{3}\phi_{00} - \phi_{\rm SW})}{\sin\phi_{\rm SW}}\ ,$$

where $\phi_{\rm SW} = (43.51 \pm 0.05)°$, the superweak angle. Using our best values of the CP-violation parameters, we get $|(m_{\overline{K}^0} - m_{K^0})/m_{K^0}| \leq 0.6 \times 10^{-18}$ at CL=90%. Limits can also be placed on specific CPT-violating decay amplitudes. Given the small value of $(1 - |\eta_{00}/\eta_{+-}|)$, the value of $\phi_{00} - \phi_{+-}$ provides a measure of CPT violation in $K_L^0 \to 2\pi$ decay. Results from CERN [1] and Fermilab [2] indicate no CPT-violating effect.

CP AND T INVARIANCE

Given CPT invariance, CP violation and T violation are equivalent. The original evidence for CP violation came from the measurement of $|\eta_{+-}| = |A(K_L^0 \to \pi^+\pi^-)/A(K_S^0 \to \pi^+\pi^-)| = (2.232 \pm 0.011) \times 10^{-3}$. This could be explained in terms of K^0–$\overline{K}^0$ mixing, which also leads to the asymmetry $[\Gamma(K_L^0 \to \pi^- e^+ \nu) - \Gamma(K_L^0 \to \pi^+ e^- \overline{\nu})]/[\text{sum}] = (0.334 \pm 0.007)\%$. Evidence for CP violation in the kaon decay amplitude comes from the measurement of $(1 - |\eta_{00}/\eta_{+-}|)/3 = Re(\epsilon'/\epsilon) = (1.66 \pm 0.23) \times 10^{-3}$. In the Standard Model much larger CP-violating effects are expected. The first of these, which is associated with B–$\overline{B}$ mixing, is the parameter $sin(2\beta)$ now measured quite accurately to be 0.679 ± 0.020. A number of other CP-violating observables are being measured in B decays; direct evidence for CP violation in the B decay amplitude comes from the asymmetry $[\Gamma(\overline{B}^0 \to K^-\pi^+) - \Gamma(B^0 \to K^+\pi^-)]/[\text{sum}] = -0.082 \pm 0.006$. Direct tests of T violation are much more difficult; a measurement by CPLEAR of the difference between the oscillation probabilities of K^0 to $\overline{K^0}$ and $\overline{K^0}$ to K^0 is related to T violation [3]. A nonzero value of the electric dipole moment of the neutron and electron requires both P and T violation. The current experimental results are $< 3.0 \times 10^{-26}$ e cm (neutron), and $< 8.7 \times 10^{-29}$ e cm (electron) at the 90% C.L. The BABAR experiment reported the first direct observation of T violation in the B system. The measured T-violating parameters in the time evolution of the neutral B mesons are $\Delta S_T^+ = -1.37 \pm 0.15$ and $\Delta S_T^- = 1.17 \pm 0.21$, with a significance of 14σ [4]. This observation of T violation, with exchange of initial and final states of the neutral B, was made possible in a B-factory using the Einstein-Podolsky-Rosen Entanglement of the two B's produced in the decay of the $\Upsilon(4S)$ and the two time-ordered decays of the B's as filtering measurements of the meson state [5].

CONSERVATION OF LEPTON NUMBERS

Present experimental evidence and the standard electroweak theory are consistent with the absolute conservation of three separate lepton numbers: electron number L_e, muon number L_μ, and tau number L_τ, except for the effect of neutrino mixing associated with neutrino masses. Searches for violations are of the following types:

a) $\Delta L = 2$ for one type of charged lepton. The best limit comes from the search for neutrinoless double beta decay $(Z, A) \to (Z + 2, A) + e^- + e^-$. The best laboratory limit is $t_{1/2} > 1.07 \times 10^{26}$ yr (CL=90%) for ^{136}Xe from the KamLAND-Zen experiment [6].

b) Conversion of one charged-lepton type to another. For purely leptonic processes, the best limits are on $\mu \to e\gamma$ and $\mu \to 3e$, measured as $\Gamma(\mu \to e\gamma)/\Gamma(\mu \to \text{all}) < 5.7 \times 10^{-13}$ and $\Gamma(\mu \to 3e)/\Gamma(\mu \to \text{all}) < 1.0 \times 10^{-12}$. For semileptonic processes, the best limit comes from the coherent conversion process in a muonic atom, $\mu^- + (Z, A) \to e^- + (Z, A)$, measured as $\Gamma(\mu^-\text{Ti} \to e^-\text{Ti})/\Gamma(\mu^-\text{Ti} \to \text{all}) < 4.3 \times 10^{-12}$. Of special interest is the case in which the hadronic flavor also changes, as in $K_L \to e\mu$ and $K^+ \to \pi^+ e^- \mu^+$, measured as $\Gamma(K_L \to e\mu)/\Gamma(K_L \to \text{all}) < 4.7 \times 10^{-12}$ and $\Gamma(K^+ \to \pi^+ e^- \mu^+)/\Gamma(K^+ \to \text{all}) < 1.3 \times 10^{-11}$. Limits on the conversion of τ into e or μ are found in τ decay and are much less stringent than those for $\mu \to e$ conversion, *e.g.*, $\Gamma(\tau \to \mu\gamma)/\Gamma(\tau \to \text{all}) < 4.4 \times 10^{-8}$ and $\Gamma(\tau \to e\gamma)/\Gamma(\tau \to \text{all}) < 3.3 \times 10^{-8}$.

c) Conversion of one type of charged lepton into another type of charged antilepton. The case most studied is $\mu^- + (Z, A) \to e^+ + (Z - 2, A)$, the strongest limit being $\Gamma(\mu^-\text{Ti} \to e^+\text{Ca})/\Gamma(\mu^-\text{Ti} \to \text{all}) < 3.6 \times 10^{-11}$.

d) Neutrino oscillations. It is expected even in the standard electroweak theory that the lepton numbers are not separately conserved, as a consequence of lepton mixing analogous to Cabibbo-Kobayashi-Maskawa quark mixing. However, if the only source of lepton-number violation is the mixing of low-mass neutrinos then processes such as $\mu \to e\gamma$ are expected to have extremely small unobservable probabilities. For small neutrino masses, the lepton-number violation would be observed first in neutrino oscillations, which have been the subject of extensive experimental studies. Compelling evidence for neutrino mixing has come from atmospheric, solar, accelerator, and reactor neutrinos. Recently, the reactor neutrino experiments have measured the last neutrino mixing angle θ_{13} and found it to be relatively large. For a comprehensive review on neutrino mixing, including the latest results on θ_{13}, see the review *"Neutrino Mass, Mixing, and Oscillations"* by K. Nakamura and S.T. Petcov in this edition of RPP.

CONSERVATION OF HADRONIC FLAVORS

In strong and electromagnetic interactions, hadronic flavor is conserved, *i.e.* the conversion of a quark of one flavor (d, u, s, c, b, t) into a quark of another flavor is forbidden. In the Standard Model, the weak interactions violate these conservation laws in a manner described by the Cabibbo-Kobayashi-Maskawa mixing (see the section "Cabibbo-Kobayashi-Maskawa Mixing Matrix"). The way in which these conservation laws are violated is tested as follows:

(a) $\Delta S = \Delta Q$ rule. In the strangeness-changing semileptonic decay of strange particles, the strangeness change equals the change in charge of the hadrons. Tests come from limits on decay rates such as $\Gamma(\Sigma^+ \to ne^+\nu)/\Gamma(\Sigma^+ \to \text{all}) < 5 \times 10^{-6}$, and from a detailed analysis of $K_L \to \pi e\nu$, which yields the parameter x, measured to be $(\text{Re}\, x,\ \text{Im}\, x) = (-0.002 \pm 0.006,\ 0.0012 \pm 0.0021)$. Corresponding rules are $\Delta C = \Delta Q$ and $\Delta B = \Delta Q$.

(b) Change of flavor by two units. In the Standard Model this occurs only in second-order weak interactions. The classic example is $\Delta S = 2$ via $K^0 - \overline{K}^0$ mixing, which is directly measured by $m(K_L) - m(K_S) = (0.5293 \pm 0.0009) \times 10^{10}\ \hbar s^{-1}$. The $\Delta B = 2$ transitions in the B^0 and B_s^0 systems via mixing are also well established. The measured mass differences between the eigenstates are $(m_{B^0_{\rm H}} - m_{B^0_{\rm L}}) = (0.5096 \pm 0.0034) \times 10^{12}\ \hbar s^{-1}$ and $(m_{B^0_{s\rm H}} - m_{B^0_{s\rm L}}) = (17.757 \pm 0.021) \times 10^{12}\ \hbar s^{-1}$. There is now strong evidence of $\Delta C = 2$ transition in the charm sector with the mass difference $m_{D^0_H} - m_{D^0_L} = (0.95^{+0.41}_{-0.44}) \times 10^{10}\ \hbar s^{-1}$. All results are consistent with the second-order calculations in the Standard Model.

(c) Flavor-changing neutral currents. In the Standard Model the neutral-current interactions do not change flavor. The low rate $\Gamma(K_L \to \mu^+\mu^-)/\Gamma(K_L \to \text{all}) = (6.84 \pm 0.11) \times 10^{-9}$ puts limits on such interactions; the nonzero value for this rate is attributed to a combination of the weak and electromagnetic interactions. The best test should come from $K^+ \to \pi^+\nu\overline{\nu}$, which occurs in the Standard Model only as a second-order weak process with a branching fraction of (0.4 to 1.2)$\times 10^{-10}$. Combining results from BNL-E787 and BNL-E949 experiments yield $\Gamma(K^+ \to \pi^+\nu\overline{\nu})/\Gamma(K^+ \to \text{all}) = (1.7 \pm 1.1) \times 10^{-10}$ [7]. Limits for charm-changing or bottom-changing neutral currents are less stringent: $\Gamma(D^0 \to \mu^+\mu^-)/\Gamma(D^0 \to \text{all}) < 6.2 \times 10^{-9}$ and $\Gamma(B^0 \to \mu^+\mu^-)/\Gamma(B^0 \to \text{all}) = (3.9^{+1.6}_{-1.4}) \times 10^{-10}$. One cannot isolate flavor-changing neutral current (FCNC) effects in non leptonic decays. For example, the FCNC transition $s \to d + (\overline{u} + u)$ is equivalent to the charged-current transition $s \to u + (\overline{u} + d)$. Tests for FCNC are therefore limited to hadron decays into lepton pairs. Such decays are expected only in second-order in the electroweak coupling in the Standard Model. The LHCb and CMS experiments have recently observed the FCNC decay of $B_s^0 \to \mu^+\mu^-$. The current world average value is $\Gamma(B_s^0 \to \mu^+\mu^-)/\Gamma(B_s^0 \to \text{all}) = (2.9^{+0.7}_{-0.6})\times 10^{-9}$, which is consistent with the Standard Model expectation.

NOTES

In this Summary Table:

When a quantity has "(S = ...)" to its right, the error on the quantity has been enlarged by the "scale factor" S, defined as $S = \sqrt{\chi^2/(N-1)}$, where N is the number of measurements used in calculating the quantity. We do this when $S > 1$, which often indicates that the measurements are inconsistent. When $S > 1.25$, we also show in the Particle Listings an ideogram of the measurements. For more about S, see the Introduction.

[a] C parity forbids this to occur as a single-photon process.

[b] See the Particle Listings for the (complicated) definition of this quantity.

[c] Time-reversal invariance requires this to be 0° or 180°.

[d] This coefficient is zero if time invariance is not violated.

[e] Allowed by higher-order electroweak interactions.

[f] Violates CP in leading order. Test of direct CP violation since the indirect CP-violating and CP-conserving contributions are expected to be suppressed.

[g] In the 2010 *Review*, the values for these quantities were given using a measure of the asymmetry that was inconsistent with the usual definition.

[h] $\text{Re}(\epsilon'/\epsilon) = \epsilon'/\epsilon$ to a very good approximation provided the phases satisfy CPT invariance.

[i] This mode includes gammas from inner bremsstrahlung but not the direct emission mode $K_L^0 \to \pi^+ \pi^- \gamma$(DE).

Unless otherwise stated, limits are given at the 90% confidence level, while errors are given as ±1 standard deviation.

[j] Neglecting photon channels. See, *e.g.*, A. Pais and S.B. Treiman, Phys. Rev. **D12**, 2744 (1975).

[k] Derived from measured values of ϕ_{+-}, ϕ_{00}, $|\eta|$, $|m_{K_L^0} - m_{K_S^0}|$, and $\tau_{K_S^0}$, as described in the introduction to "Tests of Conservation Laws."

[l] The $|m_p - m_{\overline{p}}|/m_p$ and $|q_p + q_{\overline{p}}|/e$ are not independent, and both use the more precise measurement of $|q_{\overline{p}}/m_{\overline{p}}|/(q_p/m_p)$.

[n] The value is for the sum of the charge states or particle/antiparticle states indicated.

[o] A test of additive vs. multiplicative lepton family number conservation.

[p] The sign of Δm^2_{32} is not known at this time. The range quoted is for the absolute value.

[q] Derived from an analysis of neutrino-oscillation experiments.

[r] This limit is for either D^0 or $\overline{D}^0$ to $p\,e^-$.

[s] This limit is for either D^0 or $\overline{D}^0$ to $\overline{p}\,e^+$.

[t] The first limit is for $p \to$ anything or "disappearance" modes of a bound proton. The second entry, a rough range of limits, assumes the dominant decay modes are among those investigated. For antiprotons the best limit, inferred from the observation of cosmic ray $\overline{p}$'s is $\tau_{\overline{p}} > 10^7$ yr, the cosmic-ray storage time, but this limit depends on a number of assumptions. The best direct observation of stored antiprotons gives $\tau_{\overline{p}}/\mathrm{B}(\overline{p} \to e^-\gamma) > 7 \times 10^5$ yr.

[u] There is some controversy about whether nuclear physics and model dependence complicate the analysis for bound neutrons (from which the best limit comes). The first limit here is from reactor experiments with free neutrons.

[v] This is the best limit for the mode $e^- \to \nu\gamma$. The best limit for "electron disappearance" is 6.4×10^{24} yr.

[x] See the K_S^0 Particle Listings for the energy limits used in this measurement.

[y] See the K_L^0 Particle Listings for the energy limits used in this measurement.

[z] An ℓ indicates an e or a μ mode, not a sum over these modes.

[aa] Here S and P are the hypothetical scalar and pseudoscalar particles with masses of 2.5 GeV/c^2 and 214.3 MeV/c^2, respectively.

[bb] This limit is for $\Gamma(t \to Z\,q)/\Gamma(t \to W\,b)$.

REVIEWS, TABLES, AND PLOTS

MAJOR REVIEWS IN THE PARTICLE LISTINGS

1. PHYSICAL CONSTANTS

Table 1.1. Reviewed 2015 by P.J. Mohr and D.B. Newell (NIST). Mainly from the "CODATA Recommended Values of the Fundamental Physical Constants: 2014" by P.J. Mohr, D.B. Newell, and B.N. Taylor in arXiv:1507.07956 (2015) and RMP (to be submitted). The last group of constants (beginning with the Fermi coupling constant) comes from the Particle Data Group. The figures in parentheses after the values give the 1-standard-deviation uncertainties in the last digits; the corresponding fractional uncertainties in parts per 10^9 (ppb) are given in the last column. This set of constants (aside from the last group) is recommended for international use by CODATA (the Committee on Data for Science and Technology). The full 2014 CODATA set of constants may be found at `http://physics.nist.gov/constants`. See also P.J. Mohr and D.B. Newell, "Resource Letter FC-1: The Physics of Fundamental Constants," Am. J. Phys. **78**, 338 (2010).

* The meter is the length of the path traveled by light in vacuum during a time interval of 1/299 792 458 of a second.
† At $Q^2 = 0$. At $Q^2 \approx m_W^2$ the value is $\sim 1/128$.
‡ Absolute lab measurements of G_N have been made only on scales of about 1 cm to 1 m.
** See the discussion in Sec. 10, "Electroweak model and constraints on new physics."
†† The corresponding $\sin^2\theta$ for the effective angle is 0.23155(5).

2. ASTROPHYSICAL CONSTANTS AND PARAMETERS

Table 2.1. Revised March 2016 by D.E. Groom (LBNL). The figures in parentheses after some values give the 1-σ uncertainties in the last digit(s). Physical constants are from Ref. 1. While every effort has been made to obtain the most accurate current values of the listed quantities, the table does not represent a critical review or adjustment of the constants, and is not intended as a primary reference.

The values and uncertainties for the cosmological parameters depend on the exact data sets, priors, and basis parameters used in the fit. Many of the derived parameters reported in this table have non-Gaussian likelihoods. Parameters may be highly correlated, so care must be taken in propagating errors. Unless otherwise specified, cosmological parameters are derived from 6-parameter fits to a flat ΛCDM cosmology *Planck* 2015 temperature (TT) + low ℓ polarization data (lowP) + lensing [2]. For more information see Ref. 3 and the original papers.

12. 4π (1 au)$^2 \times \mathcal{S}_\odot$, assuming isotropic irradiance.
13. Product of $2/c^2$ and the geocentric gravitational constant $G_N M_\oplus$ [5]. Truncated to 8 places so that TCB, TT, and TDB time scale values agree.
14. $G_N M_\oplus$ [5] $\div\, G_N$ [1].
15. XXIXth IAU General Assembly, Resolution B2, "on recommended zero points for the absolute and apparent bolometric magnitude scales".
16. J. B. Oke and J. E. Gunn, Astrophys. J. **266**, 713 (1983). Note that in the definition of AB the sign of the constant is wrong.
17. M.J. Reid, *et al.*, Astrophys. J. **700**, 137 (2009). Note that Θ_0/R_0 is better determined than either Θ_0 or R_0.
18. Z.M. Malkin, arXiv:1202.6128 and Astron. Rep. **57**, 128 (2013). 52 determinations of R_0 over 20 years are given. The weighted mean of these *unevaluated* results is 7.94 ± 0.05 kpc, with $\chi^2/N_{\rm dof} = 1.26$. If the 8 values more than 3σ from the mean are eliminated, $\langle R_0 \rangle = 8.02 \pm 0.06$ kpc and $\chi^2/N_{\rm dof} = 0.67$. The author suggests using $R_0 = 8.00 \pm 0.25$ kpc.

33. Summary Tables in this *Review* list $N_\nu = 2.984(8)$ (Standard Model fits to LEP-SLC data). Because neutrinos are not completely decoupled at $e^\pm$ annihilation, the effective number of massless neutrino species is 3.046, rather than 3.
34. The sum is over all neutrino mass eigenstates. The lower limit follows from neutrino mixing results reported in this *Review* combined with the assumptions that there are three light neutrinos ($m_\nu < 45$ GeV/c^2) and that the lightest neutrino is substantially less massive than the others: $\Delta m^2_{32} = (2.44 \pm 0.06) \times 10^{-3}$ eV^2, so $\sum m_{\nu_j} \geq m_{\nu_3} \approx \sqrt{\Delta m^2_{32}} = 0.05$ eV. About the same limit obtains if the mass hierarchy is inverted, with $m_{\nu_1} \approx m_{\nu_2} \gg m_{\nu_3}$. Alternatively, if the limit obtained from tritium decay experiments ($m_\nu < 2\,{\rm eV}$) is used for the upper limit, then $\Omega_\nu < 0.05$.
35. Astrophysical determinations of $\sum m_{\nu_j}$, reported in the Full Listings of this *Review* under "Sum of the neutrino masses," range from < 0.17 eV to < 2.3 eV in papers published since 2003.

Table 4.1. Revised June 2016 by D.E. Groom (LBNL). The atomic number (top left) is the number of protons in the nucleus. The atomic masses (bottom) of stable elements are weighted by isotopic abundances in the Earth's surface. Atomic masses are relative to the mass of ^{12}C, defined to be exactly 12 unified atomic mass units (u) (approx. g/mole). The exceptions are Th, Pa, and U, which have no stable isotopes but do have characteristic terrestrial compositions. Relative isotopic abundances often vary considerably, both in natural and commercial samples; this is reflected in the number of significant figures given for the mass. Masses may be found at `http://physics.nist.gov/cgi-bin/Compositions/stand_alone.pl` . If there is no stable isotope the atomic mass of the most stable isotope is given in parentheses.

IUPAC announced verification of the discoveries of elements 113, 115, 117, and 118 in December 2015. Provisional names were assigned in June 2016. The 7th period of the periodic table is now complete.

5. ELECTRONIC STRUCTURE OF THE ELEMENTS

Table 5.1. Reviewed 2011 by J.E. Sansonetti (NIST). The electronic configurations and the ionization energies are from the NIST database, "Ground Levels and Ionization Energies for the Neutral Atoms," W.C. Martin, A. Musgrove, S. Kotochigova, and J.E. Sansonetti, `http://www.nist.gov/pml/data/ion_energy.cfm`. The electron configuration for, say, iron indicates an argon electronic core (see argon) plus six $3d$ electrons and two $4s$ electrons.

	Element		Electron configuration ($3d^5$ = five $3d$ electrons, *etc.*)						Ground state $^{2S+1}L_J$	Ionization energy (eV)
1	H	Hydrogen	$1s$						$^2S_{1/2}$	13.5984
2	He	Helium	$1s^2$						$^1S_0$	24.5874
3	Li	Lithium	(He) $2s$						$^2S_{1/2}$	5.3917
4	Be	Beryllium	(He) $2s^2$						$^1S_0$	9.3227
5	B	Boron	(He) $2s^2$	$2p$					$^2P_{1/2}$	8.2980
6	C	Carbon	(He) $2s^2$	$2p^2$					$^3P_0$	11.2603
7	N	Nitrogen	(He) $2s^2$	$2p^3$					$^4S_{3/2}$	14.5341
8	O	Oxygen	(He) $2s^2$	$2p^4$					$^3P_2$	13.6181
9	F	Fluorine	(He) $2s^2$	$2p^5$					$^2P_{3/2}$	17.4228

Lanthanides

Transition elements

Actinides

* The usual LS coupling scheme does not apply for these three elements. See the introductory note to the NIST table from which this table is taken.

6. ATOMIC AND NUCLEAR PROPERTIES OF MATERIALS

Table 6.1 Abridged from `pdg.lbl.gov/AtomicNuclearProperties` by D.E. Groom (2015). See web pages for more detail about entries in this table and for several hundred other substances. Parentheses in the dE/dx and density columns indicate gases at 20° C and 1 atm. Boiling points are at 1 atm. Refractive indices n are evaluated at the sodium D line blend (589.2 nm); values $\gg 1$ in brackets indicate $(n-1)\times 10^6$ for gases at 0° C and 1 atm.

Material	Z	A	$\langle Z/A\rangle$	Nucl.coll. length λ_T {g cm^{-2}}	Nucl.inter. length λ_I {g cm^{-2}}	Rad.len. X_0 {g cm^{-2}}	$dE/dx\|_{\rm min}$ { MeV g^{-1}cm^2}	Density {g cm^{-3}} ({gℓ^{-1}})	Melting point (K)	Boiling point (K)	Refract. index @ Na D

7.1. Impedances (SI units)

ρ = resistivity at room temperature in $10^{-8}\,\Omega$ m:

~ 1.7 for Cu	~ 5.5 for W
~ 2.4 for Au	~ 73 for SS 304
~ 2.8 for Al	~ 100 for Nichrome

(Al alloys may have double the Al value.)

For alternating currents, instantaneous current I, voltage V, angular frequency ω:

$$V = V_0\, e^{j\omega t} = ZI\ . \tag{7.1}$$

Impedance of self-inductance L: $Z = j\omega L$.

Impedance of capacitance C: $Z = 1/j\omega C$.

Impedance of free space: $Z = \sqrt{\mu_0/\epsilon_0} = 376.7\ \Omega$.

High-frequency surface impedance of a good conductor:

$$Z = \frac{(1+j)\,\rho}{\delta}\ , \quad \text{where } \delta = \text{skin depth}\ ; \tag{7.2}$$

$$\delta = \sqrt{\frac{\rho}{\pi\nu\mu}} \approx \frac{6.6\text{ cm}}{\sqrt{\nu\,(\text{Hz})}} \quad \text{for Cu}\ . \tag{7.3}$$

7.2. Capacitors, inductors, and transmission Lines

The capacitance between two parallel plates of area A spaced by the distance d and enclosing a medium with the dielectric constant ε is

$$C = K\varepsilon A/d\,, \tag{7.4}$$

where the correction factor K depends on the extent of the fringing field. If the dielectric fills the capacitor volume without extending beyond the electrodes. the correction factor $K \approx 0.8$ for capacitors of typical geometry.

The inductance at high frequencies of a straight wire whose length ℓ is much greater than the wire diameter d is

$$L \approx 2.0\left[\frac{\text{nH}}{\text{cm}}\right]\cdot\ell\left(\ln\left(\frac{4\ell}{d}\right)-1\right)\ . \tag{7.5}$$

For very short wires, representative of vias in a printed circuit board, the inductance is

$$L(\text{in nH}) \approx \ell/d\,. \tag{7.6}$$

A transmission line is a pair of conductors with inductance L and capacitance C. The characteristic impedance $Z = \sqrt{L/C}$ and the phase velocity $v_p = 1/\sqrt{LC} = 1/\sqrt{\mu\varepsilon}$, which decreases with the inverse square root of the dielectric constant of the medium. Typical coaxial and ribbon cables have a propagation delay of about 5 ns/cm.

The impedance of a coaxial cable with outer diameter D and inner diameter d is

$$Z = 60\,\Omega\cdot\frac{1}{\sqrt{\varepsilon_r}}\ln\frac{D}{d}\,, \tag{7.7}$$

where the relative dielectric constant $\varepsilon_r = \varepsilon/\varepsilon_0$. A pair of parallel wires of diameter d and spacing $a > 2.5\,d$ has the impedance

$$Z = 120\,\Omega\cdot\frac{1}{\sqrt{\varepsilon_r}}\ln\frac{2a}{d}\,. \tag{7.8}$$

This yields the impedance of a wire at a spacing h above a ground plane,

$$Z = 60\,\Omega\cdot\frac{1}{\sqrt{\varepsilon_r}}\ln\frac{4h}{d}\,. \tag{7.9}$$

A common configuration utilizes a thin rectangular conductor above a ground plane with an intermediate dielectric (microstrip). Detailed calculations for this and other transmission line configurations are given by Gunston.*

7.3. Synchrotron radiation (CGS units)

For a particle of charge e, velocity $v = \beta c$, and energy $E = \gamma mc^2$, traveling in a circular orbit of radius R, the classical energy loss per revolution δE is

$$\delta E = \frac{4\pi}{3}\,\frac{e^2}{R}\,\beta^3\,\gamma^4\ . \tag{7.10}$$

For high-energy electrons or positrons ($\beta \approx 1$), this becomes

$$\delta E\ (\text{in MeV}) \approx 0.0885\ [E(\text{in GeV})]^4/R(\text{in m})\ . \tag{7.11}$$

For $\gamma \gg 1$, the energy radiated per revolution into the photon energy interval $d(\hbar\omega)$ is

$$dI = \frac{8\pi}{9}\alpha\,\gamma\,F(\omega/\omega_c)\,d(\hbar\omega)\ , \tag{7.12}$$

where $\alpha = e^2/\hbar c$ is the fine-structure constant and

$$\omega_c = \frac{3\gamma^3 c}{2R} \tag{7.13}$$

is the critical frequency. The normalized function $F(y)$ is

$$F(y) = \frac{9}{8\pi}\sqrt{3}\,y\int_y^\infty K_{5/3}\,(x)\ dx\ , \tag{7.14}$$

where $K_{5/3}\,(x)$ is a modified Bessel function of the third kind. For electrons or positrons,

$$\hbar\omega_c\,(\text{in keV}) \approx 2.22\ [E(\text{in GeV})]^3/R(\text{in m})\ . \tag{7.15}$$

Fig. 7.1 shows $F(y)$ over the important range of y.

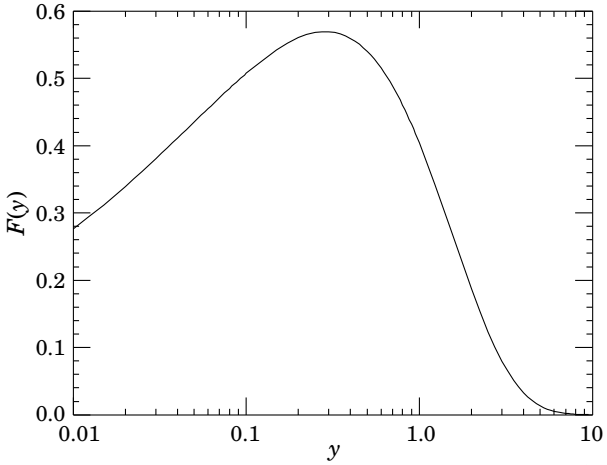

Figure 7.1: The normalized synchrotron radiation spectrum $F(y)$.

For $\gamma \gg 1$ and $\omega \ll \omega_c$,

$$\frac{dI}{d(\hbar\omega)} \approx 3.3\alpha\,(\omega R/c)^{1/3}\ , \tag{7.16}$$

whereas for

$$\gamma \gg 1 \text{ and } \omega \gtrsim 3\omega_c\ ,$$

$$\frac{dI}{d(\hbar\omega)} \approx \sqrt{\frac{3\pi}{2}}\,\alpha\,\gamma\left(\frac{\omega}{\omega_c}\right)^{1/2} e^{-\omega/\omega_c}\left[1+\frac{55}{72}\frac{\omega_c}{\omega}+\ldots\right]\ . \tag{7.17}$$

The radiation is confined to angles $\lesssim 1/\gamma$ relative to the instantaneous direction of motion. For $\gamma \gg 1$, where Eq. (7.12) applies, the mean number of photons emitted per revolution is

$$N_\gamma = \frac{5\pi}{\sqrt{3}}\alpha\gamma\ , \tag{7.18}$$

and the mean energy per photon is

$$\langle\hbar\omega\rangle = \frac{8}{15\sqrt{3}}\hbar\omega_c\ . \tag{7.19}$$

When $\langle\hbar\omega\rangle \gtrsim \mathrm{O}(E)$, quantum corrections are important.

See J.D. Jackson, *Classical Electrodynamics*, 3rd edition (John Wiley & Sons, New York, 1998) for more formulae and details. (Note that earlier editions had ω_c twice as large as Eq. (7.13).

8. NAMING SCHEME FOR HADRONS

Revised 2004 by M. Roos (University of Finland) and C.G. Wohl (LBNL).

8.1. Introduction

We introduced in the 1986 edition [1] a new naming scheme for the hadrons. Changes from older terminology affected mainly the heavier mesons made of the light (u, d, and s) quarks. Old and new names were listed alongside until 1994. Names also change from edition to edition because some characteristic like mass or spin changes. The Summary Tables give both the new and old names whenever a change occurred.

8.2. "Neutral-flavor" mesons ($S=C=B=T=0$)

Table 8.1 shows the names for mesons having the strangeness and all heavy-flavor quantum numbers equal to zero. The scheme is designed for all ordinary non-exotic mesons, but it will work for many exotic types too, if needed.

Table 8.1: Symbols for mesons with the strangeness and all heavy-flavor quantum numbers equal to zero.

	$J^{PC}=$	0^{-+}	1^{+-}	1^{--}	0^{++}
		2^{-+}	3^{+-}	2^{--}	1^{++}
		$\vdots$	$\vdots$	$\vdots$	$\vdots$
$q\overline{q}$ content	$^{2S+1}L_J=$	$^1(L\,\text{even})_J$	$^1(L\,\text{odd})_J$	$^3(L\,\text{even})_J$	$^3(L\,\text{odd})_J$
$u\overline{d}, u\overline{u}-d\overline{d}, d\overline{u}$	$(I=1)$	π	b	ρ	a
$d\overline{d}+u\overline{u}$ and/or $s\overline{s}$	$(I=0)$	η,η'	h,h'	ω,ϕ	f,f'
$c\overline{c}$		η_c	h_c	$\psi^\dagger$	χ_c
$b\overline{b}$		η_b	h_b	Υ	χ_b
$t\overline{t}$		η_t	h_t	θ	χ_t

†The J/ψ remains the J/ψ.

First, we assign names to those states with quantum numbers compatible with being $q\overline{q}$ states. The rows of the Table give the possible $q\overline{q}$ content. The columns give the possible parity/charge-conjugation states,

$$PC = -+,\ +-,\ --, \text{ and } ++\ ;$$

these combinations correspond one-to-one with the angular-momentum state $^{2S+1}L_J$ of the $q\overline{q}$ system being

$$^1(L\text{ even})_J,\ ^1(L\text{ odd})_J,\ ^3(L\text{ even})_J, \text{ or } ^3(L\text{ odd})_J\ .$$

Here S, L, and J are the spin, orbital, and total angular momenta of the $q\overline{q}$ system. The quantum numbers are related by $P=(-1)^{L+1}$, $C=(-1)^{L+S}$, and G parity $=(-1)^{L+S+I}$, where of course the C quantum number is only relevant to neutral mesons.

The entries in the Table give the meson names. The spin J is added as a subscript except for pseudoscalar and vector mesons, and the mass is added in parentheses for mesons that decay strongly. However, for the lightest meson resonances, we omit the mass.

Measurements of the mass, quark content (where relevant), and quantum numbers I, J, P, and C (or G) of a meson thus fix its symbol. Conversely, these properties may be inferred unambiguously from the symbol.

If the main symbol cannot be assigned because the quantum numbers are unknown, X is used. Sometimes it is not known whether a meson is mainly the isospin-0 mix of $u\overline{u}$ and $d\overline{d}$ or is mainly $s\overline{s}$. A prime (or pair ω, ϕ) may be used to distinguish two such mixing states.

We follow custom and use spectroscopic names such as $\Upsilon(1S)$ as the primary name for most of those ψ, Υ, and χ states whose spectroscopic identity is known. We use the form $\Upsilon(9460)$ as an alternative, and as the primary name when the spectroscopic identity is not known.

Names are assigned for $t\overline{t}$ mesons, although the top quark is evidently so heavy that it is expected to decay too rapidly for bound states to form.

Gluonium states or other mesons that are not $q\overline{q}$ states are, if the quantum numbers are *not* exotic, to be named just as are the $q\overline{q}$ mesons. Such states will probably be difficult to distinguish from $q\overline{q}$ states and will likely mix with them, and we make no attempt to distinguish those "mostly gluonium" from those "mostly $q\overline{q}$."

An "exotic" meson with J^{PC} quantum numbers that a $q\overline{q}$ system cannot have, namely $J^{PC}=0^{--}, 0^{+-}, 1^{-+}, 2^{+-}, 3^{-+}, \cdots$, would use the same symbol as does an ordinary meson with all the same quantum numbers as the exotic meson except for the C parity. But then the J subscript may still distinguish it; for example, an isospin-0 1^{-+} meson could be denoted ω_1.

8.3. Mesons with nonzero S, C, B, and/or T

Since the strangeness or a heavy flavor of these mesons is nonzero, none of them are eigenstates of charge conjugation, and in each of them one of the quarks is heavier than the other. The rules are:

1. The main symbol is an upper-case italic letter indicating the heavier quark as follows:
$$s\to\overline{K} \qquad c\to D \qquad b\to\overline{B} \qquad t\to T\ .$$
We use the convention that *the flavor and the charge of a quark have the same sign.* Thus the strangeness of the s quark is negative, the charm of the c quark is positive, and the bottom of the b quark is negative. In addition, I_3 of the u and d quarks are positive and negative, respectively. The effect of this convention is as follows: *Any flavor carried by a charged meson has the same sign as its charge.* Thus the K^+, D^+, and B^+ have positive strangeness, charm, and bottom, respectively, and all have positive I_3. The D_s^+ has positive charm *and* strangeness. Furthermore, the $\Delta(\text{flavor})=\Delta Q$ rule, best known for the kaons, applies to every flavor.
2. If the lighter quark is not a u or a d quark, its identity is given by a subscript. The D_s^+ is an example.
3. If the spin-parity is in the "normal" series, $J^P=0^+, 1^-, 2^+, \cdots$, a superscript "*" is added.
4. The spin is added as a subscript except for pseudoscalar or vector mesons.

8.4. Ordinary (3-quark) baryons

The symbols N, Δ, Λ, Σ, Ξ, and Ω used for more than 30 years for the baryons made of light quarks (u, d, and s quarks) tell the isospin and quark content, and the same information is conveyed by the symbols used for the baryons containing one or more heavy quarks (c and b quarks). The rules are:

1. Baryons with *three* u and/or d quarks are N's (isospin 1/2) or Δ's (isospin 3/2).
2. Baryons with *two* u and/or d quarks are Λ's (isospin 0) or Σ's (isospin 1). If the third quark is a c, b, or t quark, its identity is given by a subscript.
3. Baryons with *one* u or d quark are Ξ's (isospin 1/2). One or two subscripts are used if one or both of the remaining quarks are heavy: thus Ξ_c, Ξ_{cc}, Ξ_b, *etc.**
4. Baryons with *no* u or d quarks are Ω's (isospin 0), and subscripts indicate any heavy-quark content.
5. A baryon that decays strongly has its mass as part of its name. Thus p, Σ^-, Ω^-, Λ_c^+, *etc.*, but $\Delta(1232)^0$, $\Sigma(1385)^-$, $\Xi_c(2645)^+$, *etc.*

In short, the number of u plus d quarks together with the isospin determine the main symbol, and subscripts indicate any content of heavy quarks. A Σ always has isospin 1, an Ω always has isospin 0, *etc.*

8.5. Exotic baryons

In 2003, several experiments reported finding a strangeness $S = +1$, charge $Q = +1$ baryon, and one experiment reported finding an $S = -2$, $Q = -2$ baryon. Baryons with such quantum numbers cannot be made from three quarks, and thus they are exotic. The $S = +1$ baryon, which once would have been called a Z, was quickly dubbed the $\Theta(1540)^+$, and we proposed to name the $S = -2$ baryon the $\Phi(1860)$. However, these "discoveries" were then completely ruled out by many experiments with far larger statistics: See our 2008 *Review* [2].

Footnote and Reference:

* Sometimes a prime is necessary to distinguish two Ξ_c's in the same SU(n) multiplet. See the "Note on Charmed Baryons" in the Charmed Baryon Listings.

9. QUANTUM CHROMODYNAMICS

Revised September 2015 (April 2016 for section on α_s) by S. Bethke (Max-Planck-Institute of Physics, Munich), G. Dissertori (ETH Zurich), and G.P. Salam (CERN).[1]

9.1. Basics

Quantum Chromodynamics (QCD), the gauge field theory that describes the strong interactions of colored quarks and gluons, is the SU(3) component of the SU(3)×SU(2)×U(1) Standard Model of Particle Physics.

The Lagrangian of QCD is given by

$$\mathcal{L} = \sum_q \bar{\psi}_{q,a}(i\gamma^\mu \partial_\mu \delta_{ab} - g_s \gamma^\mu t^C_{ab} \mathcal{A}^C_\mu - m_q \delta_{ab})\psi_{q,b} - \frac{1}{4} F^A_{\mu\nu} F^{A\,\mu\nu}\,, \quad (9.1)$$

where repeated indices are summed over. The γ^μ are the Dirac γ-matrices. The $\psi_{q,a}$ are quark-field spinors for a quark of flavor q and mass m_q, with a color-index a that runs from $a = 1$ to $N_c = 3$, *i.e.* quarks come in three "colors." Quarks are said to be in the fundamental representation of the SU(3) color group.

The $\mathcal{A}^C_\mu$ correspond to the gluon fields, with C running from 1 to $N_c^2 - 1 = 8$, *i.e.* there are eight kinds of gluon. Gluons transform under the adjoint representation of the SU(3) color group. The t^C_{ab} correspond to eight 3×3 matrices and are the generators of the SU(3) group (*cf.* the section on "SU(3) isoscalar factors and representation matrices" in this *Review*, with $t^C_{ab} \equiv \lambda^C_{ab}/2$). They encode the fact that a gluon's interaction with a quark rotates the quark's color in SU(3) space. The quantity g_s is the QCD coupling constant. Finally, the field tensor $F^A_{\mu\nu}$ is given by

$$F^A_{\mu\nu} = \partial_\mu \mathcal{A}^A_\nu - \partial_\nu \mathcal{A}^A_\mu - g_s\, f_{ABC} \mathcal{A}^B_\mu \mathcal{A}^C_\nu \qquad [t^A, t^B] = i f_{ABC} t^C\,, \quad (9.2)$$

where the f_{ABC} are the structure constants of the SU(3) group.

Neither quarks nor gluons are observed as free particles. Hadrons are color-singlet (*i.e.* color-neutral) combinations of quarks, anti-quarks, and gluons.

Ab-initio predictive methods for QCD include lattice gauge theory and perturbative expansions in the coupling. The Feynman rules of QCD involve a quark-antiquark-gluon ($q\bar{q}g$) vertex, a 3-gluon vertex (both proportional to g_s), and a 4-gluon vertex (proportional to g_s^2). A full set of Feynman rules is to be found for example in Ref. 1.

Useful color-algebra relations include: $t^A_{ab} t^A_{bc} = C_F \delta_{ac}$, where $C_F \equiv (N_c^2 - 1)/(2N_c) = 4/3$ is the color-factor ("Casimir") associated with gluon emission from a quark; $f_{ACD} f_{BCD} = C_A \delta_{AB}$ where $C_A \equiv N_c = 3$ is the color-factor associated with gluon emission from a gluon; $t^A_{ab} t^B_{ab} = T_R \delta_{AB}$, where $T_R = 1/2$ is the color-factor for a gluon to split to a $q\bar{q}$ pair.

The fundamental parameters of QCD are the coupling g_s (or $\alpha_s = \dfrac{g_s^2}{4\pi}$) and the quark masses m_q.

There is freedom for an additional CP-violating term to be present in the QCD Lagrangian, $\theta \dfrac{\alpha_s}{8\pi} F^A_{\mu\nu} \tilde{F}^{A\,\mu\nu}$, where $\tilde{F}^{A\,\mu\nu}$ is the dual of the gluon field tensor, $\dfrac{1}{2}\epsilon_{\mu\nu\sigma\rho} F^{A\,\sigma\rho}$, where $\epsilon_{\mu\nu\sigma\rho}$ is the fully antisymmetric Levi-Cevita symbol. Experimental limits on the neutron electric dipole moment [2] constrain the coefficient of this contribution to satisfy $|\theta| \lesssim 10^{-10}$. Further discussion is to be found in Ref. 3 and in the Axions section in the Listings of this *Review*.

This section will concentrate mainly on perturbative aspects of QCD as they relate to collider physics. Related textbooks and reviews include Refs. 1,4–7. Aspects specific to Monte Carlo event generators are reviewed in the dedicated section 41. Lattice QCD is also reviewed in a section of its own, Sec. 18, with further discussion of perturbative and non-perturbative aspects to be found in the sections on "Quark Masses", "The CKM quark-mixing matrix", "Structure Functions", "Fragmentation Functions", and "Heavy-Quark and Soft-Collinear Effective Theory" in this *Review*. For an overview of some of the QCD issues and recent results in heavy-ion physics, see for example Refs. [8–10].

[1] On leave from LPTHE, UMR 7589, CNRS, Paris, France

9.1.1. *Running coupling* :

In the framework of perturbative QCD (pQCD), predictions for observables are expressed in terms of the renormalized coupling $\alpha_s(\mu_R^2)$, a function of an (unphysical) renormalization scale μ_R. When one takes μ_R close to the scale of the momentum transfer Q in a given process, then $\alpha_s(\mu_R^2 \simeq Q^2)$ is indicative of the effective strength of the strong interaction in that process.

The coupling satisfies the following renormalization group equation (RGE):

$$\mu_R^2 \frac{d\alpha_s}{d\mu_R^2} = \beta(\alpha_s) = -(b_0 \alpha_s^2 + b_1 \alpha_s^3 + b_2 \alpha_s^4 + \cdots) \quad (9.3)$$

where $b_0 = (11C_A - 4n_f T_R)/(12\pi) = (33 - 2n_f)/(12\pi)$ is referred to as the 1-loop β-function coefficient, the 2-loop coefficient is $b_1 = (17C_A^2 - n_f T_R(10C_A + 6C_F))/(24\pi^2) = (153 - 19n_f)/(24\pi^2)$, and the 3-loop coefficient is $b_2 = (2857 - \frac{5033}{9} n_f + \frac{325}{27} n_f^2)/(128\pi^3)$ for the SU(3) values of C_A and C_F. The 4-loop coefficient, b_3, is to be found in Refs. 11, 12. The coefficients b_2 and b_3 (and beyond) are renormalization-scheme-dependent, and given here in the modified minimal subtraction ($\overline{\rm MS}$) scheme [13], by far the most widely used scheme in QCD.

The minus sign in Eq. (9.3) is the origin of Asymptotic Freedom [14,15], *i.e.* the fact that the strong coupling becomes weak for processes involving large momentum transfers ("hard processes"). For momentum transfers in the 100 GeV – TeV range, $\alpha_s \sim 0.1$, while the theory is strongly interacting for scales around and below 1 GeV.

The β-function coefficients, the b_i, are given for the coupling of an *effective theory* in which n_f of the quark flavors are considered light ($m_q \ll \mu_R$), and in which the remaining heavier quark flavors decouple from the theory. One may relate the coupling for the theory with $n_f + 1$ light flavors to that with n_f flavors through an equation of the form

$$\alpha_s^{(n_f+1)}(\mu_R^2) = \alpha_s^{(n_f)}(\mu_R^2) \left(1 + \sum_{n=1}^{\infty} \sum_{\ell=0}^{n} c_{n\ell} \,[\alpha_s^{(n_f)}(\mu_R^2)]^n \ln^\ell \frac{\mu_R^2}{m_h^2}\right), \quad (9.4)$$

where m_h is the mass of the $(n_f+1)^{\rm th}$ flavor, and the first few $c_{n\ell}$ coefficients are $c_{11} = \frac{1}{6\pi}$, $c_{10} = 0$, $c_{22} = c_{11}^2$, $c_{21} = \frac{19}{24\pi^2}$, and $c_{20} = -\frac{11}{72\pi^2}$ when m_h is the $\overline{\rm MS}$ mass at scale m_h ($c_{20} = \frac{7}{24\pi^2}$ when m_h is the pole mass — mass definitions are discussed below and in the review on "Quark Masses"). Terms up to $c_{4\ell}$ are to be found in Refs. 16, 17. Numerically, when one chooses $\mu_R = m_h$, the matching is a modest effect, owing to the zero value for the c_{10} coefficient. Relations between n_f and (n_f+2) flavors where the two heavy flavors are close in mass are given to three loops in Ref. 18.

Working in an energy range where the number of flavors is taken constant, a simple exact analytic solution exists for Eq. (9.3) only if one neglects all but the b_0 term, giving $\alpha_s(\mu_R^2) = (b_0 \ln(\mu_R^2/\Lambda^2))^{-1}$. Here Λ is a constant of integration, which corresponds to the scale where the perturbatively-defined coupling would diverge. Its value is indicative of the energy range where non-perturbative dynamics dominates. A convenient approximate analytic solution to the RGE that includes also the b_1, b_2, and b_3 terms is given by (see for example Ref. 19),

$$\alpha_s(\mu_R^2) \simeq \frac{1}{b_0 t}\left(1 - \frac{b_1}{b_0^2}\frac{\ln t}{t} + \frac{b_1^2(\ln^2 t - \ln t - 1) + b_0 b_2}{b_0^4 t^2} - \frac{b_1^3(\ln^3 t - \frac{5}{2}\ln^2 t - 2\ln t + \frac{1}{2}) + 3b_0 b_1 b_2 \ln t - \frac{1}{2} b_0^2 b_3}{b_0^6 t^3}\right),$$

$$t \equiv \ln \frac{\mu_R^2}{\Lambda^2}\,, \quad (9.5)$$

again parametrized in terms of a constant Λ. Note that Eq. (9.5) is one of several possible approximate 4-loop solutions for $\alpha_s(\mu_R^2)$, and that a value for Λ only defines $\alpha_s(\mu_R^2)$ once one knows which particular

approximation is being used. An alternative to the use of formulas such as Eq. (9.5) is to solve the RGE exactly, numerically (including the discontinuities, Eq. (9.4), at flavor thresholds). In such cases the quantity Λ is not defined at all. For these reasons, in determinations of the coupling, it has become standard practice to quote the value of α_s at a given scale (typically the mass of the Z boson, M_Z) rather than to quote a value for Λ.

The value of the coupling, as well as the exact forms of the b_2, c_{10} (and higher-order) coefficients, depend on the renormalization scheme in which the coupling is defined, *i.e.* the convention used to subtract infinities in the context of renormalization. The coefficients given above hold for a coupling defined in the $\overline{\rm MS}$ scheme.

A discussion of determinations of the coupling and a graph illustrating its scale dependence ("running") are to be found in Section 9.4. The RunDec package [20,21] is often used to calculate the evolution of the coupling. For a discussion of electroweak effects in the evolution of the QCD coupling, see Ref. 22 and references therein.

9.1.2. *Quark masses* :

Free quarks have never been observed, which is understood as a result of a long-distance, confining property of the strong QCD force: up, down, strange, charm, and bottom quarks all *hadronize*, *i.e.* become part of a meson or baryon, on a timescale $\sim 1/\Lambda$; the top quark instead decays before it has time to hadronize. This means that the question of what one means by the quark mass is a complex one, which requires that one adopts a specific prescription. A perturbatively defined prescription is the pole mass, m_q, which corresponds to the position of the divergence of the propagator. This is close to one's physical picture of mass. However, when relating it to observable quantities, it suffers from substantial non-perturbative ambiguities (see *e.g.* Ref. 23). An alternative is the $\overline{\rm MS}$ mass, $\overline{m}_q(\mu_R^2)$, which depends on the renormalization scale μ_R.

Results for the masses of heavier quarks are often quoted either as the pole mass or as the $\overline{\rm MS}$ mass evaluated at a scale equal to the mass, $\overline{m}_q(\overline{m}_q^2)$; light quark masses are often quoted in the $\overline{\rm MS}$ scheme at a scale $\mu_R \sim 2$ GeV. The pole and $\overline{\rm MS}$ masses are related by a slowly converging series that starts $m_q = \overline{m}_q(\overline{m}_q^2)(1 + \dfrac{4\alpha_s(\overline{m}_q^2)}{3\pi} + \mathcal{O}(\alpha_s^2))$, while the scale-dependence of $\overline{\rm MS}$ masses is given by

$$\mu_R^2 \frac{d\overline{m}_q(\mu_R^2)}{d\mu_R^2} = \left[-\frac{\alpha_s(\mu_R^2)}{\pi} + \mathcal{O}(\alpha_s^2)\right]\overline{m}_q(\mu_R^2)\,. \tag{9.6}$$

More detailed discussion is to be found in a dedicated section of the *Review*, "Quark Masses."

In perturbative QCD calculations of scattering processes, it is common to work in an approximation in which one neglects (*i.e.* sets to zero) the masses of all quarks whose mass is significantly smaller than the momentum transfer in the process.

9.2. Structure of QCD predictions

9.2.1. *Fully inclusive cross sections* :

The simplest observables in perturbative QCD are those that do not involve initial-state hadrons and that are fully inclusive with respect to details of the final state. One example is the total cross section for $e^+e^- \to$ hadrons at center-of-mass energy Q, for which one can write

$$\frac{\sigma(e^+e^- \to \text{hadrons}, Q)}{\sigma(e^+e^- \to \mu^+\mu^-, Q)} \equiv R(Q) = R_{\rm EW}(Q)(1 + \delta_{\rm QCD}(Q))\,, \tag{9.7}$$

where $R_{\rm EW}(Q)$ is the purely electroweak prediction for the ratio and $\delta_{\rm QCD}(Q)$ is the correction due to QCD effects. To keep the discussion simple, we can restrict our attention to energies $Q \ll M_Z$, where the process is dominated by photon exchange ($R_{\rm EW} = 3\sum_q e_q^2$, neglecting finite-quark-mass corrections, where the e_q are the electric charges of the quarks),

$$\delta_{\rm QCD}(Q) = \sum_{n=1}^{\infty} c_n \cdot \left(\frac{\alpha_s(Q^2)}{\pi}\right)^n + \mathcal{O}\left(\frac{\Lambda^4}{Q^4}\right)\,. \tag{9.8}$$

The first four terms in the α_s series expansion are then to be found in Ref. 24,

$$c_1 = 1\,, \qquad c_2 = 1.9857 - 0.1152 n_f\,, \tag{9.9a}$$

$$c_3 = -6.63694 - 1.20013 n_f - 0.00518 n_f^2 - 1.240\eta\,, \tag{9.9b}$$

$$c_4 = -156.61 + 18.775 n_f - 0.7974 n_f^2 + 0.0215 n_f^3 + (17.828 - 0.575 n_f)\eta\,, \tag{9.9c}$$

with $\eta = (\sum e_q)^2/(3\sum e_q^2)$. For corresponding expressions including also Z exchange and finite-quark-mass effects, see Refs. [25–27].

A related series holds also for the QCD corrections to the hadronic decay width of the τ lepton, which essentially involves an integral of $R(Q)$ over the allowed range of invariant masses of the hadronic part of the τ decay (see *e.g.* Ref. 28). The series expansions for QCD corrections to Higgs-boson hadronic (partial) decay widths are summarized in Refs. 29, 30.

One characteristic feature of Eqs. (9.8) and (9.9) is that the coefficients of α_s^n increase rapidly order by order: calculations in perturbative QCD tend to converge more slowly than would be expected based just on the size of α_s[††]. Another feature is the existence of an extra "power-correction" term $\mathcal{O}(\Lambda^4/Q^4)$ in Eq. (9.8), which accounts for contributions that are fundamentally non-perturbative. All high-energy QCD predictions involve such corrections, though the exact power of Λ/Q depends on the observable. For many processes and observables, it is possible to introduce an operator product expansion and associate power suppressed terms with specific higher-dimension (non-perturbative) operators.

Scale dependence. In Eq. (9.8) the renormalization scale for α_s has been chosen equal to Q. The result can also be expressed in terms of the coupling at an arbitrary renormalization scale μ_R,

$$\delta_{\rm QCD}(Q) = \sum_{n=1}^{\infty} \overline{c}_n\left(\frac{\mu_R^2}{Q^2}\right) \cdot \left(\frac{\alpha_s(\mu_R^2)}{\pi}\right)^n + \mathcal{O}\left(\frac{\Lambda^4}{Q^4}\right)\,, \tag{9.10}$$

where $\overline{c}_1(\mu_R^2/Q^2) \equiv c_1$, $\overline{c}_2(\mu_R^2/Q^2) = c_2 + \pi b_0 c_1 \ln(\mu_R^2/Q^2)$, $\overline{c}_3(\mu_R^2/Q^2) = c_3 + (2b_0c_2\pi + b_1c_1\pi^2)\ln(\mu_R^2/Q^2) + b_0^2c_1\pi^2\ln^2(\mu_R^2/Q^2)$, *etc.* Given an infinite number of terms in the α_s expansion, the μ_R dependence of the $\overline{c}_n(\mu_R^2/Q^2)$ coefficients will exactly cancel that of $\alpha_s(\mu_R^2)$, and the final result will be independent of the choice of μ_R: physical observables do not depend on unphysical scales.[**]

With just terms up to some finite $n = N$, a residual μ_R dependence will remain, which implies an uncertainty on the prediction of $R(Q)$ due to the arbitrariness of the scale choice. This uncertainty will be $\mathcal{O}(\alpha_s^{N+1})$, *i.e.* of the same order as the neglected terms. For this reason it is customary to use QCD predictions' scale dependence as an estimate of the uncertainties due to neglected terms. One usually takes a central value for $\mu_R \sim Q$, in order to avoid the poor convergence of the perturbative series that results from the large $\ln^{n-1}(\mu_R^2/Q^2)$ terms in the $\overline{c}_n$ coefficients when $\mu_R \ll Q$ or $\mu_R \gg Q$. Uncertainties are then commonly determined by varying μ_R by a factor of two up and down around the central scale choice, as discussed in more detail below in Section 9.2.4.

[††] The situation is significantly worse near thresholds, *e.g.* the $t\bar{t}$ production threshold. An overview of some of the methods used in such cases is to be found for example in Ref. 31.

[**] There is an important caveat to this statement: at sufficiently high orders, perturbative series generally suffer from "renormalon" divergences $\alpha_s^n n!$ (reviewed in Ref. 23). This phenomenon is not usually visible with the limited number of perturbative terms available today. However it is closely connected with non-perturbative contributions and sets a limit on the possible precision of perturbative predictions. The cancellation of scale dependence will also ultimately be affected by this renormalon-induced breakdown of perturbation theory.

9.2.2. ***Processes with initial-state hadrons*** :

Deep Inelastic Scattering. To illustrate the key features of QCD cross sections in processes with initial-state hadrons, let us consider deep-inelastic scattering (DIS), $ep \to e + X$, where an electron e with four-momentum k emits a highly off-shell photon (momentum q) that interacts with the proton (momentum p). For photon virtualities $Q^2 \equiv -q^2$ far above the squared proton mass (but far below the Z mass), the differential cross section in terms of the kinematic variables Q^2, $x = Q^2/(2p\cdot q)$ and $y = (q\cdot p)/(k\cdot p)$ is

$$\frac{d^2\sigma}{dxdQ^2} = \frac{4\pi\alpha}{2xQ^4}\left[(1+(1-y)^2)F_2(x,Q^2) - y^2F_L(x,Q^2)\right], \quad (9.11)$$

where α is the electromagnetic coupling and $F_2(x,Q^2)$ and $F_L(x,Q^2)$ are proton structure functions, which encode the interaction between the photon (in given polarization states) and the proton. In the presence of parity-violating interactions (*e.g.* νp scattering) an additional F_3 structure function is present. For an extended review, including equations for the full electroweak and polarized cases, see Sec. 19 of this *Review*.

Structure functions are not calculable in perturbative QCD, nor is any other cross section that involves initial-state hadrons. To zeroth order in α_s, the structure functions are given directly in terms of non-perturbative parton (quark or gluon) distribution functions (PDFs),

$$F_2(x,Q^2) = x\sum_q e_q^2 f_{q/p}(x), \qquad F_L(x,Q^2) = 0, \quad (9.12)$$

where $f_{q/p}(x)$ is the PDF for quarks of type q inside the proton, *i.e.* the number density of quarks of type q inside a fast-moving proton that carry a fraction x of its longitudinal momentum (the quark flavor index q, here, is not to be confused with the photon momentum q in the lines preceding Eq. (9.11)). PDFs are non-perturbative, and only just starting to be extracted in lattice QCD in a phenomenologically relevant way [32]. Accordingly, for all practical uses, they are determined from data (*cf.* Sec. 19 of this *Review* and also Ref. 33).

The above result, with PDFs $f_{q/p}(x)$ that are independent of the scale Q, corresponds to the "quark-parton model" picture in which the photon interacts with point-like free quarks, or equivalently, one has incoherent elastic scattering between the electron and individual constituents of the proton. As a consequence, in this picture also F_2 and F_L are independent of Q [34]. When including higher orders in pQCD, Eq. (9.12) becomes

$$F_2(x,Q^2) = x\sum_{n=0}^{\infty}\frac{\alpha_s^n(\mu_R^2)}{(2\pi)^n}\sum_{i=q,g}\int_x^1\frac{dz}{z}C_{2,i}^{(n)}(z,Q^2,\mu_R^2,\mu_F^2)\, f_{i/p}\Big(\frac{x}{z},\mu_F^2\Big) + \mathcal{O}\Big(\frac{\Lambda^2}{Q^2}\Big). \quad (9.13)$$

Just as in Eq. (9.10), we have a series in powers of $\alpha_s(\mu_R^2)$, each term involving a coefficient $C_{2,i}^{(n)}$ that can be calculated using Feynman graphs. An important difference is the additional integral over z. The parton that comes from the proton can emit a gluon before it interacts with the photon. As a result, the $C_{2,i}^{(n)}$ coefficients are functions that depend on the ratio, z, of the parton's momentum before and after the gluon emission, and one must integrate over that ratio. For the electromagnetic component of DIS with light quarks and gluons, the zeroth order coefficient functions are $C_{2,q}^{(0)} = e_q^2\delta(1-z)$ and $C_{2,g}^{(0)} = 0$, and corrections are known up to $\mathcal{O}(\alpha_s^3)$ (next-to-next-next-to-leading order, N^{3}LO) [35]. For weak currents they are known fully to α_s^2 (next-to-next-to-leading order, NNLO) [36], with substantial results known also at N^{3}LO [37]. For heavy quark production they are known to $\mathcal{O}(\alpha_s^2)$ [38] (next-to-leading order, NLO, insofar as the series starts at $\mathcal{O}(\alpha_s)$), with ongoing work towards NNLO summarized in Ref. 39.

The majority of the emissions that modify a parton's momentum are collinear (parallel) to that parton, and don't depend on the fact that the parton is destined to interact with a photon. It is natural to view these emissions as modifying the proton's structure rather than being part of the coefficient function for the parton's interaction with the photon. Technically, one uses a procedure known as *collinear factorization* to give a well-defined meaning to this distinction, most commonly through the $\overline{\rm MS}$ factorization scheme, defined in the context of dimensional regularization. The $\overline{\rm MS}$ factorization scheme involves an arbitrary choice of *factorization scale*, μ_F, whose meaning can be understood roughly as follows: emissions with transverse momenta above μ_F are included in the $C_{2,q}^{(n)}(z,Q^2,\mu_R^2,\mu_F^2)$; emissions with transverse momenta below μ_F are accounted for within the PDFs, $f_{i/p}(x,\mu_F^2)$. While collinear factorization is generally believed to be valid for suitable (sufficiently inclusive) observables in processes with hard scales, Ref. 40, which reviews the factorization proofs in detail, is cautious in the statements it makes about their exhaustivity, notably for the hadron-collider processes that we shall discuss below. Further discussion is to be found in Refs. 41,42.

The PDFs' resulting dependence on μ_F is described by the Dokshitzer-Gribov-Lipatov-Altarelli-Parisi (DGLAP) equations [43], which to leading order (LO) read*

$$\mu_F^2\frac{\partial f_{i/p}(x,\mu_F^2)}{\partial\mu_F^2} = \sum_j\frac{\alpha_s(\mu_F^2)}{2\pi}\int_x^1\frac{dz}{z}P_{i\leftarrow j}^{(1)}(z)f_{j/p}\Big(\frac{x}{z},\mu_F^2\Big), \quad (9.14)$$

with, for example, $P_{q\leftarrow g}^{(1)}(z) = T_R(z^2+(1-z)^2)$. The other LO splitting functions are listed in Sec. 19 of this *Review*, while results up to NLO, α_s^2, and NNLO, α_s^3, are given in Refs. 44 and 45 respectively. Beyond LO, the coefficient functions are also μ_F dependent, for example $C_{2,i}^{(1)}(x,Q^2,\mu_R^2,\mu_F^2) = C_{2,i}^{(1)}(x,Q^2,\mu_R^2,Q^2) - \ln\left(\frac{\mu_F^2}{Q^2}\right)\sum_j\int_x^1\frac{dz}{z}C_{2,j}^{(0)}(\frac{x}{z})P_{j\leftarrow i}^{(1)}(z)$.

As with the renormalization scale, the choice of factorization scale is arbitrary, but if one has an infinite number of terms in the perturbative series, the μ_F-dependences of the coefficient functions and PDFs will compensate each other fully. Given only N terms of the series, a residual $\mathcal{O}(\alpha_s^{N+1})$ uncertainty is associated with the ambiguity in the choice of μ_F. As with μ_R, varying μ_F provides an input in estimating uncertainties on predictions. In inclusive DIS predictions, the default choice for the scales is usually $\mu_R = \mu_F = Q$.

As is the case for the running coupling, in DGLAP evolution one can introduce flavor thresholds near the heavy quark masses: below a given heavy quark's mass, that quark is not considered to be part of the proton's structure, while above it is considered to be part of the proton's structure and evolves with massless DGLAP splitting kernels. With appropriate parton distribution matching terms at threshold, such a variable flavor number scheme (VFNS), when used with massless coefficient functions, gives the full heavy-quark contributions at high Q^2 scales. For scales near the threshold, it is instead necessary to appropriately adapt the standard massive coefficient functions to account for the heavy-quark contribution already included in the PDFs [46,47,48].

Hadron-hadron collisions. The extension to processes with two initial-state hadrons can be illustrated with the example of the total (inclusive) cross section for W boson production in collisions of hadrons h_1 and h_2, which can be written as

$$\sigma(h_1h_2\to W+X) = \sum_{n=0}^{\infty}\alpha_s^n(\mu_R^2)\sum_{i,j}\int dx_1dx_2\, f_{i/h_1}\Big(x_1,\mu_F^2\Big)f_{j/h_2}\Big(x_2,\mu_F^2\Big) \times\hat\sigma_{ij\to W+X}^{(n)}\Big(x_1x_2s,\mu_R^2,\mu_F^2\Big) + \mathcal{O}\left(\frac{\Lambda^2}{M_W^4}\right), \quad (9.15)$$

* LO is generally taken to mean the lowest order at which a quantity is non-zero. This definition is nearly always unambiguous, the one major exception being for the case of the hadronic branching ratio of virtual photons, Z, τ, *etc.*, for which two conventions exist: LO can either mean the lowest order that contributes to the hadronic branching fraction, *i.e.* the term "1" in Eq. (9.7); or it can mean the lowest order at which the hadronic branching ratio becomes sensitive to the coupling, $n = 1$ in Eq. (9.8), as is relevant when extracting the value of the coupling from a measurement of the branching ratio. Because of this ambiguity, we avoid use of the term "LO" in that context.

where s is the squared center-of-mass energy of the collision. At LO, $n = 0$, the hard (partonic) cross section $\hat{\sigma}^{(0)}_{ij\to W+X}(x_1x_2s, \mu_R^2, \mu_F^2)$ is simply proportional to $\delta(x_1x_2s - M_W^2)$, in the narrow W-boson width approximation (see Sec. 49 of this *Review* for detailed expressions for this and other hard scattering cross sections). It is non-zero only for choices of i, j that can directly give a W, such as $i = u$, $j = \bar{d}$. At higher orders, $n \geq 1$, new partonic channels contribute, such as gq, and there is no restriction $x_1x_2s = M_W^2$.

Equation (9.15) involves a collinear factorization between the hard cross section and the PDFs, just like Eq. (9.13). As long as the same factorization scheme is used in DIS and pp or $p\bar{p}$ (usually the $\overline{\rm MS}$ scheme), then PDFs extracted in DIS can be directly used in pp and $p\bar{p}$ predictions [49,40] (with the anti-quark distributions in an anti-proton being the same as the quark distributions in a proton).

Fully inclusive hard cross sections are known to NNLO, *i.e.* corrections up to relative order α_s^2, for Drell-Yan (DY) lepton-pair and vector-boson production [50,51], Higgs-boson production in association with a vector boson [52], Higgs-boson production via vector-boson fusion [53] (in an approximation that factorizes the production of the two vector bosons), Higgs-pair production [54], top-antitop production [55] and vector-boson pair production [56,57]. † Recently, inclusive Higgs production through gluon fusion was calculated at N^{3}LO [58]. A discussion of many other inclusive Higgs results is to be found in Ref. 59.

Photoproduction. γp (and $\gamma\gamma$) collisions are similar to pp collisions, with the subtlety that the photon can behave in two ways: there is "direct" photoproduction, in which the photon behaves as a point-like particle and takes part directly in the hard collision, with hard subprocesses such as $\gamma g \to q\bar{q}$; there is also resolved photoproduction, in which the photon behaves like a hadron, with non-perturbative partonic substructure and a corresponding PDF for its quark and gluon content, $f_{i/\gamma}(x, Q^2)$.

While useful to understand the general structure of γp collisions, the distinction between direct and resolved photoproduction is not well defined beyond leading order, as discussed for example in Ref. 60.

The high-energy (BFKL) limit. In situations in which the total center-of-mass energy $\sqrt{s}$ is much larger than all other momentum-transfer scales in the problem (*e.g.* Q in DIS, m_b for $b\bar{b}$ production in pp collisions, *etc.*), each power of α_s beyond LO can be accompanied by a power of $\ln(s/Q^2)$ (or $\ln(s/m_b^2)$, *etc.*). This is variously referred to as the high-energy, small-x or Balitsky-Fadin-Kuraev-Lipatov (BFKL) limit [61–63]. Currently it is possible to account for the dominant and first subdominant [64,65] power of $\ln s$ at each order of α_s, and also to estimate further subdominant contributions that are numerically large (see Refs. 66–69 and references therein). Progress towards NNLO is discussed in Refs. 70,71.

Physically, the summation of all orders in α_s can be understood as leading to a growth with s of the gluon density in the proton. At sufficiently high energies this implies non-linear effects (commonly referred to as parton saturation), whose treatment has been the subject of intense study (see for example Refs. 72, 73 and references thereto). Note that it is not straightforward to relate these results to the genuinely non-perturbative total, elastic and diffractive cross sections for hadron-hadron scattering (experimental results for which are summarized in section 51 of this *Review*).

9.2.3. *Non fully inclusive cross sections* :

QCD final states always consist of hadrons, while perturbative QCD calculations deal with partons. Physically, an energetic parton fragments ("showers") into many further partons, which then, on later timescales, undergo a transition to hadrons ("hadronization"). Fixed-order perturbation theory captures only a small part of these dynamics.

This does not matter for the fully inclusive cross sections discussed above: the showering and hadronization stages are approximately unitary, *i.e.* they do not substantially change the overall probability of hard scattering, because they occur long after it has taken place (they introduce at most a correction proportional to a power of the ratio of timescales involved, *i.e.* a power of Λ/Q, where Q is the hard scattering scale).

Less inclusive measurements, in contrast, may be affected by the extra dynamics. For those sensitive just to the main directions of energy flow (jet rates, event shapes, *cf.* Sec. 9.3.1) fixed order perturbation theory is often still adequate, because showering and hadronization don't substantially change the overall energy flow. This means that one can make a prediction using just a small number of partons, which should correspond well to a measurement of the same observable carried out on hadrons. For observables that instead depend on distributions of individual hadrons (which, *e.g.*, are the inputs to detector simulations), it is mandatory to account for showering and hadronization. The range of predictive techniques available for QCD final states reflects this diversity of needs of different measurements.

While illustrating the different methods, we shall for simplicity mainly use expressions that hold for e^+e^- scattering. The extension to cases with initial-state partons will be mostly straightforward (space constraints unfortunately prevent us from addressing diffraction and exclusive hadron-production processes; extensive discussion is to be found in Refs. 74, 75).

9.2.3.1. *Soft and collinear limits:*

Before examining specific predictive methods, it is useful to be aware of a general property of QCD matrix elements in the soft and collinear limits. Consider a squared tree-level matrix element $|M_n^2(p_1, \ldots, p_n)|$ for the process $e^+e^- \to n$ partons with momenta $p_1, \ldots, p_n$, and a corresponding phase-space integration measure $d\Phi_n$. If particle n is a gluon, and additionally it becomes collinear (parallel) to another particle i and its momentum tends to zero (it becomes "soft"), the matrix element simplifies as follows,

$$\lim_{\theta_{in}\to 0,\, E_n\to 0} d\Phi_n |M_n^2(p_1, \ldots, p_n)| = d\Phi_{n-1} |M_{n-1}^2(p_1, \ldots, p_{n-1})| \frac{\alpha_s C_i}{\pi} \frac{d\theta_{in}^2}{\theta_{in}^2} \frac{dE_n}{E_n}\,, \quad (9.16)$$

where $C_i = C_F$ (C_A) if i is a quark (gluon). This formula has non-integrable divergences both for the inter-parton angle $\theta_{in} \to 0$ and for the gluon energy $E_n \to 0$, which are mirrored also in the structure of divergences in loop diagrams. These divergences are important for at least two reasons: firstly, they govern the typical structure of events (inducing many emissions either with low energy or at small angle with respect to hard partons); secondly, they will determine which observables can be calculated within perturbative QCD.

9.2.3.2. *Fixed-order predictions:*

Let us consider an observable $\mathcal{O}$ that is a function $\mathcal{O}_n(p_1, \ldots, p_n)$ of the four-momenta of the n final-state particles in an event (whether partons or hadrons). In what follows, we shall consider the cross section for events weighted with the value of the observable, $\sigma_{\mathcal{O}}$. As examples, if $\mathcal{O}_n \equiv 1$ for all n, then $\sigma_{\mathcal{O}}$ is just the total cross section; if $\mathcal{O}_n \equiv \hat{\tau}(p_1, \ldots, p_n)$ where $\hat{\tau}$ is the value of the Thrust for that event (see Sec. 9.3.1.2), then the average value of the Thrust is $\langle\tau\rangle = \sigma_{\mathcal{O}}/\sigma_{\rm tot}$; if $\mathcal{O}_n \equiv \delta(\tau - \hat{\tau}(p_1, \ldots, p_n))$ then one gets the differential cross section as a function of the Thrust, $\sigma_{\mathcal{O}} \equiv d\sigma/d\tau$.

In the expressions below, we shall omit to write the non-perturbative power correction term, which for most common observables is proportional to a single power of Λ/Q.

LO. If the observable $\mathcal{O}$ is non-zero only for events with at least n final-state particles, then the LO QCD prediction for the weighted cross section in e^+e^- annihilation is

$$\sigma_{\mathcal{O},LO} = \alpha_s^{n-2}(\mu_R^2) \int d\Phi_n |M_n^2(p_1, \ldots, p_n)|\, \mathcal{O}_n(p_1, \ldots, p_n)\,, \quad (9.17)$$

where the squared tree-level matrix element, $|M_n^2(p_1, \ldots, p_n)|$, includes relevant symmetry factors, has been summed over all subprocesses (*e.g.* $e^+e^- \to q\bar{q}q\bar{q}$, $e^+e^- \to q\bar{q}gg$) and has had all factors of α_s

† Processes with jets or photons in the final state have divergent cross sections unless one places cut on the jet or photon momentum. Accordingly they are discussed below in Section 9.2.3.2.

extracted in front. In processes other than e^+e^- collisions, the center-of-mass energy of the LO process is generally not fixed, and so the powers of the coupling are often brought inside the integrals, with the scale μ_R chosen event by event, as a function of the event kinematics.

Other than in the simplest cases (see the review on Cross Sections in this *Review*), the matrix elements in Eq. (9.17) are usually calculated automatically with programs such as CompHEP [76], MadGraph [77], Alpgen [78], Comix/Sherpa [79], and Helac/Phegas [80]. Some of these (CompHEP, MadGraph) use formulas obtained from direct evaluations of Feynman diagrams. Others (Alpgen, Helac/Phegas and Comix/Sherpa) use methods designed to be particularly efficient at high multiplicities, such as Berends-Giele recursion [81], which builds up amplitudes for complex processes from simpler ones (see also the reviews and discussion in Refs. [82–84]).

The phase-space integration is usually carried out by Monte Carlo sampling, in order to deal with the sometimes complicated cuts that are used in corresponding experimental measurements. Because of the divergences in the matrix element, Eq. (9.16), the integral converges only if the observable vanishes for kinematic configurations in which one of the n particles is arbitrarily soft or it is collinear to another particle. As an example, the cross section for producing any configuration of n partons will lead to an infinite integral, whereas a finite result will be obtained for the cross section for producing n deposits of energy (or jets, see Sec. 9.3.1.1), each above some energy threshold and well separated from each other in angle.

LO calculations can be carried out for $2 \to n$ processes with $n \lesssim 6-10$. The exact upper limit depends on the process, the method used to evaluate the matrix elements (recursive methods are more efficient), and the extent to which the phase-space integration can be optimized to work around the large variations in the values of the matrix elements.

NLO. Given an observable that is non-zero starting from n final-state particles, its prediction at NLO involves supplementing the LO result, Eq. (9.17), with the $2 \to (n+1)$-particle squared tree-level matrix element ($|M^2_{n+1}|$), and the interference of an $2 \to n$ tree-level and $2 \to n$ 1-loop amplitude ($2\mathrm{Re}(M_n M^*_{n,1-\mathrm{loop}})$),

$$\begin{aligned}\sigma^{NLO}_{\mathcal{O}} = \\ \sigma^{LO}_{\mathcal{O}} + \alpha_s^{n-1}(\mu_R^2)\int d\Phi_{n+1} |M^2_{n+1}(p_1,\ldots,p_{n+1})|\, \mathcal{O}_{n+1}(p_1,\ldots,p_{n+1}) \\ + \alpha_s^{n-1}(\mu_R^2)\int d\Phi_n\, 2\mathrm{Re}\left[\, M_n(p_1,\ldots,p_n)\, M^*_{n,1-\mathrm{loop}}(p_1,\ldots,p_n)\,\right] \\ \times \mathcal{O}_n(p_1,\ldots,p_n)\,. \qquad (9.18)\end{aligned}$$

Relative to LO calculations, two important issues appear in the NLO calculations. Firstly, the extra complexity of loop-calculations relative to tree-level calculations means that their automation has been achieved only in recent years (see below). Secondly, loop amplitudes are infinite in 4 dimensions, while tree-level amplitudes are finite, but their *integrals* are infinite, due to the divergences of Eq. (9.16). These two sources of infinities have the same soft and collinear origins and cancel after the integration only if the observable $\mathcal{O}$ satisfies the property of infrared and collinear safety,

$$\begin{aligned}\mathcal{O}_{n+1}(p_1,\ldots,p_s,\ldots,p_n) &\to \mathcal{O}_n(p_1,\ldots,p_n) \qquad \text{if } p_s \to 0 \\ \mathcal{O}_{n+1}(p_1,\ldots,p_a,p_b,\ldots,p_n) &\to \mathcal{O}_n(p_1,\ldots,p_a+p_b,\ldots,p_n) \\ &\qquad \text{if } p_a \,||\, p_b\,. \qquad (9.19)\end{aligned}$$

Examples of infrared-safe quantities include event-shape distributions and jet cross sections (with appropriate jet algorithms, see below). Unsafe quantities include the distribution of the momentum of the hardest QCD particle (which is not conserved under collinear splitting), observables that require the complete absence of radiation in some region of phase space (*e.g.* rapidity gaps or 100% isolation cuts, which are affected by soft emissions), or the particle multiplicity (affected by both soft and collinear emissions). The non-cancellation of divergences at NLO due to infrared or collinear unsafety compromises the usefulness not only of the NLO calculation, but also that of a LO calculation, since LO is only an acceptable approximation if one can prove that higher-order terms are smaller. Infrared and collinear unsafety usually also imply large non-perturbative effects.

As with LO calculations, the phase-space integrals in Eq. (9.18) are usually carried out by Monte Carlo integration, so as to facilitate the study of arbitrary observables. Various methods exist to obtain numerically efficient cancellation among the different infinities. These include notably dipole [85], FKS [86] and antenna [87] subtraction.

NLO calculations exist for a wide range of processes. Historically, many calculations have been performed process by process and are available in dedicated packages, among them NLOJet++ [88] for e^+e^-, DIS, and hadron-hadron processes involving just light partons in the final state, MCFM [89] for hadron-hadron processes with Higgs or vector bosons and/or heavy quarks in the final state, VBFNLO for vector-boson fusion, di- and tri-boson processes [90], and the Phox family [91] for processes with photons in the final state. Many of these programs are still widely used today.

Recent years have seen very active development of automated NLO calculational tools, and a number of programs are available publicly: Madgraph5_aMC@NLO [77] and Helac-NLO [92] provide full frameworks for NLO calculations; GoSam [93], Njet [94], OpenLoops [95] calculate just the 1-loop part and are typically interfaced with an external tool such as Sherpa [96] for combination with the appropriate tree-level amplitudes. Other tools such as BlackHat [97] and Recola [98] are not currently available publicly, though in the case of the former many of its results can be accessed in the form of ntuples [99] to which a range of cuts, and histogramming options, as well as PDF and scale-changes, can be applied *a posteriori*; an alternative approach for *a posteriori* PDF and scale change represents NLO (or NNLO) results, for a given set of cuts and binning, as an effective coefficient function on a grid in parton momentum fractions and factorization scales [100–103].

In some cases the above programs (or development versions of them) can be used to calculate also NLO electroweak or beyond-standard-model corrections [104–107]. Electroweak corrections are especially important for transverse momenta significantly above the W and Z masses, because they are enhanced by two powers of $\ln p_t/M_W$ for each power of the electroweak coupling.

The above tools rely in part on a wide array of developments reviewed in Refs. 83,108. Examples of the most complex processes for which NLO QCD corrections have been obtained so far include $e^+e^- \to 7$ jets [109], $pp \to W + 5$ jets [110] and $pp \to 5$ jets [111].

NNLO. Conceptually, NNLO and NLO calculations are similar, except that one must add a further order in α_s, consisting of: the squared $(n+2)$-parton tree-level amplitude, the interference of the $(n+1)$-parton tree-level and 1-loop amplitudes, the interference of the n-parton tree-level and 2-loop amplitudes, and the squared n-parton 1-loop amplitude.

Each of these elements involves large numbers of soft and collinear divergences, satisfying relations analogous to Eq. (9.16) that now involve multiple collinear or soft particles and higher loop orders (see *e.g.* Refs. [112–114]). Arranging for the cancellation of the divergences after numerical Monte Carlo integration has been one of the significant challenges of NNLO calculations, as has the determination of the relevant 2-loop amplitudes. For the cancellations of divergences a wide range of methods has been developed. Some of them [115–119] retain the approach, inherent in NLO methods, of directly combining the separate loop and tree-level amplitudes. Others combine a suitably chosen, partially inclusive $2 \to n$ NNLO calculation with a fully differential $2 \to n+1$ NLO calculation [120–123].

Quite a number of processes have been calculated differentially at NNLO so far. The state of the art for e^+e^- collisions is $e^+e^- \to 3$ jets [124–126]. For hadron colliders, all $2 \to 1$ processes are known, specifically vector boson [127,128] and Higgs boson production [129,120]. For most of the above calculations there exist public codes (EERAD3 for e^+e^-, DYNNLO and FEWZ for W and Z production, fehipro and HNNLO for Higgs production), links to which are to be found among the above references. Substantial progress has been made in the past couple of years for hadron-collider $2 \to 2$ processes, with calculations having been

performed for nearly all relevant processes: HH [54], WH [130] and ZH [131], ZZ [57] and WW [56], $\gamma\gamma$ [132], $Z\gamma$ [133] and $W\gamma$ [134], $H+$jet [135,136], $W+$jet [121] and $Z+$jet [137] (the latter in a leading-color approximation for the dominant partonic channels), t-channel single-top [138] (in a so-called "structure-function" approximation) and $t\bar{t}$ production [139]. Of notable interest, but still with only partial NNLO results, is dijet production [140]. One $2 \to 3$ process is known at NNLO, Higgs production through vector-boson fusion, using an approximation in which the two underlying DIS-like $q \to qV$ scatterings are factorised [123].

9.2.3.3. *Resummation:*

Many experimental measurements place tight constraints on emissions in the final state. For example, in e^+e^- events, that (one minus) the Thrust should be less than some value $\tau \ll 1$, or in $pp \to Z$ events that the Z-boson transverse momentum should be much smaller than its mass, $p_t^Z \ll M_Z$. A further example is the production of heavy particles or jets near threshold (so that little energy is left over for real emissions) in DIS and pp collisions.

In such cases, the constraint vetoes a significant part of the integral over the soft and collinear divergence of Eq. (9.16). As a result, there is only a partial cancellation between real emission terms (subject to the constraint) and loop (virtual) contributions (not subject to the constraint), causing each order of α_s to be accompanied by a large coefficient $\sim L^2$, where *e.g.* $L = \ln\tau$ or $L = \ln(M_Z/p_t^Z)$. One ends up with a perturbative series whose terms go as $\sim (\alpha_s L^2)^n$. It is not uncommon that $\alpha_s L^2 \gg 1$, so that the perturbative series converges very poorly if at all.** In such cases one may carry out a "resummation," which accounts for the dominant logarithmically enhanced terms to all orders in α_s, by making use of known properties of matrix elements for multiple soft and collinear emissions, and of the all-orders properties of the divergent parts of virtual corrections, following original works such as Refs. 141–150 and also through soft-collinear effective theory [151,152] (*cf.* also the section on "Heavy-Quark and Soft-Collinear Effective Theory" in this *Review*, as well as Ref. 153).

For cases with double logarithmic enhancements (two powers of logarithm per power of α_s), there are two classification schemes for resummation accuracy. Writing the cross section including the constraint as $\sigma(L)$ and the unconstrained (total) cross section as $\sigma_{\rm tot}$, the series expansion takes the form

$$\sigma(L) \simeq \sigma_{\rm tot} \sum_{n=0}^{\infty} \sum_{k=0}^{2n} R_{nk} \alpha_s^n(\mu_R^2) L^k, \qquad L \gg 1 \tag{9.20}$$

and leading log (LL) resummation means that one accounts for all terms with $k = 2n$, next-to-leading-log (NLL) includes additionally all terms with $k = 2n-1$, *etc.* Often $\sigma(L)$ (or its Fourier or Mellin transform) *exponentiates* ‡,

$$\sigma(L) \simeq \sigma_{\rm tot} \exp\left[\sum_{n=1}^{\infty} \sum_{k=0}^{n+1} G_{nk} \alpha_s^n(\mu_R^2) L^k\right], \qquad L \gg 1\,, \tag{9.21}$$

where one notes the different upper limit on k ($\leq n+1$) compared to Eq. (9.20). This is a more powerful form of resummation: the G_{12} term alone reproduces the full LL series in Eq. (9.20). With the form Eq. (9.21) one still uses the nomenclature LL, but this now means that all terms with $k = n+1$ are included, and NLL implies all terms with $k = n$, *etc.*

For a large number of observables, NLL resummations are available in the sense of Eq. (9.21) (see Refs. 157–159 and references therein). NNLL has been achieved for the DY and Higgs-boson p_t distributions [160–163] (also available in the CuTe [164], HRes [165] and ResBos [166] families of programs and also differentially in vector-boson decay products [167]) and related variables [168], for the p_t of vector-boson pairs [169], for the back-to-back energy-energy correlation in e^+e^- [170], the jet broadening in e^+e^- collisions [171], the jet-veto survival probability in Higgs and Z boson production in pp collisions [172], an event-shape type observable known as the beam Thrust [173], hadron-collider jet masses in specific limits [174] (see also Ref. 175), the production of top anti-top pairs near threshold [176–178] (and references therein), and high-p_t W and Z production [179]. Automation of NNLL jet-veto resummations for different processes has been achieved in Ref. 180 (*cf.* also the NLL automation in Ref. 181), while automation for a certain class of e^+e^- observables has been achieved in Ref. 182. The parts believed to be dominant in the N^{3}LL resummation are available for the Thrust variable, C-parameter and heavy-jet mass in e^+e^- annihilations [183–185] (confirmed for Thrust at NNLL in Ref. 186), and full N^{3}LL has been achieved for Higgs- and vector-boson production near threshold [187]. An extensive discussion of jet masses for heavy-quark induced jets has been given in Ref. 188. Recently, there has also been progress in resummed calculations for jet substructure, whose observables involve more complicated definitions than is the case for standard resummations [189–193]. The inputs and methods involved in these various calculations are somewhat too diverse to discuss in detail here, so we recommend that the interested reader consult the original references for further details.

9.2.3.4. *Fragmentation functions:*

Since the parton-hadron transition is non-perturbative, it is not possible to perturbatively calculate quantities such as the energy-spectra of specific hadrons in high-energy collisions. However, one can factorize perturbative and non-perturbative contributions via the concept of fragmentation functions. These are the final-state analogue of the parton distribution functions that are used for initial-state hadrons. Like parton distribution functions, they depend on a (fragmentation) factorization scale and satisfy a DGLAP evolution equation.

It should be added that if one ignores the non-perturbative difficulties and just calculates the energy and angular spectrum of partons in perturbative QCD with some low cutoff scale $\sim \Lambda$ (using resummation to sum large logarithms of $\sqrt{s}/\Lambda$), then this reproduces many features of the corresponding hadron spectra [194]. This is often taken to suggest that hadronization is "local", in the sense it mainly involves partons that are close both in position and in momentum.

Section 20 of this *Review* provides further information (and references) on these topics, including also the question of heavy-quark fragmentation.

9.2.3.5. *Parton-shower Monte Carlo generators:*

Parton-shower Monte Carlo (MC) event generators like PYTHIA [195–197], HERWIG [198–200] and SHERPA [96] provide fully exclusive simulations of QCD events.† Because they provide access to "hadron-level" events, they are a crucial tool for all applications that involve simulating the response of detectors to QCD events. Here we give only a brief outline of how they work and refer the reader to Sec. 41 and Ref. 202 for a full overview.

The MC generation of an event involves several stages. It starts with the random generation of the kinematics and partonic channels of whatever *hard scattering process* the user has requested at some high scale Q_0 (for complex processes, this may be carried out by an external program). This is followed by a *parton shower*, usually based on the successive random generation of gluon emissions (or $g \to q\bar{q}$ splittings). Each is generated at a scale lower than the previous emission, following a (soft and collinear resummed) perturbative QCD

** To be precise one should be aware of two causes of the divergence of perturbative series. That which interests us here is associated with the presence of a new large parameter (*e.g.* ratio of scales). It is distinct from the "renormalon" induced factorial divergences of perturbation theory that were discussed above.

‡ Whether or not this happens depends on the quantity being resummed. A classic example involves jet rates in e^+e^- collisions as a function of a jet-resolution parameter $y_{\rm cut}$. The logarithms of $1/y_{\rm cut}$ exponentiate for the k_t (Durham) jet algorithm [154], but not [155] for the JADE algorithm [156] (both are discussed below in Sec. 9.3.1.1).

† The program ARIADNE [201] has also been widely used for simulating e^+e^- and DIS collisions.

distribution that depends on the momenta of all previous emissions. Common choices of scale for the ordering of emissions are virtuality, transverse momentum or angle. Parton showering stops at a scale of order 1 GeV, at which point a *hadronization model* is used to convert the resulting partons into hadrons. One widely-used model involves stretching a color "string" across quarks and gluons, and breaking it up into hadrons [203,204]. Another breaks each gluon into a $q\bar{q}$ pair and then groups quarks and anti-quarks into colorless "clusters", which then give the hadrons [198]. For pp and γp processes, modeling is also needed to treat the collision between the two hadron remnants, which generates an *underlying event* (UE), usually implemented via additional $2 \to 2$ scatterings ("multiple parton interactions") at a scale of a few GeV, following Ref. 205.

A deficiency of the soft and collinear approximations that underlie parton showers is that they may fail to reproduce the full pattern of hard wide-angle emissions, important, for example, in many new physics searches. It is therefore common to use LO multi-parton matrix elements to generate hard high-multiplicity partonic configurations as additional starting points for the showering, supplemented with some prescription (CKKW [206], MLM [207]) for consistently merging samples with different initial multiplicities.

MCs, as described above, generate cross sections for the requested hard process that are correct at LO. A wide variety of processes are available in MC implementations that are correct to NLO, using the MC@NLO [208] or POWHEG [209] prescriptions, notably through the Madgraph5_aMC@NLO [77], POWHEGBox [210] and Sherpa [79,211] programs. Techniques have also been developed recently to combine NLO plus shower accuracy for different multiplicities of final-state jets [212]. Building in part on some of that work, several groups have also obtained NNLO plus shower accuracy for Drell-Yan and Higgs production [213].

9.2.4. *Accuracy of predictions* :

Estimating the accuracy of perturbative QCD predictions is not an exact science. It is often said that LO calculations are accurate to within a factor of two. This is based on experience with NLO corrections in the cases where these are available. In processes involving new partonic scattering channels at NLO and/or large ratios of scales (such as jet observables in processes with vector bosons, or the production of high-p_t jets containing B-hadrons), the ratio of the NLO to LO predictions, commonly called the "K-factor", can be substantially larger than 2.

For calculations beyond LO, a conservative approach to estimate the perturbative uncertainty is to take it to be the last known perturbative order; a more widely used method is to estimate it from the change in the prediction when varying the renormalization and factorization scales around a central value Q that is taken close to the physical scale of the process. A conventional range of variation is $Q/2 < \mu_R, \mu_F < 2Q$. This should not be assumed to always estimate the full uncertainty from missing higher orders, but it does indicate the size of one important known source of higher-order ambiguity.[‡‡]

There does not seem to be a broad consensus on whether μ_R and μ_F should be kept identical or varied independently. One common option is to vary them independently with the restriction $\frac{1}{2}\mu_R < \mu_F < 2\mu_R$ [221]. This limits the risk of misleadingly small uncertainties due to fortuitous cancellations between the μ_F and μ_R dependence when both are varied together, while avoiding the appearance of large logarithms of μ_R^2/μ_F^2 when both are varied completely independently.

Calculations that involve resummations usually have an additional source of uncertainty associated with the choice of argument of the logarithms being resummed, *e.g.* $\ln(2\frac{p_T^Z}{M_Z})$ as opposed to $\ln(\frac{1}{2}\frac{p_T^Z}{M_Z})$. In addition to varying renormalization and factorization scales, it is therefore also advisable to vary the argument of the logarithm by a suitable factor in either direction with respect to the "natural" argument.

The accuracy of QCD predictions is limited also by non-perturbative corrections, which typically scale as a power of Λ/Q. For measurements that are directly sensitive to the structure of the hadronic final state, the corrections are usually linear in Λ/Q. The non-perturbative corrections are further enhanced in processes with a significant underlying event (*i.e.* in pp and $p\bar{p}$ collisions) and in cases where the perturbative cross sections fall steeply as a function of p_t or some other kinematic variable, for example in inclusive jet spectra or dijet mass spectra.

Non-perturbative corrections are commonly estimated from the difference between Monte Carlo events at the parton level and after hadronization. An issue to be aware of with this procedure is that "parton level" is not a uniquely defined concept. For example, in an event generator it depends on a (somewhat arbitrary and tunable) internal cutoff scale that separates the parton showering from the hadronization. In contrast no such cutoff scale exists in a NLO or NNLO partonic calculation. For this reason there are widespread reservations as to the appropriateness of deriving hadronization corrections from a Monte Carlo program and then applying them to NLO or NNLO predictions. There exist alternative methods for estimating hadronization corrections, which attempt to analytically deduce non-perturbative effects in one observable based on measurements of other observables (see the reviews [23,222]). While they directly address the problem of different possible definitions of parton level, it should also be said that they are far less flexible than Monte Carlo programs and not always able to provide equally good descriptions of the data.

9.3. Experimental studies of QCD

Since we are not able to directly measure partons (quarks or gluons), but only hadrons and their decay products, a central issue for every experimental study of perturbative QCD is establishing a correspondence between observables obtained at the partonic and the hadronic level. The only theoretically sound correspondence is achieved by means of *infrared and collinear safe* quantities, which allow one to obtain finite predictions at any order of perturbative QCD.

As stated above, the simplest case of infrared- and collinear-safe observables are total cross sections. More generally, when measuring fully inclusive observables, the final state is not analyzed at all regarding its (topological, kinematical) structure or its composition. Basically the relevant information consists in the rate of a process ending up in a partonic or hadronic final state. In e^+e^- annihilation, widely used examples are the ratios of partial widths or branching ratios for the electroweak decay of particles into hadrons or leptons, such as Z or τ decays, (*cf.* Sec. 9.2.1). Such ratios are often favored over absolute cross sections or partial widths because of large cancellations of experimental and theoretical systematic uncertainties. The strong suppression of non-perturbative effects, $\mathcal{O}(\Lambda^4/Q^4)$, is one of the attractive features of such observables, however, at the same time the sensitivity to radiative QCD corrections is small, which for example affects the statistical uncertainty when using them for the determination of the strong coupling constant. In the case of τ decays not only the hadronic branching ratio is of interest, but also moments of the spectral functions of hadronic tau decays, which sample different parts of the decay spectrum and thus provide additional information. Other examples of fully inclusive observables are structure functions (and related sum rules) in DIS. These are extensively discussed in Sec. 19 of this *Review*.

On the other hand, often the structure or composition of the final state are analyzed and cross sections differential in one or more variables characterizing this structure are of interest. Examples are jet rates, jet substructure, event shapes or transverse momentum distributions of jets or vector bosons in hadron collisions. The case of fragmentation functions, *i.e.* the measurement of hadron production as a function of the hadron momentum relative to some hard scattering scale, is discussed in Sec. 20 of this *Review*.

[‡‡] A number of prescriptions also exist for setting the scale automatically, *e.g.* Refs. 214–217, eliminating uncertainties from scale variation, though not from the truncation of the perturbative series itself. Recently, there have also been studies of how to estimate uncertainties from missing higher orders that go beyond scale variations [218,219,220].

It is worth mentioning that, besides the correspondence between the parton and hadron level, also a correspondence between the hadron level and the actually measured quantities in the detector has to be established. The simplest examples are corrections for finite experimental acceptance and efficiencies. Whereas acceptance corrections essentially are of theoretical nature, since they involve extrapolations from the measurable (partial) to the full phase space, other corrections such as for efficiency, resolution and response, are of experimental nature. For example, measurements of differential cross sections such as jet rates require corrections in order to relate, *e.g.* the energy deposits in a calorimeter to the jets at the hadron level. Typically detector simulations and/or data-driven methods are used in order to obtain these corrections. Care should be taken here in order to have a clear separation between the parton-to-hadron level and hadron-to-detector level corrections. Finally, for the sake of an easy comparison to the results of other experiments and/or theoretical calculations, it is suggested to provide, whenever possible, measurements corrected for detector effects and/or all necessary information related to the detector response (*e.g.* the detector response matrix).

9.3.1. *Hadronic final-state observables* :

9.3.1.1. *Jets:*

In hard interactions, final-state partons and hadrons appear predominantly in collimated bunches, which are generically called *jets*. To a first approximation, a jet can be thought of as a hard parton that has undergone soft and collinear showering and then hadronization. Jets are used both for testing our understanding and predictions of high-energy QCD processes, and also for identifying the hard partonic structure of decays of massive particles like top quarks.

In order to map observed hadrons onto a set of jets, one uses a *jet definition*. The mapping involves explicit choices: for example when a gluon is radiated from a quark, for what range of kinematics should the gluon be part of the quark jet, or instead form a separate jet? Good jet definitions are infrared and collinear safe, simple to use in theoretical and experimental contexts, applicable to any type of inputs (parton or hadron momenta, charged particle tracks, and/or energy deposits in the detectors) and lead to jets that are not too sensitive to non-perturbative effects.

An extensive treatment of the topic of jet definitions is given in Ref. 223 (for e^+e^- collisions) and Refs. [224–226]. Here we briefly review the two main classes: cone algorithms, extensively used at older hadron colliders, and sequential recombination algorithms, more widespread in e^+e^- and ep colliders and at the LHC.

Very generically, most (iterative) cone algorithms start with some seed particle i, sum the momenta of all particles j within a cone of opening-angle R, typically defined in terms of (pseudo-)rapidity and azimuthal angle. They then take the direction of this sum as a new seed and repeat until the cone is stable, and call the contents of the resulting stable cone a jet if its transverse momentum is above some threshold $p_{t,\min}$. The parameters R and $p_{t,\min}$ should be chosen according to the needs of a given analysis.

There are many variants of cone algorithm, and they differ in the set of seeds they use and the manner in which they ensure a one-to-one mapping of particles to jets, given that two stable cones may share particles ("overlap"). The use of seed particles is a problem w.r.t. infrared and collinear safety, and seeded algorithms are generally not compatible with higher-order (or sometimes even leading-order) QCD calculations, especially in multi-jet contexts, as well as potentially subject to large non-perturbative corrections and instabilities. Seeded algorithms (JetCLU, MidPoint, and various other experiment-specific iterative cone algorithms) are therefore to be deprecated. A modern alternative is to use a seedless variant, SISCone [227].

Sequential recombination algorithms at hadron colliders (and in DIS) are characterized by a distance $d_{ij} = \min(k_{t,i}^{2p}, k_{t,j}^{2p})\Delta_{ij}^2/R^2$ between all pairs of particles i, j, where Δ_{ij} is their separation in the rapidity-azimuthal plane, $k_{t,i}$ is the transverse momentum w.r.t. the incoming beams, and R is a free parameter. They also involve a "beam" distance $d_{iB} = k_{t,i}^{2p}$. One identifies the smallest of all the d_{ij} and d_{iB}, and if it is a d_{ij}, then i and j are merged into a new pseudo-particle (with some prescription, a recombination scheme, for the definition of the merged four-momentum). If the smallest distance is a d_{iB}, then i is removed from the list of particles and called a jet. As with cone algorithms, one usually considers only jets above some transverse-momentum threshold $p_{t,\min}$. The parameter p determines the kind of algorithm: $p = 1$ corresponds to the (*inclusive-*)k_t algorithm [154,228,229], $p = 0$ defines the *Cambridge-Aachen* algorithm [230,231], while for $p = -1$ we have the *anti-*k_t algorithm [232]. All these variants are infrared and collinear safe to all orders of perturbation theory. Whereas the former two lead to irregularly shaped jet boundaries, the latter results in cone-like boundaries. The *anti-*k_t algorithm has become the de-facto standard for the LHC experiments.

In e^+e^- annihilations the k_t algorithm [154] uses $y_{ij} = 2\min(E_i^2, E_j^2)(1-\cos\theta_{ij})/Q^2$ as distance measure and repeatedly merges the pair with smallest y_{ij}, until all y_{ij} distances are above some threshold $y_{\rm cut}$, the jet resolution parameter. The (pseudo)-particles that remain at this point are called the jets. Here it is $y_{\rm cut}$ (rather than R and $p_{t,\min}$) that should be chosen according to the needs of the analysis. As mentioned earlier, the k_t algorithm has the property that logarithms $\ln(1/y_{\rm cut})$ exponentiate in resummation calculations. This is one reason why it is preferred over the earlier JADE algorithm [156], which uses the distance measure $y_{ij} = 2\,E_i\,E_j\,(1-\cos\theta_{ij})/Q^2$. Note that other variants of sequential recombination algorithms for e^+e^- annhilations, using different definitions of the resolution measure y_{ij}, exhibit much larger sensitivities to fragmentation and hadronization effects than the k_t and JADE algorithms [233].

Efficient implementations of the above algorithms are available through the *FastJet* package [234].

9.3.1.2. *Event Shapes:*

Event-shape variables are functions of the four momenta of the particles in the final state and characterize the topology of an event's energy flow. They are sensitive to QCD radiation (and correspondingly to the strong coupling) insofar as gluon emission changes the shape of the energy flow.

The classic example of an event shape is the *Thrust* [235,236] in e^+e^- annihilations, defined as

$$\hat{\tau} = \max_{\vec{n}_\tau} \frac{\sum_i |\vec{p}_i \cdot \vec{n}_\tau|}{\sum_i |\vec{p}_i|} \,, \tag{9.22}$$

where $\vec{p}_i$ are the momenta of the particles or the jets in the final-state and the maximum is obtained for the Thrust axis $\vec{n}_\tau$. In the Born limit of the production of a perfect back-to-back $q\bar{q}$ pair the limit $\hat{\tau} \to 1$ is obtained, whereas a perfectly spherical many-particle configuration leads to $\hat{\tau} \to 1/2$. Further event shapes of similar nature have been extensively measured at LEP and at HERA, and for their definitions and reviews we refer to Refs. 1,4,222,237,238. The energy-energy correlation function [239], namely the energy-weighted angular distribution of produced hadron pairs, and its associated asymmetry are further shape variables that have been studied in detail at e^+e^- colliders. For hadron colliders the appropriate modification consists in only taking the transverse momentum component [240]. More recently, the event shape *N-jettiness* has been proposed [241], that measures the degree to which the hadrons in the final state are aligned along N jet axes or the beam direction. It vanishes in the limit of exactly N infinitely narrow jets.

Phenomenological discussions of event shapes at hadron colliders can be found in Refs. [241–243]. Measurements of hadronic event-shape distributions have been published by CDF [244], ATLAS [245–247] and CMS [248–250].

Event shapes are used for many purposes. These include measuring the strong coupling, tuning the parameters of Monte Carlo programs, investigating analytical models of hadronization and distinguishing QCD events from events that might involve decays of new particles (giving event-shape values closer to the spherical limit).

9.3.1.3. *Jet substructure, quark vs. gluon jets:*

Jet substructure, which can be resolved by finding subjets or by measuring jet shapes, is sensitive to the details of QCD radiation in the shower development inside a jet and has been extensively used to study differences in the properties of quark and gluon induced jets, strongly related to their different color charges. In general there is clear experimental evidence that gluon jets have a softer particle spectrum and are "broader" than (light-) quark jets, when looking at observables such as the jet shape $\Psi(r/R)$. This is the fractional transverse momentum contained within a sub-cone of cone-size r for jets of cone-size R. It is sensitive to the relative fractions of quark and gluon jets in an inclusive jet sample and receives contributions from soft-gluon initial-state radiation and the underlying event. Therefore, it has been widely employed for validation and tuning of Monte Carlo models. Furthermore, this quantity turns out to be sensitive to the modification of the gluon radiation pattern in heavy ion collisions (see *e.g.* Ref. 251).

The most recent jet shape measurements using proton-proton collision data have been presented for inclusive jet samples [252,253] and for top-quark production [254]. Further discussions, references and recent summaries can be found in Refs. 238, 255, 256 and Sec. 4 of Ref. 257.

The use of jet substructure has also been investigated in order to distinguish QCD jets from jets that originate from hadronic decays of boosted massive particles (high-p_t electroweak bosons, top quarks and hypothesized new particles). Recently, a considerable number of experimental studies have been carried out with Tevatron and LHC data, in order to investigate on the performance of the proposed algorithms for resolving jet substructure and to apply them to searches for new physics. For reviews of this rapidly growing field, see sec. 5.3 of Ref. 224, Ref. 226 and Refs. [257–260].

9.3.2. ***QCD measurements at colliders*** :

There exists a wealth of data on QCD-related measurements in e^+e^-, ep, pp, and $p\bar{p}$ collisions, to which a short overview like this would not be able to do any justice. Extensive reviews of the subject have been published in Refs. 237, 238 for e^+e^- colliders and in Ref. 261 for ep scattering, whereas for hadron colliders comprehensive overviews are given in, *e.g.*, Refs. 225, 256 and Refs. [262–264].

Below we concentrate our discussion on measurements that are most sensitive to hard QCD processes, with focus on jet production.

9.3.2.1. e^+e^- *colliders:* Analyses of jet production in e^+e^- collisions are mostly based on data from the JADE experiment at center-of-mass energies between 14 and 44 GeV, as well as on LEP collider data at the Z resonance and up to 209 GeV. They cover the measurements of (differential or exclusive) jet rates (with multiplicities typically up to 4, 5 or 6 jets), the study of 3-jet events and particle production between the jets as a tool for testing hadronization models, as well as 4-jet production and angular correlations in 4-jet events.

Event-shape distributions from e^+e^- data have been an important input to the tuning of parton shower MC models, typically matched to matrix elements for 3-jet production. In general these models provide good descriptions of the available, highly precise data. Especially for the large LEP data sample at the Z peak, the statistical uncertainties are mostly negligible and the experimental systematic uncertainties are at the percent level or even below. These are usually dominated by the uncertainties related to the MC model dependence of the efficiency and acceptance corrections (often referred to as "detector corrections").

Observables measured in e^+e^- collisions have been used for determinations of the strong coupling constant (*cf.* Section 9.4 below) and for putting constraints on the QCD color factors (*cf.* Sec. 9.1 for their definitions), thus probing the non-abelian nature of QCD. Typically, cross sections can be expressed as functions of these color factors, for example $\sigma = f(\alpha_s C_F, C_A/C_F, n_f T_R/C_F)$. Angular correlations in 4-jet events give sensitivity at leading order. Some sensitivity to these color factors, although only at NLO, is also obtained from event-shape distributions. Scaling violations of fragmentation functions and the different subjet structure in quark and gluon induced jets also give access to these color factors. In order to extract absolute values, *e.g.* for C_F and C_A, certain assumptions have to be made for other parameters, such as T_R, n_f or α_s, since typically only combinations (ratios, products) of all the relevant parameters appear in the perturbative predictions. A compilation of results [238] quotes world average values of $C_A = 2.89 \pm 0.03(\text{stat}) \pm 0.21(\text{syst})$ and $C_F = 1.30 \pm 0.01(\text{stat}) \pm 0.09(\text{syst})$, with a correlation coefficient of 82%. These results are in perfect agreement with the expectations from SU(3) of $C_A = 3$ and $C_F = 4/3$.

9.3.2.2. *DIS and photoproduction:* Multi-jet production in ep collisions at HERA, both in the DIS and photoproduction regime, allows for tests of QCD factorization (one initial-state proton and its associated PDF versus the hard scattering which leads to high-p_t jets) and NLO calculations which exist for 2- and 3-jet final states. Sensitivity is also obtained to the product of the coupling constant and the gluon PDF. Experimental uncertainties of the order of 5–10% have been achieved, mostly dominated by the jet energy scale, whereas statistical uncertainties are negligible to a large extent. For comparison to theoretical predictions, at large jet p_t the PDF uncertainty dominates the theoretical uncertainty (typically of order 5–10%, in some regions of phase space up to 20%), therefore jet observables become useful inputs for PDF fits.

In general, the data are well described by NLO matrix-element calculations, combined with DGLAP evolution equations, in particular at large Q^2 and central values of jet pseudo-rapidity. At low values of Q^2 and x, in particular for large jet pseudo-rapidities, certain features of the data have been interpreted as requiring BFKL-type evolution, though the predictions for such schemes are still limited. It is worth noting that there is lack of consensus throughout the community regarding this need of BFKL-evolution at currently probed x, Q^2 values, and an alternative approach [265] that implements the merging of LO matrix-element based event generation with a parton shower (using the SHERPA framework) successfully describes the data in all kinematical regions, including the low Q^2, low x domain. At moderately small x values, it should perhaps not be surprising that the BFKL approach and fixed-order matrix-element merging with parton showers may both provide adequate descriptions of the data, because some part of the multi-parton phase space that they model is common to both approaches.

In the case of photoproduction, a wealth of measurements with low p_t jets were performed in order to constrain the photon PDFs. The uncertainties related to these photon PDFs play a minor role at high jet p_t, which has allowed for precise tests of pQCD calculations.

A few examples of recent measurements can be found in Refs. 266–274 for DIS and in Refs. 275–279 for photoproduction.

9.3.2.3. *Hadron colliders:* The spectrum of observables and the number of measurements performed at hadron colliders is enormous, probing many regions of phase space and covering a huge range of cross sections, as illustrated in Fig. 9.1 for the case of the ATLAS and CMS experiments at the LHC. For the sake of brevity, in the following only certain classes of those measurements will be discussed, that allow addressing particular aspects of the various QCD studies performed. Most of our discussion will focus on recent LHC results, which are available for center-of-mass energies of 2.76, 7 and 8 TeV with integrated luminosities of up to $20\,\text{fb}^{-1}$. Generally speaking, besides representing a general test of the standard model and QCD in particular, these measurements serve several purposes, such as: (i) probing pQCD and its various approximations and implementations in MC models, in order to quantify the order of magnitude of not yet calculated contributions and to gauge their precision when used as background predictions, or (ii) extracting/constraining model parameters such as the strong coupling constant or PDFs.

Among the most important cross sections measured is the inclusive jet spectrum as a function of the jet transverse energy (E_t) or the jet transverse momentum (p_t), for several rapidity regions and for p_t up to 700 GeV at the Tevatron and ~ 2 TeV at the LHC. It is worth noting that this upper limit in p_t corresponds to a distance scale of $\sim 10^{-19}$ m: no other experiment so far is able to directly probe smaller distance scales of nature than this measurement. Whereas the Tevatron measurements (Refs. 282–284) were based on the infrared-

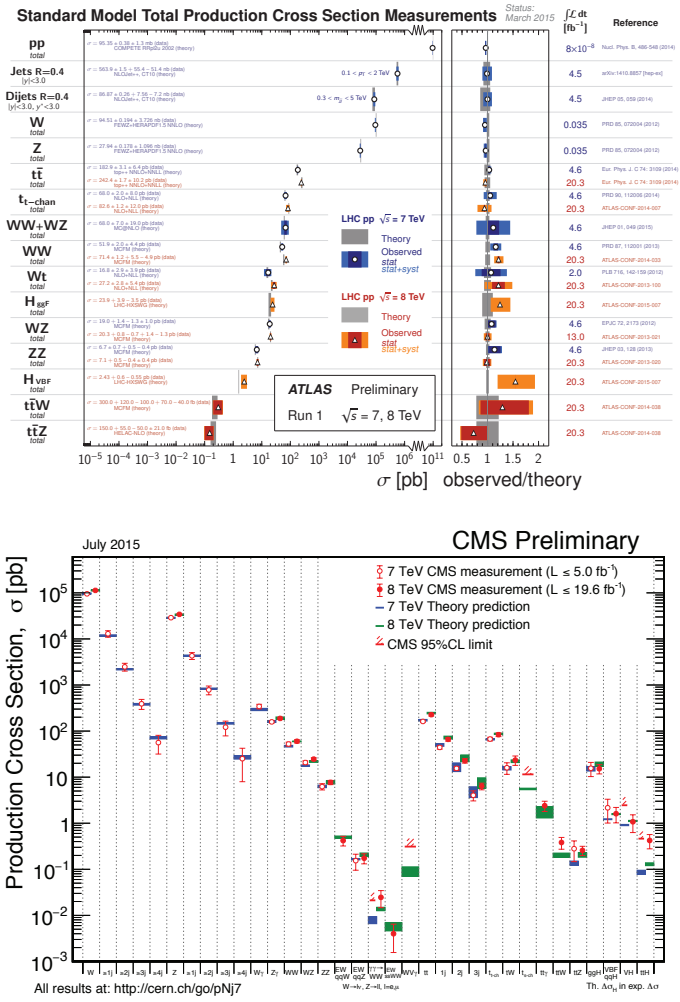

Figure 9.1: Overview of cross section measurements for a wide class of processes and observables, as obtained by the ATLAS [280] and CMS [281] experiments at the LHC, for centre-of-mass energies of 7 and 8 TeV. Also shown are the theoretical predictions and their uncertainties.

and collinear-safe k_t algorithm in addition to the more widely used Midpoint and JetCLU algorithms of the past, the LHC experiments focus on the *anti-k_t* algorithm using various radius parameters. Recent measurements by ALICE, ATLAS and CMS have been published in Refs. 285–288. Reviews can be found in, *e.g.*, Refs. 256,289,290 and a compilation of inclusive jet cross section results is presented in Fig. 51.1 [291] of this *Review*.

In general we observe a good description of the data by the NLO QCD predictions, over about 11 orders of magnitude in cross section. The experimental systematic uncertainties are dominated by the jet energy scale uncertainty, quoted to be in the range of a few percent (see for instance the review in Ref. 292), leading to uncertainties of $\sim 5-30\%$ on the cross section, increasing with p_t and rapidity. The PDF uncertainties dominate the theoretical uncertainty at large p_t and rapidity. In fact, inclusive jet data are important inputs to global PDF fits (see [293] for a recent review). Constraints on the PDFs can also be obtained from ratios of inclusive cross sections at different center-of-mass energies [286]. In general, ratios of jet cross sections are a means to (at least partially) cancel the jet energy scale uncertainties and thus provide jet observables with significantly improved precision.

Dijet events are analyzed in terms of their invariant mass and angular distributions, which allows for tests of NLO QCD predictions (see *e.g.* Refs. [288,294] for recent LHC results), and setting stringent limits on deviations from the Standard Model, such as quark compositeness (some examples can be found in Refs. 295–299). Furthermore, dijet azimuthal correlations between the two leading jets, normalized to the total dijet cross section, are an extremely valuable tool for studying the spectrum of gluon radiation in the event. The azimuthal separation of the two leading jets is sensitive to multi-jet production, avoiding at the same time large systematic uncertainties from the jet energy calibration. For example, results from the Tevatron [300,301] and the LHC [302,303] show that the LO (non-trivial) prediction for this observable, with at most three partons in the final state, is not able to describe the data for an azimuthal separation below $2\pi/3$, where NLO contributions (with 4 partons) restore the agreement with data. In addition, this observable can be employed to tune Monte Carlo predictions of soft gluon radiation.

Further examples of dijet observables that probe special corners of phase space are those which involve forward (large rapidity) jets and where a large rapidity separation, possibly also a rapidity gap, is required between the two jets. Reviews of such measurements can be found in Refs. [256,304], showing that no single prediction is capable of describing the data in all phase-space regions. In particular, no conclusive evidence for BFKL effects in these observables has been established so far.

Beyond dijet final states, measurements of the production of three or more jets, including cross section ratios, have been performed (see Refs. [256,305] for recent reviews), as a means of testing perturbative QCD predictions, determining the strong coupling constant (at NLO precision so far), and probing/tuning MC models, in particular those combining multi-parton matrix elements with parton showers.

In terms of precision achieved, measurements of inclusive vector boson (W, Z) production outperform the jet studies described above and provide the most precisely determined observables at hadron colliders so far. This is because the experimental signatures are based on leptons that are measured much more accurately than jets. At the LHC [306–310], the dominant uncertainty stems from the luminosity determination (∼2–4%), while other uncertainties (*e.g.* statistics, lepton efficiencies) are controlled at the 1–3% level. The uncertainty from the acceptance correction of about 1–2% can be reduced by measuring so-called fiducial cross sections, ie. by applying kinematic cuts also to the particle level of the theoretical predictions. A further reduction or even complete elimination of particular uncertainties (*e.g.* luminosity) is achieved by measuring cross section ratios (W/Z or W^+/W^-) or differential distributions that are normalised to the inclusive cross section.

On the theory side, as discussed earlier in this review, the production of these color-singlet states has been calculated up to NNLO accuracy. Since currently the dominant theoretical uncertainty (of order 5% and thus similar or larger than the experimental errors) is related to the choice of PDFs, these data provide useful handles for PDF determinations.

Further insights are obtained from measurements of differential vector boson production, as a function of the invariant dilepton mass, the boson's rapidity or its transverse momentum. For example, the dilepton invariant mass distribution has been measured [311–314] for masses between 15 and 2000 GeV, covering more than 8 orders of magnitude in cross section. NNLO QCD predictions, together with modern PDF sets and including higher-order electroweak and QED final-state radiation corrections, describe the data to within 5–10% over this large range, whereas NLO predictions show larger deviations, unless matched to a parton shower.

Similar conclusions can be drawn from the observed rapidity distribution of the dilepton system or, in the case of W production, from the observed charged lepton rapidity distribution and its charge asymmetry. The latter is particularly sensitive to differences among PDF sets [315], also thanks to the high precision achieved by the ATLAS and CMS experiments for central rapidity ranges. These measurements are nicely extended to the very forward region, up to 4.5 in lepton rapidity, by the LHCb experiment.

An overview of recent results can be found in Ref. 256. There one can also find a discussion of and references to recent LHC results from studies of the vector boson's transverse momentum distribution, p_t^V. This observable probes different aspects of higher-order QCD

effects and is sensitive to jet production in association to the vector boson, without suffering from the large jet energy scale uncertainties since there is no explicit jet reconstruction. Whereas in the p_t^V region of several tens to hundreds of GeV the NNLO predictions (that effectively are of NLO accuracy for this variable) agree with the data to within about 10%, at transverse momentum below ∼5–10 GeV the fixed order predictions fail and soft-gluon resummation is needed to restore the agreement with data. Correspondingly, MC models implementing parton shower matching to LO or NLO matrix elements provide good predictions at low and intermediate p_t^V, but deviate up to 40% at high p_t^V.

While in principle inclusive and differential photon production represents a similar tool for studying effects as described above, the experimental results are less precise than for W and Z production, related to the greater challenges encountered in photon reconstruction and purity determination compared to lepton final states.

In terms of complexity, probably the most challenging class of processes is vector boson (photon, W, Z) production together with jets. By now the amount of results obtained both at the Tevatron and at the LHC is so extensive that a comprehensive discussion with a complete citation list would go much beyond the scope of this *Review*. We rather refer to recent summaries such as those in Refs. 256,316 and to previous versions of this *Review*.

The measurements cover a very large phase space, *e.g.* with jet transverse momenta between 30 GeV and ∼ 800 GeV and jet rapidities up to $|y| < 4.4$. Jet multiplicities as high as seven jets accompanying the vector boson have already been probed at the LHC, together with a substantial number of other kinematical observables, such as angular correlations among the various jets or among the jets and the vector boson, or the sum of jet transverse momenta, H_T. Whereas the jet p_t and H_T distributions are dominated by jet energy scale uncertainties at levels similar to those discussed above for inclusive jet production, angular correlations and jet multiplicity ratios have been measured with a precision of ∼ 10%, see eg. Refs. 317,249.

A general observation is that MC models, which implement a matching of matrix-element calculations with parton showers, provide a good description of the data within uncertainties. Also NLO calculations for up to five jets [110] in addition to the vector boson are in good agreement with the data over that phase space, where the calculations are applicable; that is, one can not expect such predictions to work for, eg., the p_t distribution of the $n+1$st jet with $V+n$ jets calculated at NLO. However, with the high statistics available to and the high precision achieved by the LHC experiments, some more detailed observations can be made. MC models that implement parton shower matching to LO matrix elements (LO+PS) tend to overpredict the data at large jet and/or boson p_t, while parton shower matching to NLO matrix elements gives better agreement. These problems of LO+PS models are less acute when looking at angular correlations.

Also, electroweak corrections are expected to become more and more relevant now that the TeV energy range starts to be explored. For example, such corrections were found [318] to be sizeable (tens of percent) when studying the ratio $(d\sigma^\gamma/dp_t)/(d\sigma^Z/dp_t)$ in $\gamma\,(Z)$+jet production, p_t being the boson's transverse momentum, and might account for (some of) the differences observed in a recent CMS measurement [319] of this quantity.

The challenges get even more severe in the case of vector boson plus heavy quark (b, c) production, both because of theoretical issues (an additional scale is introduced by the heavy quark mass and different schemes exist for the handling of heavy quarks and their mass effects in the initial and/or final state) and because of additional experimental uncertainties related to the heavy-flavour tagging. A recent review of heavy quark production at the LHC can be found in Ref. 320. There it is stated that studies of b-jet production with or without associated W and Z bosons reveal the di-b-jet p_t and mass spectra to be well modelled, within experimental and theoretical uncertainties, by most generators on the market. However, sizeable differences between data and predictions are seen in the modelling of events with single b jets, particularly at large b-jet p_t, where gluon splitting processes become dominant, as also confirmed by studies of b-hadron and b-jet angular correlations.

A number of interesting developments, in terms of probing higher-order QCD effects, have recently occurred in the sector of diboson production, in particular for the WW and $\gamma\gamma$ cases. Regarding the former, a disagreement of about 10% between the LHC measurements and the NLO predictions has led to a number of speculations of possible new physics effects in this channel. However, the latest CMS measurement [321], with a relative accuracy of 8%, is in excellent agreement with a recent NNLO calculation [56], that has an estimated 3% residual uncertainty from missing contributions beyond NNLO.

In the case of diphoton production, ATLAS [322] and CMS [323] have provided accurate measurements, in particular for phase-space regions that are sensitive to radiative QCD corrections (multi-jet production), such as small azimuthal photon separation. While there are large deviations between data and NLO predictions in this region, a calculation [132] at NNLO accuracy manages to mostly fill this gap. This is an interesting example where scale variations can not provide a reliable estimate of missing contributions beyond NLO, since at NNLO new channels appear in the initial state (gluon fusion in this case).

In terms of heaviest particle involved, top-quark production at the LHC has become an important tool for probing higher-order QCD calculations, thanks to very impressive achievements both on the experimental and theoretical side, as extensively summarised in Ref. 324. Regarding $t\bar{t}$ production, the most precise inclusive cross section measurements are achieved using the dilepton ($e\,\mu$) final state, with a total uncertainty of 4%. This is of about the same size as the uncertainty on the most advanced theoretical prediction [55], obtained at NNLO with additional soft-gluon resummation at NNLL accuracy. There is excellent agreement between data and QCD prediction.

A large number of differential cross section measurements have been performed at 7 and 8 TeV centre-of-mass energy, studying distributions such as the top-quark p_t and rapidity, the transverse momentum and invariant mass of the $t\bar{t}$ system (probing scales up to the TeV range), or the number of additional jets. These measurements have been compared to a wide range of predictions, at fixed order up to NNLO as well as using LO or NLO matrix elements matched to parton showers. While in general there is good agreement observed with data, most MC simulations predict a somewhat harder top-quark p_t distribution than seen in data, an effect that is currently under investigation.

Thanks to both the precise measurements of and predictions for the inclusive top-pair cross section, that is sensitive to the strong coupling constant and the top-quark mass, this observable has been used to measure the strong coupling constant for the first time at NNLO accuracy from hadron collider data [325] (*cf.* Section 9.4 below), as well as to obtain a measurement of the top-quark's pole mass without employing direct reconstruction methods [325,326].

Finally, it is worth mentioning that first steps are being undertaken towards using the newly found Higgs boson as a new tool for QCD studies, since Higgs production, dominated by the gluon fusion process, is subject to very large QCD corrections. First studies of fiducial and differential cross sections, using the ZZ and $\gamma\gamma$ decay channels, have already been performed [327–329], and the current experimental precision of ∼ 20% or more is expected to be substantially reduced with the future LHC data.

9.4. Determinations of the strong coupling constant

Beside the quark masses, the only free parameter in the QCD Lagrangian is the strong coupling constant α_s. The coupling constant in itself is not a physical observable, but rather a quantity defined in the context of perturbation theory, which enters predictions for experimentally measurable observables, such as R in Eq. (9.7).

Many experimental observables are used to determine α_s. Considerations in such determinations include:

- The observable's sensitivity to α_s as compared to the experimental precision. For example, for the e^+e^- cross section to hadrons (*cf.* R in Sec. 9.2.1), QCD effects are only a small correction, since the perturbative series starts at order α_s^0; 3-jet production or event shapes in e^+e^- annihilations are directly sensitive to

α_s since they start at order α_s; the hadronic decay width of heavy quarkonia, $\Gamma(\Upsilon \to \text{hadrons})$, is very sensitive to α_s since its leading order term is $\propto \alpha_s^3$.

- The accuracy of the perturbative prediction, or equivalently of the relation between α_s and the value of the observable. The minimal requirement is generally considered to be an NLO prediction. Some observables are predicted to NNLO (many inclusive observables, 3-jet rates and event shapes in e^+e^- collisions) or even N^{3}LO (e^+e^- hadronic cross section and τ branching fraction to hadrons). In certain cases, fixed-order predictions are supplemented with resummation. The precise magnitude of theory uncertainties is usually estimated as discussed in Sec. 9.2.4.
- The size of non-perturbative effects. Sufficiently inclusive quantities, like the e^+e^- cross section to hadrons, have small non-perturbative contributions $\sim \Lambda^4/Q^4$. Others, such as event-shape distributions, have contributions $\sim \Lambda/Q$.
- The scale at which the measurement is performed. An uncertainty δ on a measurement of $\alpha_s(Q^2)$, at a scale Q, translates to an uncertainty $\delta' = (\alpha_s^2(M_Z^2)/\alpha_s^2(Q^2)) \cdot \delta$ on $\alpha_s(M_Z^2)$. For example, this enhances the already important impact of precise low-Q measurements, such as from τ decays, in combinations performed at the M_Z scale.

In this review, we update the measurements of α_s summarized in the 2013 edition, and we extract a new world average value of $\alpha_s(M_Z^2)$ from the most significant and complete results available today[♯].

We restrict the selection of results from which to determine the world average value of $\alpha_s(M_Z^2)$ to those which are

- published in a peer-reviewed journal,
- based on the most complete perturbative QCD predictions, *i.e.* to those using NNLO or higher-order expansions.

This excludes *e.g.* results from jet production in DIS at HERA and at hadron colliders, for which calculations are available at NLO only. These will nevertheless be discussed in this review, as they are important ingredients for the experimental evidence of the energy dependence of α_s, *i.e.* for Asymptotic Freedom, one of the key features of QCD. Note that results which do not include reliable estimates of experimental, systematic and theoretical uncertainties, which are based on not commonly accepted procedures like scale optimization, or which omit discussion or accounting of non-perturbative corrections and effects, will not be referenced at all in this review.

In order to calculate the world average value of $\alpha_s(M_Z^2)$, we apply an intermediate step of pre-averaging results within certain sub-fields like e^+e^- annihilation, DIS and hadronic τ-decays, and calculate the overall world average from those pre-averages rather than from individual measurements. This is done because in most sub-fields one observes that different determinations of the strong coupling from substantially similar datasets lead to values of α_s that are only marginally compatible with each other, or with the final world average value, which presumably is a reflection of the challenges of evaluating and including appropriate systematic uncertainties.

So for each sub-field, the *unweighted average* of all selected results is taken as the pre-average value of $\alpha_s(M_Z^2)$, and the unweighted average of the quoted uncertainties is assigned to be the respective overall error of this pre-average. However, if this error appears to be smaller than the unweighted standard deviation - i.e. the *spread* - of the results, the standard deviation is taken as the overall uncertainty instead. This is done in order to arrive at an unbiased estimator of the average value of $\alpha_s(M_Z^2)$ from this sub-field, and to avoid that singular, optimistic estimates of systematic uncertainties dominate the field if these are not backed up by a broader consensus [†].

Assuming that the resulting pre-averages are largely independent of each other, we determine the final world average value using the method of 'χ^2 *averaging*', as proposed, *e.g.*, in Ref. 333, in order to treat cases of possible (unknown) correlations as well as possibly underestimated systematic uncertainties in a meaningful and well defined manner: the central value is determined as the weighted average of the different input values. An initial uncertainty of the central value is determined treating the uncertainties of all individual measurements as being uncorrelated and of Gaussian nature, and the overall χ^2 to the central value is calculated. If this initial χ^2 is larger than the number of degrees of freedom, then all individual uncertainties are enlarged by a common factor such that χ^2/d.o.f. equals unity. If the initial value of χ^2 is smaller than the number of degrees of freedom, an overall correlation coefficient is introduced and determined by requiring that the total χ^2/d.o.f. equals unity. In both cases, the resulting overall uncertainty of α_s is larger than the initial estimate of the uncertainty.

[♯] The time evolution of α_s combinations can be followed by consulting Refs. [330–332] as well as earlier editions of this *Review*.

[†] In most practical cases, this procedure arrives at similar values as obtained from the '*range averaging*' method which we used in previous *Reviews*, while it avoids potential shortcomings and biases of the latter.

9.4.1. ***Hadronic τ decays*** :
Based on complete N^{3}LO predictions [28], analyses of the τ hadronic decay width and spectral functions have been performed, leading to precise determinations of α_s at the energy scale of M_τ^2 [28,334–340]. They are based on different approaches to treat perturbative and non-perturbative contributions, the impacts of which are a matter of intense discussions, see *e.g.* [338] and [341].

In particular, there is a significant difference between results obtained using fixed-order (FOPT) or contour improved perturbation theory (CIPT), such that analyses based on CIPT generally arrive at about 7% larger values of $\alpha_s(M_\tau^2)$ than those based on FOPT. When converted to $\alpha_s(M_Z^2)$, the difference is about 2%. This uncertainty is about 5 times larger than the typically achieved experimental precision. In addition, most recent results show differences of up to 10% in $\alpha_s(M_\tau^2)$ (3% at M_Z), between different groups using the same data sets and perturbative calculations, most likely due to different treatments of the non-perturbative contributions, c.f. Ref. [340] with Refs. [338,339].

We determine the pre-average value of $\alpha_s(M_Z^2)$ for this sub-field from studies which employ both, FOPT and CIPT expansions, and which include the difference among these in the quoted overall uncertainty: $\alpha_s(M_Z^2) = 0.1202 \pm 0.0019$ [28], $\alpha_s(M_Z^2) = 0.1200 \pm 0.0015$ [338], $\alpha_s(M_Z^2) = 0.1199 \pm 0.0015$ [339], and $\alpha_s(M_Z^2) = 0.1165 \pm 0.0019$ [340].

We also include the result from τ decay and lifetime measurements, obtained in Sec. *Electroweak Model and constraints on New Physics* of the 2013 edition of this *Review*, $\alpha_s(M_Z^2) = 0.1193 \pm 0.0023$. All these are summarised in Fig. 9.2. Determining the unweighted average of the central values and their overall uncertainties, we arrive at $\alpha_s(M_Z^2) = 0.1192 \pm 0.0018$ which we will use as the first input for determining the world average value of $\alpha_s(M_Z^2)$. This corresponds to $\alpha_s(M_\tau^2) = 0.325 \pm 0.015$ at the scale of the τ-mass.

9.4.2. ***Lattice QCD*** :
There are several current results on α_s from lattice QCD, see also Sec. *Lattice QCD* in this *Review*. The HPQCD collaboration [342] computes Wilson loops and similar short-distance quantities with lattice QCD and analyzes them with NNLO perturbative QCD. This yields a value for α_s, but the lattice scale must be related to a physical energy/momentum scale. This is achieved with the Υ'-Υ mass difference, however, many other quantities could be used as well [343]. HPQCD obtains $\alpha_s(M_Z^2) = 0.1184 \pm 0.0006$, where the uncertainty includes effects from truncating perturbation theory, finite lattice spacing and extrapolation of lattice data. An independent perturbative analysis of a subset of the same lattice-QCD data yields $\alpha_s(M_Z^2) = 0.1192 \pm 0.0011$ [344]. Using another, independent methodology, the current-current correlator method, HPQCD obtains $\alpha_s(M_Z^2) = 0.1182 \pm 0.0007$ [342,345]. The analysis of Ref. 346, which uses the Schroedinger functional scheme and avoids the staggered fermion treatment of Ref. 342, finds $\alpha_s(M_Z^2) = 0.1205 \pm 0.0008 \pm 0.0005\,^{+0.0000}_{-0.0017}$, where the first uncertainty is statistical and the others are from systematics. Since this approach uses a different discretization of lattice fermions and a different general methodology, it provides an independent cross check of other lattice extractions of α_s. A study of the ETM collaboration [347] used lattice data with u, d, s and c quarks in the sea and examined the ghost-gluon coupling, obtaining $\alpha_s(M_Z^2) = 0.1196 \pm 0.0012$. Finally, a determination of α_s from the

QCD static potential [348] results in $\alpha_s(M_Z^2) = 0.1166^{+0.0012}_{-0.0008}$. The JLQCD collaboration, in an analysis of Adler functions, has recently corrected their initial result of $\alpha_s(M_Z^2) = 0.1181^{+0.0014}_{-0.0012}$ downwards, by more than 5 standard deviations of their assigned uncertainty, to $\alpha_s(M_Z^2) = 0.1118^{+0.0016}_{-0.0017}$ [349]. For this and other reasons discussed in [350], we do not include this result in our determination of the average lattice result.

A summary of the results discussed above is given in Fig. 9.2. They average, applying the method of taking the unweighted averages of the central values and their quoted uncertainties at face value, to $\alpha_s(M_Z^2) = 0.1188 \pm 0.0011$, which we take as our second result for the determination of the world average value of α_s. This compares well to a similar compilation and summary provided by the FLAG Working Group [350], suggesting $\alpha_s(M_Z^2) = 0.1184 \pm 0.0012$ as the overall average of lattice determinations of α_s. Both these error estimates are more conservative than the one (± 0.0005) we used in our previous *Review* where we applied the χ^2 *averaging* method.

9.4.3. ***Deep inelastic lepton-nucleon scattering (DIS)*** :
Studies of DIS final states have led to a number of precise determinations of α_s: a combination [351] of precision measurements at HERA, based on NLO fits to inclusive jet cross sections in neutral current DIS at high Q^2, provides combined values of α_s at different energy scales Q, as shown in Fig. 9.3, and quotes a combined result of $\alpha_s(M_Z^2) = 0.1198 \pm 0.0032$. A more recent study of multijet production [352], based on improved reconstruction and data calibration, confirms the general picture, albeit with a somewhat smaller value of $\alpha_s(M_Z^2) = 0.1165 \pm 0.0039$, still in NLO. An evaluation of inclusive jet production, including *approximate* NNLO contributions [353], reduces the theoretical prediction for jet production in DIS, improves the description of the final HERA data in particular at high photon virtuality Q^2 and increases the central fit value of the strong coupling constant.

Another class of studies, analyzing structure functions in NNLO QCD (and partly beyond), provide results which serve as relevant inputs for the world average of α_s. Most of these studies do *not*, however, explicitly include estimates of theoretical uncertainties when quoting fit results of α_s. In such cases we add, in quadrature, half of the difference between the results obtained in NNLO and NLO to the quoted errors: A combined analysis of non-singlet structure functions from DIS [354], based on QCD predictions up to N^{3}LO in some of its parts, results in $\alpha_s(M_Z^2) = 0.1141 \pm 0.0022$ (BBG). Studies of singlet and non-singlet structure functions, based on NNLO predictions, result in $\alpha_s(M_Z^2) = 0.1134 \pm 0.0025$ [355] (ABM) and in $\alpha_s(M_Z^2) = 0.1158 \pm 0.0036$ [356] (JR). The MSTW group [357], also including data on jet production at the Tevatron, obtains, at NNLO[##], $\alpha_s(M_Z^2) = 0.1171 \pm 0.0024$. A recent update of this analysis, also including hadron collider data, determined a new set of parton density functions (MMHT2014) [358], together with $\alpha_s(M_Z^2) = 0.1172 \pm 0.0013$. The NNPDF group [359] presented a result, $\alpha_s(M_Z^2) = 0.1173 \pm 0.0011$, which is in line with the one from the MMHT group, including rather small experimental and theoretical uncertainties of only 6 and 9 per-mille, respectively.

We note that criticism has been expressed on some of the above extractions. Among the issues raised, we mention the neglect of singlet contributions at $x \geq 0.3$ in pure non-singlet fits [360], the impact and detailed treatment of particular classes of data in the fits [360,361], possible biases due to insufficiently flexible parametrizations of the PDFs [362] and the use of a fixed-flavor number scheme [363,364].

Summarizing the results from world data on structure functions, taking the *unweighted average* of the central values and errors of all selected results, leads to a pre-average value of $\alpha_s(M_Z^2) = 0.1156 \pm 0.0021$, see Fig. 9.2.

[##] Note that for jet production at a hadron collider, only NLO predictions are available, while for the structure functions full NNLO was utilized.

9.4.4. ***Heavy quarkonia decays*** :
The most recent extraction of the strong coupling constant from an analysis of radiative Υ decays [365] resulted in $\alpha_s(M_Z^2) = 0.119^{+0.006}_{-0.005}$. This determination is based on QCD at NLO only, so it will not be considered for the final extraction of the world average value of α_s; it is, however, an important ingredient for the demonstration of Asymptotic Freedom as given in Fig. 9.3.

9.4.5. ***Hadronic final states of e^+e^- annihilations*** :
Re-analyses of event shapes in e^+e^- annihilation, measured around the Z peak and at LEP2 center-of-mass energies up to 209 GeV, using NNLO predictions matched to NLL resummation and Monte Carlo models to correct for hadronization effects, resulted in $\alpha_s(M_Z^2) = 0.1224 \pm 0.0039$ (ALEPH) [366], with a dominant theoretical uncertainty of 0.0035, and in $\alpha_s(M_Z^2) = 0.1189 \pm 0.0043$ (OPAL) [367]. Similarly, an analysis of JADE data [368] at center-of-mass energies between 14 and 46 GeV gives $\alpha_s(M_Z^2) = 0.1172 \pm 0.0051$, with contributions from hadronization model and from perturbative QCD uncertainties of 0.0035 and 0.0030, respectively. Precise determinations of α_s from 3-jet production alone, in NNLO, resulted in $\alpha_s(M_Z^2) = 0.1175 \pm 0.0025$ [369] from ALEPH data and in $\alpha_s(M_Z^2) = 0.1199 \pm 0.0059$ [370] from JADE. These results are summarized in the upper half of Fig. 9.2(d).

Another class of α_s determinations is based on analytic calculations of non-perturbative and hadronization effects, rather than on Monte Carlo models [371–374], using methods like power corrections, factorization of soft-collinear effective field theory, dispersive models and low scale QCD effective couplings. In these studies, the world data on Thrust distributions, or - most recently - C-parameter distributions, are analysed and fitted to perturbative QCD predictions in NNLO matched with resummation of leading logs up to N^{3}LL accuracy, see Sec. 9.2.3.3. The results are $\alpha_s(M_Z^2) = 0.1164^{+0.0028}_{-0.0024}$ [371], $\alpha_s(M_Z^2) = 0.1135 \pm 0.0011$ [372] and $\alpha_s(M_Z^2) = 0.1137^{+0.0034}_{-0.0027}$ [373] from Thrust, and $\alpha_s(M_Z^2) = 0.1123 \pm 0.0015$ [374] from C-parameter. They are also displayed in Fig. 9.2.

Not to be included in the computation of the world average but worth mentioning are a computation of the NLO corrections to 5-jet production and comparison to the measured 5-jet rates at LEP [375], giving $\alpha_s(M_Z^2) = 0.1156^{+0.0041}_{-0.0034}$, and a computation of non-perturbative and perturbative QCD contributions to the scale evolution of quark and gluon jet multiplicities, including resummation, resulting in $\alpha_s(M_Z^2) = 0.1199 \pm 0.0026$ [376].

We note that there is criticism on both classes of α_s extractions described above: those based on corrections of non-perturbative hadronization effects using QCD-inspired Monte Carlo generators (since the parton level of a Monte Carlo simulation is not defined in a manner equivalent to that of a fixed-order calculation), as well as studies based on non-perturbative analytic calculations, as their systematics have not yet been fully verified. In particular, quoting rather small overall experimental, hadronization and theoretical uncertainties of only 2, 5 and 9 per-mille, respectively [372,374], seems unrealistic and has neither been met nor supported by other authors or groups.

In view of these open questions, the determination of the *unweighted average* and uncertainties is supposed to provide the most appropriate and unbiased estimate of the average value of $\alpha_s(M_Z^2)$ for this sub-field, which results in $\alpha_s(M_Z^2) = 0.1169 \pm 0.0034$.

9.4.6. ***Hadron collider results*** :
Significant determinations of α_s from data at hadron colliders, *i.e.* the Tevatron and the LHC, are obtained, however mostly still limited to QCD at NLO. At $\sqrt{s} = 1.96$ TeV,

$$\alpha_s(M_Z^2) = 0.1161^{+0.0041}_{-0.0048} \text{ and}$$
$$\alpha_s(M_Z^2) = 0.1191^{+0.0048}_{-0.0071}$$

result from studies of inclusive jet cross sections [377] and from jet angular correlations [378], respectively. ATLAS data on inclusive jet production at $\sqrt{s} = 7$ TeV [379] lead to [380]

$$\alpha_s(M_Z^2) = 0.1151^{+0.0093}_{-0.0087} .$$

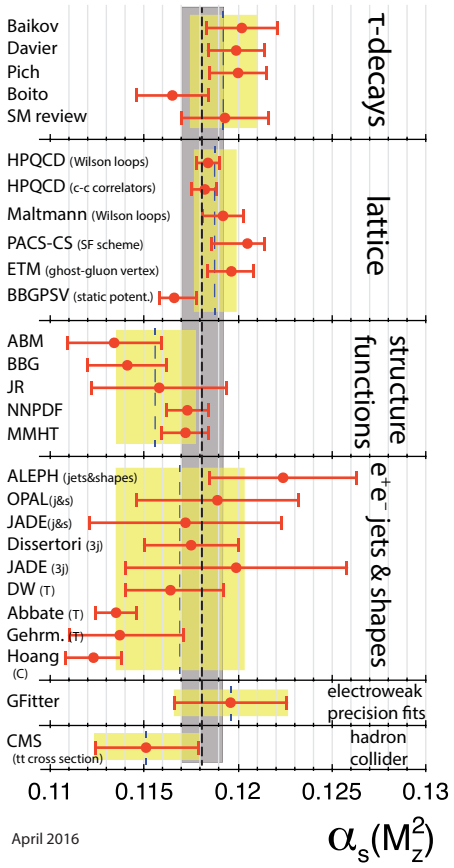

Figure 9.2: Summary of determinations of $\alpha_s(M_Z^2)$ from the six sub-fields discussed in the text. The yellow (light shaded) bands and dashed lines indicate the pre-average values of each sub-field. The dotted line and grey (dark shaded) band represent the final world average value of $\alpha_s(M_Z^2)$.

Here, experimental systematics, the choice of jet scale and the use of different PDFs dominate the large overall uncertainties. Determinations of α_s from CMS data on the ratio of inclusive 3-jet to 2-jet cross sections [381], from inclusive jet production [382] and from the 3-jet differential cross section [383] quoted values of

$$\alpha_s(M_Z^2) = 0.1148 \pm 0.0014(\text{exp.})^{+0.0053}_{-0.0023}(\text{theo.}) \ ,$$
$$\alpha_s(M_Z^2) = 0.1185 \pm 0.0019(\text{exp.})^{+0.0060}_{-0.0037}(\text{theo.}) \ \text{ and}$$
$$\alpha_s(M_Z^2) = 0.1171 \pm 0.0013(\text{exp.})^{+0.0073}_{-0.0047}(\text{theo.}) \ ,$$

respectively. Most recently, the ATLAS collaboration reported

$$\alpha_s(M_Z^2) = 0.1173 \pm 0.0010(\text{exp.})^{+0.0065}_{-0.0026}(\text{theo.}) \ \text{ and}$$
$$\alpha_s(M_Z^2) = 0.1195 \pm 0.0018(\text{exp.})^{+0.0062}_{-0.0022}(\text{theo.})$$

using the transverse energy-energy correlation function (TEEC) and its associated azimuthal asymmetry (ATEEC), respectively [247]. All these results are at NLO only, however they provide valuable new values of α_s at energy scales now extending up to 1.4 TeV. Although not contributing to the overall world average of α_s which we determine below, it may be worth mentioning that the collider results listed above average to a value of $\alpha_s(M_Z^2) = 0.1172 \pm 0.0059$.

So far, only one analysis is available which involves the determination of α_s from hadron collider data in NNLO of QCD: from a measurement of the $t\bar{t}$ cross section at $\sqrt{s} = 7$ TeV, CMS [325] determined

$$\alpha_s(M_Z^2) = 0.1151^{+0.0028}_{-0.0027} \ ,$$

whereby the dominating contributions to the overall error are experimental $(^{+0.0017}_{-0.0018})$, from parton density functions $(^{+0.0013}_{-0.0011})$ and the value of the top quark pole mass (± 0.0013).

This latter result will enter our determination of the new world average of α_s, and will thereby open a new sub-field of α_s determinations in this *Review*. We note, however, that so far there is only this one result in this sub-field. While there are more recent measurements of $t\bar{t}$ cross sections from ATLAS and from CMS, at $\sqrt{s} = 7$, 8 and at 13 TeV, none quotes further extractions of α_s. A more reliable result will thus be left to the next *Review*, however we note that the most recent measurements of $t\bar{t}$ cross sections imply larger values of $\alpha_s(M_Z^2)$ than the one which we use, at this time, as result for this sub-field.

9.4.7. *Electroweak precision fit* :

The N^{3}LO calculation of the hadronic Z decay width [28] was used in the latest update of the global fit to electroweak precision data [384], resulting in

$$\alpha_s(M_Z^2) = 0.1196 \pm 0.0030 \ ,$$

claiming a negligible theoretical uncertainty. We note that results from electroweak precision data, however, strongly depend on the strict validity of Standard Model predictions and the existence of the minimal Higgs mechanism to implement electroweak symmetry breaking. Any - even small - deviation of nature from this model could strongly influence this extraction of α_s.

9.4.8. *Determination of the world average value of $\alpha_s(M_Z^2)$* :

Obtaining a world average value for $\alpha_s(M_Z^2)$ is a non-trivial exercise. A certain arbitrariness and subjective component is inevitable because of the choice of measurements to be included in the average, the treatment of (non-Gaussian) systematic uncertainties of mostly theoretical nature, as well as the treatment of correlations among the various inputs, of theoretical as well as experimental origin.

We have chosen to determine pre-averages for sub-fields of measurements which are considered to exhibit a maximum of independence between each other, considering experimental as well as theoretical issues. The six pre-averages are summarized in Fig. 9.2. We recall that these are exclusively obtained from extractions which are based on (at least) full NNLO QCD predictions, and are published in peer-reviewed journals at the time of completing this *Review*. These pre-averages are then combined to the final world average value of $\alpha_s(M_Z^2)$, using the χ^2 *averaging method* and error treatment as described above. From these, we determine the new world average value of

$$\alpha_s(M_Z^2) = 0.1181 \pm 0.0011 \ , \qquad (9.23)$$

with an uncertainty of 0.9 %.*** This world average value is in reasonable agreement with that from the 2013 version of this *Review*, which was $\alpha_s(M_Z^2) = 0.1185 \pm 0.0006$, however at a somewhat decreased central value and with an overall uncertainty that has almost doubled. These changes are mainly due to the following developments:

- the uncertainty of the combined lattice result, now using the same averaging procedure as applied to the other sub-fields, is more conservative than that used in our previous *Review*, leading to a larger final uncertainty of the new world average, and to a reduced fixing power towards the central average value;
- the relatively low value of α_s from hadron collider results, which currently consists of only one measurement of the $t\bar{t}$ cross section at $\sqrt{s} = 7$ TeV [325] that is likely to be a fluctuation to the low side.

For convenience, we also provide the values for $\Lambda_{\overline{MS}}$ which correspond to the new world average:

$$\Lambda^{(6)}_{\overline{MS}} = (89 \pm 6) \ \text{MeV}, \qquad (9.24a)$$

*** The weighted average, treating all inputs as uncorrelated measurements with Gaussian uncertainties, results in $\alpha_s(M_Z^2) = 0.11810 \pm 0.00078$ with $\chi^2/\text{d.o.f.} = 3.7/5$. Requiring $\chi^2/\text{d.o.f.}$ to reach unity calls for an overall correlation factor of 0.28, which increases the overall uncertainty to ± 0.00114.

$$\Lambda^{(5)}_{\overline{MS}} = (210 \pm 14)\ \text{MeV}, \quad (9.24b)$$

$$\Lambda^{(4)}_{\overline{MS}} = (292 \pm 16)\ \text{MeV}, \quad (9.24c)$$

$$\Lambda^{(3)}_{\overline{MS}} = (332 \pm 17)\ \text{MeV}, \quad (9.24d)$$

for $n_f = 6$, 5, 4 and 3 quark flavors, which are determined using the 4-loop expression for the running of α_s according to Eq. (9.5) and 3-loop matching at the charm-, bottom- and top-quark pole masses of 1.3, 4.2 and 173 GeV/c^2, respectively. Note that for scales below a few GeV, Eq. (9.5) starts to differ significantly from the exact solution of the renormalization group equation Eq. (9.3) and the latter is then to be preferred.

In order to further test and verify the sensitivity of the new average value of $\alpha_s(M_Z^2)$ to the different pre-averages and fields of α_s determinations, we give each of the averages obtained when leaving out one of the six input values, as well as the respective, initial value of χ^2 :

$$\alpha_s(M_Z^2) = 0.1179 \pm 0.0011 \ \ (\text{w/o } \tau \text{ results};\ \chi^2_0/\text{d.o.f.} = 3.3/4), \quad (9.25a)$$

$$\alpha_s(M_Z^2) = 0.1174 \pm 0.0016 \ \ (\text{w/o lattice results};\ \chi^2_0/\text{d.o.f.} = 2.9/4), \quad (9.25b)$$

$$\alpha_s(M_Z^2) = 0.1185 \pm 0.0013 \ \ (\text{w/o DIS results};\ \chi^2_0/\text{d.o.f.} = 2.0/4), \quad (9.25c)$$

$$\alpha_s(M_Z^2) = 0.1182 \pm 0.0010 \ \ (\text{w/o } e^+e^- \text{ results};\ \chi^2_0/\text{d.o.f.} = 3.5/4), \quad (9.25d)$$

$$\alpha_s(M_Z^2) = 0.1184 \pm 0.0012 \ \ (\text{w/o hadron collider};\ \chi^2_0/\text{d.o.f.} = 2.4/4) \text{ and} \quad (9.25e)$$

$$\alpha_s(M_Z^2) = 0.1180 \pm 0.0010 \ \ (\text{w/o e.w. precision fit};\ \chi^2_0/\text{d.o.f.} = 3.4/4). \quad (9.25f)$$

They are well within the uncertainty of the overall world average quoted above. Note, however, that the average *excluding* the lattice result is no longer as close to the value obtained from lattice alone as was the case in the 2013 *Review*, but is now smaller by almost one standard deviation of its assigned uncertainty.

Notwithstanding the many open issues still present within each of the sub-fields summarised in this *Review*, the wealth of available results provides a rather precise and reasonably stable world average value of $\alpha_s(M_Z^2)$, as well as a clear signature and proof of the energy dependence of α_s, in full agreement with the QCD prediction of Asymptotic Freedom. This is demonstrated in Fig. 9.3, where results of $\alpha_s(Q^2)$ obtained at discrete energy scales Q, now also including those based just on NLO QCD, are summarized. Thanks to the results from the Tevatron and from the LHC, the energy scales at which α_s is determined now extend up to more than 1 TeV$^\diamondsuit$.

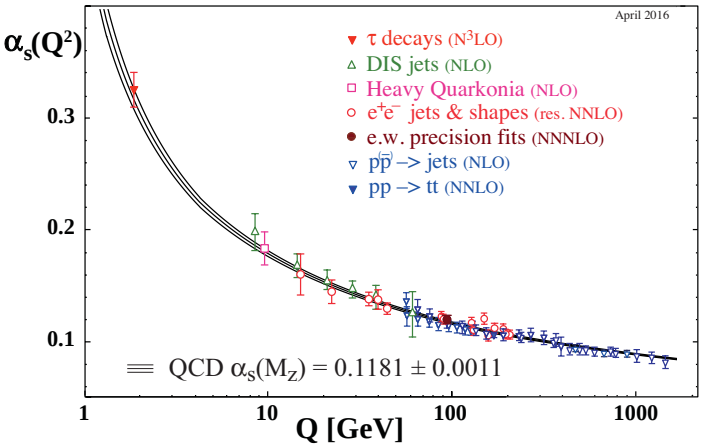

Figure 9.3: Summary of measurements of α_s as a function of the energy scale Q. The respective degree of QCD perturbation theory used in the extraction of α_s is indicated in brackets (NLO: next-to-leading order; NNLO: next-to-next-to leading order; res. NNLO: NNLO matched with resummed next-to-leading logs; NNNLO (N^{3}LO): next-to-NNLO).

Lüscher, M. d'Onofrio, S. Sharpe, R. Sommer, G. Sterman, D. Treille, N. Varelas, M. Wobisch, W.M. Yao, C.P. Yuan, and G. Zanderighi for discussions, suggestions and comments on this and earlier versions of this *Review*.

$^\diamondsuit$ We note, however, that in many such studies, like those based on exclusive states of jet multiplicities, the relevant energy scale of the measurement is not uniquely defined. For instance, in studies of the ratio of 3- to 2-jet cross sections at the LHC, the relevant scale was taken to be the average of the transverse momenta of the two leading jets [381], but could alternatively have been chosen to be the transverse momentum of the 3^{rd} jet.

10. ELECTROWEAK MODEL AND CONSTRAINTS ON NEW PHYSICS

Revised November 2015 by J. Erler (U. Mexico) and A. Freitas (Pittsburgh U.).

10.1. Introduction

The standard model of the electroweak interactions (SM) [1] is based on the gauge group SU(2) × U(1), with gauge bosons W^i_μ, $i = 1, 2, 3$, and B_μ for the SU(2) and U(1) factors, respectively, and the corresponding gauge coupling constants g and g'. The left-handed fermion fields of the $i^{\rm th}$ fermion family transform as doublets $\Psi_i = \begin{pmatrix} \nu_i \\ \ell_i^- \end{pmatrix}$ and $\begin{pmatrix} u_i \\ d'_i \end{pmatrix}$ under SU(2), where $d'_i \equiv \sum_j V_{ij}\, d_j$, and V is the Cabibbo-Kobayashi-Maskawa mixing matrix. [Constraints on V and tests of universality are discussed in Ref. 2 and in the Section on "The CKM Quark-Mixing Matrix". The extension of the formalism to allow an analogous leptonic mixing matrix is discussed in the Section on "Neutrino Mass, Mixing, and Oscillations".] The right-handed fields are SU(2) singlets. From Higgs and electroweak precision data it is known that there are precisely three sequential fermion families.

A complex scalar Higgs doublet, $\phi \equiv \begin{pmatrix} \phi^+ \\ \phi^0 \end{pmatrix}$, is added to the model for mass generation through spontaneous symmetry breaking with potential* given by,

$$V(\phi) = \mu^2 \phi^\dagger \phi + \frac{\lambda^2}{2} (\phi^\dagger \phi)^2. \tag{10.1}$$

For μ^2 negative, ϕ develops a vacuum expectation value, $v/\sqrt{2} = \mu/\lambda$, where $v \approx 246$ GeV, breaking part of the electroweak (EW) gauge symmetry, after which only one neutral Higgs scalar, H, remains in the physical particle spectrum. In non-minimal models there are additional charged and neutral scalar Higgs particles [3].

After the symmetry breaking the Lagrangian for the fermion fields, ψ_i, is

$$\begin{aligned} \mathscr{L}_F = & \sum_i \overline{\psi}_i \left(i\,\partial\!\!\!/ - m_i - \frac{m_i H}{v} \right) \psi_i \\ & - \frac{g}{2\sqrt{2}} \sum_i \overline{\Psi}_i\, \gamma^\mu\, (1-\gamma^5) (T^+\, W^+_\mu + T^-\, W^-_\mu)\, \Psi_i \\ & - e \sum_i Q_i\, \overline{\psi}_i\, \gamma^\mu\, \psi_i\, A_\mu \\ & - \frac{g}{2\cos\theta_W} \sum_i \overline{\psi}_i\, \gamma^\mu (g^i_V - g^i_A \gamma^5)\, \psi_i\, Z_\mu\ . \end{aligned} \tag{10.2}$$

Here $\theta_W \equiv \tan^{-1}(g'/g)$ is the weak angle; $e = g \sin\theta_W$ is the positron electric charge; and $A \equiv B\cos\theta_W + W^3 \sin\theta_W$ is the photon field (γ). $W^\pm \equiv (W^1 \mp i W^2)/\sqrt{2}$ and $Z \equiv -B \sin\theta_W + W^3 \cos\theta_W$ are the charged and neutral weak boson fields, respectively. The Yukawa coupling of H to ψ_i in the first term in $\mathscr{L}_F$, which is flavor diagonal in the minimal model, is $g m_i/2M_W$. The boson masses in the EW sector are given (at tree level, *i.e.*, to lowest order in perturbation theory) by,

$$M_H = \lambda\, v, \tag{10.3a}$$

$$M_W = \frac{1}{2}\, g\, v = \frac{e\, v}{2 \sin\theta_W}, \tag{10.3b}$$

$$M_Z = \frac{1}{2} \sqrt{g^2 + g'^2}\, v = \frac{e\, v}{2 \sin\theta_W \cos\theta_W} = \frac{M_W}{\cos\theta_W}, \tag{10.3c}$$

$$M_\gamma = 0. \tag{10.3d}$$

* There is no generally accepted convention to write the quartic term. Our numerical coefficient simplifies Eq. (10.3*a*) below and the squared coupling preserves the relation between the number of external legs and the power counting of couplings at a given loop order. This structure also naturally emerges from physics beyond the SM, such as supersymmetry.

The second term in $\mathscr{L}_F$ represents the charged-current weak interaction [4–7], where T^+ and T^- are the weak isospin raising and lowering operators. For example, the coupling of a W to an electron and a neutrino is

$$-\frac{e}{2\sqrt{2}\sin\theta_W} \left[W^-_\mu\, \overline{e}\, \gamma^\mu (1-\gamma^5) \nu + W^+_\mu\, \overline{\nu}\, \gamma^\mu\, (1-\gamma^5) e \right]. \tag{10.4}$$

For momenta small compared to M_W, this term gives rise to the effective four-fermion interaction with the Fermi constant given by $G_F/\sqrt{2} = 1/2v^2 = g^2/8M_W^2$. CP violation is incorporated into the EW model by a single observable phase in V_{ij}.

The third term in $\mathscr{L}_F$ describes electromagnetic interactions (QED) [8,9], and the last is the weak neutral-current interaction [5–7]. The vector and axial-vector couplings are

$$g^i_V \equiv t_{3L}(i) - 2 Q_i \sin^2\theta_W, \tag{10.5a}$$

$$g^i_A \equiv t_{3L}(i), \tag{10.5b}$$

where $t_{3L}(i)$ is the weak isospin of fermion i ($+1/2$ for u_i and ν_i; $-1/2$ for d_i and e_i) and Q_i is the charge of ψ_i in units of e.

The first term in Eq. (10.2) also gives rise to fermion masses, and in the presence of right-handed neutrinos to Dirac neutrino masses. The possibility of Majorana masses is discussed in the Section on "Neutrino Mass, Mixing, and Oscillations".

10.2. Renormalization and radiative corrections

In addition to the Higgs boson mass, M_H, the fermion masses and mixings, and the strong coupling constant, α_s, the SM has three parameters. The set with the smallest experimental errors contains the Z mass**, the Fermi constant, and the fine structure constant, which will be discussed in turn (if not stated otherwise, the numerical values quoted in Sec. 10.2–10.5 correspond to the main fit result in Table 10.6):

The Z boson mass, $M_Z = 91.1876 \pm 0.0021$ GeV, has been determined from the Z lineshape scan at LEP 1 [10]. This value of M_Z corresponds to a definition based on a Breit-Wigner shape with an energy-dependent width (see the Section on "The Z Boson" in the Gauge and Higgs Boson Particle Listings of this *Review*).

The Fermi constant, $G_F = 1.1663787(6) \times 10^{-5}$ GeV^{-2}, is derived from the muon lifetime formula***,

$$\frac{\hbar}{\tau_\mu} = \frac{G_F^2 m_\mu^5}{192\pi^3}\, F(\rho) \left[1 + H_1(\rho) \frac{\widehat{\alpha}(m_\mu)}{\pi} + H_2(\rho) \frac{\widehat{\alpha}^2(m_\mu)}{\pi^2} \right], \tag{10.6}$$

where $\rho = m_e^2/m_\mu^2$, and where

$$F(\rho) = 1 - 8\rho + 8\rho^3 - \rho^4 - 12\rho^2 \ln\rho = 0.99981295, \tag{10.7a}$$

$$\begin{aligned} H_1(\rho) = & \frac{25}{8} - \frac{\pi^2}{2} - \left(9 + 4\pi^2 + 12 \ln\rho \right) \rho \\ & + 16\pi^2 \rho^{3/2} + \mathcal{O}(\rho^2) = -1.80793, \end{aligned} \tag{10.7b}$$

$$\begin{aligned} H_2(\rho) = & \frac{156815}{5184} - \frac{518}{81}\pi^2 - \frac{895}{36}\zeta(3) + \frac{67}{720}\pi^4 + \frac{53}{6}\pi^2 \ln 2 \\ & - (0.042 \pm 0.002)_{\rm had} - \frac{5}{4}\pi^2 \sqrt{\rho} + \mathcal{O}(\rho) = 6.64, \end{aligned} \tag{10.7c}$$

$$\widehat{\alpha}(m_\mu)^{-1} = \alpha^{-1} + \frac{1}{3\pi} \ln\rho + \mathcal{O}(\alpha) = 135.901 \tag{10.7d}$$

** We emphasize that in the fits described in Sec. 10.6 and Sec. 10.7 the values of the SM parameters are affected by all observables that depend on them. This is of no practical consequence for α and G_F, however, since they are very precisely known.

*** In the spirit of the Fermi theory, we incorporated the small propagator correction, $3/5\ m_\mu^2/M_W^2$, into Δr (see below). This is also the convention adopted by the MuLan collaboration [11]. While this breaks with historical consistency, the numerical difference was negligible in the past.

H_1 and H_2 capture the QED corrections within the Fermi model. The results for $\rho = 0$ have been obtained in Refs. 12 and 13, respectively, where the term in parentheses is from the hadronic vacuum polarization [13]. The mass corrections to H_1 have been known for some time [14], while those to H_2 are more recent [15]. Notice the term linear in m_e whose appearance was unforeseen and can be traced to the use of the muon pole mass in the prefactor [15]. The remaining uncertainty in G_F is experimental and has recently been reduced by an order of magnitude by the MuLan collaboration [11] at the PSI.

The experimental determination of the fine structure constant, $\alpha = 1/137.035999139(31)$, is currently dominated by the $e^{\pm}$ anomalous magnetic moment [16]. In most EW renormalization schemes, it is convenient to define a running α dependent on the energy scale of the process, with $\alpha^{-1} \sim 137$ appropriate at very low energy, *i.e.* close to the Thomson limit. (The running has also been observed [17] directly.) For scales above a few hundred MeV this introduces an uncertainty due to the low energy hadronic contribution to vacuum polarization. In the modified minimal subtraction ($\overline{\rm MS}$) scheme [18] (used for this *Review*), and with $\alpha_s(M_Z) = 0.1182 \pm 0.0016$ we have $\widehat{\alpha}(m_\tau)^{-1} = 133.471 \pm 0.016$ and $\widehat{\alpha}(M_Z)^{-1} = 127.950 \pm 0.017$. (In this Section we denote quantities defined in the modified minimal subtraction ($\overline{\rm MS}$) scheme by a caret; the exception is the strong coupling constant, α_s, which will always correspond to the $\overline{\rm MS}$ definition and where the caret will be dropped.) The latter corresponds to a quark sector contribution (without the top) to the conventional (on-shell) QED coupling, $\alpha(M_Z) = \dfrac{\alpha}{1 - \Delta\alpha(M_Z)}$, of $\Delta\alpha^{(5)}_{\rm had}(M_Z) = 0.02764 \pm 0.00013$. These values are updated from Ref. 19 with $\Delta\alpha^{(5)}_{\rm had}(M_Z)$ moved downwards and its uncertainty reduced (partly due to a more precise charm quark mass). Its correlation with the $\mu^{\pm}$ anomalous magnetic moment (see Sec. 10.5), as well as the non-linear α_s dependence of $\widehat{\alpha}(M_Z)$ and the resulting correlation with the input variable α_s, are fully taken into account in the fits. This is done by using as actual input (fit constraint) instead of $\Delta\alpha^{(5)}_{\rm had}(M_Z)$ the low energy contribution by the three light quarks, $\Delta\alpha^{(3)}_{\rm had}(2.0\ {\rm GeV}) = (58.04 \pm 1.10) \times 10^{-4}$ [20], and by calculating the perturbative and heavy quark contributions to $\widehat{\alpha}(M_Z)$ in each call of the fits according to Ref. 19. Part of the uncertainty ($\pm 0.92 \times 10^{-4}$) is from e^+e^- annihilation data below 1.8 GeV and τ decay data (including uncertainties from isospin breaking effects), but uncalculated higher order perturbative ($\pm 0.41 \times 10^{-4}$) and non-perturbative ($\pm 0.44 \times 10^{-4}$) QCD corrections and the $\overline{\rm MS}$ quark mass values (see below) also contribute. Various evaluations of $\Delta\alpha^{(5)}_{\rm had}$ are summarized in Table 10.1 where the relation[†] between the $\overline{\rm MS}$ and on-shell definitions (obtained using Ref. 23) is given by,

$$\Delta\widehat{\alpha}(M_Z) - \Delta\alpha(M_Z) = \frac{\alpha}{\pi}\left[\left(\frac{100}{27} - \frac{1}{6} - \frac{7}{4}\ln\frac{M_Z^2}{M_W^2}\right) + \frac{\alpha_s(M_Z)}{\pi}\left(\frac{605}{108} - \frac{44}{9}\zeta(3)\right) + \frac{\alpha_s^2(M_Z)}{\pi^2}\left(\frac{976481}{23328} - \frac{253}{36}\zeta(2) - \frac{781}{18}\zeta(3) + \frac{275}{27}\zeta(5)\right)\right] = 0.007127(2), \quad (10.8)$$

and where the first entry of the lowest order term is from fermions and the other two are from $W^{\pm}$ loops, which are usually excluded from the on-shell definition. The most recent results typically assume the validity of perturbative QCD (PQCD) at scales of 1.8 GeV or above, and are in reasonable agreement with each other. In regions where PQCD is not trusted, one can use $e^+e^- \to$ hadrons cross-section data and τ decay spectral functions [31], where the latter derive from OPAL [34], CLEO [35], ALEPH [36], and Belle [37]. The dominant $e^+e^- \to \pi^+\pi^-$ cross-section was measured with the CMD-2 [38] and SND [39] detectors at the VEPP-2M e^+e^- collider at Novosibirsk. As an alternative to cross-section scans, one can use the high statistics radiative return events at e^+e^- accelerators operating at resonances such as the Φ or the $\Upsilon(4S)$. The method [40] is systematics limited but dominates over the Novosibirsk data throughout. The BaBar collaboration [41] studied multi-hadron events radiatively returned from the $\Upsilon(4S)$, reconstructing the radiated photon and normalizing to $\mu^{\pm}\gamma$ final states. Their result is higher compared to VEPP-2M, while the shape and smaller overall cross-section from the $\pi^+\pi^-$ radiative return results from the Φ obtained by the KLOE collaboration [42] differ significantly from what is observed by BaBar. The discrepancy originates from the kinematic region $\sqrt{s} \gtrsim 0.6$ GeV, and is most pronounced for $\sqrt{s} \gtrsim 0.85$ GeV. All measurements including older data [43] and multi-hadron final states (there are also discrepancies in the $e^+e^- \to 2\pi^+2\pi^-$ channel [31]) are accounted for and corrections have been applied for missing channels. Further improvement of this dominant theoretical uncertainty in the interpretation of precision data will require better measurements of the cross-section for $e^+e^- \to$ hadrons below the charmonium resonances including multi-pion and other final states. To improve the precisions in $\widehat{m}_c(\widehat{m}_c)$ and $\widehat{m}_b(\widehat{m}_b)$ it would help to remeasure the threshold regions of the heavy quarks as well as the electronic decay widths of the narrow $c\bar{c}$ and $b\bar{b}$ resonances.

Table 10.1: Evaluations of the on-shell $\Delta\alpha^{(5)}_{\rm had}(M_Z)$ by different groups (for a more complete list of evaluations see the 2012 edition of this *Review*). For better comparison we adjusted central values and errors to correspond to a common and fixed value of $\alpha_s(M_Z) = 0.120$. References quoting results without the top quark decoupled are converted to the five flavor definition. Ref. [28] uses $\Lambda_{\rm QCD} = 380 \pm 60$ MeV; for the conversion we assumed $\alpha_s(M_Z) = 0.118 \pm 0.003$.

Further free parameters entering into Eq. (10.2) are the quark and lepton masses, where m_i is the mass of the $i^{\rm th}$ fermion ψ_i. For the light quarks, as described in the note on "Quark Masses" in the Quark Listings, $\widehat{m}_u = 2.3^{+0.7}_{-0.5}$ MeV, $\widehat{m}_d = 4.8^{+0.5}_{-0.3}$ MeV, and $\widehat{m}_s = 95 \pm 5$ MeV. These are running $\overline{\rm MS}$ masses evaluated at the scale $\mu = 2$ GeV. For the heavier quarks we use QCD sum rule [44] constraints [45] and recalculate their masses in each call of our fits to account for their direct α_s dependence. We find[¶],

[†] In practice, $\alpha(M_Z)$ is directly evaluated in the $\overline{\rm MS}$ scheme using the FORTRAN package GAPP [21], including the QED contributions of both leptons and quarks. The leptonic three-loop contribution in the on-shell scheme has been obtained in Ref. 22.

[¶] Other authors [46] advocate to evaluate and quote $\widehat{m}_c(\mu = 3\ {\rm GeV})$ instead. We use $\widehat{m}_c(\mu = \widehat{m}_c)$ because in the global analysis it is convenient to nullify any explicitly m_c dependent logarithms. Note also that

$\widehat{m}_c(\mu=\widehat{m}_c) = 1.265^{+0.030}_{-0.038}$ GeV and $\widehat{m}_b(\mu=\widehat{m}_b) = 4.199 \pm 0.023$ GeV, with a correlation of 23%.

There are two recent combinations of measurements of the top quark "pole" mass (the quotation marks are a reminder that the experiments do not strictly measure the pole mass and that quarks do not form asymptotic states), all of them utilizing kinematic reconstruction. The most recent result, which we will use as our default input value, $m_t = 173.34 \pm 0.37_{\,\rm stat.} \pm 0.52_{\,\rm syst.}$ GeV [48], is internal to the Tevatron and combines 12 individual CDF and DØ measurements including Run I and other less precise determinations. The other one, $m_t = 173.34 \pm 0.27_{\,\rm stat.} \pm 0.71_{\,\rm syst.}$ GeV [49], is a Tevatron/LHC combination based on a selection of 11 individual results. The above averages differ slightly from the value, $m_t = 173.21 \pm 0.51_{\,\rm stat.} \pm 0.71_{\,\rm syst.}$ GeV, which appears in the top quark Listings in this *Review* and which is based exclusively on published Tevatron results. We are working, however, with $\overline{\rm MS}$ masses in all expressions to minimize theoretical uncertainties. Such a short distance mass definition (unlike the pole mass) is free from non-perturbative and renormalon [50] uncertainties. We therefore convert to the top quark $\overline{\rm MS}$ mass using the three-loop formula [51]. (Very recently, the four-loop result has been obtained in Ref. 52.) This introduces an additional uncertainty which we estimate to 0.5 GeV (the size of the three-loop term) and add in quadrature to the experimental pole mass error. This is convenient because we use the pole mass as an external constraint while fitting to the $\overline{\rm MS}$ mass. We are assuming that the kinematic mass extracted from the collider events corresponds within this uncertainty to the pole mass. In summary, we will use the fit constraint,

$$m_t = 173.34 \pm 0.64_{\,\rm exp.} \pm 0.5_{\,\rm QCD}\ \text{GeV} = 173.34 \pm 0.81\ \text{GeV}. \quad (10.9)$$

While there seems to be perfect agreement between all these averages, we observe a 2.6 σ deviation (or more in case of correlated systematics) between the two most precise determinations, 174.98 ± 0.76 GeV [53] (by the DØ Collaboration) and 172.22 ± 0.73 GeV [54] (by the CMS Collaboration), both from the lepton + jets channels [55]. For more details, see the Section on "The Top Quark" and the Quarks Listings in this *Review*.

The observables $\sin^2\theta_W$ and M_W can be calculated from M_Z, $\widehat{\alpha}(M_Z)$, and G_F, when values for m_t and M_H are given, or conversely, M_H can be constrained by $\sin^2\theta_W$ and M_W. The value of $\sin^2\theta_W$ is extracted from neutral-current processes (see Sec. 10.3) and Z pole observables (see Sec. 10.4) and depends on the renormalization prescription. There are a number of popular schemes [56–62] leading to values which differ by small factors depending on m_t and M_H. The notation for these schemes is shown in Table 10.2.

Table 10.2: Notations used to indicate the various schemes discussed in the text. Each definition of $\sin^2\theta_W$ leads to values that differ by small factors depending on m_t and M_H. Numerical values and the uncertainties induced by the imperfectly known SM parameters are also given for illustration.

Scheme	Notation	Value	Parametric uncertainty
On-shell	s^2_W	0.22336	±0.00010
$\overline{\rm MS}$	$\widehat{s}^2_Z$	0.23129	±0.00005
$\overline{\rm MS}$ ND	$\widehat{s}^2_{\rm ND}$	0.23148	±0.00005
$\overline{\rm MS}$	$\widehat{s}^2_0$	0.23865	±0.00008
Effective angle	$\overline{s}^2_\ell$	0.23152	±0.00005

our uncertainty for m_c (and to a lesser degree for m_b) is larger than in Refs. 46 and 47, for example. The reason is that we determine the continuum contribution for charm pair production using only resonance data and theoretical consistency across various sum rule moments, and then use any difference to the experimental continuum data as an additional uncertainty. We also include an uncertainty for the condensate terms which grows rapidly for higher moments in the sum rule analysis.

(*i*) The on-shell scheme [56] promotes the tree-level formula $\sin^2\theta_W = 1 - M^2_W/M^2_Z$ to a definition of the renormalized $\sin^2\theta_W$ to all orders in perturbation theory, *i.e.*, $\sin^2\theta_W \to s^2_W \equiv 1 - M^2_W/M^2_Z$:

$$M_W = \frac{A_0}{s_W(1-\Delta r)^{1/2}}\ , \qquad M_Z = \frac{M_W}{c_W}\ , \quad (10.10)$$

where $c_W \equiv \cos\theta_W$, $A_0 = (\pi\alpha/\sqrt{2}G_F)^{1/2} = 37.28039(1)$ GeV, and Δr includes the radiative corrections relating α, $\alpha(M_Z)$, G_F, M_W, and M_Z. One finds $\Delta r \sim \Delta r_0 - \rho_t/\tan^2\theta_W$, where $\Delta r_0 = 1 - \alpha/\widehat{\alpha}(M_Z) = 0.06630(13)$ is due to the running of α, and $\rho_t = 3G_F m^2_t/8\sqrt{2}\pi^2 = 0.00940\,(m_t/173.34\ \text{GeV})^2$ represents the dominant (quadratic) m_t dependence. There are additional contributions to Δr from bosonic loops, including those which depend logarithmically on M_H and higher-order corrections[$$]. One has $\Delta r = 0.03648 \mp 0.00028 \pm 0.00013$, where the first uncertainty is from m_t and the second is from $\alpha(M_Z)$. Thus the value of s^2_W extracted from M_Z includes an uncertainty (∓ 0.00009) from the currently allowed range of m_t. This scheme is simple conceptually. However, the relatively large ($\sim 3\%$) correction from ρ_t causes large spurious contributions in higher orders.

s^2_W depends not only on the gauge couplings but also on the spontaneous-symmetry breaking, and it is awkward in the presence of any extension of the SM which perturbs the value of M_Z (or M_W). Other definitions are motivated by the tree-level coupling constant definition $\theta_W = \tan^{-1}(g'/g)$:

(*ii*) In particular, the modified minimal subtraction ($\overline{\rm MS}$) scheme introduces the quantity $\sin^2\widehat{\theta}_W(\mu) \equiv \widehat{g}'^2(\mu)/\big[\widehat{g}^{\,2}(\mu) + \widehat{g}'^2(\mu)\big]$, where the couplings $\widehat{g}$ and $\widehat{g}'$ are defined by modified minimal subtraction and the scale μ is conveniently chosen to be M_Z for many EW processes. The value of $\widehat{s}^{\,2}_Z = \sin^2\widehat{\theta}_W(M_Z)$ extracted from M_Z is less sensitive than s^2_W to m_t (by a factor of $\tan^2\theta_W$), and is less sensitive to most types of new physics. It is also very useful for comparing with the predictions of grand unification. There are actually several variant definitions of $\sin^2\widehat{\theta}_W(M_Z)$, differing according to whether or how finite $\alpha\ln(m_t/M_Z)$ terms are decoupled (subtracted from the couplings). One cannot entirely decouple the $\alpha\ln(m_t/M_Z)$ terms from all EW quantities because $m_t \gg m_b$ breaks SU(2) symmetry. The scheme that will be adopted here decouples the $\alpha\ln(m_t/M_Z)$ terms from the γ–Z mixing [18,57], essentially eliminating any $\ln(m_t/M_Z)$ dependence in the formulae for asymmetries at the Z pole when written in terms of $\widehat{s}^{\,2}_Z$. (A similar definition is used for $\widehat{\alpha}$.) The on-shell and $\overline{\rm MS}$ definitions are related by

$$\widehat{s}^{\,2}_Z = c\,(m_t, M_H) s^2_W = (1.0355 \pm 0.0003) s^2_W\ . \quad (10.11)$$

The quadratic m_t dependence is given by $c \sim 1 + \rho_t/\tan^2\theta_W$. The expressions for M_W and M_Z in the $\overline{\rm MS}$ scheme are

$$M_W = \frac{A_0}{\widehat{s}_Z(1-\Delta\widehat{r}_W)^{1/2}}\ , \qquad M_Z = \frac{M_W}{\widehat{\rho}^{\,1/2}\,\widehat{c}_Z}\ , \quad (10.12)$$

and one predicts $\Delta\widehat{r}_W = 0.06952 \pm 0.00013$. $\Delta\widehat{r}_W$ has no quadratic m_t dependence, because shifts in M_W are absorbed into the observed G_F, so that the error in $\Delta\widehat{r}_W$ is almost entirely due to $\Delta r_0 = 1 - \alpha/\widehat{\alpha}(M_Z)$. The quadratic m_t dependence has been shifted into $\widehat{\rho} \sim 1 + \rho_t$, where including bosonic loops, $\widehat{\rho} = 1.01032 \pm 0.00009$.

(*iii*) A variant $\overline{\rm MS}$ quantity $\widehat{s}^{\,2}_{\rm ND}$ (used in the 1992 edition of this *Review*) does not decouple the $\alpha\ln(m_t/M_Z)$ terms [58]. It is related to $\widehat{s}^{\,2}_Z$ by

$$\widehat{s}^{\,2}_Z = \widehat{s}^{\,2}_{\rm ND}/\Big(1 + \frac{\widehat{\alpha}}{\pi}d\Big), \quad (10.13a)$$

$$d = \frac{1}{3}\Big(\frac{1}{\widehat{s}^{\,2}} - \frac{8}{3}\Big)\left[(1+\frac{\alpha_s}{\pi})\ln\frac{m_t}{M_Z} - \frac{15\alpha_s}{8\pi}\right], \quad (10.13b)$$

[$$] All explicit numbers quoted here and below include the two- and three-loop corrections described near the end of Sec. 10.2.

Thus, $\widehat{s}^2_Z - \widehat{s}^2_{\rm ND} \approx -0.0002$.

(*iv*) Some of the low-energy experiments discussed in the next section are sensitive to the weak mixing angle at almost vanishing momentum transfer (for a review, see Ref. 59). Thus, Table 10.2 also includes $\widehat{s}^2_0 \equiv \sin^2\widehat{\theta}_W(0)$.

(*v*) Yet another definition, the effective angle [60–62] $\overline{s}^2_f = \sin\theta^f_{\rm eff}$ for the Z vector coupling to fermion f, is based on Z pole observables and described in Sec. 10.4.

Experiments are at such level of precision that complete one-loop, dominant two-loop, and partial three and four-loop radiative corrections must be applied. For neutral-current and Z pole processes, these corrections are conveniently divided into two classes:

1. QED diagrams involving the emission of real photons or the exchange of virtual photons in loops, but not including vacuum polarization diagrams. These graphs often yield finite and gauge-invariant contributions to observable processes. However, they are dependent on energies, experimental cuts, *etc.*, and must be calculated individually for each experiment.

2. EW corrections, including $\gamma\gamma$, γZ, ZZ, and WW vacuum polarization diagrams, as well as vertex corrections, box graphs, *etc.*, involving virtual W and Z bosons. The one-loop corrections are included for all processes, and many two-loop corrections are also important. In particular, two-loop corrections involving the top quark modify ρ_t in $\widehat{\rho}$, Δr, and elsewhere by

$$\rho_t \to \rho_t[1 + R(M_H, m_t)\rho_t/3]. \tag{10.14}$$

$R(M_H, m_t)$ can be described as an expansion in M^2_Z/m^2_t, for which the leading m^4_t/M^4_Z [63] and next-to-leading m^2_t/M^2_Z [64] terms are known. The complete two-loop calculation of Δr (without further approximation) has been performed in Refs. 65 and 66 for fermionic and purely bosonic diagrams, respectively. Similarly, the EW two-loop calculation for the relation between $\overline{s}^2_\ell$ and s^2_W is complete [67,68]. Very recently, Ref. 69 obtained the $\overline{\rm MS}$ quantities $\Delta\widehat{r}_W$ and $\widehat{\rho}$ to two-loop accuracy, confirming the prediction of M_W in the on-shell scheme from Refs. 66 and 70 within about 4 MeV.

Mixed QCD-EW contributions to gauge boson self-energies of order $\alpha\alpha_s m^2_t$ [71], $\alpha\alpha^2_s m^2_t$ [72], and $\alpha\alpha^3_s m^2_t$ [73] increase the predicted value of m_t by 6%. This is, however, almost entirely an artifact of using the pole mass definition for m_t. The equivalent corrections when using the $\overline{\rm MS}$ definition $\widehat{m}_t(\widehat{m}_t)$ increase m_t by less than 0.5%. The subleading $\alpha\alpha_s$ corrections [74] are also included. Further three-loop corrections of order $\alpha\alpha^2_s$ [75,76], $\alpha^3 m^6_t$, and $\alpha^2\alpha_s m^4_t$ [77], are rather small. The same is true for $\alpha^3 M^4_H$ [78] corrections unless M_H approaches 1 TeV.

The theoretical uncertainty from unknown higher-order corrections is estimated to amount to 4 MeV for the prediction of M_W [70] and 4.5×10^{-5} for $\overline{s}^2_\ell$ [79].

Throughout this *Review* we utilize EW radiative corrections from the program GAPP [21], which works entirely in the $\overline{\rm MS}$ scheme, and which is independent of the package ZFITTER [62].

10.3. Low energy electroweak observables

In the following we discuss EW precision observables obtained at low momentum transfers [6], *i.e.* $Q^2 \ll M^2_Z$. It is convenient to write the four-fermion interactions relevant to ν-hadron, ν-e, as well as parity violating e-hadron and e-e neutral-current processes in a form that is valid in an arbitrary gauge theory (assuming massless left-handed neutrinos). One has★

$$-\mathscr{L}^{\nu e} = \frac{G_F}{\sqrt{2}}\,\overline{\nu}\gamma_\mu(1-\gamma^5)\nu\;\overline{e}\,\gamma^\mu(g^{\nu e}_{LV} - g^{\nu e}_{LA}\,\gamma^5)e, \tag{10.15}$$

$$-\mathscr{L}^{\nu h} = \frac{G_F}{\sqrt{2}}\,\overline{\nu}\,\gamma_\mu(1-\gamma^5)\nu\sum_q[g^{\nu q}_{LL}\,\overline{q}\,\gamma^\mu(1-\gamma^5)q + g^{\nu q}_{LR}\,\overline{q}\,\gamma^\mu(1+\gamma^5)q], \tag{10.16}$$

$$-\mathscr{L}^{ee} = -\frac{G_F}{\sqrt{2}}\,g^{ee}_{AV}\,\overline{e}\,\gamma_\mu\gamma^5 e\;\overline{e}\,\gamma^\mu e, \tag{10.17}$$

$$-\mathscr{L}^{eh} = -\frac{G_F}{\sqrt{2}}\sum_q\left[g^{eq}_{AV}\,\overline{e}\,\gamma_\mu\gamma^5 e\;\overline{q}\,\gamma^\mu q + g^{eq}_{VA}\,\overline{e}\,\gamma_\mu e\;\overline{q}\;\gamma^\mu\gamma^5 q\right], \tag{10.18}$$

where one must include the charged-current contribution for ν_e-e and $\overline{\nu}_e$-e and the parity-conserving QED contribution for electron scattering.

Table 10.3: SM tree level expressions for the neutral-current parameters for ν-hadron, ν-e, and e^--scattering processes. To obtain the SM values in the last column, the tree level expressions have to be multiplied by the low-energy neutral-current ρ parameter, $\rho_{\rm NC} = 1.00066$, and further vertex and box corrections need to be added as detailed in Ref. 80. The dominant m_t dependence is again given by $\rho_{\rm NC} \sim 1 + \rho_t$.

Quantity	SM tree level	SM value
$g^{\nu_\mu e}_{LV}$	$-\frac{1}{2} + 2\,\widehat{s}^2_0$	-0.0396
$g^{\nu_\mu e}_{LA}$	$-\frac{1}{2}$	-0.5064
$g^{\nu_\mu u}_{LL}$	$\frac{1}{2} - \frac{2}{3}\,\widehat{s}^2_0$	0.3457
$g^{\nu_\mu d}_{LL}$	$-\frac{1}{2} + \frac{1}{3}\,\widehat{s}^2_0$	-0.4288
$g^{\nu_\mu u}_{LR}$	$-\frac{2}{3}\,\widehat{s}^2_0$	-0.1553
$g^{\nu_\mu d}_{LR}$	$\frac{1}{3}\,\widehat{s}^2_0$	0.0777
g^{ee}_{AV}	$\frac{1}{2} - 2\,\widehat{s}^2_0$	0.0225
g^{eu}_{AV}	$-\frac{1}{2} + \frac{4}{3}\,\widehat{s}^2_0$	-0.1887
g^{ed}_{AV}	$\frac{1}{2} - \frac{2}{3}\,\widehat{s}^2_0$	0.3419
g^{eu}_{VA}	$-\frac{1}{2} + 2\,\widehat{s}^2_0$	-0.0351
g^{ed}_{VA}	$\frac{1}{2} - 2\,\widehat{s}^2_0$	0.0247

The SM tree level expressions for the four-Fermi couplings are given in Table 10.3. Note that they differ from the respective products of the gauge couplings in Eq. (10.5) in the radiative corrections and in the presence of possible physics beyond the SM.

10.3.1. ***Neutrino scattering*** : For a general review on ν-scattering we refer to Ref. 81 (nonstandard neutrino scattering interactions are surveyed in Ref. 82).

The cross-section in the laboratory system for $\nu_\mu e \to \nu_\mu e$ or $\overline{\nu}_\mu e \to \overline{\nu}_\mu e$ elastic scattering [83] is (in this subsection we drop the redundant index L in the effective neutrino couplings)

$$\frac{d\sigma_{\nu,\bar\nu}}{dy} =$$

★ We use here slightly different definitions (and to avoid confusion also a different notation) for the coefficients of these four-Fermi operators than we did in previous editions of this *Review*. The new couplings [80] are defined in the static limit, $Q^2 \to 0$, with specific radiative corrections included, while others (more experiment specific ones) are assumed to be removed by the experimentalist. They are convenient in that their determinations from very different types of processes can be straightforwardly combined.

$$\frac{G_F^2 m_e E_\nu}{2\pi}\left[(g_V^{\nu e} \pm g_A^{\nu e})^2 + (g_V^{\nu e} \mp g_A^{\nu e})^2(1-y)^2 - (g_V^{\nu e 2} - g_A^{\nu e 2})\frac{y\, m_e}{E_\nu}\right], \tag{10.19}$$

where the upper (lower) sign refers to $\nu_\mu(\overline{\nu}_\mu)$, and $y \equiv T_e/E_\nu$ (which runs from 0 to $(1 + m_e/2E_\nu)^{-1}$) is the ratio of the kinetic energy of the recoil electron to the incident ν or $\overline{\nu}$ energy. For $E_\nu \gg m_e$ this yields a total cross-section

$$\sigma = \frac{G_F^2 m_e E_\nu}{2\pi}\left[(g_V^{\nu e} \pm g_A^{\nu e})^2 + \frac{1}{3}(g_V^{\nu e} \mp g_A^{\nu e})^2\right]. \tag{10.20}$$

The most accurate measurements [83–88] of $\sin^2\theta_W$ from ν-lepton scattering (see Sec. 10.6) are from the ratio $R \equiv \sigma_{\nu_\mu e}/\sigma_{\overline{\nu}_\mu e}$, in which many of the systematic uncertainties cancel. Radiative corrections (other than m_t effects) are small compared to the precision of present experiments and have negligible effect on the extracted $\sin^2\theta_W$. The most precise experiment (CHARM II) [86] determined not only $\sin^2\theta_W$ but $g_{V,A}^{\nu e}$ as well, which are shown in Fig. 10.1. The cross-sections for ν_e-e and $\overline{\nu}_e$-e may be obtained from Eq. (10.19) by replacing $g_{V,A}^{\nu e}$ by $g_{V,A}^{\nu e} + 1$, where the 1 is due to the charged-current contribution.

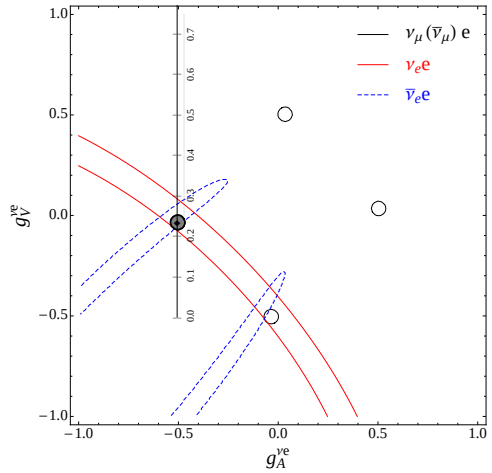

Figure 10.1: Allowed contours in $g_A^{\nu e}$ *vs.* $g_V^{\nu e}$ from neutrino-electron scattering and the SM prediction as a function of $\widehat{s}^2_Z$. (The SM best fit value $\widehat{s}^2_Z = 0.23129$ is also indicated.) The $\nu_e e$ [87] and $\overline{\nu}_e e$ [88] constraints are at 1 σ, while each of the four equivalent $\nu_\mu(\overline{\nu}_\mu)e$ [83–86] solutions ($g_{V,A} \to -g_{V,A}$ and $g_{V,A} \to g_{A,V}$) are at the 90% C.L. The global best fit region (shaded) almost exactly coincides with the corresponding $\nu_\mu(\overline{\nu}_\mu)e$ region. The solution near $g_A = 0, g_V = -0.5$ is eliminated by $e^+e^- \to \ell^+\ell^-$ data under the weak additional assumption that the neutral current is dominated by the exchange of a single Z boson.

A precise determination of the on-shell s^2_W, which depends only very weakly on m_t and M_H, is obtained from deep inelastic scattering (DIS) of neutrinos from (approximately) isoscalar targets [89]. The ratio $R_\nu \equiv \sigma_{\nu N}^{NC}/\sigma_{\nu N}^{CC}$ of neutral-to-charged-current cross-sections has been measured to 1% accuracy by CDHS [90] and CHARM [91] at CERN. CCFR [92] at Fermilab has obtained an even more precise result, so it is important to obtain theoretical expressions for R_ν and $R_{\overline{\nu}} \equiv \sigma_{\overline{\nu}N}^{NC}/\sigma_{\overline{\nu}N}^{CC}$ to comparable accuracy. Fortunately, many of the uncertainties from the strong interactions and neutrino spectra cancel in the ratio. A large theoretical uncertainty is associated with the c-threshold, which mainly affects σ^{CC}. Using the slow rescaling prescription [93] the central value of $\sin^2\theta_W$ from CCFR varies as $0.0111(m_c/\text{GeV} - 1.31)$, where m_c is the effective mass which is numerically close to the $\overline{\text{MS}}$ mass $\widehat{m}_c(\widehat{m}_c)$, but their exact relation is unknown at higher orders. For $m_c = 1.31 \pm 0.24$ GeV (determined from ν-induced dimuon production [94]) this contributes ± 0.003 to the total uncertainty $\Delta\sin^2\theta_W \sim \pm 0.004$. (The experimental uncertainty is also ± 0.003.) This uncertainty largely cancels, however, in the Paschos-Wolfenstein ratio [95],

$$R^- = \frac{\sigma_{\nu N}^{NC} - \sigma_{\overline{\nu}N}^{NC}}{\sigma_{\nu N}^{CC} - \sigma_{\overline{\nu}N}^{CC}}\,. \tag{10.21}$$

It was measured by Fermilab's NuTeV collaboration [96] for the first time, and required a high-intensity and high-energy anti-neutrino beam.

A simple zero$^{\text{th}}$-order approximation is

$$R_\nu = g_L^2 + g_R^2 r, \quad R_{\overline{\nu}} = g_L^2 + \frac{g_R^2}{r}, \quad R^- = g_L^2 - g_R^2, \tag{10.22}$$

where

$$g_L^2 \equiv (g_{LL}^{\nu_\mu u})^2 + (g_{LL}^{\nu_\mu d})^2 \approx \frac{1}{2} - \sin^2\theta_W + \frac{5}{9}\sin^4\theta_W, \tag{10.23a}$$

$$g_R^2 \equiv (g_{LR}^{\nu_\mu u})^2 + (g_{LR}^{\nu_\mu d})^2 \approx \frac{5}{9}\sin^4\theta_W, \tag{10.23b}$$

and $r \equiv \sigma_{\overline{\nu}N}^{CC}/\sigma_{\nu N}^{CC}$ is the ratio of $\overline{\nu}$ to ν charged-current cross-sections, which can be measured directly. [In the simple parton model, ignoring hadron energy cuts, $r \approx (\frac{1}{3} + \epsilon)/(1 + \frac{1}{3}\epsilon)$, where $\epsilon \sim 0.125$ is the ratio of the fraction of the nucleon's momentum carried by anti-quarks to that carried by quarks.] In practice, Eq. (10.22) must be corrected for quark mixing, quark sea effects, c-quark threshold effects, non-isoscalarity, W–Z propagator differences, the finite muon mass, QED and EW radiative corrections. Details of the neutrino spectra, experimental cuts, x and Q^2 dependence of structure functions, and longitudinal structure functions enter only at the level of these corrections and therefore lead to very small uncertainties. CCFR quotes $s^2_W = 0.2236 \pm 0.0041$ for $(m_t, M_H) = (175, 150)$ GeV with very little sensitivity to (m_t, M_H).

The NuTeV collaboration found $s^2_W = 0.2277 \pm 0.0016$ (for the same reference values), which was 3.0 σ higher than the SM prediction [96]. The deviation was in g_L^2 (initially 2.7 σ low) while g_R^2 was consistent with the SM. Since then a number of experimental and theoretical developments changed the interpretation of the measured cross-section ratios, affecting the extracted $g^2_{L,R}$ (and thus s^2_W) including their uncertainties and correlation. In the following paragraph we give a semi-quantitative and preliminary discussion of these effects, but we stress that the precise impact of them needs to be evaluated carefully by the collaboration with a new and self-consistent set of PDFs, including new radiative corrections, while simultaneously allowing isospin breaking and asymmetric strange seas. Until the time that such an effort is completed we do not include the νDIS constraints in our default set of fits.

(i) In the original analysis NuTeV worked with a symmetric strange quark sea but subsequently measured [97] the difference between the strange and antistrange momentum distributions, $S^- \equiv \int_0^1 dx\, x[s(x) - \bar{s}(x)] = 0.00196 \pm 0.00143$, from dimuon events utilizing the first complete next-to-leading order QCD description [98] and parton distribution functions (PDFs) according to Ref. 99. (ii) The measured branching ratio for K_{e3} decays enters crucially in the determination of the $\nu_e(\bar{\nu}_e)$ contamination of the $\nu_\mu(\bar{\nu}_\mu)$ beam. This branching ratio has moved from $4.82 \pm 0.06\%$ at the time of the original publication [96] to the current value of $5.07 \pm 0.04\%$, *i.e.* a change by more than 4 σ. This moves s^2_W about one standard deviation further away from the SM prediction while reducing the $\nu_e(\bar{\nu}_e)$ uncertainty. (iii) PDFs seem to violate isospin symmetry at levels much stronger than generally expected [100]. A minimum χ^2 set of PDFs [101] allowing charge symmetry violation for both valence quarks $[d_V^p(x) \neq u_V^n(x)]$ and sea quarks $[\bar{d}^p(x) \neq \bar{u}^n(x)]$ shows a reduction in the NuTeV discrepancy by about 1 σ. But isospin symmetry violating PDFs are currently not well constrained phenomenologically and within uncertainties the NuTeV anomaly could be accounted for in full or conversely made larger [101]. Still, the leading contribution from quark mass differences turns out to be largely model-independent [102] (at least in sign) and a shift, $\delta s^2_W = -0.0015 \pm 0.0003$ [103], has been estimated. (iv) QED splitting

effects also violate isospin symmetry with an effect on s^2_W whose sign (reducing the discrepancy) is model-independent. The corresponding shift of $\delta s^2_W = -0.0011$ has been calculated in Ref. 104 but has a large uncertainty. (v) Nuclear shadowing effects [105] are likely to affect the interpretation of the NuTeV result at some level, but the NuTeV collaboration argues that their data are dominated by values of Q^2 at which nuclear shadowing is expected to be relatively small. However, another nuclear effect, known as the isovector EMC effect [106], is much larger (because it affects all neutrons in the nucleus, not just the excess ones) and model-independently works to reduce the discrepancy. It is estimated to lead to a shift of $\delta s^2_W = -0.0019 \pm 0.0006$ [103]. It would be important to verify and quantify this kind of effect experimentally, *e.g.*, in polarized electron scattering. (vi) The extracted s^2_W may also shift at the level of the quoted uncertainty when analyzed using the most recent QED and EW radiative corrections [107,108], as well as QCD corrections to the structure functions [109]. However, these are scheme-dependent and in order to judge whether they are significant they need to be adapted to the experimental conditions and kinematics of NuTeV, and have to be obtained in terms of observable variables and for the differential cross-sections. In addition, there is the danger of double counting some of the QED splitting effects. (vii) New physics could also affect $g^2_{L,R}$ [110] but it is difficult to convincingly explain the entire effect that way.

10.3.2. ***Parity violation*** : For a review on weak polarized electron scattering we refer to Ref. 111. The SLAC polarized electron-deuteron DIS (eDIS) experiment [112] measured the right-left asymmetry,

$$A = \frac{\sigma_R - \sigma_L}{\sigma_R + \sigma_L} \,, \tag{10.24}$$

where $\sigma_{R,L}$ is the cross-section for the deep-inelastic scattering of a right- or left-handed electron: $e_{R,L}N \to e\mathrm{X}$. In the quark parton model,

$$\frac{A}{Q^2} = a_1 + a_2 \frac{1-(1-y)^2}{1+(1-y)^2} \,, \tag{10.25}$$

where $Q^2 > 0$ is the momentum transfer and y is the fractional energy transfer from the electron to the hadrons. For the deuteron or other isoscalar targets, one has, neglecting the s-quark and anti-quarks,

$$a_1 = \frac{3G_F}{5\sqrt{2}\pi\alpha}\left(g^{eu}_{AV} - \frac{1}{2}g^{ed}_{AV}\right) \approx \frac{3G_F}{5\sqrt{2}\pi\alpha}\left(-\frac{3}{4} + \frac{5}{3}\widehat{s}^2_0\right) \tag{10.26a}$$

$$a_2 = \frac{3G_F}{5\sqrt{2}\pi\alpha}\left(g^{eu}_{VA} - \frac{1}{2}g^{ed}_{VA}\right) \approx \frac{9G_F}{5\sqrt{2}\pi\alpha}\left(\widehat{s}^2_0 - \frac{1}{4}\right). \tag{10.26b}$$

The Jefferson Lab Hall A Collaboration [113] improved on the SLAC result by determining A at $Q^2 = 1.085$ GeV and 1.901 GeV, and determined the weak mixing angle to 2% precision. In another polarized-electron scattering experiment on deuterons, but in the quasi-elastic kinematic regime, the SAMPLE experiment [114] at MIT-Bates extracted the combination $g^{eu}_{VA} - g^{ed}_{VA}$ at Q^2 values of 0.1 GeV^2 and 0.038 GeV^2. What was actually determined were nucleon form factors from which the quoted results were obtained by the removal of a multi-quark radiative correction [115]. Other linear combinations of the effective couplings have been determined in polarized-lepton scattering at CERN in μ-C DIS, at Mainz in e-Be (quasi-elastic), and at Bates in e-C (elastic). See the review articles in Refs. 116 and 117 for more details. Recent polarized electron scattering experiments, *i.e.*, SAMPLE, the PVA4 experiment at Mainz, and the HAPPEX and GØ experiments at Jefferson Lab, have focussed on the strange quark content of the nucleon. These are reviewed in Refs. 118 and 119.

The parity violating asymmetry, A_{PV}, in fixed target polarized Møller scattering, $e^-e^- \to e^-e^-$, is defined as in Eq. (10.24) and reads [120],

$$\frac{A_{PV}}{Q^2} = -2\, g^{ee}_{AV} \frac{G_F}{\sqrt{2}\pi\alpha} \frac{1-y}{1+y^4+(1-y)^4} \,, \tag{10.27}$$

where y is again the energy transfer. It has been measured at low $Q^2 = 0.026$ GeV^2 in the SLAC E158 experiment [121], with the result $A_{PV} = (-1.31 \pm 0.14_{\,\mathrm{stat.}} \pm 0.10_{\,\mathrm{syst.}}) \times 10^{-7}$. Expressed in terms of the weak mixing angle in the $\overline{\mathrm{MS}}$ scheme, this yields $\widehat{s}^2(Q^2) = 0.2403 \pm 0.0013$, and established the scale dependence of the weak mixing angle (see $Q_W(e)$ in Fig. 10.2) at the level of 6.4 σ. One can also extract the model-independent effective coupling, $g^{ee}_{AV} = 0.0190 \pm 0.0027$ [80] (the implications are discussed in Ref. 123).

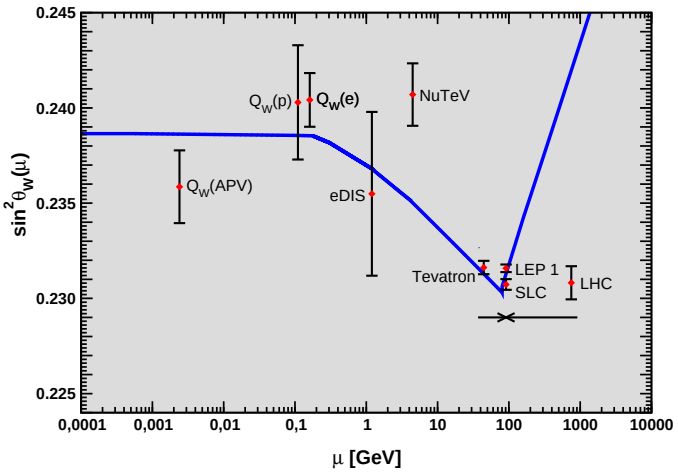

Figure 10.2: Scale dependence of the weak mixing angle defined in the $\overline{\mathrm{MS}}$ scheme [122] (for the scale dependence of the weak mixing angle defined in a mass-dependent renormalization scheme, see Ref. 123). The minimum of the curve corresponds to $\mu = M_W$, below which we switch to an effective theory with the $W^\pm$ bosons integrated out, and where the β-function for the weak mixing angle changes sign. At the location of the W boson mass and each fermion mass there are also discontinuities arising from scheme dependent matching terms which are necessary to ensure that the various effective field theories within a given loop order describe the same physics. However, in the $\overline{\mathrm{MS}}$ scheme these are very small numerically and barely visible in the figure provided one decouples quarks at $\mu = \widehat{m}_q(\widehat{m}_q)$. The width of the curve reflects the theory uncertainty from strong interaction effects which at low energies is at the level of $\pm 7 \times 10^{-5}$ [122]. Following the estimate [124] of the typical momentum transfer for parity violation experiments in Cs, the location of the APV data point is given by $\mu = 2.4$ MeV. For NuTeV we display the updated value from Ref. 125 and chose $\mu = \sqrt{20}$ GeV which is about half-way between the averages of $\sqrt{Q^2}$ for ν and $\overline{\nu}$ interactions at NuTeV. The Tevatron and LHC measurements are strongly dominated by invariant masses of the final state dilepton pair of $\mathcal{O}(M_Z)$ and can thus be considered as additional Z pole data points. For clarity we displayed the Tevatron and LHC points horizontally to the left and to the right, respectively.

In a similar experiment and at about the same $Q^2 = 0.025$ GeV^2, Qweak at Jefferson Lab [126] will be able to measure the weak charge of the proton (which is proportional to $2g^{eu}_{AV} + g^{ed}_{AV}$) and $\sin^2\theta_W$ in polarized ep scattering with relative precisions of 4% and 0.3%, respectively. The result based on the collaborations commissioning run [127] and about 4% of the data corresponds to the constraint $2g^{eu}_{AV} + g^{ed}_{AV} = 0.064 \pm 0.012$.

There are precise experiments measuring atomic parity violation (APV) [128] in cesium [129,130] (at the 0.4% level [129]) , thallium [131], lead [132], and bismuth [133]. The EW physics is contained in the nuclear weak charges $Q^{Z,N}_W$, where Z and N are the numbers of protons and neutrons in the nucleus. In terms of the nucleon vector couplings,

$$g^{ep}_{AV} \equiv 2g^{eu}_{AV} + g^{ed}_{AV} \approx -\frac{1}{2} + 2\widehat{s}^2_0, \tag{10.28}$$

$$g^{en}_{AV} \equiv g^{eu}_{AV} + 2g^{ed}_{AV} \approx \frac{1}{2}, \tag{10.29}$$

one has,

$$Q_W^{Z,N} \equiv -2\left[Z(g_{AV}^{ep}+0.00005)+N(g_{AV}^{en}+0.00006)\right]\left(1-\frac{\alpha}{2\pi}\right), \tag{10.30}$$

where the numerically small adjustments are discussed in Ref. 80 and include the result of the γZ-box correction from Ref. 134. *E.g.*, $Q_W(^{133}\mathrm{Cs})$ is extracted by measuring experimentally the ratio of the parity violating amplitude, $E_{\rm PNC}$, to the Stark vector transition polarizability, β, and by calculating theoretically $E_{\rm PNC}$ in terms of Q_W. One can then write,

$$Q_W = N\left(\frac{\mathrm{Im}\,E_{\rm PNC}}{\beta}\right)_{\rm exp.}\left(\frac{|e|\,a_B}{\mathrm{Im}\,E_{\rm PNC}}\frac{Q_W}{N}\right)_{\rm th.}\left(\frac{\beta}{a_B^3}\right)_{\rm exp.+th.}\left(\frac{a_B^2}{|e|}\right),$$

where a_B is the Bohr radius. The uncertainties associated with atomic wave functions are quite small for cesium [135]. The semi-empirical value of β used in early analyses added another source of theoretical uncertainty [136]. However, the ratio of the off-diagonal hyperfine amplitude to the polarizability was subsequently measured directly by the Boulder group [137]. Combined with the precisely known hyperfine amplitude [138] one finds $\beta = (26.991 \pm 0.046)\,a_B^3$, in excellent agreement with the earlier results, reducing the overall theory uncertainty (while slightly increasing the experimental error). Utilizing the state-of-the-art many-body calculation in Ref. 139 yields $\mathrm{Im}\,E_{\rm PNC} = (0.8906 \pm 0.0026) \times 10^{-11}|e|\,a_B\,Q_W/N$, while the two measurements [129,130] combine to give $\mathrm{Im}\,E_{\rm PNC}/\beta = -1.5924 \pm 0.0055$ mV/cm, and we would obtain $Q_W(^{133}_{78}\mathrm{Cs}) = -73.20 \pm 0.35$, or equivalently $55g_{AV}^{ep} + 78g_{AV}^{en} = 36.64 \pm 0.18$ which is in excellent agreement with the SM prediction of 36.66. However, a very recent atomic structure calculation [140] found significant corrections to two non-dominating terms, changing the result to $\mathrm{Im}\,E_{\rm PNC} = (0.8977 \pm 0.0040) \times 10^{-11}|e|\,a_B\,Q_W/N$, and yielding the constraint, $55g_{AV}^{ep}+78g_{AV}^{en} = 36.35\pm0.21$ [$Q_W(^{133}_{78}\mathrm{Cs}) = -72.62\pm0.43$], *i.e.* a 1.5 σ SM deviation. Thus, the various theoretical efforts in [139–141] together with an update of the SM calculation [142] reduced an earlier 2.3 σ discrepancy from the SM (see the year 2000 edition of this *Review*), but there still appears to remain a small deviation. The theoretical uncertainties are 3% for thallium [143] but larger for the other atoms. The Boulder experiment in cesium also observed the parity-violating weak corrections to the nuclear electromagnetic vertex (the anapole moment [144]) .

In the future it could be possible to further reduce the theoretical wave function uncertainties by taking the ratios of parity violation in different isotopes [128,145]. There would still be some residual uncertainties from differences in the neutron charge radii, however [146]. Experiments in hydrogen and deuterium are another possibility for reducing the atomic theory uncertainties [147], while measurements of single trapped radium ions are promising [148] because of the much larger parity violating effect.

10.4. Physics of the massive electroweak bosons

If the CM energy $\sqrt{s}$ is large compared to the fermion mass m_f, the unpolarized Born cross-section for $e^+e^- \to f\bar{f}$ can be written as

$$\frac{d\sigma}{d\cos\theta} = \frac{\pi\alpha^2(s)}{2s}\left[F_1(1+\cos^2\theta)+2F_2\cos\theta\right]+B, \tag{10.31a}$$

where

$$F_1 = Q_e^2Q_f^2 - 2\chi Q_eQ_f\overline{g}_V^e\overline{g}_V^f\cos\delta_R+\chi^2(\overline{g}_V^{e2}+\overline{g}_A^{e2})(\overline{g}_V^{f2}+\overline{g}_A^{f2}) \tag{10.31b}$$

$$F_2 = -2\chi\,Q_eQ_f\overline{g}_A^e\overline{g}_A^f\cos\delta_R + 4\chi^2\overline{g}_V^e\overline{g}_A^e\overline{g}_V^f\overline{g}_A^f \tag{10.31c}$$

$$\tan\delta_R = \frac{\overline{M}_Z\overline{\Gamma}_Z}{\overline{M}_Z^2-s}\ ,\ \chi = \frac{G_F}{2\sqrt{2}\pi\alpha(s)}\frac{s\overline{M}_Z^2}{\left[(\overline{M}_Z^2-s)^2+\overline{M}_Z^2\overline{\Gamma}_Z^2\right]^{1/2}}, \tag{10.32}$$

and B accounts for box graphs involving virtual Z and W bosons, and $\overline{g}_{V,A}^f$ are defined in Eq. (10.33) below. $\overline{M}_Z$ and $\overline{\Gamma}_Z$ correspond to mass and width definitions based on a Breit-Wigner shape with an energy-independent width (see the Section on "The Z Boson" in the Gauge and Higgs Boson Particle Listings of this *Review*). The differential cross-section receives important corrections from QED effects in the initial and final state, and interference between the two (see *e.g.* Ref. 149). For $q\bar{q}$ production, there are additional final-state QCD corrections, which are relatively large. Note also that the equations above are written in the CM frame of the incident e^+e^- system, which may be boosted due to the initial-state QED radiation.

Some of the leading virtual EW corrections are captured by the running QED coupling $\alpha(s)$ and the Fermi constant G_F. The remaining corrections to the $Zf\bar{f}$ interaction are absorbed by replacing the tree-level couplings in Eq. (10.5) with the s-dependent *effective couplings* [150],

$$\overline{g}_V^f = \sqrt{\rho_f}\,(t_{3L}^{(f)} - 2Q_f\kappa_f\sin^2\theta_W), \qquad \overline{g}_A^f = \sqrt{\rho_f}\,t_{3L}^{(f)}. \tag{10.33}$$

In these equations, the effective couplings are to be taken at the scale $\sqrt{s}$, but for notational simplicity we do not show this explicitly. At tree-level $\rho_f = \kappa_f = 1$, but inclusion of EW radiative corrections leads to non-zero $\rho_f - 1$ and $\kappa_f - 1$, which depend on the fermion f and on the renormalization scheme. In the on-shell scheme, the quadratic m_t dependence is given by $\rho_f \sim 1+\rho_t$, $\kappa_f \sim 1+\rho_t/\tan^2\theta_W$, while in $\overline{\rm MS}$, $\widehat{\rho}_f \sim \widehat{\kappa}_f \sim 1$, for $f \neq b$ ($\widehat{\rho}_b \sim 1 - \frac{4}{3}\rho_t$, $\widehat{\kappa}_b \sim 1 + \frac{2}{3}\rho_t$). In the $\overline{\rm MS}$ scheme the normalization is changed according to $G_FM_Z^2/2\sqrt{2}\pi \to \widehat{\alpha}/4\widehat{s}_Z^2\widehat{c}_Z^2$ in Eq. (10.32).

For the high-precision Z-pole observables discussed below, additional bosonic and fermionic loops, vertex corrections, and higher order contributions, *etc.*, must be included [67,68,151,152,153]. For example, in the $\overline{\rm MS}$ scheme one has $\widehat{\rho}_\ell = 0.9980$, $\widehat{\kappa}_\ell = 1.0010$, $\widehat{\rho}_b = 0.9868$, and $\widehat{\kappa}_b = 1.0065$.

To connect to measured quantities, it is convenient to define an effective angle $\overline{s}_f^2 \equiv \sin^2\overline{\theta}_{Wf} \equiv \widehat{\kappa}_f\widehat{s}_Z^2 = \kappa_f s_W^2$, in terms of which $\overline{g}_V^f$ and $\overline{g}_A^f$ are given by $\sqrt{\rho_f}$ times their tree-level formulae. One finds that the $\widehat{\kappa}_f$ ($f \neq b$) are almost independent of (m_t, M_H), and thus one can write

$$\overline{s}_\ell^2 = \widehat{s}_Z^2 + 0.00023, \tag{10.34}$$

while the κ's for the other schemes are m_t dependent.

10.4.1. e^+e^- *scattering below the Z pole* :

Experiments at PEP, PETRA and TRISTAN have measured the unpolarized forward-backward asymmetry, A_{FB}, and the total cross-section relative to pure QED, R, for $e^+e^- \to \ell^+\ell^-$, $\ell = \mu$ or τ at CM energies $\sqrt{s} < M_Z$. They are defined as

$$A_{FB} \equiv \frac{\sigma_F - \sigma_B}{\sigma_F + \sigma_B}\ , \qquad R = \frac{\sigma}{\mathcal{R}_{\rm ini}4\pi\alpha^2/3s}\ , \tag{10.35}$$

where σ_F (σ_B) is the cross-section for ℓ^- to travel forward (backward) with respect to the e^- direction. Neglecting box graph contribution, they are given by

$$A_{FB} = \frac{3}{4}\frac{F_2}{F_1}\ , \qquad R = F_1\ . \tag{10.36}$$

For the available data, it is sufficient to approximate the EW corrections through the leading running $\alpha(s)$ and quadratic m_t contributions [154,155] as described above. Reviews and formulae for $e^+e^- \to$ hadrons may be found in Ref. 156.

10.4.2. *Z pole physics* :

High-precision measurements of various Z pole ($\sqrt{s} \approx M_Z$) observables have been performed at LEP 1 and SLC [10,157–162], as summarized in Table 10.5. These include the Z mass and total width, Γ_Z, and partial widths $\Gamma(f\overline{f})$ for $Z \to f\overline{f}$, where $f = e$, μ, τ, light hadrons, b, or c. It is convenient to use the variables M_Z, Γ_Z, $R_\ell \equiv \Gamma(\mathrm{had})/\Gamma(\ell^+\ell^-)$ ($\ell = e, \mu, \tau$), $\sigma_{\rm had} \equiv 12\pi\,\Gamma(e^+e^-)\,\Gamma(\mathrm{had})/M_Z^2\,\Gamma_Z^2$ [††],

[††] Note that $\sigma_{\rm had}$ receives additional EW corrections that are not captured in the partial widths [163,153], but they only enter at two-loop order.

$R_b \equiv \Gamma(b\bar{b})/\Gamma(\text{had})$, and $R_c \equiv \Gamma(c\bar{c})/\Gamma(\text{had})$, most of which are weakly correlated experimentally. (Γ(had) is the partial width into hadrons.) The three values for R_ℓ are consistent with lepton universality (although R_τ is somewhat low compared to R_e and R_μ), but we use the general analysis in which the three observables are treated as independent. Similar remarks apply to $A_{FB}^{0,\ell}$ defined through Eq. (10.39) with $P_e = 0$ ($A_{FB}^{0,\tau}$ is somewhat high). $\mathcal{O}(\alpha^3)$ QED corrections introduce a large anti-correlation (−30%) between Γ_Z and σ_{had}. The anti-correlation between R_b and R_c is −18% [10]. The R_ℓ are insensitive to m_t except for the $Z \to b\bar{b}$ vertex and final state corrections and the implicit dependence through $\sin^2\theta_W$. Thus, they are especially useful for constraining α_s. The invisible decay width [10], $\Gamma(\text{inv}) = \Gamma_Z - 3\,\Gamma(\ell^+\ell^-) - \Gamma(\text{had}) = 499.0 \pm 1.5$ MeV, can be used to determine the number of neutrino flavors, $N_\nu = \Gamma(\text{inv})/\Gamma^{\text{theory}}(\nu\overline{\nu})$, much lighter than $M_Z/2$. In practice, we determine N_ν by allowing it as an additional fit parameter and obtain,

$$N_\nu = 2.992 \pm 0.007\ . \tag{10.37}$$

Additional constraints follow from measurements of various Z-pole asymmetries. These include the forward-backward asymmetry A_{FB} and the polarization or left-right asymmetry,

$$A_{LR} \equiv \frac{\sigma_L - \sigma_R}{\sigma_L + \sigma_R}\ , \tag{10.38}$$

where $\sigma_L(\sigma_R)$ is the cross-section for a left-(right-)handed incident electron. A_{LR} was measured precisely by the SLD collaboration at the SLC [159], and has the advantages of being very sensitive to $\sin^2\theta_W$ and that systematic uncertainties largely cancel. After removing initial state QED corrections and contributions from photon exchange, γ–Z interference and EW boxes, see Eq. (10.31), one can use the effective tree-level expressions

$$A_{LR} = A_e P_e\ , \qquad A_{FB} = \frac{3}{4} A_f\, \frac{A_e + P_e}{1 + P_e A_e}\ , \tag{10.39}$$

where

$$A_f \equiv \frac{2\overline{g}_V^f\, \overline{g}_A^f}{\overline{g}_V^{f2} + \overline{g}_A^{f2}} = \frac{1 - 4|Q_f|\bar{s}_f^2}{1 - 4|Q_f|\bar{s}_f^2 + 8(|Q_f|\bar{s}_f^2)^2}\ . \tag{10.40}$$

P_e is the initial e^- polarization, so that the second equality in Eq. (10.41) is reproduced for $P_e = 1$, and the Z pole forward-backward asymmetries at LEP 1 ($P_e = 0$) are given by $A_{FB}^{(0,f)} = \frac{3}{4} A_e A_f$ where $f = e,\ \mu,\ \tau,\ b,\ c,\ s$ [10], and q, and where $A_{FB}^{(0,q)}$ refers to the hadronic charge asymmetry. Corrections for t-channel exchange and s/t-channel interference cause $A_{FB}^{(0,e)}$ to be strongly anti-correlated with R_e (−37%). The correlation between $A_{FB}^{(0,b)}$ and $A_{FB}^{(0,c)}$ amounts to 15%.

In addition, SLD extracted the final-state couplings A_b, A_c [10], A_s [160], A_τ, and A_μ [161], from left-right forward-backward asymmetries, using

$$A_{LR}^{FB}(f) = \frac{\sigma_{LF}^f - \sigma_{LB}^f - \sigma_{RF}^f + \sigma_{RB}^f}{\sigma_{LF}^f + \sigma_{LB}^f + \sigma_{RF}^f + \sigma_{RB}^f} = \frac{3}{4} A_f\ , \tag{10.41}$$

where, for example, σ_{LF}^f is the cross-section for a left-handed incident electron to produce a fermion f traveling in the forward hemisphere. Similarly, A_τ and A_e were measured at LEP 1 [10] through the τ polarization, $\mathcal{P}_\tau$, as a function of the scattering angle θ, which can be written as

$$\mathcal{P}_\tau = -\frac{A_\tau(1 + \cos^2\theta) + 2A_e\cos\theta}{(1 + \cos^2\theta) + 2A_\tau A_e\cos\theta} \tag{10.42}$$

The average polarization, $\langle\mathcal{P}_\tau\rangle$, obtained by integrating over $\cos\theta$ in the numerator and denominator of Eq. (10.42), yields $\langle\mathcal{P}_\tau\rangle = -A_\tau$, while A_e can be extracted from the angular distribution of $\mathcal{P}_\tau$.

The initial state coupling, A_e, was also determined through the left-right charge asymmetry [162] and in polarized Bhabba scattering [161] at SLC. Because $\overline{g}_V^\ell$ is very small, not only $A_{LR}^0 = A_e$, $A_{FB}^{(0,\ell)}$, and $\mathcal{P}_\tau$, but also $A_{FB}^{(0,b)}$, $A_{FB}^{(0,c)}$, $A_{FB}^{(0,s)}$, and the hadronic asymmetries are mainly sensitive to $\overline{s}_\ell^2$.

As mentioned in Sec. 10.2, radiative corrections to $\bar{s}_\ell^2$ have been computed with full two-loop and partial higher-order corrections. Moreover, fermionic two-loop EW corrections to $\bar{s}_q^2$ ($q = b,\ c,\ s$) have been obtained [79,152], but the purely bosonic contributions of this order are still missing. Similarly, for the partial widths, $\Gamma(f\overline{f})$, and the hadronic peak cross-section, σ_{had}, the fermionic two-loop EW corrections are known [153]. Non-factorizable $\mathcal{O}(\alpha\alpha_s)$ corrections to the $Z \to q\bar{q}$ vertex are also available [151]. They add coherently, resulting in a sizable effect and shift $\alpha_s(M_Z)$ when extracted from Z lineshape observables by $\approx +0.0007$. As an example of the precision of the Z-pole observables, the values of $\bar{g}_A^f$ and $\bar{g}_V^f$, $f = e, \mu, \tau, \ell$, extracted from the LEP and SLC lineshape and asymmetry data, are shown in Fig. 10.3, which should be compared with Fig. 10.1. (The two sets of parameters coincide in the SM at tree-level.)

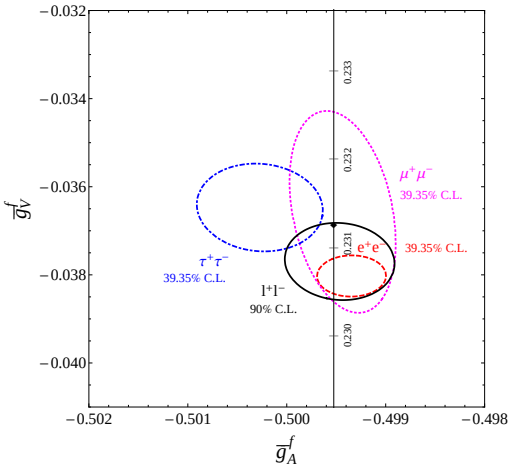

Figure 10.3: 1 σ (39.35% C.L.) contours for the Z-pole observables $\bar{g}_A^f$ and $\bar{g}_V^f$, $f = e, \mu, \tau$ obtained at LEP and SLC [10], compared to the SM expectation as a function of $\hat{s}_Z^2$. (The SM best fit value $\hat{s}_Z^2 = 0.23129$ is also indicated.) Also shown is the 90% CL allowed region in $\bar{g}_{A,V}^\ell$ obtained assuming lepton universality.

As for hadron colliders, the forward-backward asymmetry, A_{FB}, for e^+e^- and $\mu^+\mu^-$ final states (with invariant masses restricted to or dominated by values around M_Z) in $p\bar{p}$ collisions has been measured by the DØ [164] (only e^+e^-) and CDF [165,166] collaborations, and the values $\overline{s}_\ell^2 = 0.23146 \pm 0.00047$ and $\overline{s}_\ell^2 = 0.23222 \pm 0.00046$, were extracted, respectively. Assuming that the smaller systematic uncertainty (±0.00018 from CDF [166]) is common to both experiments, these measurements combine to

$$\overline{s}_\ell^2 = 0.23185 \pm 0.00035\ \text{(Tevatron)} \tag{10.43}$$

By varying the invariant mass and the scattering angle (and assuming the electron couplings), information on the effective Z couplings to light quarks, $\overline{g}_{V,A}^{u,d}$, could also be obtained [167,168], but with large uncertainties and mutual correlations and not independently of $\overline{s}_\ell^2$ above. Similar analyses have also been reported by the H1 and ZEUS collaborations at HERA [169] and by the LEP collaborations [10]. This kind of measurement is harder in the pp environment due to the difficulty to assign the initial quark and antiquark in the underlying Drell-Yan process to the protons. Nevertheless, measurements of A_{FB} have been reported by the ATLAS [170], CMS [171] and LHCb [172] collaborations (the latter two only for the $\mu^+\mu^-$ final state), which obtained $\overline{s}_\ell^2 = 0.2308 \pm 0.0012$, $\overline{s}_\ell^2 = 0.2287 \pm 0.0032$ and $\overline{s}_\ell^2 = 0.23142 \pm 0.00106$, respectively. Assuming that the smallest

theoretical uncertainty (± 0.00056 from LHCb [172]) is fully correlated among all three experiments, these measurements combine to

$$\overline{s}^2_\ell = 0.23105 \pm 0.00087 \text{ (LHC)} \tag{10.44}$$

10.4.3. *LEP 2* :

LEP 2 [173,174] ran at several energies above the Z pole up to ~ 209 GeV. Measurements were made of a number of observables, including the cross-sections for $e^+e^- \to f\bar{f}$ for $f = q, \mu, \tau$; the differential cross-sections for $f = e, \mu, \tau$; R_q for $q = b, c$; $A_{FB}(f)$ for $f = \mu, \tau, b, c$; W branching ratios; and $\gamma\gamma$, WW, $WW\gamma$, ZZ, single W, and single Z cross-sections. They are in good agreement with the SM predictions, with the exceptions of R_b (2.1 σ low), $A_{FB}(b)$ (1.6 σ low), and the $W \to \tau\nu_\tau$ branching fraction (2.6 σ high).

The Z boson properties are extracted assuming the SM expressions for the γ–Z interference terms. These have also been tested experimentally by performing more general fits [173,175] to the LEP 1 and LEP 2 data. Assuming family universality this approach introduces three additional parameters relative to the standard fit [10], describing the γ–Z interference contribution to the total hadronic and leptonic cross-sections, $j^{\rm tot}_{\rm had}$ and $j^{\rm tot}_\ell$, and to the leptonic forward-backward asymmetry, $j^{\rm fb}_\ell$. *E.g.*,

$$j^{\rm tot}_{\rm had} \sim g^\ell_V g^{\rm had}_V = 0.277 \pm 0.065, \tag{10.45}$$

which is in agreement with the SM expectation [10] of 0.21 ± 0.01. These are valuable tests of the SM; but it should be cautioned that new physics is not expected to be described by this set of parameters, since (i) they do not account for extra interactions beyond the standard weak neutral current, and (ii) the photonic amplitude remains fixed to its SM value.

Strong constraints on anomalous triple and quartic gauge couplings have been obtained at LEP 2 and the Tevatron as described in the Gauge & Higgs Bosons Particle Listings.

10.4.4. *W and Z decays* :

The partial decay widths for gauge bosons to decay into massless fermions $f_1\overline{f}_2$ (the numerical values include the small EW radiative corrections and final state mass effects) are given by

$$\Gamma(W^+ \to e^+\nu_e) = \frac{G_F M_W^3}{6\sqrt{2}\pi} \approx 226.27 \pm 0.05 \text{ MeV} , \tag{10.46a}$$

$$\Gamma(W^+ \to u_i\overline{d}_j) = \frac{\mathcal{R}^q_V G_F M_W^3}{6\sqrt{2}\pi} |V_{ij}|^2$$

$$\approx 705.1 \pm 0.3 \text{ MeV } |V_{ij}|^2, \tag{10.46b}$$

$$\Gamma(Z \to f\bar{f}) = \frac{G_F M_Z^3}{6\sqrt{2}\pi}\left[\mathcal{R}^f_V \bar{g}^{f2}_V + \mathcal{R}^f_A \bar{g}^{f2}_A\right]$$

$$\approx \begin{cases} 167.17 \pm 0.02 \text{ MeV } (\nu\overline{\nu}), \\ 83.97 \pm 0.01 \text{ MeV } (e^+e^-), \\ 299.91 \pm 0.19 \text{ MeV } (u\overline{u}), \\ 382.80 \pm 0.14 \text{ MeV } (d\overline{d}), \\ 375.69 \mp 0.17 \text{ MeV } (b\overline{b}). \end{cases} \tag{10.46c}$$

Final-state QED and QCD corrections to the vector and axial-vector form factors are given by

$$\mathcal{R}^f_{V,A} = N_C[1 + \frac{3}{4}(Q^2_f \frac{\alpha(s)}{\pi} + \frac{N_C^2 - 1}{2N_C}\frac{\alpha_s(s)}{\pi}) + \cdots], \tag{10.47}$$

where $N_C = 3$ (1) is the color factor for quarks (leptons) and the dots indicate finite fermion mass effects proportional to m^2_f/s which are different for $\mathcal{R}^f_V$ and $\mathcal{R}^f_A$, as well as higher-order QCD corrections, which are known to $\mathcal{O}(\alpha_s^4)$ [176–178]. These include singlet contributions starting from two-loop order which are large, strongly top quark mass dependent, family universal, and flavor non-universal [179]. Also the $\mathcal{O}(\alpha^2)$ self-energy corrections from Ref. 180 are taken into account.

For the W decay into quarks, Eq. (10.46*b*), only the universal massless part (non-singlet and $m_q = 0$) of the final-state QCD radiator function in $\mathcal{R}_V$ from Eq. (10.47) is used, and the QED corrections are modified. Expressing the widths in terms of $G_F M^3_{W,Z}$ incorporates the largest radiative corrections from the running QED coupling [56,181]. EW corrections to the Z widths are then taken into account through the effective couplings $\overline{g}^{i2}_{V,A}$. Hence, in the on-shell scheme the Z widths are proportional to $\rho_i \sim 1 + \rho_t$. There is additional (negative) quadratic m_t dependence in the $Z \to b\overline{b}$ vertex corrections [182] which causes $\Gamma(b\overline{b})$ to decrease with m_t. The dominant effect is to multiply $\Gamma(b\overline{b})$ by the vertex correction $1 + \delta\rho_{b\bar{b}}$, where $\delta\rho_{b\bar{b}} \sim 10^{-2}(-\frac{1}{2}m_t^2/M_Z^2 + \frac{1}{5})$. In practice, the corrections are included in ρ_b and κ_b, as discussed in Sec. 10.4.

For three fermion families the total widths are predicted to be

$$\Gamma_Z \approx 2.4943 \pm 0.0008 \text{ GeV} , \qquad \Gamma_W \approx 2.0888 \pm 0.0007 \text{ GeV} . \tag{10.48}$$

The uncertainties in these predictions are almost entirely induced from the fit error in $\alpha_s(M_Z) = 0.1182 \pm 0.0016$. These predictions are to be compared with the experimental results, $\Gamma_Z = 2.4952 \pm 0.0023$ GeV [10] and $\Gamma_W = 2.085 \pm 0.042$ GeV (see the Gauge & Higgs Boson Particle Listings for more details).

10.4.5. *H decays* :

The ATLAS and CMS collaborations at LHC observed a Higgs boson [183] with properties appearing well consistent with the SM Higgs (see the note on "The Higgs Boson H^0" in the Gauge & Higgs Boson Particle Listings). A recent combination [184] of ATLAS and CMS results for the Higgs boson mass from kinematical reconstruction yields

$$M_H = 125.09 \pm 0.24 \text{ GeV}. \tag{10.49}$$

In analogy to the W and Z decays discussed in the previous subsection, we can include some of the Higgs decay properties into the global analysis of Sec. 10.6. However, the total Higgs decay width, which in the SM amounts to

$$\Gamma_H = 4.15 \pm 0.06 \text{ MeV}, \tag{10.50}$$

is too small to be resolved at the LHC. However, one can employ results of Higgs branching ratios into different final states. The most useful channels are Higgs decays into WW^* and ZZ^* (with at least one gauge boson off-shell), as well as $\gamma\gamma$ and $\tau\tau$. We define

$$\rho_{XY} \equiv \ln \frac{\text{BR}_{H\to XX}}{\text{BR}_{H\to YY}} . \tag{10.51}$$

These quantities are constructed to have a SM expectation of zero, and their physical range is over all real numbers, which allows one to straightforwardly use Gaussian error propagation (in view of the fairly large errors). Moreover, possible effects of new physics on Higgs production rates would also cancel and one may focus on the decay side of the processes. From a combination of ALTAS and CMS results [184], we find

$$\rho_{\gamma W} = -0.03 \pm 0.20 , \qquad \rho_{\tau Z} = -0.27 \pm 0.31 ,$$

which we take to be uncorrelated as they involve distinct final states. We evaluate the decay rates with the package HDECAY [185].

10.5. Precision flavor physics

In addition to cross-sections, asymmetries, parity violation, W and Z decays, there is a large number of experiments and observables testing the flavor structure of the SM. These are addressed elsewhere in this *Review*, and are generally not included in this Section. However, we identify three precision observables with sensitivity to similar types of new physics as the other processes discussed here. The branching fraction of the flavor changing transition $b \to s\gamma$ is of comparatively low precision, but since it is a loop-level process (in the SM) its sensitivity to new physics (and SM parameters, such as heavy quark masses) is enhanced. A discussion can be found in the 2010 edition of this *Review*. The τ-lepton lifetime and leptonic branching

ratios are primarily sensitive to α_s and not affected significantly by many types of new physics. However, having an independent and reliable low energy measurement of α_s in a global analysis allows the comparison with the Z lineshape determination of α_s which shifts easily in the presence of new physics contributions. By far the most precise observable discussed here is the anomalous magnetic moment of the muon (the electron magnetic moment is measured to even greater precision and can be used to determine α, but its new physics sensitivity is suppressed by an additional factor of m_e^2/m_μ^2, unless there is a new light degree of freedom such as a dark Z [186] boson). Its combined experimental and theoretical uncertainty is comparable to typical new physics contributions.

The extraction of α_s from the τ lifetime [187] is standing out from other determinations because of a variety of independent reasons: (i) the τ-scale is low, so that upon extrapolation to the Z scale (where it can be compared to the theoretically clean Z lineshape determinations) the α_s error shrinks by about an order of magnitude; (ii) yet, this scale is high enough that perturbation theory and the operator product expansion (OPE) can be applied; (iii) these observables are fully inclusive and thus free of fragmentation and hadronization effects that would have to be modeled or measured; (iv) duality violation (DV) effects are most problematic near the branch cut but there they are suppressed by a double zero at $s = m_\tau^2$; (v) there are data [34,188] to constrain non-perturbative effects both within and breaking the OPE; (vi) a complete four-loop order QCD calculation is available [178]; (vii) large effects associated with the QCD β-function can be re-summed [189] in what has become known as contour improved perturbation theory (CIPT). However, while there is no doubt that CIPT shows faster convergence in the lower (calculable) orders, doubts have been cast on the method by the observation that at least in a specific model [190], which includes the exactly known coefficients and theoretical constraints on the large-order behavior, ordinary fixed order perturbation theory (FOPT) may nevertheless give a better approximation to the full result. We therefore use the expressions [45,177,178,191],

$$\tau_\tau = \hbar \frac{1-\mathcal{B}_\tau^s}{\Gamma_\tau^e + \Gamma_\tau^\mu + \Gamma_\tau^{ud}} = 290.88 \pm 0.35 \text{ fs}, \tag{10.52}$$

$$\begin{aligned}\Gamma_\tau^{ud} =& \frac{G_F^2 m_\tau^5 |V_{ud}|^2}{64\pi^3} S(m_\tau, M_Z) \left(1 + \frac{3}{5}\frac{m_\tau^2 - m_\mu^2}{M_W^2}\right) \times \\ & [1 + \frac{\alpha_s(m_\tau)}{\pi} + 5.202\,\frac{\alpha_s^2}{\pi^2} + 26.37\,\frac{\alpha_s^3}{\pi^3} + \\ & 127.1\,\frac{\alpha_s^4}{\pi^4} + \frac{\widehat{\alpha}}{\pi}(\frac{85}{24} - \frac{\pi^2}{2}) + \delta_{\rm NP}],\end{aligned} \tag{10.53}$$

and Γ_τ^e and Γ_τ^μ can be taken from Eq. (10.6) with obvious replacements. The relative fraction of decays with $\Delta S = -1$, $\mathcal{B}_\tau^s = 0.0287 \pm 0.0005$, is based on experimental data since the value for the strange quark mass, $\widehat{m}_s(m_\tau)$, is not well known and the QCD expansion proportional to $\widehat{m}_s^2$ converges poorly and cannot be trusted. $S(m_\tau, M_Z) = 1.01907 \pm 0.0003$ is a logarithmically enhanced EW correction factor with higher orders re-summed [192]. $\delta_{\rm NP}$ collects non-perturbative and quark-mass suppressed contributions, including the dimension four, six and eight terms in the OPE, as well as DV effects. We use the average, $\delta_{\rm NP} = 0.0114 \pm 0.0072$, of the slightly conflicting results, $\delta_{\rm NP} = -0.004 \pm 0.012$ [193] and $\delta_{\rm NP} = 0.020 \pm 0.0009$ [194], based on OPAL [34] and ALEPH [188] τ spectral functions, respectively. The dominant uncertainty arises from the truncation of the FOPT series and is conservatively taken as the α_s^4 term (this is re-calculated in each call of the fits, leading to an α_s-dependent and thus asymmetric error) until a better understanding of the numerical differences between FOPT and CIPT has been gained. Our perturbative error covers almost the entire range from using CIPT to assuming that the nearly geometric series in Eq. (10.53) continues to higher orders. The experimental uncertainty in Eq. (10.52), is from the combination of the two leptonic branching ratios with the direct τ_τ. Included are also various smaller uncertainties (± 0.5 fs) from other sources which are dominated by the evolution from the Z scale. In total we obtain a $\sim 1.5\%$ determination of $\alpha_s(M_Z) = 0.1174^{+0.0019}_{-0.0017}$, which corresponds to $\alpha_s(m_\tau) = 0.314^{+0.016}_{-0.013}$, and updates the result of Refs. 45 and 195. For more details, see Refs. 193 and 194 where the τ spectral functions themselves and an estimate of the unknown α_s^5 term are used as additional inputs.

The world average of the muon anomalous magnetic moment[‡],

$$a_\mu^{\rm exp} = \frac{g_\mu - 2}{2} = (1165920.91 \pm 0.63) \times 10^{-9}, \tag{10.54}$$

is dominated by the final result of the E821 collaboration at BNL [196]. The QED contribution has been calculated to five loops [197] (fully analytic to three loops [198,199]). The estimated SM EW contribution [200–202], $a_\mu^{\rm EW} = (1.54 \pm 0.01) \times 10^{-9}$, which includes two-loop [201] and leading three-loop [202] corrections, is at the level of twice the current uncertainty.

The limiting factor in the interpretation of the result are the uncertainties from the two- and three-loop hadronic contribution [203]. *E.g.,* Ref. 31 obtained the value $a_\mu^{\rm had} = (69.23 \pm 0.42) \times 10^{-9}$ which combines CMD-2 [38] and SND [39] $e^+e^- \to$ hadrons cross-section data with radiative return results from BaBar [41] and KLOE [42]. The most recent analysis [20] includes τ decay data corrected for isospin symmetry violation and γ-ρ mixing effects and yields $a_\mu^{\rm had} = (68.72 \pm 0.35) \times 10^{-9}$. The largest isospin symmetry violating effect is due to higher-order EW corrections [204] but introduces a negligible uncertainty [192]. The γ-ρ mixing effect [205] resolves an earlier discrepancy between the spectral functions obtained from e^+e^- and τ decay data. A recent lattice QCD calculation finds agreement with the results of the dispersive approach discussed above although within a much larger error [206].

An additional uncertainty is induced by the hadronic three-loop light-by-light scattering contribution. Several recent independent model calculations yield compatible results: $a_\mu^{\rm LBLS}(\alpha^3) = (+1.36 \pm 0.25) \times 10^{-9}$ [207], $a_\mu^{\rm LBLS}(\alpha^3) = +1.37^{+0.15}_{-0.27} \times 10^{-9}$ [208], $a_\mu^{\rm LBLS}(\alpha^3) = (+1.16 \pm 0.40) \times 10^{-9}$ [209], and $a_\mu^{\rm LBLS}(\alpha^3) = (+1.05 \pm 0.26) \times 10^{-9}$ [210]. The sign of this effect is opposite [211] to the one quoted in the 2002 edition of this *Review*, and its magnitude is larger than previous evaluations [211,212]. There is also an upper bound $a_\mu^{\rm LBLS}(\alpha^3) < 1.59 \times 10^{-9}$ [208] but this requires an *ad hoc* assumption, too. Partial results (diagrams with several disconnected quark loops still need to be considered) from lattice simulations are promising, with small (about 5%) statistical uncertainty [213]. Various sources of systematic uncertainties are currently being investigated. For the fits, we take the result from Ref. 210, shifted by 2×10^{-11} to account for the more accurate charm quark treatment of Ref. 208, and with increased error to cover all recent evaluations, resulting in $a_\mu^{\rm LBLS}(\alpha^3) = (+1.07 \pm 0.32) \times 10^{-9}$.

Other hadronic effects at three-loop order [214] (udated in Ref. 20) contribute $a_\mu^{\rm had}(\alpha^3) = (-0.99 \pm 0.01) \times 10^{-9}$. Correlations with the two-loop hadronic contribution and with $\Delta\alpha(M_Z)$ (see Sec. 10.2) were considered in Ref. 199 which also contains analytic results for the perturbative QCD contribution. Very recently, hadronic four-loop effects have also been obtained, where the contributions without hadronic LBLS subgraphs [215] amount to $a_\mu^{\rm had}(\alpha^4) = (0.123 \pm 0.001) \times 10^{-9}$ [20]. The contributions with a hadronic LBLS subgraph have been estimated in Ref. 216, with the result $a_\mu^{\rm LBLS}(\alpha^4) = (0.03 \pm 0.02) \times 10^{-9}$.

Altogether, the SM prediction is

$$a_\mu^{\rm theory} = (1165917.63 \pm 0.46) \times 10^{-9}\ , \tag{10.55}$$

[‡] In what follows, we summarize the most important aspects of $g_\mu - 2$, and give some details on the evaluation in our fits. For more details see the dedicated contribution on "The Muon Anomalous Magnetic Moment" in this *Review*. There are some numerical differences, which are well understood and arise because internal consistency of the fits requires the calculation of all observables from analytical expressions and common inputs and fit parameters, so that an independent evaluation is necessary for this Section. Note, that in the spirit of a global analysis based on all available information we have chosen here to use an analysis [20] which considers the τ decay data, as well.

where the error is from the hadronic uncertainties excluding parametric ones such as from α_s and the heavy quark masses. Estimating a correlation of about 68% from the data input to the vacuum polarization integrals, we evaluate the correlation of the total (experimental plus theoretical) uncertainty in a_μ with $\Delta\alpha(M_Z)$ as 24%. The overall 4.2 σ discrepancy between the experimental and theoretical a_μ values could be due to fluctuations (the E821 result is statistics dominated) or underestimates of the theoretical uncertainties. On the other hand, the deviation could also arise from physics beyond the SM, such as supersymmetric models with large $\tan\beta$ and moderately light superparticle masses [217], or a dark Z boson [186].

10.6. Global fit results

In this section we present the results of global fits to the experimental data discussed in Sec. 10.3–Sec. 10.5. For earlier analyses see Refs. [10,117,218]

Table 10.4: Principal non-Z pole observables, compared with the SM best fit predictions. The first M_W and Γ_W values are from the Tevatron [219,220] and the second ones from LEP 2 [173]. The value of m_t differs from the one in the Particle Listings since it includes recent preliminary results. The world averages for $g^{\nu e}_{V,A}$ are dominated by the CHARM II [86] results, $g^{\nu e}_V = -0.035 \pm 0.017$ and $g^{\nu e}_A = -0.503 \pm 0.017$. The errors are the total (experimental plus theoretical) uncertainties. The τ_τ value is the τ lifetime world average computed by combining the direct measurements with values derived from the leptonic branching ratios [45]; in this case, the theory uncertainty is included in the SM prediction. In all other SM predictions, the uncertainty is from M_Z, M_H, m_t, m_b, m_c, $\widehat{\alpha}(M_Z)$, and α_s, and their correlations have been accounted for. The column denoted Pull gives the standard deviations.

Quantity	Value	Standard Model	Pull
m_t [GeV]	173.34 ± 0.81	173.76 ± 0.76	-0.5
M_W [GeV]	80.387 ± 0.016	80.361 ± 0.006	1.6
	80.376 ± 0.033		0.4
Γ_W [GeV]	2.046 ± 0.049	2.089 ± 0.001	-0.9
	2.195 ± 0.083		1.3
M_H [GeV]	125.09 ± 0.24	125.11 ± 0.24	0.0
$\rho_{\gamma W}$	-0.03 ± 0.20	-0.02 ± 0.02	0.0
$\rho_{\tau Z}$	-0.27 ± 0.31	0.00 ± 0.03	-0.9
$g^{\nu e}_V$	-0.040 ± 0.015	-0.0397 ± 0.0002	0.0
$g^{\nu e}_A$	-0.507 ± 0.014	-0.5064	0.0

The values for m_t [48], M_W [173,219], Γ_W [173,220], M_H and the ratios of Higgs branching fractions [184] discussed in Sec. 10.4.5, ν-lepton scattering [83–88], the weak charges of the electron [121], the proton [126], cesium [129,130] and thallium [131], the weak mixing angle extracted from eDIS [113], the muon anomalous magnetic moment [196], and the τ lifetime are listed in Table 10.4. Likewise, the principal Z pole observables can be found in Table 10.5 where the LEP 1 averages of the ALEPH, DELPHI, L3 and OPAL results include common systematic errors and correlations [10]. The heavy flavor results of LEP 1 and SLD are based on common inputs and correlated, as well [10]. Note that the values of $\Gamma(\ell^+\ell^-)$, Γ(had), and Γ(inv) are not independent of Γ_Z, the R_ℓ, and $\sigma_{\rm had}$ and that the SM errors in those latter are largely dominated by the uncertainty in

Table 10.5: Principal Z pole observables and their SM predictions (*cf.* Table 10.4). The first $\overline{s}^2_\ell$ is the effective weak mixing angle extracted from the hadronic charge asymmetry, the second is the combined value from the Tevatron [164–166], and the third from the LHC [170–172]. The values of A_e are (i) from A_{LR} for hadronic final states [159]; (ii) from A_{LR} for leptonic final states and from polarized Bhabba scattering [161]; and (iii) from the angular distribution of the τ polarization at LEP 1. The A_τ values are from SLD and the total τ polarization, respectively.

α_s. Also shown in both tables are the SM predictions for the values of M_Z, M_H, $\alpha_s(M_Z)$, $\Delta\alpha^{(3)}_{\rm had}$ and the heavy quark masses shown in Table 10.6. The predictions result from a global least-square (χ^2) fit to all data using the minimization package MINUIT [221] and the EW library GAPP [21]. In most cases, we treat all input errors (the uncertainties of the values) as Gaussian. The reason is not that we assume that theoretical and systematic errors are intrinsically bell-shaped (which they are not) but because in most cases the input errors are either dominated by the statistical components or they are combinations of many different (including statistical) error sources, which should yield approximately Gaussian *combined* errors by the large number theorem. An exception is the theory dominated error on the τ lifetime, which we recalculate in each χ^2-function call since it depends itself on α_s. Sizes and shapes of the output errors (the uncertainties of the predictions and the SM fit parameters) are fully determined by the fit, and 1 σ errors are defined to correspond to $\Delta\chi^2 = \chi^2 - \chi^2_{\rm min} = 1$, and do not necessarily correspond to the 68.3% probability range or the 39.3% probability contour (for 2 parameters).

The agreement is generally very good. Despite the few discrepancies discussed in the following, the fit describes the data well, with a χ^2/d.o.f. = 53.6/42. The probability of a larger χ^2 is 11%. Only

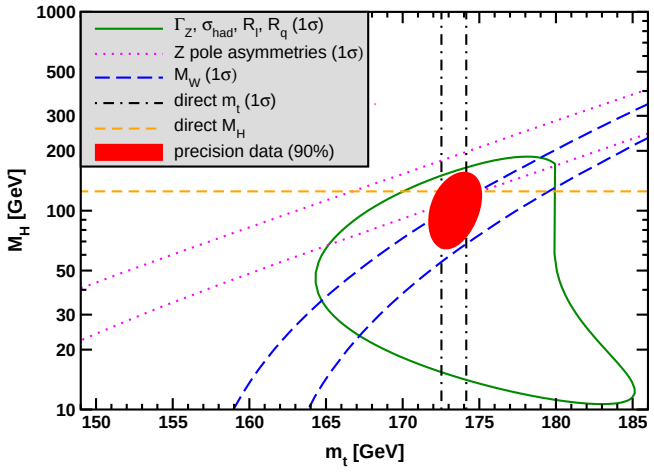

Figure 10.4: Fit result and one-standard-deviation (39.35% for the closed contours and 68% for the others) uncertainties in M_H as a function of m_t for various inputs, and the 90% CL region ($\Delta\chi^2 = 4.605$) allowed by all data. $\alpha_s(M_Z) = 0.1182$ is assumed except for the fits including the Z lineshape. The width of the horizontal dashed (yellow) band is not visible on the scale of the plot.

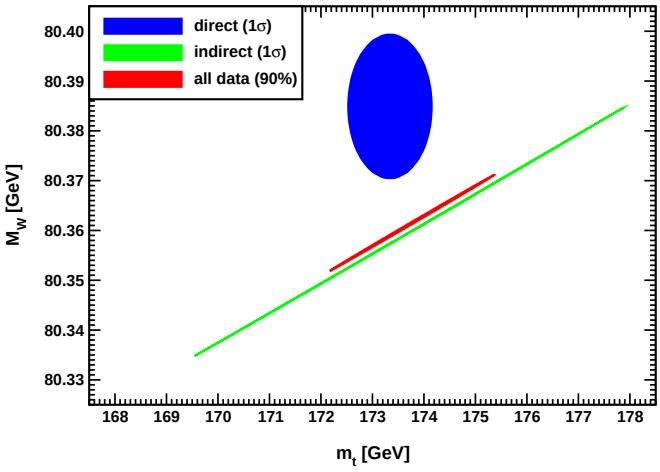

Figure 10.5: One-standard-deviation (39.35%) region in M_W as a function of m_t for the direct and indirect data, and the 90% CL region ($\Delta\chi^2 = 4.605$) allowed by all data.

the final result for $g_\mu - 2$ from BNL is currently showing a large (4.2 σ) conflict. In addition, $A_{FB}^{(0,b)}$ from LEP 1 and A_{LR}^0 (SLD) from hadronic final states deviate at the 2 σ level. g_L^2 from NuTeV is nominally in conflict with the SM, as well, but the precise status is under investigation (see Sec. 10.3).

A_b can be extracted from $A_{FB}^{(0,b)}$ when $A_e = 0.1501 \pm 0.0016$ is taken from a fit to leptonic asymmetries (using lepton universality). The result, $A_b = 0.881 \pm 0.017$, is 3.1 σ below the SM prediction[§] and also 1.6 σ below $A_b = 0.923 \pm 0.020$ obtained from $A_{LR}^{FB}(b)$ at SLD. Thus, it appears that at least some of the problem in A_b is due to a statistical fluctuation or other experimental effect in one of the asymmetries. Note, however, that the uncertainty in $A_{FB}^{(0,b)}$ is strongly statistics dominated. The combined value, $A_b = 0.899 \pm 0.013$ deviates by 2.8 σ.

The left-right asymmetry, $A_{LR}^0 = 0.15138 \pm 0.00216$ [159], based on all hadronic data from 1992–1998 differs 2.0 σ from the SM expectation of 0.1470 ± 0.0004. The combined value of $A_\ell = 0.1513 \pm 0.0021$ from SLD (using lepton-family universality and including correlations) is also 2.0 σ above the SM prediction; but there is experimental agreement between this SLD value and the LEP 1 value, $A_\ell = 0.1481 \pm 0.0027$, obtained from a fit to $A_{FB}^{(0,\ell)}$, $A_e(\mathcal{P}_\tau)$, and $A_\tau(\mathcal{P}_\tau)$, again assuming universality.

The observables in Table 10.4 and Table 10.5, as well as some other less precise observables, are used in the global fits described below. In all fits, the errors include full statistical, systematic, and theoretical uncertainties. The correlations on the LEP 1 lineshape and τ polarization, the LEP/SLD heavy flavor observables, the SLD lepton asymmetries, and the ν-e scattering observables, are included. The theoretical correlations between $\Delta\alpha_{\rm had}^{(5)}$ and $g_\mu - 2$, and between the charm and bottom quark masses, are also accounted for.

The electroweak data allow a simultaneous determination of M_Z, M_H, m_t, and the strong coupling $\alpha_s(M_Z)$. ($\widehat{m}_c$, $\widehat{m}_b$, and $\Delta\alpha_{\rm had}^{(3)}$ are also allowed to float in the fits, subject to the theoretical constraints [19,45] described in Sec. 10.2. These are correlated with α_s.) α_s is determined mainly from R_ℓ, Γ_Z, $\sigma_{\rm had}$, and τ_τ. The global fit to all data, including the hadron collider average $m_t = 173.34 \pm 0.81$ GeV, yields the result in Table 10.6 (the $\overline{\rm MS}$ top quark mass given there corresponds to $m_t = 173.76 \pm 0.76$ GeV). The weak mixing angle, see Table 10.2, is determined to

$$\widehat{s}_Z^2 = 0.23129 \pm 0.00005, \qquad s_W^2 = 0.22336 \pm 0.00010,$$

while the corresponding effective angle is $\overline{s}_\ell^2 = 0.23152 \pm 0.00005$.

As a cross-check, one can also perform a fit without the direct mass constraint, $M_H = 125.09 \pm 0.24$ GeV, in Eq. (10.49). In this case we obtain a 2% indirect mass determination,

$$M_H = 126.1 \pm 1.9 \text{ GeV}\ , \tag{10.56}$$

arising predominantly from the quantities in Eq. (10.51), since the branching ratio for $H \to ZZ^*$ varies very rapidly as a function of M_H for Higgs masses near 125 GeV. Removing also the branching ratio constraints gives the loop-level determination from the precision data alone,

$$M_H = 96^{+22}_{-19} \text{ GeV}\ , \tag{10.57}$$

which is 1.2 σ below the kinematical constraint, but the latter is inside the 90% central confidence range,

$$66 \text{ GeV} < M_H < 134 \text{ GeV}\ . \tag{10.58}$$

This is mostly a reflection of the Tevatron determination of M_W, which is 1.6 σ higher than the SM best fit value in Table 10.4. This is illustrated in Fig. 10.4 where one sees that the precision data together with M_H from the LHC prefer that m_t is closer to the upper end of its 1σ allowed range. Conversely, one can remove the direct M_W and Γ_W constraints from the fits and use Eq. (10.49) to obtain $M_W = 80.357 \pm 0.006$ GeV. This is 1.7 σ below the Tevatron/LEP 2 average, $M_W = 80.385 \pm 0.015$ GeV.

Finally, one can carry out a fit without including the constraint, $m_t = 173.34 \pm 0.81$ GeV, from the hadron colliders. (The indirect prediction is for the $\overline{\rm MS}$ mass, $\widehat{m}_t(\widehat{m}_t) = 166.8 \pm 2.0$ GeV, which is in the end converted to the pole mass.) One obtains $m_t = 176.7 \pm 2.1$ GeV, which is 1.5 σ higher than the direct Tevatron/LHC average. The situation is summarized in Fig. 10.5 showing the 1 σ contours in the M_W-m_t plane from the direct and indirect determinations, as well as the combined 90% CL region.

As described in the paragraph following Eq. (10.54) in Sec. 10.5, there is some stress in the experimental e^+e^- and τ spectral functions. These are below or above the 2 σ level (depending on what is actually compared) but not larger than the deviations of some other quantities entering our analyses. The number and size or these deviations are not inconsistent with what one would expect to happen as a result of random fluctuations. It is nevertheless instructive to study the effect of doubling the uncertainty in $\Delta\alpha_{\rm had}^{(3)}(2 \text{ GeV}) = (58.04 \pm 1.10) \times 10^{-4}$ (see Sec. 10.2) on the loop-level determination. The result, $M_H = 90^{+23}_{-19}$ GeV, deviates even

[§] Alternatively, one can use $A_\ell = 0.1481 \pm 0.0027$, which is from LEP 1 alone and in excellent agreement with the SM, and obtain $A_b = 0.893 \pm 0.022$ which is 1.9 σ low. This illustrates that some of the discrepancy is related to the one in A_{LR}.

slightly *more* (1.4 σ) than Eq. (10.57), and demonstrates that the uncertainty in $\Delta\alpha_{\rm had}$ is currently of only secondary importance. Note also that a shift of $\pm 10^{-4}$ in $\Delta\alpha^{(3)}_{\rm had}(2\ {\rm GeV})$ corresponds to a shift of ∓ 4.5 GeV in M_H. The hadronic contribution to $\alpha(M_Z)$ is correlated with $g_\mu - 2$ (see Sec. 10.5). The measurement of the latter is higher than the SM prediction, and its inclusion in the fit favors a larger $\alpha(M_Z)$ and a lower M_H from the precision data (currently by 6.4 GeV).

Table 10.6: Principal SM fit result including mutual correlations (all masses in GeV).

M_Z	91.1880 ± 0.0020	1.00	−0.08	−0.01	−0.02	0.01	0.04	0.00

low energy + $M_{H,Z}$	0.2328(14)	0.2291(55)	0.1175(18)	$121 \quad \pm 50$	125.1 ± 0.2

The weak mixing angle can be determined from Z pole observables, M_W, and from a variety of neutral-current processes spanning a very wide Q^2 range. The results (for the older low energy neutral-current data see Refs. 117 and 218, as well as earlier editions of this *Review*) shown in Table 10.7 are in reasonable agreement with each other, indicating the quantitative success of the SM. The largest discrepancy is the value $\widehat{s}^2_Z = 0.23200 \pm 0.00029$ from the forward-backward asymmetries into bottom and charm quarks, which is 2.4 σ above the value 0.23129 ± 0.00005 from the global fit to all data (see Table 10.5). Similarly, $\widehat{s}^2_Z = 0.23074 \pm 0.00028$ from the SLD asymmetries (in both cases when combined with M_Z) is 2.0 σ low.

The extracted Z pole value of $\alpha_s(M_Z)$ is based on a formula with negligible theoretical uncertainty if one assumes the exact validity of the SM. One should keep in mind, however, that this value, $\alpha_s(M_Z) = 0.1203 \pm 0.0028$, is very sensitive to certain types of new physics such as non-universal vertex corrections. In contrast, the value derived from τ decays, $\alpha_s(M_Z) = 0.1174^{+0.0019}_{-0.0017}$, is theory dominated but less sensitive to new physics. The two values are in reasonable agreement with each other. They are also in good agreement with the averages from jet-event shapes in e^+e^- annihilation (0.1169 ± 0.0034) and lattice simulations (0.1187 ± 0.0012), whereas the DIS average (0.1156 ± 0.0023) is somewhat lower than the Z pole value. For more details, other determinations, and references, see Section 9 on "Quantum Chromodynamics" in this *Review*.

Using $\alpha(M_Z)$ and $\widehat{s}^2_Z$ as inputs, one can predict $\alpha_s(M_Z)$ assuming grand unification. One finds [225] $\alpha_s(M_Z) = 0.130 \pm 0.001 \pm 0.01$ for the simplest theories based on the minimal supersymmetric extension of the SM, where the first (second) uncertainty is from the inputs (thresholds). This is slightly larger, but consistent with $\alpha_s(M_Z) = 0.1182 \pm 0.0016$ from our fit, as well as with most other determinations. Non-supersymmetric unified theories predict the low value $\alpha_s(M_Z) = 0.073 \pm 0.001 \pm 0.001$. See also the note on "Supersymmetry" in the Searches Particle Listings.

Most of the parameters relevant to ν-hadron, ν-e, e-hadron,

and $e^-e^\pm$ processes are determined uniquely and precisely from the data in "model-independent" fits (*i.e.*, fits which allow for an arbitrary EW gauge theory). The values for the parameters defined in Eqs. (10.16)–(10.17) are given in Table 10.8 along with the predictions of the SM. The agreement is very good. (The ν-hadron results including the original NuTeV data can be found in the 2006 edition of this *Review*, and fits with modified NuTeV constraints in the 2008 and 2010 editions.) The off Z pole e^+e^- results are difficult to present in a model-independent way because Z propagator effects are non-negligible at TRISTAN, PETRA, PEP, and LEP 2 energies. However, assuming e-μ-τ universality, the low energy lepton asymmetries imply [156] $4\,(g_A^e)^2 = 0.99 \pm 0.05$, in good agreement with the SM prediction $\simeq 1$.

Table 10.8: Values of the model-independent neutral-current parameters, compared with the SM predictions. There is a second $g^{\nu e}_{LV,LA}$ solution, given approximately by $g^{\nu e}_{LV} \leftrightarrow g^{\nu e}_{LA}$, which is eliminated by e^+e^- data under the assumption that the neutral current is dominated by the exchange of a single Z boson. The $g^{\nu q}_{LL}$, as well as the $g^{\nu q}_{LR}$, are strongly correlated and non-Gaussian, so that for implementations we recommend the parametrization using g_i^2 and $\tan\theta_i = g^{\nu u}_{Li}/g^{\nu d}_{Li}$ where $i = L, R$. In the SM predictions, the parametric uncertainties from M_Z, M_H, m_t, m_b, m_c, $\widehat{\alpha}(M_Z)$, and α_s are negligible.

10.7. Constraints on new physics

The masses and decay properties of the electroweak bosons and low energy data can be used to search for and set limits on deviations from the SM. We will mainly discuss the effects of exotic particles (with heavy masses $M_{\rm new} \gg M_Z$ in an expansion in $M_Z/M_{\rm new}$) on the gauge boson self-energies. (Brief remarks are made on new physics which is not of this type.) Most of the effects on precision measurements can be described by three gauge self-energy parameters S, T, and U. We will define these, as well as the related parameters ρ_0, ϵ_i, and $\widehat{\epsilon}_i$, to arise from new physics only. In other words, they are equal to zero ($\rho_0 = 1$) exactly in the SM, and do not include any (loop induced) contributions that depend on m_t or M_H, which are treated separately. Our treatment differs from most of the original papers.

The dominant effect of many extensions of the SM can be described by the ρ_0 parameter,

$$\rho_0 \equiv \frac{M_W^2}{M_Z^2\,\widehat{c}_Z^{\,2}\,\widehat{\rho}}\ , \tag{10.59}$$

which describes new sources of SU(2) breaking that cannot be accounted for by the SM Higgs doublet or m_t effects. $\widehat{\rho}$ is calculated as in Eq. (10.12) assuming the validity of the SM. In the presence of $\rho_0 \neq 1$, Eq. (10.59) generalizes the second Eq. (10.12) while the first remains unchanged. Provided that the new physics which yields $\rho_0 \neq 1$ is a small perturbation which does not significantly affect other radiative corrections, ρ_0 can be regarded as a phenomenological parameter which multiplies G_F in Eqs. (10.16)–(10.17), (10.32), and Γ_Z in Eq. (10.46c). There are enough data to determine ρ_0, M_H, m_t, and α_s, simultaneously. From the global fit,

$$\rho_0 = 1.00037 \pm 0.00023\ , \tag{10.60}$$

$$\alpha_s(M_Z) = 0.1183 \pm 0.0016, \tag{10.61}$$

The result in Eq. (10.60) is 1.6 σ above the SM expectation, $\rho_0 = 1$. It can be used to constrain higher-dimensional Higgs representations to have vacuum expectation values of less than a few percent of those of the doublets. Indeed, the relation between M_W and M_Z is modified if there are Higgs multiplets with weak isospin $> 1/2$ with significant vacuum expectation values. For a general (charge-conserving) Higgs structure,

$$\rho_0 = \frac{\sum_i [t(i)(t(i)+1) - t_3(i)^2]|v_i|^2}{2\sum_i t_3(i)^2|v_i|^2}, \tag{10.62}$$

where v_i is the expectation value of the neutral component of a Higgs multiplet with weak isospin $t(i)$ and third component $t_3(i)$. In order to calculate to higher orders in such theories one must define a set of four fundamental renormalized parameters which one may conveniently choose to be α, G_F, M_Z, and M_W, since M_W and M_Z are directly measurable. Then $\widehat{s}_Z^{\,2}$ and ρ_0 can be considered dependent parameters.

Eq. (10.60) can also be used to constrain other types of new physics. For example, non-degenerate multiplets of heavy fermions or scalars break the vector part of weak SU(2) and lead to a decrease in the value of M_Z/M_W. Each non-degenerate SU(2) doublet $\binom{f_1}{f_2}$ yields a positive contribution to ρ_0 [226] of

$$\frac{C\,G_F}{8\sqrt{2}\pi^2}\Delta m^2, \tag{10.63}$$

where

$$\Delta m^2 \equiv m_1^2 + m_2^2 - \frac{4m_1^2m_2^2}{m_1^2 - m_2^2}\ln\frac{m_1}{m_2} \geq (m_1 - m_2)^2, \tag{10.64}$$

and $C = 1$ (3) for color singlets (triplets). Eq. (10.60) taken together with Eq. (10.63) implies the following constraint on the mass splitting at the 95% CL,

$$\sum_i \frac{C_i}{3}\,\Delta m_i^2 \leq (49\ {\rm GeV})^2. \tag{10.65}$$

where the sum runs over all new-physics doublets, for example fourth-family quarks or leptons, $\binom{t'}{b'}$ or $\binom{\nu'}{\ell'-}$, vector-like fermion doublets (which contribute to the sum in Eq. (10.65) with an extra factor of 2), and scalar doublets such as $\binom{\tilde{t}}{\tilde{b}}$ in Supersymmetry (in the absence of L–R mixing).

Non-degenerate multiplets usually imply $\rho_0 > 1$. Similarly, heavy Z' bosons decrease the prediction for M_Z due to mixing and generally lead to $\rho_0 > 1$ [227]. On the other hand, additional Higgs doublets which participate in spontaneous symmetry breaking [228] or heavy lepton doublets involving Majorana neutrinos [229], both of which have more complicated expressions, as well as the vacuum expectation values of Higgs triplets or higher-dimensional representations can contribute to ρ_0 with either sign. Allowing for the presence of heavy degenerate chiral multiplets (the S parameter, to be discussed below) affects the determination of ρ_0 from the data, at present leading to a larger value.

A number of authors [230–235] have considered the general effects on neutral-current and Z and W boson observables of various types of heavy (*i.e.*, $M_{\rm new} \gg M_Z$) physics which contribute to the W and Z self-energies but which do not have any direct coupling to the ordinary fermions. In addition to non-degenerate multiplets, which break the vector part of weak SU(2), these include heavy degenerate multiplets of chiral fermions which break the axial generators.

Such effects can be described by just three parameters, S, T, and U, at the (EW) one-loop level. (Three additional parameters are needed if the new physics scale is comparable to M_Z [236]. Further generalizations, including effects relevant to LEP 2, are described in Ref. 237.) T is proportional to the difference between the W and Z self-energies at $Q^2 = 0$ (*i.e.*, vector SU(2)-breaking), while S ($S+U$) is associated with the difference between the Z (W) self-energy at $Q^2 = M^2_{Z,W}$ and $Q^2 = 0$ (axial SU(2)-breaking). Denoting the contributions of new physics to the various self-energies by $\Pi^{\rm new}_{ij}$, we have

$$\widehat{\alpha}(M_Z)T \equiv \frac{\Pi^{\rm new}_{WW}(0)}{M^2_W} - \frac{\Pi^{\rm new}_{ZZ}(0)}{M^2_Z}\ , \tag{10.66a}$$

$$\frac{\widehat{\alpha}(M_Z)}{4\,\widehat{s}^2_Z\widehat{c}^2_Z}S \equiv \frac{\Pi^{\rm new}_{ZZ}(M^2_Z) - \Pi^{\rm new}_{ZZ}(0)}{M^2_Z} - \frac{\widehat{c}^2_Z - \widehat{s}^2_Z}{\widehat{c}_Z\widehat{s}_Z}\,\frac{\Pi^{\rm new}_{Z\gamma}(M^2_Z)}{M^2_Z} - \frac{\Pi^{\rm new}_{\gamma\gamma}(M^2_Z)}{M^2_Z}\ , \tag{10.66b}$$

$$\frac{\widehat{\alpha}(M_Z)}{4\,\widehat{s}^2_Z}(S+U) \equiv \frac{\Pi^{\rm new}_{WW}(M^2_W) - \Pi^{\rm new}_{WW}(0)}{M^2_W} - \frac{\widehat{c}_Z}{\widehat{s}_Z}\,\frac{\Pi^{\rm new}_{Z\gamma}(M^2_Z)}{M^2_Z} - \frac{\Pi^{\rm new}_{\gamma\gamma}(M^2_Z)}{M^2_Z}\ . \tag{10.66c}$$

S, T, and U are defined with a factor proportional to $\widehat{\alpha}$ removed, so that they are expected to be of order unity in the presence of new physics. In the $\overline{\rm MS}$ scheme as defined in Ref. 57, the last two terms in Eqs. (10.66*b*) and (10.66*c*) can be omitted (as was done in some earlier editions of this *Review*). These three parameters are related to other parameters (S_i, h_i, $\widehat{\epsilon}_i$) defined in Refs. [57,231,232] by

$$\begin{aligned} T &= h_V = \widehat{\epsilon}_1/\widehat{\alpha}(M_Z), \\ S &= h_{AZ} = S_Z = 4\,\widehat{s}^2_Z\,\widehat{\epsilon}_3/\widehat{\alpha}(M_Z), \\ U &= h_{AW} - h_{AZ} = S_W - S_Z \\ &= -4\,\widehat{s}^2_Z\,\widehat{\epsilon}_2/\widehat{\alpha}(M_Z). \end{aligned} \tag{10.67}$$

A heavy non-degenerate multiplet of fermions or scalars contributes positively to T as

$$\rho_0 - 1 = \frac{1}{1-\widehat{\alpha}(M_Z)T} - 1 \simeq \widehat{\alpha}(M_Z)T, \tag{10.68}$$

where $\rho_0 - 1$ is given in Eq. (10.63). The effects of non-standard Higgs representations cannot be separated from heavy non-degenerate multiplets unless the new physics has other consequences, such as vertex corrections. Most of the original papers defined T to include the effects of loops only. However, we will redefine T to include all new sources of SU(2) breaking, including non-standard Higgs, so that T and ρ_0 are equivalent by Eq. (10.68).

A multiplet of heavy degenerate chiral fermions yields

$$S = \frac{C}{3\pi}\sum_i \Big(t_{3L}(i) - t_{3R}(i)\Big)^2, \tag{10.69}$$

where $t_{3L,R}(i)$ is the third component of weak isospin of the left-(right-)handed component of fermion i and C is the number of colors. For example, a heavy degenerate ordinary or mirror family would contribute $2/3\pi$ to S. In models with warped extra dimensions, sizeable correction to the S parameter are generated by mixing effects between the SM gauge bosons and their Kaluza-Klein (KK) excitations. One finds $S \approx 30v^2/M^2_{KK}$, where M_{KK} is the mass of the KK gauge bosons [238]. Large positive values $S > 0$ can also be generated in Technicolor models with QCD-like dynamics, where one expects [230] $S \sim 0.45$ for an iso-doublet of techni-fermions, assuming $N_{TC} = 4$ techni-colors, while $S \sim 1.62$ for a full techni-generation with $N_{TC} = 4$. However, the QCD-like models are excluded on other grounds (flavor changing neutral currents, too-light quarks and pseudo-Goldstone bosons [239], and absence of a Higgs-like scalar).

On the other hand, negative values $S < 0$ are possible, for example, for models of walking Technicolor [240] or loops involving scalars or Majorana particles [241]. The simplest origin of $S < 0$ would probably be an additional heavy Z' boson [227]. Supersymmetric extensions of the SM generally give very small effects. See Refs. 242 and 243 and the note on "Supersymmetry" in the Searches Particle Listings for a complete set of references.

Most simple types of new physics yield $U = 0$, although there are counter-examples, such as the effects of anomalous triple gauge vertices [232].

The SM expressions for observables are replaced by

$$\begin{aligned} M^2_Z &= M^2_{Z0}\,\frac{1-\widehat{\alpha}(M_Z)T}{1 - G_F M^2_{Z0} S/2\sqrt{2}\pi}\ , \\ M^2_W &= M^2_{W0}\,\frac{1}{1 - G_F M^2_{W0}(S+U)/2\sqrt{2}\pi}\ , \end{aligned} \tag{10.70}$$

where M_{Z0} and M_{W0} are the SM expressions (as functions of m_t and M_H) in the $\overline{\rm MS}$ scheme. Furthermore,

$$\Gamma_Z = \frac{M^3_Z\beta_Z}{1-\widehat{\alpha}(M_Z)T}, \Gamma_W = M^3_W\beta_W, A_i = \frac{A_{i0}}{1-\widehat{\alpha}(M_Z)T}\ , \tag{10.71}$$

where β_Z and β_W are the SM expressions for the reduced widths Γ_{Z0}/M^3_{Z0} and Γ_{W0}/M^3_{W0}, M_Z and M_W are the physical masses, and A_i (A_{i0}) is a neutral-current amplitude (in the SM).

The data allow a simultaneous determination of $\widehat{s}^2_Z$ (from the Z pole asymmetries), S (from M_Z), U (from M_W), T (mainly from Γ_Z), α_s (from R_ℓ, $\sigma_{\rm had}$, and τ_τ), M_H and m_t (from the hadron colliders), with little correlation among the SM parameters:

$$\begin{aligned} S &= 0.05 \pm 0.10, \\ T &= 0.08 \pm 0.12, \\ U &= 0.02 \pm 0.10, \end{aligned} \tag{10.72}$$

$\widehat{s}^2_Z = 0.23131 \pm 0.00015$, and $\alpha_s(M_Z) = 0.1182 \pm 0.0017$, where the uncertainties are from the inputs. The parameters in Eqs. (10.72), which by definition are due to new physics only, are in excellent agreement with the SM values of zero. Fixing $U = 0$ (as is also done in Fig. 10.6) moves S and T slightly upwards,

$$\begin{aligned} S &= 0.07 \pm 0.08, \\ T &= 0.10 \pm 0.07, \end{aligned} \tag{10.73}$$

with T showing a 1.5 σ deviation from zero. Using Eq. (10.68), the value of ρ_0 corresponding to T in Eq. (10.72) is 1.0006 ± 0.0009, while the one corresponding to Eq. (10.73) is 1.0008 ± 0.0005.

There is a strong correlation (91%) between the S and T parameters. The U parameter is -61% (-82%) anti-correlated with S (T). The allowed regions in S–T are shown in Fig. 10.6. From Eqs. (10.72) one obtains $S < 0.22$ and $T < 0.27$ at 95% CL, where the former puts the constraint $M_{KK} \gtrsim 2.9$ TeV on the masses of KK gauge bosons in warped extra dimensions.

The S parameter can also be used to constrain the number of fermion families, *under the assumption* that there are no new contributions to T or U and therefore that any new families are degenerate; then an extra generation of SM fermions is excluded at the 7 σ level corresponding to $N_F = 2.83 \pm 0.17$. This can be compared to the fit to the number of light neutrinos given in Eq. (10.37), $N_\nu = 2.992 \pm 0.007$. However, the S parameter fits are valid even for a very heavy fourth family neutrino. Allowing T to vary as well, the constraint on a fourth family is weaker [244]. However, a heavy fourth family would increase the Higgs production cross-section through gluon fusion by a factor ~ 9, which is in considerable tension with the observed Higgs signal at LHC. Combining the limits from electroweak precision data with the measured Higgs production rate and limits from direct searches for heavy quarks [245], a fourth family of chiral fermions is now excluded by more than five standard deviations [246]. Similar remarks apply to a heavy mirror family [247] involving right-handed SU(2) doublets and left-handed singlets. In contrast, new doublets that receive most of their mass from a different

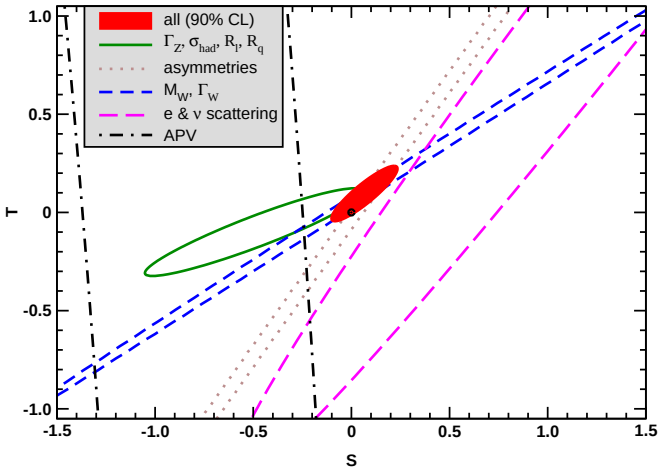

Figure 10.6: 1 σ constraints (39.35% for the closed contours and 68% for the others) on S and T (for $U = 0$) from various inputs combined with M_Z. S and T represent the contributions of new physics only. Data sets not involving M_W or Γ_W are insensitive to U. With the exception of the fit to all data, we fix $\alpha_s = 0.1182$. The black dot indicates the Standard Model values $S = T = 0$.

source than the Higgs vacuum expectation value, such as vector-like fermion doublets or scalar doublets in Supersymmetry, give small or no contribution to S, T, U and the Higgs production cross-section and thus are still allowed. Partial or complete vector-like fermion families are predicted in many grand unified theories [248].

As discussed in Sec. 10.6, there is a 4.0% deviation in the asymmetry parameter A_b. Assuming that this is due to new physics affecting preferentially the third generation, we can perform a fit allowing additional $Z \to b\bar{b}$ vertex corrections ρ_b and κ_b as in Eq. (10.33) (here defined to be due to new physics only with the SM contributions removed), as well as S, T, U, and the SM parameters, with the result,

$$\rho_b = 0.056 \pm 0.020, \qquad \kappa_b = 0.182 \pm 0.068, \qquad (10.74)$$

with an almost perfect correlation of 99% (because R_b is much better determined than A_b). The central values of the oblique parameters are close to their SM values of zero, and there is little change in the SM parameters, except that the value of $\alpha_s(M_Z)$ is lower by 0.0006 compared to the SM fit. Given that almost a $\sim 20\%$ correction to κ_b would be necessary, it would be difficult to account for the deviation in A_b by new physics that enters only at the level of radiative corrections. Thus, if it is due to new physics, it is most likely of tree-level type affecting preferentially the third generation. Examples include the decay of a scalar neutrino resonance [249], mixing of the b quark with heavy exotics [250], and a heavy Z' with family non-universal couplings [251,252]. It is difficult, however, to simultaneously account for R_b without tuning, which has been measured on the Z peak and off-peak [253] at LEP 1. An average of R_b measurements at LEP 2 at energies between 133 and 207 GeV is 2.1 σ below the SM prediction, while $A_{FB}^{(b)}$ (LEP 2) is 1.6 σ low [174].

There is no simple parametrization to describe the effects of every type of new physics on every possible observable. The S, T, and U formalism describes many types of heavy physics which affect only the gauge self-energies, and it can be applied to all precision observables. However, new physics which couples directly to ordinary fermions, such as heavy Z' bosons [227], mixing with exotic fermions [254], or leptoquark exchange [173,255] cannot be fully parametrized in the S, T, and U framework. It is convenient to treat these types of new physics by parameterizations that are specialized to that particular class of theories (*e.g.*, extra Z' bosons), or to consider specific models (which might contain, *e.g.*, Z' bosons and exotic fermions with correlated parameters). Fits to Supersymmetric models are described in Ref. 243. Models involving strong dynamics (such as composite Higgs scenarios) for EW breaking are considered in Ref. 256. The effects of compactified extra spatial dimensions at the TeV scale are reviewed in Ref. 257, and constraints on Little Higgs models in Ref. 258. The implications of non-standard Higgs sectors, e.g., involving Higgs singlets or triplets, are discussed in Ref. 259, while additional Higgs doublets are considered in Refs. 228 and 260. Limits on new four-Fermi operators and on leptoquarks using LEP 2 and lower energy data are given in Refs. 173 and 261. Constraints on various types of new physics are reviewed in Refs. [7,117,142,158,262,263], and implications for the LHC in Ref. 264.

An alternate formalism [265] defines parameters, ϵ_1, ϵ_2, ϵ_3, and ϵ_b in terms of the specific observables M_W/M_Z, $\Gamma_{\ell\ell}$, $A_{FB}^{(0,\ell)}$, and R_b. The definitions coincide with those for $\widehat{\epsilon}_i$ in Eqs. (10.66) and (10.67) for physics which affects gauge self-energies only, but the ϵ's now parametrize arbitrary types of new physics. However, the ϵ's are not related to other observables unless additional model-dependent assumptions are made. Another approach [266] parametrizes new physics in terms of gauge-invariant sets of operators. It is especially powerful in studying the effects of new physics on non-Abelian gauge vertices. The most general approach introduces deviation vectors [262]. Each type of new physics defines a deviation vector, the components of which are the deviations of each observable from its SM prediction, normalized to the experimental uncertainty. The length (direction) of the vector represents the strength (type) of new physics.

For a particularly well motivated and explored type of physics beyond the SM, see the note on "The Z' Searches" in the Gauge & Higgs Boson Particle Listings.

11. STATUS OF HIGGS BOSON PHYSICS

Revised May 2016 by M. Carena (Fermi National Accelerator Laboratory and the University of Chicago), C. Grojean (DESY, Hamburg, on leave from ICREA, Barcelona), M. Kado (Laboratoire de l'Accélérateur Linéaire, Orsay), and V. Sharma (University of California, San Diego).

I. Introduction

Understanding the mechanism that breaks the electroweak symmetry and generates the masses of the known elementary particles[1] has been one of the fundamental endeavors in particle physics. The discovery in 2012 by the ATLAS [1] and the CMS [2] Collaborations of a new resonance with a mass of approximately 125 GeV and the subsequent studies of its properties with a much

[1] In the case of neutrinos, it is possible that the electroweak symmetry breaking mechanism plays only a partial role in generating the observed neutrino masses, with additional contributions at a higher scale via the so called see-saw mechanism.

larger data set have provided the first portrait of this mechanism. The mass of this boson has been precisely measured and its production and decay rates are found to be consistent, within errors, with the standard model (SM) predictions. Nevertheless, many theoretical questions remain unanswered and new conundrums about what lies behind the Higgs boson have come to fore. Four years since its discovery, the Higgs boson has turned into a new tool to explore the manifestations of the SM and to probe the physics landscape beyond it.

In the SM [3] the electroweak interactions are described by a gauge field theory invariant under the $\mathrm{SU}(2)_L \times \mathrm{U}(1)_Y$ symmetry group. The mechanism of electroweak symmetry breaking (EWSB) [4] provides a general framework to keep untouched the structure of these gauge interactions at high energies and still generate the observed masses of the W and Z gauge bosons. The EWSB mechanism posits a self-interacting complex doublet scalar field, whose CP-even neutral component acquires a vacuum expectation value (VEV) $v \approx 246\,\mathrm{GeV}$, which sets the scale of electroweak symmetry breaking. Three massless Goldstone bosons are generated and are absorbed to give masses to the W and Z gauge bosons. The remaining component of the complex doublet becomes the Higgs boson – a new fundamental scalar particle. The masses of all fermions are also a consequence of EWSB since the Higgs doublet is postulated to couple to the fermions through Yukawa interactions.

The true structure behind the newly discovered boson – including the exact dynamics that triggers the Higgs VEV– and the corresponding ultraviolet completion is, however, still unsolved. Even if the discovered boson has weak couplings to all known SM degrees of freedom, it is not excluded that it is part of an extended symmetry structure or that it emerges from a light resonance of a strongly coupled sector. It needs to be established whether the Higgs boson is solitary or whether other states populate the EWSB sector.

Without the Higgs boson, the calculability of the SM would have been spoiled. In particular, perturbative unitarity [5, 6] would be lost at high energies as the longitudinal W/Z boson scattering amplitude would grow as the centre-of-mass energy increases. Moreover, the radiative corrections to the gauge boson self-energies would exhibit dangerous logarithmic divergences that would be difficult to reconcile with EW precision data. With the discovery of the Higgs boson, it has been experimentally established that the SM is based on a gauge theory that could a priori be consistently extrapolated to the Planck scale. The Higgs boson must have couplings to W/Z gauge bosons and fermions precisely as those in the SM to maintain the consistency of the theory at high energies, hence, formally there is no need for new physics at the EW scale. However, as the SM Higgs boson is a scalar particle, and therefore without a symmetry to protect its mass, at the quantum level it has sensitivity to the physics in the ultraviolet. Quite generally, the Higgs mass parameter m may be affected by the presence of heavy particles. Specifically, in presence of fermion and boson particles with squared masses $m_i^2 + \lambda_i^2\phi^2/2$, the running of the mass parameter from the scale μ to the scale Q reads

$$m^2(Q) = m^2(\mu) + \delta m^2, \tag{11.1}$$

$$\delta m^2 = \sum_i g_i(-1)^{2S_i}\frac{\lambda_i^2 m_i^2}{32\pi^2}\log(\frac{Q^2}{\mu^2}), \tag{11.2}$$

where the sum is over all particles and g_i and S_i correspond to the number of degrees of freedom and the spin of the particle i. Therefore, particles that couple to the Higgs and have a large squared mass parameter m_i^2 would induce very large corrections to the Higgs mass parameter, demanding a large fine tuning to explain why m^2 remains small. Hence, in general, light scalars like the Higgs boson cannot naturally survive in the presence of heavy states at the grand-unification, string or Planck scales. This is known as the hierarchy or naturalness problem [7].

There are two broad classes of models addressing the naturalness problem[2]: one is based on a new fermion-boson symmetry in nature called supersymmetry (SUSY) [9–11]. This is a weakly coupled approach to EWSB, and in this case, the Higgs boson remains elementary and the corrections to its mass are screened at the scale at which SUSY is broken and remain insensitive to the details of the physics at higher scales. These theories predict at least three neutral Higgs particles and a pair of charged Higgs particles [12]. One of the neutral Higgs bosons, most often the lightest CP-even Higgs, has properties that resemble those of the SM Higgs boson. It is referred to as a SM-like Higgs boson, meaning that its VEV is predominantly responsible for EWSB, and hence has SM-like couplings to the W and Z gauge bosons.

The other approach invokes the existence of strong interactions at a scale of the order of a TeV or above and induces strong breaking of the electroweak symmetry [13]. In the original incarnation of this second approach, dubbed technicolor, the strong interactions themselves trigger EWSB without the need of a Higgs boson. Another possibility, more compatible with the ATLAS and CMS discovery, is that the strong interactions produce four light resonances identified with the Higgs doublet and EWSB proceeds through vacuum misalignment [14] (see Refs. [15, 16] for recent reviews).

Both approaches can have important effects on the phenomenology of the Higgs boson associated with EWSB. Also, in each case the Higgs role in unitarization is shared by other particles: additional Higgs bosons in supersymmetry, or new particles in the strong sector.

A third option has also been considered in the literature. It is also a variation of technicolor or Higgsless models [13, 17]. In light of the Higgs boson discovery these models are ruled out. Nevertheless, there still exists the possibility that the Higgs boson discovered at the LHC is in fact the Goldstone boson of the spontaneous breaking of scale invariance at a scale f [18, 19]. However, given the good agreement of the coupling measurements with the SM predictions, this dilaton/radion scenario now requires involved model-building.

The naturalness problem has been the prime argument for new physics at the TeV scale, and sizable effects on the Higgs boson properties were expected. But the apparent agreement of the Higgs couplings with the SM predictions, together with the strong bounds inherited from precision electroweak and flavor data leaves open the possibility that the Higgs boson may very well be elementary, weakly coupled and solitary up to the Planck scale. However, absence of evidence is not evidence of absence. It is possible that new states present at the TeV scale to stabilize the Higgs mass might simply be elusive at the LHC because they do not carry a color charge. Twin Higgs [20] models were the first incarnation of this neutral naturalness idea [21]. A more extreme recent proposal [22] relies on the cosmological evolution of the Universe to drive the Higgs boson mass to a value much smaller than the cutoff of the theory and alleviates the hierarchy problem without the need for TeV scale new physics.

Extensions of the SM Higgs sector without low-energy supersymmetry will also be discussed in this review. These type of models do not address the naturalness problem in a specific manner, but provide grounds to explore new Higgs boson signals in a more model-independent way, with different types of coupling structure to fermions and gauge bosons. Extended Higgs sectors are usually quite restricted by experimental constraints from precision electroweak measurements as well as constraints from flavor-changing neutral- and charged-current effects.

Section II is a review of the Higgs boson of the SM, discussing its properties and the production mechanisms and decay rates. In Section III, the SM Higgs boson analysis channels are described. In Section IV, the combination of the main analysis channels is discussed. In Section V, measurements of the main quantum numbers and the total width of the Higgs boson are given. In Section VI, a general theoretical framework to describe the deviations of the Higgs couplings from the SM predictions is introduced and the experimental measurements of these Higgs couplings is reviewed together with the analysis establishing the spin and CP-properties of the Higgs boson. Section VII presents, in detail, some of the most interesting models proposed for Higgs extensions of the SM and considers their experimental signatures. Section VIII provides a brief outlook.

[2] Another solution to the naturalness problem is to lower the fundamental scale of quantum gravity, like for instance in models with large extra-dimensions, see Ref. [8].

II. The standard model and the mechanism of electroweak symmetry breaking

In the SM [3], electroweak symmetry breaking [4] is responsible for generating mass for the W and Z gauge bosons rendering the weak interactions short range. The SM scalar potential reads:

$$V(\Phi) = m^2\Phi^\dagger\Phi + \lambda(\Phi^\dagger\Phi)^2 \tag{11.3}$$

with the Higgs field Φ being a self-interacting SU(2) complex doublet (four real degrees of freedom) with weak hypercharge Y=1 (the hypercharge is normalized such that $Q = T_{3L} + Y/2$):

$$\Phi = \frac{1}{\sqrt{2}}\begin{pmatrix}\sqrt{2}\phi^+\\ \phi^0 + ia^0\end{pmatrix}, \tag{11.4}$$

where ϕ^0 and a^0 are the CP-even and CP-odd neutral components, and ϕ^+ is the complex charged component of the Higgs doublet, respectively. $V(\Phi)$ is the most general renormalizable scalar potential and if the quadratic term is negative the neutral component of the scalar doublet acquires a non-zero vacuum expectation value (VEV)

$$\langle\Phi\rangle = \frac{1}{\sqrt{2}}\begin{pmatrix}0\\ v\end{pmatrix}, \tag{11.5}$$

with $\phi^0 = H + \langle\phi^0\rangle$ and $\langle\phi^0\rangle \equiv v$, inducing the spontaneous breaking of the SM gauge symmetry $\mathrm{SU(3)}_C \times \mathrm{SU(2)}_L \times \mathrm{U(1)}_Y$ into $\mathrm{SU(3)}_C \times \mathrm{U(1)}_{\rm em}$. The global minimum of the theory defines the ground state, and spontaneous symmetry breaking implies that there is a symmetry of the system (Lagrangian) that is not respected by the ground state. The Higgs field permeates the entire universe and through its self-interactions can cause spontaneous electroweak symmetry breaking (EWSB) in the vacuum. From the four generators of the $\mathrm{SU(2)}_L \times \mathrm{U(1)}_Y$ gauge group, three are spontaneously broken, implying that they lead to non-trivial transformations of the ground state and indicate the existence of three massless Goldstone bosons identified with three of the four Higgs field degrees of freedom. The Higgs field couples to the W_μ and B_μ gauge fields associated with the $\mathrm{SU(2)}_L \times \mathrm{U(1)}_Y$ local symmetry through the covariant derivative appearing in the kinetic term of the Higgs Lagrangian,

$$\mathcal{L}_{\rm Higgs} = (D_\mu\Phi)^\dagger(D^\mu\Phi) - V(\Phi)\,, \tag{11.6}$$

where $D_\mu\Phi = (\partial_\mu + ig\sigma^a W^a_\mu/2 + ig'YB_\mu/2)\Phi$, g and g' are the SU(2) and U(1) gauge couplings, respectively, and $\sigma^a, a = 1,2,3$ are the usual Pauli matrices. As a result, the neutral and the two charged massless Goldstone degrees of freedom mix with the gauge fields corresponding to the broken generators of $\mathrm{SU(2)}_L \times \mathrm{U(1)}_Y$ and become the longitudinal components of the Z and W physical gauge bosons, respectively. The Z and W gauge bosons acquire masses,

$$M_W^2 = \frac{g^2v^2}{4}\,, \quad M_Z^2 = \frac{(g'^2+g^2)v^2}{4}. \tag{11.7}$$

The fourth generator remains unbroken since it is the one associated to the conserved $\mathrm{U(1)}_{\rm em}$ gauge symmetry, and its corresponding gauge field, the photon, remains massless. Similarly the eight color gauge bosons, the gluons, corresponding to the conserved $\mathrm{SU(3)}_C$ gauge symmetry with 8 unbroken generators, also remain massless. Hence, from the initial four degrees of freedom of the Higgs field, two are absorbed by the $W^\pm$ gauge bosons, one by the Z gauge boson, and there is one remaining degree of freedom, H, that is the physical Higgs boson — a new scalar particle. The Higgs boson is neutral under the electromagnetic interactions and transforms as a singlet under $\mathrm{SU(3)}_C$ and hence does not couple at tree level to the massless photons and gluons.

The fermions of the SM acquire mass through new renormalizable interactions between the Higgs field and the fermions: the Yukawa interactions,

$$\mathcal{L}_{\rm Yukawa} = -\hat{h}_{d_{ij}}\bar{q}_{L_i}\Phi\, d_{R_j} - \hat{h}_{u_{ij}}\bar{q}_{L_i}\tilde{\Phi}u_{R_j} - \hat{h}_{l_{ij}}\bar{l}_{L_i}\Phi\, e_{R_j} + h.c., \tag{11.8}$$

which respect the symmetries of the SM but generate fermion masses once EWSB occurs. In the above, $\tilde{\Phi} = i\sigma_2\Phi^*$ and q_L (l_L) and u_R, d_R (e_R) are the quark (lepton) $\mathrm{SU(2)}_L$ doublets and singlets, respectively, while each term is parametrized by a 3×3 matrix in family space. The mass term for neutrinos is omitted, but could be added in an analogous manner to the up-type quarks when right-handed neutrinos are supplementing the SM particle content. Once the Higgs acquires a VEV, and after rotation to the fermion mass eigenstate basis that also diagonalizes the Higgs-fermion interactions, $\hat{h}_{f_{ij}} \to h_{f_i}\delta_{ij}$, all fermions acquire a mass given by $m_{f_i} = h_{f_i}v/\sqrt{2}$. The indices $i,j = 1,2,3$ refer to the three families in the up-quark, down-quark or charged lepton sectors. It should be noted that the EWSB mechanism provides no additional insight on possible underlying reasons for the large variety of masses of the fermions, often referred to as the flavor hierarchy. The fermion masses, accounting for a large number of the free parameters of the SM, are simply translated into Yukawa couplings h_f.

II.1. The SM Higgs boson mass, couplings and quantum numbers

The SM Higgs boson is a CP-even scalar of spin 0. Its mass is given by $m_H = \sqrt{2\lambda}\,v$, where λ is the Higgs self-coupling parameter in $V(\Phi)$. The expectation value of the Higgs field, $v = (\sqrt{2}G_F)^{-1/2} \approx 246\,\mathrm{GeV}$, is fixed by the Fermi coupling G_F, which is determined with a precision of 0.6 ppm from muon decay measurements [23]. The quartic coupling λ is a free parameter in the SM, and hence, there is no a priori prediction for the Higgs mass. Moreover the sign of the mass parameter $m^2 = -\lambda v^2$ is crucial for the EW symmetry breaking to take place, but it is not specified in the SM. The experimentally measured Higgs mass, $m_H \simeq 125\,\mathrm{GeV}$, implies that $\lambda \simeq 0.13$ and $|m| \simeq 88.8\,\mathrm{GeV}$. It is interesting to observe that in the SM one needs to assume that the mass term in the potential is negative in order to trigger EWSB. In other theories beyond the SM (BSM), such as supersymmetry, the analogue of the Higgs mass parameter can be made negative dynamically.

The Higgs boson couplings to the fundamental particles are set by their masses. This is a new type of interaction; very weak for light particles, such as up and down quarks, and electrons, but strong for heavy particles such as the W and Z bosons and the top quark. More precisely, the SM Higgs couplings to fundamental fermions are linearly proportional to the fermion masses, whereas the couplings to bosons are proportional to the square of the boson masses. The SM Higgs boson couplings to gauge bosons and fermions, as well as the Higgs boson self coupling, are summarized in the following Lagrangian:

$$\begin{aligned}\mathcal{L} = &- g_{Hff}\bar{f}fH + \frac{g_{HHH}}{6}H^3 + \frac{g_{HHHH}}{24}H^4\\ &+ \delta_V V_\mu V^\mu\left(g_{HVV}H + \frac{g_{HHVV}}{2}H^2\right)\end{aligned} \tag{11.9}$$

with

$$g_{Hf\bar{f}} = \frac{m_f}{v}\,, \quad g_{HVV} = \frac{2m_V^2}{v}\,, \quad g_{HHVV} = \frac{2m_V^2}{v^2}\,, \tag{11.10}$$

$$g_{HHH} = \frac{3m_H^2}{v}\,, \quad g_{HHHH} = \frac{3m_H^2}{v^2}\,, \tag{11.11}$$

where $V = \mathrm{W}^\pm$ or Z and $\delta_W = 1, \delta_Z = 1/2$. As a result, the dominant mechanisms for Higgs boson production and decay involve the coupling of H to W, Z and/or the third generation quarks and leptons. The Higgs boson coupling to gluons [24, 25] is induced at leading order by a one-loop process in which H couples to a virtual $t\bar{t}$ pair. Likewise, the Higgs boson coupling to photons is also generated via loops, although in this case the one-loop graph with a virtual W^+W^- pair provides the dominant contribution [12] and the one involving a virtual $t\bar{t}$ pair is subdominant.

II.2. The SM custodial symmetry

The SM Higgs Lagrangian, $\mathcal{L}_{\rm Higgs} + \mathcal{L}_{\rm Yukawa}$ of Eq. (11.6) and Eq. (11.8), is, by construction, $\mathrm{SU(2)}_L \times \mathrm{U(1)}_Y$ gauge invariant, but it also has an approximate global symmetry. In the limit $g' \to 0$ and $h_f \to 0$, the Higgs sector has a global $\mathrm{SU(2)}_R$ symmetry, and hence in

such a limit it is invariant under a global $\mathrm{SU}(2)_L \times \mathrm{SU}(2)_R$ symmetry, with $\mathrm{SU}(2)_L$ just being the global variant of the SM chiral gauge symmetry. This symmetry is preserved for non-vanishing Yukawa couplings, provided $h_u = h_d$. Once the Higgs acquires a VEV, both the $\mathrm{SU}(2)_L$ and $\mathrm{SU}(2)_R$ symmetry groups are broken but the subgroup $\mathrm{SU}(2)_{L+R}$ remains unbroken and is the subgroup that defines the custodial symmetry of the SM [26].

In the limit $g' \to 0$, the W and Z gauge bosons have equal mass and form a triplet of the $\mathrm{SU}(2)_{L+R}$ unbroken global symmetry. Using the expressions for the W and Z gauge boson masses in term of the gauge couplings, one obtains

$$\frac{M_W^2}{M_Z^2} = \frac{g^2}{g'^2 + g^2} = \cos^2\theta_W \quad \text{or} \quad \rho \equiv \frac{M_W^2}{M_Z^2 \cos^2\theta_W} = 1 \qquad (11.12)$$

at tree level. The custodial symmetry protects the above relation between the W and Z masses under radiative corrections. All corrections to the ρ parameter are therefore proportional to terms that break the custodial symmetry. For instance, radiative corrections involving the Higgs are proportional to g'^2. Since $m_t \neq m_b$, there are also relevant radiative corrections generated by massive fermions. They are proportional to $m_t^2 + m_b^2 - 2(m_t^2 m_b^2)\,\log(m_t^2/m_b^2)/(m_t^2 - m_b^2)$ [27].

One can conceive of BSM theories in which the Higgs is a pseudo Nambu–Goldstone boson of a strongly interacting sector [28], and/or where there are additional degrees of freedom that may contribute to the W and Z mass via virtual loops, but in as much as the electroweak sector has a manifest custodial symmetry, the theory is protected from large radiative corrections. Precision measurements of electroweak observables are powerful in constraining such large radiative corrections. The custodial isospin symmetry is also a powerful probe of BSM physics. For a pedagogical discussion, see Ref. [29].

II.3. Stability of the Higgs potential

The discovery of a scalar particle with mass $m_H \approx 125\,\mathrm{GeV}$ has far reaching consequences within the SM framework. In particular, the precise value of m_H determines the value of the quartic coupling λ at the electroweak scale and makes it possible to study its behavior up to high energy scales. A larger value of m_H would have implied that the Higgs self-coupling would become non-perturbative at some scale Λ that could be well below the Planck scale. Specifically, from the measured values of the Higgs mass, the top-quark mass, the W and Z boson masses, and the strong gauge coupling, all within their experimental uncertainties, it follows that, as with the SM gauge and Yukawa couplings, the Higgs quartic coupling remains perturbative all the way up to M_{Planck} [5, 6, 30], thereby rendering the SM a consistent, calculable theory.

The recently measured Higgs mass, however, generates an EW Higgs potential in which the vacuum state is at the edge between being stable and metastable. Indeed, allowing all relevant SM observables to fluctuate within their experimental and theoretical uncertainties, the metastability condition seems to be favored [31]. The high energy evolution of λ shows that it becomes negative at energies $\Lambda = \mathcal{O}(10^{10} - 10^{12})\,\mathrm{GeV}$, with a broader range if the top quark mass exceeds its current measured value by 3σ. When this occurs, the SM Higgs potential develops an instability and the long term existence of the EW vacuum is challenged. This behavior may call for new physics at an intermediate scale before the instability develops, i.e., below M_{Planck} or, otherwise, the electroweak vacuum remains metastable [32]. Reference [33] studied how new physics at M_{Planck} could influence the stability of the EW vacuum and possibly modify this conclusion. The consequences of the instability of the EW vacuum on high-scale inflation have been discussed in Refs. [34].

Within the SM framework, the relevant question is related to the lifetime of the EW metastable vacuum that is determined by the rate of quantum tunneling from this vacuum into the true vacuum of the theory. The running of the Higgs self coupling slows down at high energies with a cancellation of its β-function at energies just one to two orders of magnitude below the Planck scale [31, 35]. This slow evolution of the quartic coupling is responsible for saving the EW vacuum from premature collapse, allowing it to survive much longer times than those relevant from astrophysical considerations. It might help the Higgs boson to play the role of an inflaton [36] (see, however, Ref. [37] and references therein for potential issues with this Higgs-as-inflaton idea).

II.4. Higgs production and decay mechanisms

Reviews of the SM Higgs boson's properties and phenomenology, with an emphasis on the impact of loop corrections to the Higgs boson decay rates and cross sections, can be found in Refs. [38–45]. The state-of-the-art of the theoretical calculations in the main different production channels is summarized in Table 11.1.

Table 11.1: State-of-the-art of the theoretical calculations in the main different Higgs production channels in the SM, and main MC tools used in the simulations

II.4.1. Production mechanisms at hadron colliders

The main production mechanisms at the Tevatron collider and the LHC are gluon fusion, weak-boson fusion, associated production with a gauge boson and associated production with a pair of top/antitop quarks. Figure 11.1 depicts representative diagrams for these dominant Higgs production processes.

The cross sections for the production of a SM Higgs boson as a function of $\sqrt{s}$, the center of mass energy, for pp collisions, including bands indicating the theoretical uncertainties, are summarized in Fig. 11.2(left) [46]. A detailed discussion, including uncertainties in the theoretical calculations due to missing higher-order effects and experimental uncertainties on the determination of SM parameters involved in the calculations can be found in Refs. [42–45]. These references also contain state-of-the-art discussions on the impact of PDF's uncertainties, QCD scale uncertainties and uncertainties due to different matching procedures when including higher-order corrections matched to parton shower simulations as well as uncertainties due to hadronization and parton-shower events.

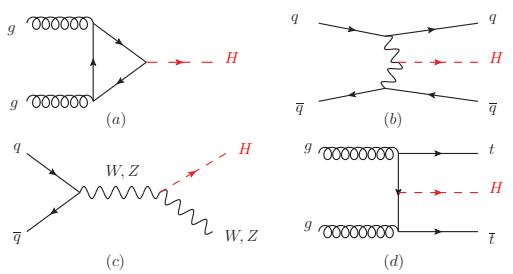

Figure 11.1: Generic Feynman diagrams contributing to the Higgs production in (a) gluon fusion, (b) weak-boson fusion, (c) Higgs-strahlung (or associated production with a gauge boson) and (d) associated production with top quarks.

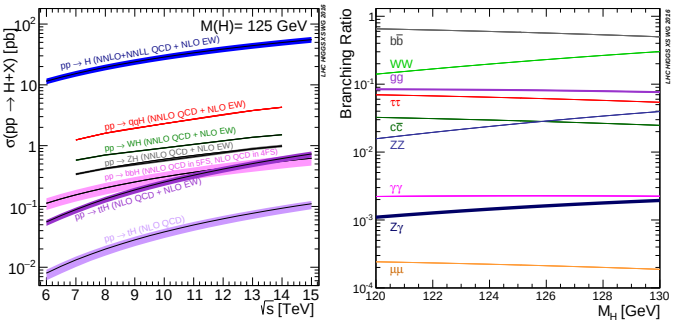

Figure 11.2: (Left) The SM Higgs boson production cross sections as a function of the center of mass energy, $\sqrt{s}$, for pp collisions. The theoretical uncertainties [46] are indicated as bands. (Right) The branching ratios for the main decays of the SM Higgs boson near $m_H = 125\,\text{GeV}$. The theoretical uncertainties [44, 45] are indicated as bands.

Table 11.2: The SM Higgs boson production cross sections for $m_H = 125\,\text{GeV}$ in pp collisions ($p\bar{p}$ collisions at $\sqrt{s} = 1.96\,\text{TeV}$ for the Tevatron), as a function of the center of mass energy, $\sqrt{s}$. The predictions for the LHC energies are taken from Refs. [42–45], the ones for the Tevatron energy are from Ref. [47]. The predictions for the ggF channel do not include the latest N3LO results which significantly reduce the theoretical uncertainties.

$\sqrt{s}$ (TeV)	Production cross section (in pb) for $m_H = 125\,\text{GeV}$					
	ggF	VBF	WH	ZH	$t\bar{t}H$	total
1.96	$0.95^{+17\%}_{-17\%}$	$0.065^{+8\%}_{-7\%}$	$0.13^{+8\%}_{-8\%}$	$0.079^{+8\%}_{-8\%}$	$0.004^{+10\%}_{-10\%}$	1.23
7	$15.3^{+10\%}_{-10\%}$	$1.24^{+2\%}_{-2\%}$	$0.58^{+3\%}_{-3\%}$	$0.34^{+4\%}_{-4\%}$	$0.09^{+8\%}_{-14\%}$	17.5
8	$19.5^{+10\%}_{-11\%}$	$1.60^{+2\%}_{-2\%}$	$0.70^{+3\%}_{-3\%}$	$0.42^{+5\%}_{-5\%}$	$0.13^{+8\%}_{-13\%}$	22.3
13	$44.1^{+11\%}_{-11\%}$	$3.78^{+2\%}_{-2\%}$	$1.37^{+2\%}_{-2\%}$	$0.88^{+5\%}_{-5\%}$	$0.51^{+9\%}_{-13\%}$	50.6
14	$49.7^{+11\%}_{-11\%}$	$4.28^{+2\%}_{-2\%}$	$1.51^{+2\%}_{-2\%}$	$0.99^{+5\%}_{-5\%}$	$0.61^{+9\%}_{-13\%}$	57.1

Table 11.2, from Refs. [42–45], summarizes the Higgs boson production cross sections and relative uncertainties for a Higgs mass of 125 GeV, for $\sqrt{s} = 7$, 8, 13 and 14 TeV. The Higgs boson production cross sections in $p\bar{p}$ collisions at $\sqrt{s} = 1.96\,\text{TeV}$ for the Tevatron are obtained from Ref. [47].

(i) Gluon fusion production mechanism

At high-energy hadron colliders, the Higgs boson production mechanism with the largest cross section is the gluon-fusion process, $gg \to H + X$, mediated by the exchange of a virtual, heavy top quark [48]. Contributions from lighter quarks propagating in the loop are suppressed proportional to m_q^2. QCD radiative corrections to the gluon-fusion process are very important and have been studied in detail. Including the full dependence on the (top, bottom, charm) quark and Higgs boson masses, the cross section has been calculated at the next-to-leading order (NLO) in α_s [49, 50]. To a very good approximation, the leading top-quark contribution can be evaluated in the limit $m_t \to \infty$ by matching the SM to an effective theory. The gluon-fusion amplitude is then evaluated from an effective Lagrangian containing a local $HG^a_{\mu\nu}G^{a\,\mu\nu}$ operator [24, 25]. In this approximation the cross section is known at NLO [51], at next-to-next-to-leading order (NNLO) [52], and recently the computation at next-to-next-to-next-to-leading order (N3LO) has been completed [53]. The validity of the large top-quark mass approximation in NNLO calculations has been established at the percent level by means of approximate calculations of the m_t dependence based on asymptotic expansions [54]. Moreover, the validity of the effective theory with infinite m_t is greatly enhanced by rescaling the result by the exact LO result: $\sigma = (\sigma^{LO}_{m_t}/\sigma^{LO}_{m_t=\infty}) \times \sigma_{m_t=\infty}$ [45].

The NLO QCD corrections increase the leading-order prediction for the cross section by about 80%, the NNLO corrections further enhance the cross section by approximately 30% (at $\mu_f = \mu_r = m_H/2$). Electroweak radiative corrections have been computed at NLO and increase the cross section by about 5% for $m_H \simeq 125\,\text{GeV}$ [55]. Mixed QCD-electroweak corrections of $O(\alpha\alpha_s)$ have been calculated in Ref. [56].

The NLO and NNLO fixed-order QCD predictions for the gluon-fusion cross section have been improved by resumming the soft, virtual and collinear gluon contributions to the cross section at next-to-next-to-leading logarithmic (NNLL) and partial NNNLL accuracy [57]. Precise predictions for the gluon-fusion cross section for different Higgs boson masses and LHC energies, and including detailed error estimates, have been obtained by combining the NNLO fixed-order QCD results with soft-gluon resummation at NNLL or NNNLL accuracy and two-loop electroweak corrections, and using the most recent sets of parton distribution functions [56, 58].

The perturbative QCD computation has been recently extended to N3LO. At this order the perturbation series is rather stable with a mere enhancement of 3% only, with a central value completely insensitive to threshold resummation effects with the scale choice mentioned above [53, 59, 45]. At the LHC with a center-of-mass energy of 13 TeV, the most up-to-date value for the production cross section of a 125 GeV Higgs boson amounts to [45]

$$\sigma^{N3LO}_{ggF} = 48.6\,\text{pb}^{+2.2\,\text{pb}(+4.6\%)}_{-3.3\,\text{pb}(-6.7\%)}(\text{theory}) \pm 1.6\,\text{pb}(3.2\%)(\text{PDF} + \alpha_s).$$

The difference between this result and the value quoted in Table 11.2 is due to several effects that include: the choice of optimal renormalization and factorization scales, the effect of the N3LO corrections, the different sets of parton distribution functions and value of α_s, as well as smaller differences due to the treatment of finite quark-mass effects [53].

Besides considering the inclusive Higgs boson production cross section at the LHC, it is important to study differential distributions in order to probe the properties of the Higgs boson in a detailed way. A more exclusive account of Higgs production is also required because experimental analyses often impose cuts on the final states in order to improve the signal-to-background ratio. To this end, it is useful to define benchmark cuts and compare the differential distributions obtained at various levels of theoretical accuracy (i.e., at NLO or NNLO) with Monte Carlo generators. Many search modes for the Higgs boson are carried out by separating the events according to the number of jets or the transverse momentum and rapidity of the Higgs boson. For $p_T < 30\,\text{GeV}$, predictions for the transverse-momentum distribution can only be trusted after large logarithms of the form $\alpha_s^n \ln^{2n-1}(m_H/p_T)$ have been resummed to all orders in perturbation theory [60]. This has been accomplished with NNLL accuracy [61], and the results have been matched onto the fixed-order prediction at NNLO [62]. Electroweak corrections have been studied in Ref. [63]. The effect of the non-zero quark mass on the pT spectrum has been considered in Refs. [64, 65], while the effect of the finite top mass on other differential observables has been studied in Refs. [66, 67]. There has been much activity in computing Higgs plus jet(s) production processes at NLO (see e.g. Refs. [68] and [69] for associated production with one and two jets, respectively), and even at NNLO [70]. In addition, efforts to improve the calculation of the Higgs production

cross section with a jet veto (the "0-jet bin") by resumming large logarithms of the form $\alpha_s^n \ln^{2n-1}(m_H/p_T^{\rm veto})$ at NNLL order and beyond [71] have been made. Recently, reference results for the resummed cross section at NNLL have been combined with the N3LO result for the inclusive cross section to obtain accurate predictions for the jet-veto efficiency and zero-jet cross section [72]. Accurate predictions for the jet-veto cross section are required, e.g., to suppress the $t\bar{t}$ background in the $H \to WW$ channel [73].

(ii) Vector boson fusion production mechanism

The SM Higgs production mode with the second-largest cross section at the LHC is vector boson fusion (VBF). At the Tevatron collider, VBF also occurred, but for $m_H = 125\,\text{GeV}$ had a smaller cross section than Higgs production in association with a W or Z boson. Higgs production via VBF, $qq \to qqH$, proceeds by the scattering of two (anti-)quarks, mediated by t- or u-channel exchange of a W or Z boson, with the Higgs boson radiated off the weak-boson propagator. The scattered quarks give rise to two hard jets in the forward and backward regions of the detector. Because of the color-singlet nature of the weak-gauge boson exchange, gluon radiation from the central-rapidity regions is strongly suppressed. These characteristic features of VBF processes can be exploited to distinguish them from overwhelming QCD backgrounds, including gluon-fusion induced Higgs + 2 jet production, and from s-channel WH or ZH production with a hadronically decaying weak gauge boson. After the application of specific selection cuts, the VBF channel provides a particularly clean environment, not only for Higgs searches but also for the determination of Higgs boson couplings at the LHC [74].

Computations for total cross sections and differential distributions to Higgs production via VBF including NLO QCD and EW corrections have been presented in Refs. [39, 75] and are available in the form of flexible parton-level Monte-Carlo generators. Parton-shower effects have been considered in Ref. [76]. The NNLO QCD corrections to the total rate have been presented in Refs. [77]. They reduce the residual scale uncertainties on the inclusive cross section to approximately 2%. The uncertainties due to parton distributions are estimated to be at the same level. Fully differential predictions at NNLO have been computed recently [78], suggesting that the cross section under VBF cuts receives NNLO corrections that are larger than in the inclusive case and may reach O(5-6%).

(iii) WH and ZH associated production mechanism

The next most relevant Higgs boson production mechanisms after gluon fusion and VBF at the LHC, and the most relevant ones after gluon fusion at the Tevatron collider, are associated production with W and Z gauge bosons. The cross sections for the associated production processes, $pp \to VH + X$, with $V = W^{\pm}, Z$ receive contributions at NLO given by NLO QCD corrections to the Drell–Yan cross section [79–81] and from NLO EW corrections. The latter, unlike the QCD corrections, do not respect the factorization into Drell–Yan production since there are irreducible box contributions already at one loop [82]. At NNLO, the Drell-Yan-like corrections to WH production also give the bulk of the corrections to ZH production [83]. For ZH production there are, however, gluon-gluon induced contributions that do not involve a virtual Z gauge boson but are such that the Z gauge boson and H boson couple to gluons via top-quark loops [84]. In addition, WH and ZH production receive non Drell–Yan-like corrections in the $q\bar{q}'$ and $q\overline{q}$ initiated channels, respectively, at the NNLO level, where the Higgs is radiated off top-quark loops [85]. The full QCD corrections up to NNLO order, the NLO EW corrections and the NLO corrections to the gluon-gluon channel are available in VH@NNLO [86].

As neither the Higgs boson nor the weak gauge bosons are stable particles, their decays also have to be taken into account. Providing full kinematical information for the decay products can furthermore help in the suppression of large QCD backgrounds. Differential distributions for the processes $pp \to WH \to \nu_\ell \ell H$ and $pp \to ZH \to \ell^+\ell^- H/\nu_\ell \bar{\nu}_\ell H$, including NLO QCD and EW corrections, have been presented in Ref. [87]. The NNLO QCD corrections to differential observables for WH production at the LHC, including the leptonic decays of the W boson and the decay of the Higgs boson into a $b\bar{b}$ pair, are presented in Ref. [88]. Calculations at the same level, including also the ZH process have been performed [89, 90]. The WH production mode has also been matched to a parton shower at NNLO accuracy [91]. The WH and ZH production modes, together with Higgs production in association with a top-quark pair, provide a relatively clean environment for studying the decay of the Higgs boson into bottom quarks.

(iv) Higgs production in association with $t\bar{t}$

Higgs radiation off top quarks, $pp \to t\bar{t}H$, can provide important information on the the top-Higgs Yukawa coupling and gives access to the Higgs decay into bottom quarks. The LO cross section for this production process was computed in Ref. [92]. Later, the NLO QCD corrections [93] were evaluated yielding a moderate increase in the total cross section of at most 20%, but reducing significantly the scale dependence of the inclusive cross section. The total theoretical errors, estimated by combining the uncertainties from factorization and renormalization scales, strong gauge coupling, and parton distributions, amount to 10–15% of the corresponding inclusive cross section. Interfaces between NLO QCD calculations for $t\bar{t}H$ production with parton-shower Monte Carlo programs have been provided in Ref. [94]. These programs provide the most flexible tools to date for the computation of differential distributions, including experimental selection cuts and vetoes on the final-state particles and their decay products.

(v) Other single Higgs production mechanisms at the LHC

The Higgs production in association with a single top quark, though subdominant, can bring valuable information, in particular regarding the sign of the top Yukawa coupling. This is due to an almost totally destructive interference between two large contributions, one where the Higgs couples to a space-like W boson and the other where it couples to the top quark. This process has been computed at NLO in a five-flavor scheme [95] and amounts to about 90 fb at $\sqrt{s} = 14\,\text{TeV}$ (with the opposite sign of the top Yukawa coupling, the cross section increases by one order of magnitude).

The Higgs boson production in association with bottom quarks is known at NNLO in the case of five quark flavors [96–98]. The coupling of the Higgs boson to a b quark is suppressed in the SM by the bottom-quark mass over the Higgs VEV, m_b/v, implying that associated production of a SM Higgs boson with b quarks is small at the LHC. Yet, at high energy, large logarithms are present and need to be resummed, leading to an enhancement of the inclusive cross section. At $\sqrt{s} = 14\,\text{TeV}$ the bbH cross section can be as large as 600 fb, still two orders of magnitude below the ggF production cross section. In a two Higgs doublet model or a supersymmetric model, which will be discussed in Section VII, this coupling is proportional to the ratio of neutral Higgs boson vacuum expectation values, $\tan\beta$, and can be significantly enhanced for large values of this ratio. Consequently, the bbH mode can even become the dominant production process for the Higgs boson.

The Higgs production in association with charm quarks is also known at NNLO and is of the order of 85 fb at $\sqrt{s} = 13\,\text{TeV}$.

(vi) Double Higgs production at the LHC

The main interest in the double Higgs production is that it provides invaluable information on the Higgs potential. In particular, it gives access to the Higgs cubic self-interaction. The dominant production is via gluon fusion $gg \to HH$. The NLO [99] and NNLO [100] fixed order corrections to $gg \to HH$ are known in the infinite top mass limit and, recently, the complete NLO corrections with all top quark mass effects also became available [101]. The QCD corrections are large, typically doubling the cross section from LO to NLO and further enhancing it by 20% from NLO to NNLO. At the differential level, the destructive interference between the box and the triangle contributions complicates the predictions made in the infinite top mass limit for both the HH invariant mass and the leading Higgs p_T distributions. With an inclusive cross section of about 40 fb at $\sqrt{s} = 13\,\text{TeV}$ and a difficult signal vs. background discrimination, the double Higgs production remains a challenging channel to probe and will greatly benefit from the high-luminosity run of the LHC.

II.4.2. Production mechanisms at e^+e^- colliders

The main Higgs boson production cross sections at an e^+e^- collider are the Higgs-strahlung process $e^+e^- \to ZH$ [6, 24, 102], and the WW fusion process [103] $e^+e^- \to \bar{\nu}_e\nu_e W^*W^* \to \bar{\nu}_e\nu_e H$. The cross-section for the Higgs-strahlung process scales as s^{-1} and is dominant at low energies, while the cross-section for the WW fusion process scales as $\ln(s/m_H^2)$ and dominates at high energies [104–106]. The ZZ fusion mechanism, $e^+e^- \to e^+e^-Z^*Z^* \to e^+e^-H$, also contributes to Higgs boson production, with a cross-section suppressed by an order of magnitude with respect to that of WW fusion. The process $e^+e^- \to t\bar{t}H$ [107, 108] becomes important for $\sqrt{s} \geq 500\,\text{GeV}$. For a more detailed discussion of Higgs production properties at lepton colliders see, for example, Refs. [40, 41, 109, 110] and references therein.

II.4.3. SM Higgs branching ratios and total width

For the understanding and interpretation of the experimental results, the computation of all relevant Higgs decay widths is essential, including an estimate of their uncertainties and, when appropriate, the effects of Higgs decays into off-shell particles with successive decays into lighter SM ones. A Higgs mass of about 125 GeV provides an excellent opportunity to explore the Higgs couplings to many SM particles. In particular the dominant decay modes are $H \to b\bar{b}$ and $H \to WW^*$, followed by $H \to gg$, $H \to \tau^+\tau^-$, $H \to c\bar{c}$ and $H \to ZZ^*$. With much smaller rates follow the Higgs decays into $H \to \gamma\gamma$, $H \to \gamma Z$ and $H \to \mu^+\mu^-$. Since the decays into gluons, diphotons and $Z\gamma$ are loop induced, they provide indirect information on the Higgs couplings to WW, ZZ and $t\bar{t}$ in different combinations. The uncertainties in the branching ratios include the missing higher-order corrections in the theoretical calculations as well as the errors in the SM input parameters, in particular fermion masses and the QCD gauge coupling, involved in the decay. In the following the state-of-the-art of the theoretical calculations will be discussed and the reader is referred to Refs. [42, 43, 111] for detail.

The evaluation of the radiative corrections to the fermionic decays of the SM Higgs are implemented in HDECAY [112] at different levels of accuracy. The computations of the $H \to b\bar{b}$ and $H \to c\bar{c}$ decays include the complete massless QCD corrections up to N4LO, with a corresponding scale dependence of about 0.1% [113]. Both the electroweak corrections to $H \to b\bar{b}$, $c\bar{c}$ as well as $H \to \tau^+\tau^-$ are known at NLO [114] providing predictions with an overall accuracy of about 1-2% for $m_H \simeq 125\,\text{GeV}$.

The loop induced decays of the SM Higgs are known at NLO and partially beyond that approximation. For $H \to gg$, the QCD corrections are known up to N3LO in the limit of heavy top quarks [115, 50] and the uncertainty from the scale dependence is about 3%. For the $H \to \gamma\gamma$, the full NLO QCD corrections are available [50, 116] and the three-loop QCD corrections have also been evaluated [117]. The NLO electroweak corrections to $H \to gg$ and $H \to \gamma\gamma$ have been computed in Ref. [118]. All these corrections are implemented in HDECAY [112]. For $m_H = 125\,\text{GeV}$, the overall impact of known QCD and EW radiative effects turns out to be well below 1%. In addition, the contribution of the $H \to \gamma e^+e^-$ decay via virtual photon conversion has been computed in Ref. [119]. The partial decay width $H \to Z\gamma$ is only implemented at LO in HDECAY, including the virtual W, top-, bottom-, and τ-loop contributions. The QCD corrections have been calculated and are at the percent level [120], The theoretical uncertainty due to unknown electroweak corrections is estimated to be less than 5%, an accuracy that will be hard to achieve in measurements of this processes at the LHC.

The decays $H \to WW/ZZ \to 4f$ can be simulated with the Prophecy4f Monte-Carlo generator [121] that includes complete NLO QCD and EW corrections for Higgs decays into any possible four-fermion final state. All calculations are consistently performed with off-shell gauge bosons, without any on-shell approximation. For the SM Higgs boson the missing higher-order corrections are estimated to be roughly 0.5%. Such uncertainties will have to be combined with the parametric uncertainties, in particular those associated to the bottom-quark mass and the strong gauge coupling, to arrive at the full theory uncertainties. A detailed treatment of the differential distributions for a Higgs decay into four charged leptons in the final state is discussed in Refs. [44, 122].

The total width of a 125 GeV SM Higgs boson is $\Gamma_H = 4.07 \times 10^{-3}\,\text{GeV}$, with a relative uncertainty of $^{+4.0\%}_{-3.9\%}$. The branching ratios for the most relevant decay modes of the SM Higgs boson as a function of m_H, including the most recent theoretical uncertainties, are shown in Fig. 11.2(right) and listed for $m_H = 125\,\text{GeV}$ in Table 11.3. Further details of these calculations can be found in Refs. [111, 123] and in the reviews [39–45].

Table 11.3: The branching ratios and the relative uncertainty [44, 45] for a SM Higgs boson with $m_H = 125\,\text{GeV}$.

Decay channel	Branching ratio	Rel. uncertainty
$H \to \gamma\gamma$	2.27×10^{-3}	$^{+5.0\%}_{-4.9\%}$
$H \to ZZ$	2.62×10^{-2}	$^{+4.3\%}_{-4.1\%}$
$H \to W^+W^-$	2.14×10^{-1}	$^{+4.3\%}_{-4.2\%}$
$H \to \tau^+\tau^-$	6.27×10^{-2}	$^{+5.7\%}_{-5.7\%}$
$H \to b\bar{b}$	5.84×10^{-1}	$^{+3.2\%}_{-3.3\%}$
$H \to Z\gamma$	1.53×10^{-3}	$^{+9.0\%}_{-8.9\%}$
$H \to \mu^+\mu^-$	2.18×10^{-4}	$^{+6.0\%}_{-5.9\%}$

III. The experimental profile of the Higgs boson

An indirect experimental bound on the SM Higgs boson can be obtained by comparing precision electroweak data with SM predictions, that have a weak, logarithmic dependence on M_H. A global fit to electroweak data suggests $m_H = 96^{+22}_{-19}\,\text{GeV}$, or $m_H < 134\,\text{GeV}$ at 90% confidence level [124].

The announcement on July 4, 2012 of the observation [1, 2] at the LHC of a narrow resonance with a mass of about 125 GeV was an important landmark in the decades-long direct search [125, 126] for the SM Higgs boson. Even as this discovery was being announced, ATLAS and CMS continued to accumulate pp collision data at $\sqrt{s} = 8\,\text{TeV}$ recording a total of about $20\,\text{fb}^{-1}$ each at this energy. This data set together with about $5\,\text{fb}^{-1}$ recorded at $\sqrt{s} = 7\,\text{TeV}$ comprised the LHC Run 1 pp collision data set. In the remainder of this section the focus will be on the final results on the measurements of Higgs boson properties with the LHC Run 1 data.

III.1. The principal discovery channels

For a given m_H, the sensitivity of a search channel depends on the production cross section of the Higgs boson, its decay branching fraction, reconstructed mass resolution, selection efficiency and the level of background in the final state. For a low-mass Higgs boson ($110 < m_H(\text{GeV}) < 150$) where the natural width is only a few MeV, the five decay channels that play an important role at the LHC are listed in Table 11.4. In the $H \to \gamma\gamma$ and $H \to ZZ \to 4\ell$ channels, all final state particles can be very precisely measured and the reconstructed m_H resolution is excellent. While the $H \to W^+W^- \to \ell^+\nu_\ell\ell'^-\bar{\nu}_{\ell'}$ channel has relatively large branching fraction, the m_H resolution is poor due to the presence of neutrinos. The $H \to b\bar{b}$ and the $H \to \tau^+\tau^-$ channels suffer from large backgrounds and a poor mass resolution. For $m_H > 150\,\text{GeV}$, the sensitive search channels are $H \to WW$ and $H \to ZZ$ where the W or Z boson decays into a variety of leptonic and hadronic final states. These decay channels of the Higgs boson are searched for in the five Higgs boson production processes (ggF, VBF, WH, ZH and $t\bar{t}H$) described in Section II.4.1.

The candidate events in each Higgs boson decay channel are split into several mutually exclusive categories (or event tags) based on the specific topological, kinematic or other features present in the candidate event. The categorization of events increases the sensitivity of the overall analysis and allows a separation of different Higgs

Table 11.4: The five principal decay channels for low mass SM Higgs boson searches at the LHC. The numbers reported are for $m_H = 125\,\text{GeV}$.

Decay channel	Mass resolution
$H \to \gamma\gamma$	1–2%
$H \to ZZ \to \ell^+\ell^-\ell'^+\ell'^-$	1–2%
$H \to W^+W^- \to \ell^+\nu_\ell\ell'^-\bar{\nu}_{\ell'}$	20%
$H \to b\bar{b}$	10%
$H \to \tau^+\tau^-$	15%

boson production processes. Most categories are dominated by signal from one Higgs decay mode but contain an admixture of various Higgs production processes. For example, a typical VBF category contains Higgs boson candidates accompanied by two energetic jets ($\geq 30\,\text{GeV}$) with a large dijet mass ($\geq 400\,\text{GeV}$) and separated by a large pseudorapidity ($\Delta\eta_{jj} \geq 3.5$). While such a category is enriched in Higgs bosons produced via VBF, the contamination from the gluon fusion production mechanism can be significant. Hence a measurement of the signal rate in the VBF category does not imply a measurement of VBF production cross-section. Simulations are used to determine the relative contributions of the various Higgs production modes in a particular category.

III.1.1. $H \to \gamma\gamma$

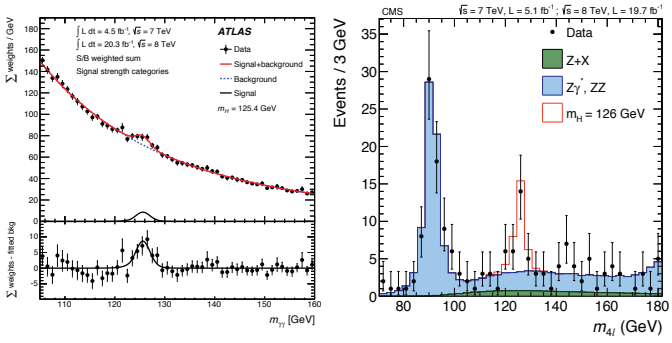

Figure 11.3: (Left) The invariant mass distribution of diphoton candidates, with each event weighted by the ratio of signal-to-background in each event category, observed by ATLAS [127]. The residuals of the data with respect to the fitted background are displayed in the lower panel. (Right) The combined $m_{4\ell}$ distribution from CMS [128] Run 1 data.

In the $H \to \gamma\gamma$ channel a search is performed for a narrow peak over a smoothly falling background in the invariant mass distribution of two high p_T photons. The background in this channel is conspicuous and stems from prompt $\gamma\gamma$, γ+jet and dijet processes. In order to optimize search sensitivity and also to separate the various Higgs production modes, ATLAS and CMS experiments split events into several mutually exclusive categories. Diphoton events containing a high p_T muon or electron, or missing energy (E_T^{miss}) consistent with the decay of a W or Z boson are tagged in the VH production category. Diphoton events containing energetic dijets with a large mass and pseudorapidity difference are assigned to the VBF production category, and the remaining events are considered either in the VH category when the two jets are compatible with the hadronic decay of a W or a Z, or in the gluon fusion production category. While the leptonic VH category is relatively pure, the VBF category has significant contamination from the gluon fusion process. A summary of all categories used in this channel is given in Section IV.1 and in Table 11.9. Events which are not picked by any of the above selections are further categorized according to their expected $m_{\gamma\gamma}$ resolution and signal-to-background ratio. Categories with good m_H resolution and larger signal-to-background ratio contribute most to the sensitivity of the search.

Both ATLAS and CMS have studied in detail the calibration of the energy response of photons, in particular using $Z \to e^+e^-$, $Z \to \mu^+\mu^-\gamma$ and the response of muons in the calorimeter (for ATLAS) from $Z \to \mu^+\mu^-$ events. This information is used to correct the fully simulated signal mass lineshapes. In each category, parametric signal models are adjusted to these lineshape to provide a functional form for the signal. Simple monotonic functional forms of the backgrounds are determined by a fit to the full $m_{\gamma\gamma}$ distribution in each category. All categories are fitted simultaneously to determine the signal yield at a particular mass. In the full dataset, the $m_{\gamma\gamma}$ distribution after combining all categories is shown for the ATLAS experiment in Fig. 11.3. ATLAS observes [127] an excess over background at $m_H = 125.4\,\text{GeV}$ with a local significance of 5.2σ compared with 4.6σ expected for SM Higgs boson at that mass. CMS observes [129] its largest excess at $m_H = 124.7\,\text{GeV}$ with a local significance of 5.7σ compared with 5.2σ expected for a SM Higgs boson of that mass.

The signal strength $\mu = (\sigma \cdot \text{BR})_{\text{obs}}/(\sigma \cdot \text{BR})_{\text{SM}}$, which is the observed product of the Higgs boson production cross section (σ) and its branching ratio (BR) in units of the corresponding SM values, is 1.17 ± 0.27 for ATLAS and $0.78^{+0.26}_{-0.23}$ for CMS at $m_H = 125.4$ and $124.7\,\text{GeV}$, respectively.

III.1.2. $H \to ZZ^* \to \ell^+\ell^-\ell'^+\ell'^-$

In the $H \to ZZ^* \to \ell^+\ell^-\ell'^+\ell'^-$ channel a search is performed for a narrow mass peak over a small continuous background dominated by non-resonant ZZ^* production from $q\overline{q}$ annihilation and gg fusion processes. The contribution and the shape of this background is taken from simulation. The subdominant and reducible backgrounds stem from $Z + b\bar{b}$, $t\bar{t}$ and Z + jets events. Their contribution is suppressed by requirements on lepton isolation and lepton impact parameter and their yield is estimated from control samples in data.

To help distinguish the Higgs signal from the dominant non-resonant ZZ^* background, both ATLAS [130] and CMS [128] use a matrix element likelihood approach to construct a kinematic discriminant built for each 4ℓ event based on the ratio of complete leading-order matrix elements $|\mathcal{M}_{sig}{}^2/\mathcal{M}_{bkg}{}^2|$ for the signal ($gg \to H \to 4\ell$) and background($q\overline{q} \to ZZ \to 4\ell$) hypotheses. The signal matrix element $\mathcal{M}_{sig}$ is computed assuming $m_H = m_{4\ell}$. To further enhance the sensitivity to a signal, the ATLAS experiment uses the matrix element as an input variable to a Boosted Decision Tree, along with the transverse momentum and rapidity of the four-leptons system [130].

To enhance the sensitivity to VBF and VH production processes, the ATLAS and CMS experiments divide 4ℓ events into mutually exclusive categories. Events containing dijets with a large mass and pseudorapidity difference populate the VBF category. ATLAS requires the presence of an additional lepton in the VH category. In events with less than two jets, CMS uses the $p_T^{4\ell}$ to distinguish between production via the gluon fusion and the VH/VBF processes.

Since the $m_{4\ell}$ resolutions and the reducible background levels are different in the 4μ, $4e$ and $2e2\mu$ subchannels, they are analyzed separately and the results are then combined.

As shown in Fig. 11.3, the CMS experiment observes [128] its largest excess at $m_H = 125.6\,\text{GeV}$ with an observed local significance of 6.8σ to be compared with an expected significance of 6.7σ at that mass. In their combined $m_{4\ell}$ distribution, ATLAS observes [130] an excess at $m_H = 125.36\,\text{GeV}$ with a local significance of 8.1σ. The expected local significance for the SM Higgs boson at that mass is 6.2σ. Both experiments also observe a clear peak at $m_{4\ell} = 91\,\text{GeV}$ from Z/γ^* production at the expected SM rate [131].

The signal strength μ for the inclusive $H \to 4\ell$ production measured by the ATLAS and CMS experiments is $1.44^{+0.40}_{-0.33}$ at $m_H = 125.36\,\text{GeV}$ and $0.93^{+0.29}_{-0.25}$ at $m_H = 125.6\,\text{GeV}$, respectively.

III.2. Measurement of the Higgs boson mass

To measure the mass of the Higgs boson, ATLAS and CMS experiments rely on the two high mass resolution and sensitive channels, $\gamma\gamma$ and ZZ. The approaches are very similar in these two analyses for both experiments, with subtle differences on

the use of categories, additional discriminating variables and per-event errors. These two channels are chosen for this precision measurement because they produce a narrow peak in mass with a resolution ranging from 1.4 GeV to 2 GeV for ATLAS and from 1.0 GeV to 2.8 GeV for CMS, where the best mass resolution is obtained for both experiments in the diphoton channel for central diphoton pairs (typically for events where both photons are not converted). For a model-independent mass measurement, the signal strengths in the $\gamma\gamma$ and ZZ channels are assumed to be independent and not constrained to the expected rate ($\mu = 1$) for the SM Higgs boson. The combined mass measured by ATLAS [132] and CMS [133] are $125.36 \pm 0.37(\text{stat.}) \pm 0.18(\text{syst.})$ GeV and $125.02^{+0.26}_{-0.27}(\text{stat.})^{+0.14}_{-0.15}(\text{syst.})$ GeV, respectively. In both experiments the measurements are dominated by the data statistics, however the systematic uncertainty is not negligible and is dominated by the precision in the knowledge of the photon energy or momentum scale. The ATLAS and CMS experiments have performed a combination of their mass measurements [134].

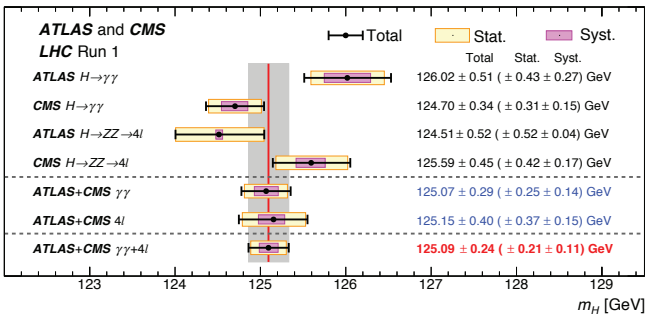

Figure 11.4: A compilation of the CMS and ATLAS mass measurements in the $\gamma\gamma$ and ZZ channels, the combined result from each experiment and their combination. From Ref. [134]

Figure 11.4 summarizes these measurements and their combination [134]. The significance of the difference between the measurements of the masses in the $\gamma\gamma$ and ZZ channels by the ATLAS experiment is 1.97σ [132]. The ATLAS and CMS combined mass measurement:

$$m_H = 125.09 \pm 0.21(\text{stat.}) \pm 0.11(\text{syst.})\ \text{GeV}$$

reaches a precision of 0.2% and is dominated by statistical uncertainties.

In the diphoton channel, as is discussed in Section V.3.2 a mass shift is expected to be induced by the deformation of the mass lineshape of the signal in presence of background, from the interference between the Higgs boson production and the continuum irreducible background. It is a small but non negligible effect of approximately 35 MeV for a Higgs boson width close to that of the SM, but this effect could be larger if the width of the discovered particle were to be completely different. This effect estimated by ATLAS with a full simulation is still relatively small with respect to the total uncertainty on the mass and is therefore neglected.

III.3. $H \to W^+W^- \to \ell^+\nu\ell^-\overline{\nu}$

While the production rate in the $H \to W^+W^- \to \ell^+\nu\ell^-\bar{\nu}$ channel is large, due to the presence of two neutrinos in the decay, the m_H resolution is quite poor ($\approx 20\%\ m_H$) so the search requires fitting in several characteristic kinematic variables.

Experiments search for an excess of events with two leptons of opposite charge accompanied by missing energy and up to two jets. Events are divided into several categories depending on the lepton flavor combination (e^+e^-, $\mu^+\mu^-$and $e^\pm\mu^\mp$) and the number of accompanying jets ($N_{\text{jet}} = 0, 1, \geq 2$). The $N_{\text{jet}} \geq 2$ category is optimized for the VBF production process by selecting two leading jets with a large pseudorapidity difference and with a large mass ($m_{jj} > 500$ GeV).

Backgrounds contributing to this channel are numerous and depend on the category of selected events. Reducing them and accurately estimating the remainder is a major challenge in this analysis. For events with opposite-flavor lepton and no accompanying high p_T jets, the dominant background stems from non-resonant WW production. Events with same-flavor leptons suffer from large Drell–Yan contamination. The $t\bar{t}$, Wt and W + jets (with the jet misidentified as a lepton) events contaminate all categories. Non-resonant WZ, ZZ and $W\gamma$ processes also contribute to the background at a sub-leading level.

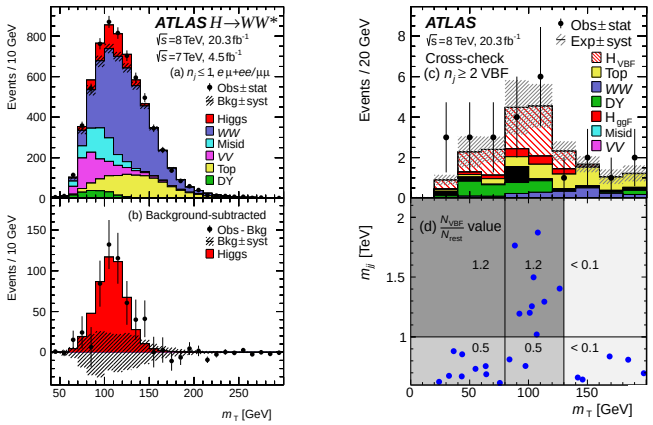

Figure 11.5: (a) The m_T distribution for selected events summed over all lepton flavors and with ≤ 1 associated jets. (b) The residual of the data over the estimated SM background and the expectation from a SM Higgs boson with $m_H = 125$ GeV indicating a clear excess with an event yield consistent with that from a SM Higgs boson [135]. The (c) m_T and (d) m_{jj} versus m_T distributions for the $N_{\text{jet}} \geq 2$ VBF-enriched category for the 8 TeV data analysis. For each region in (d), the ratio $N_{\text{VBF}}/N_{\text{rest}}$ is given (N_{rest} includes all production processes other than the VBF).

A requirement of large missing transverse energy (E_T^{miss}) is used to reduce the Drell–Yan and multijet backgrounds. In the e^+e^- and $\mu^+\mu^-$ categories, events with $m_{\ell\ell}$ consistent with the Z mass are vetoed. The $t\bar{t}$ background is suppressed by a veto against identified b-jets or low p_T muons (assumed to be coming from semileptonic b-hadron decays within jets) and tight isolation requirements diminish the W+jets background. The scalar nature of the Higgs boson and the $V-A$ nature of the W boson decay implies that the two charged leptons in the final state are preferentially emitted at small angles with respect to each other. Therefore the dilepton invariant mass ($m_{\ell\ell}$) and the azimuthal angle difference between the leptons ($\Delta\phi_{\ell\ell}$) are used to discriminate between the signal and non-resonant WW events. The transverse mass, constructed from the dilepton p_T ($p_T^{\ell\ell}$), E_T^{miss} and the azimuthal angle between E_T^{miss} and $p_T^{\ell\ell}$, is defined as $m_T = \sqrt{2p_T^{\ell\ell}E_T^{\text{miss}}(1-\cos\Delta\phi_{E_T^{\text{miss}}\ell\ell})}$ and serves as an effective discriminant against backgrounds. The transverse mass variable also tracks the Higgs boson mass but with a poor mass resolution. All residual background rates except for the small contributions from non-resonant WZ, ZZ and $W\gamma$ are evaluated from control samples devised from data.

The m_T distributions of the selected events in Run 1 data are shown in Fig. 11.5 for the ATLAS experiment. The 0-jet category is dominated by non-resonant WW background while $t\bar{t}$ dominates the 1 and 2 jet categories. A clear excess over background expectation in the 0 and 1 jet categories is observed. An excess is also observed in the VBF-enrighed 2-jets category. The observed event yield is consistent with the expectation from a 125 GeV SM Higgs boson.

ATLAS fits the m_T distributions and observes [135] an excess at $m_H = 125.36$ GeV with a local significance of 6.1σ similar to that

expected from a 125 GeV SM Higgs boson. The measured inclusive signal strength is $\mu = 1.09^{+0.23}_{-0.21}$. In the VBF category an excess with a significance of 3.2σ corresponding to a signal strength of $\mu = 1.27^{+0.53}_{-0.45}$ is observed [135]. The CMS analysis of 0 and 1 jet categories, using all lepton flavor combinations, shows [136] an excess with an observed significance of 4.3σ, lower than the expected sensitivity of 5.8σ for a 125.6 GeV SM Higgs boson. CMS observes [136] no significant excess in the VBF production mode and sets a 95% CL limit on the signal strength of $\mu_{\rm VBF} < 1.7$ for $m_H = 125.6$ GeV.

The ATLAS and CMS experiments have also searched for the associated Higgs boson production (VH) in this channel. The signal consists of up to three (WH) or four (ZH) high p_T isolated leptons with missing transverse energy and low hadronic activity. The major backgrounds stem from triboson and diboson production where each boson decays leptonically. ATLAS observes [137] an excess at $m_H = 125.36$ GeV with a local significance of 2.5σ corresponding to a $\mu_{VH} = 3.0^{+1.6}_{-1.0}$. CMS instead sets [136] a 95% CL limit of $\mu_{VH} < 4.7$.

resolution, which improves with the boost of the Higgs boson. The non-VBF categories are further subdivided according to the observed boost of the $\tau^+\tau^-$ system. The 0-jet category which has the poorest signal/background ratio is used to constrain the background yields, the reconstruction efficiencies, and the energy scales. CMS primarily uses the reconstructed $m_{\tau\tau}$ as the final discriminating variable [138] while the ATLAS experiment combines various kinematic properties of each event categories with multivariate techniques to build the final discriminant [139].

Searches for $H \to \tau^+\tau^-$ decays in the VH production mode are performed in final states where the W or Z boson decays into leptons or jets. The irreducible background in this search arises from non-resonant WZ and ZZ diboson production. The reducible backgrounds originate from W, Z, and $t\bar{t}$ events that contain at least one fake lepton in the final state due to a misidentified jet. The shape and yield of the major backgrounds in each category is estimated from control samples in data. Contributions from non-resonant WZ

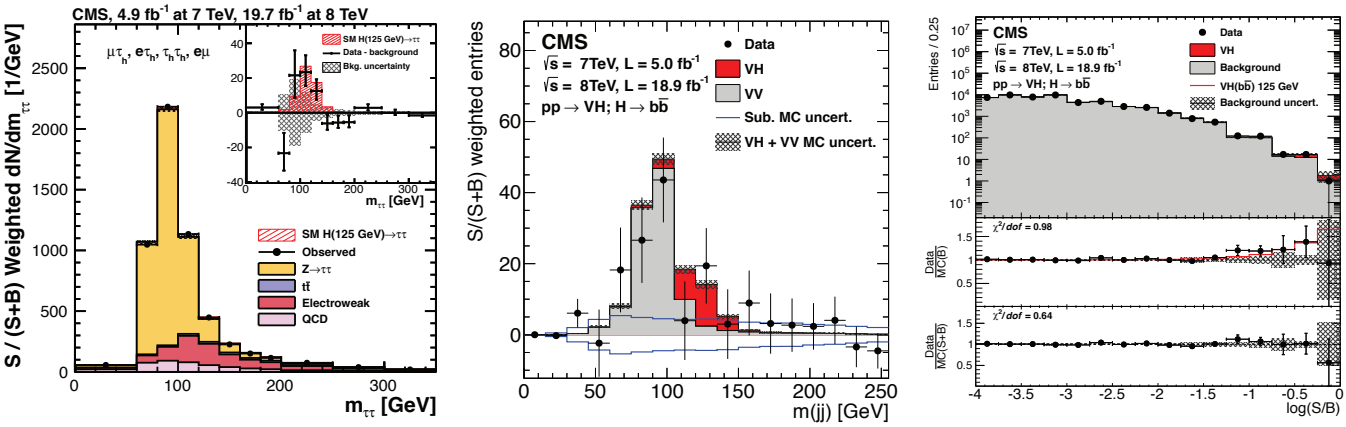

Figure 11.6: (Left) The observed and predicted $m_{\tau\tau}$ distributions for all $H \to \tau^+\tau^-$ subchannels combined by the CMS experiment. The inset shows the difference between the observed data and the expected SM background contributions, together with the expected signal distribution for a SM Higgs boson with $m_H = 125$ GeV [138]. (Center) The $m_{b\bar{b}}$ distribution for the $pp \to V(H \to b\bar{b})$ channels with all backgrounds except dibosons subtracted. The solid histograms for the backgrounds and the signal are summed cumulatively [140]. (Right) The combination of all $pp \to V(H \to b\bar{b})$ channels into a single multivariate distribution. The two bottom panels show the ratio of the data to the background-only prediction (above) and to the predicted sum of background and SM Higgs boson signal with a mass of 125 GeV (below).

III.4. Decays to fermions

At hadron colliders, the most promising channel for probing the coupling of the Higgs field to the quarks and leptons are $H \to b\bar{b}$ and $H \to \tau^+\tau^-$, respectively. For a Higgs boson with $m_H \approx 125$ GeV, the branching fraction to $b\bar{b}$ is about 57% and to $\tau^+\tau^-$ is about 6%. Nevertheless, the presence of very large backgrounds makes the isolation of a Higgs boson signal in these channels quite challenging.

III.4.1. $H \to \tau^+\tau^-$

In the $H \to \tau\tau$ search, τ leptons decaying to electrons (τ_e), muons (τ_μ) and hadrons (τ_{had}) are considered. The $\tau^+\tau^-$ invariant mass ($m_{\tau\tau}$) is reconstructed from a kinematic fit of the visible products from the two τ leptons and the missing energy observed in the event. Due to the presence of missing neutrinos, the $m_{\tau^+\tau^-}$ resolution is poor ($\approx 15\%$). As a result, a broad excess over the expected background in the $m_{\tau\tau}$ distribution is searched for. The major sources of background stem from Drell–Yan $Z \to \tau^+\tau^-$ and $Z \to e^+e^-$, W+jets, $t\bar{t}$ and multijet production. Events in all subchannels are divided into categories based on the number and kinematic properties of additional energetic jets in the event. The sensitivity of the search is generally higher for categories with one or more additional jets. The VBF category, consisting of a τ pair with two energetic jets separated by a large pseudorapidity, has the best signal-to-background ratio and search sensitivity, followed by the $\tau^+\tau^-$+1 jet category. The signal to background discrimination relies in part on the $m_{\tau\tau}$ and ZZ diboson production are estimated from simulations but corrected for reconstruction efficiency using control samples formed from observed data.

Figure 11.6 shows the CMS [138] $m_{\tau\tau}$ distributions combining all categories, weighing the distributions in each category of each subchannel by the ratio between the expected signal and background yields for that category. The inset plot shows the difference between the observed and expected background distributions, together with the expected distribution for a SM Higgs boson signal with $m_H = 125$ GeV. The significance of the observed excess at $m_H = 125$ GeV is 3.4 standard deviations, close to the expected sensitivity, and corresponds to a signal strength of $\mu = 0.86 \pm 0.29$. At $m_H = 125.36$ GeV, the observed (expected) deviation from the background-only hypothesis in ATLAS corresponds to a local significance of 4.5 (3.4) standard deviations and the best fit value of the signal strength is $\mu = 1.43^{+0.43}_{-0.37}$ [139].

When the ATLAS and CMS $H \to \tau\tau$ measurements are combined [141], the significance of the observed excess corresponding to $m_H = 125.09$ GeV is 5.5 standard deviations and the combined signal strength is $\mu = 1.11^{+0.24}_{-0.22}$.

III.4.2. $H \to b\bar{b}$

The production mode $gg \to H$ with $H \to b\bar{b}$ is overwhelmed by the background from the inclusive production of $p\bar{p} \to b\bar{b} + X$ via the strong interaction. The associated production modes WH and

ZH (collectively termed VH modes) allow use of the leptonic W and Z decays for triggering, and to purify the signal and reject QCD backgrounds. The W bosons are reconstructed via their leptonic decay $W \to \ell\bar{\nu}_\ell$ where $\ell = e, \mu$ or τ. The Z bosons are reconstructed via their decay into $e^+e^-, \mu^+\mu^-$or $\nu\bar{\nu}$. The Higgs boson candidate mass is reconstructed from two b-tagged jets in the event. Backgrounds arise from production of W and Z bosons in association with gluon, light and heavy-flavored jets (V+jets), $t\bar{t}$, diboson (ZZ and WZ with $Z \to b\bar{b}$) and QCD multijet processes. Due to the limited $m_{b\bar{b}}$ mass resolution, a SM Higgs boson signal is expected to appear as a broad enhancement in the reconstructed dijet mass distribution. The crucial elements in this search are b-jet tagging with high efficiency and low fake rate, accurate estimate of b-jet momentum and estimate of backgrounds from various signal depleted control samples constructed from data.

At the Tevatron, the $H \to b\bar{b}$ channel contributes the majority of the Higgs boson search sensitivity below $m_H = 130\,\text{GeV}$. The CDF and D0 experiments use multivariate analysis (MVA) techniques that combine several discriminating variables into a single final discriminant used to separate signal from background. Each channel is divided into exclusive subchannels according to various lepton, jet multiplicity, and b-tagging characteristics in order to group events with similar signal-to-background ratio and thus optimize the overall search sensitivity. The combined CDF and D0 data show [142, 126] an excess of events with respect to the predicted background in the 115–140 GeV mass range in the most sensitive bins of the discriminant distributions suggesting the presence of a signal. At $m_H = 125\,\text{GeV}$ the local significance of the excess is 3.0 standard deviations. At that mass, the observed signal strength $\mu = 1.59^{+0.69}_{-0.72}$.

To reduce the dominant V+jets background, following Ref. [143], the LHC experiments select a region in VH production phase space where the vector boson is significantly boosted and recoils from the $H \to b\bar{b}$ candidate with a large azimuthal angle $\Delta\phi_{VH}$. For each channel, events are categorized into different $p_T(V)$ regions with varying signal/background ratios. Events with higher $p_T(V)$ have smaller backgrounds and better $m_{b\bar{b}}$ resolution. CMS uses [140] MVA classifiers based on kinematic, topological and quality of b-jet tagging and trained on different values of m_H to separate Higgs boson signal in each category from backgrounds. The MVA outputs for all categories are then fit simultaneously. Figure 11.6(right) shows the combined MVA output of all categories where events are gathered in bins of similar expected signal-to-background ratios as predicted by the MVA discriminants. The excess of events observed in bins with the largest signal-to-background ratios is consistent with the production of a 125 GeV SM Higgs boson with a significance of 2.1 standard deviations. The observed signal strength at 125 GeV is $\mu = 1.0 \pm 0.5$. Figure 11.6(center) shows the $m_{b\bar{b}}$ distribution for all categories combined, weighted by the signal-to-background ratio in each category, with all backgrounds except dibosons subtracted. The data show the clear presence of a diboson ($W/Z + \text{Z} \to b\bar{b}$) signal, with a rate consistent with the SM expectation, together with an excess that agrees with that expected from the production of a 125 GeV SM Higgs boson. The nominal results from ATLAS are also based on a combination [144] of (i) a multivariate analysis of their 8 TeV data, incorporating various kinematic variables in addition to $m_{b\bar{b}}$ and b-tagging information and (ii) a statistical analysis of their 7 TeV data centered on $m_{b\bar{b}}$ as the main discriminant. In both cases customized control samples devised from data are used to constrain the contributions of the dominant background processes. The net observed(expected) deviation from background-only hypothesis corresponds to a significance of 1.4(2.6) standard deviations and a signal strength of $\mu = 0.5 \pm 0.4$.

In their 8 TeV data, CMS has also searched for $H \to b\bar{b}$ in the VBF production mode [145]. The event topology consists of two "VBF-tagging" energetic light-quark jets in the forward and backward direction relative to the beam direction and two b-tagged jets in the central region of the detector. Due to the electroweak nature of the process, for the signal events, no energetic jet activity is expected in the rapidity gap between the two "VBF-tagging" jets. The dominant background in this search stems from QCD production of multijet events and the hadronic decays of vector bosons accompanied by additional jets. A contribution of Higgs boson events produced in the ggF process but with two or more associated jets is expected in the signal sample. The signal is expected as a broad enhancement in the $m_{b\bar{b}}$ distribution over the smoothly falling contribution from the SM background processes. The observed (expected) excess corresponding to $m_H = 125\,\text{GeV}$ was 2.2 (0.8) standard deviations corresponding to a signal strength of $\mu = 2.8^{+1.6}_{-1.4}$. Combining with the result of the CMS VH analysis yields a signal strength signal $\mu = 1.0 \pm 0.4$ and the local significance of the excess improves marginally to 2.6 standard deviations.

III.5. First results on the main production and decay channels at 13 TeV

After a period of long shutdown between 2013 and 2015 devoted to the consolidation of the machine, in Spring 2015 the LHC delivered pp collisions at an unprecedented centre-of-mass energy of 13 TeV. During this period the ATLAS and CMS experiments have collected datasets corresponding to integrated luminosities of 2.3 to 3.2 fb^{-1} for CMS and ATLAS, respectively. The first preliminary measurements of Higgs boson production at this increased centre-of-mass energy are arriving while this review is being finalized. Only a concise section and an update in the associated production with a top-quark pair are therefore devoted to these results.

The two high-resolution channels $H \to \gamma\gamma$ and $H \to ZZ^* \to \ell^+\ell^-\ell'^+\ell'^-$ have been measured both by the ATLAS and CMS experiments. With the increase in production cross sections, a fair sensitivity is expected in these two channels even with this limited amount of data. For the $H \to \gamma\gamma$ channel ATLAS has produced a fully inclusive analysis in order to measure a fiducial cross section with a sensitivity of 1.9σ and an observed excess of 1.8σ [146]. The measurement of the total cross section, as extrapolated from the fiducial region is shown in Fig. 11.7(left). CMS has produced an analysis with event classification that has reached a sensitivity of 2.7σ and has observed an overall excess of 1.7σ [147]. For the $H \to ZZ^*$ channel, ATLAS has also produced a fully inclusive analysis with a sensitivity of 2.8σ and no significant excess with respect to the background has been observed [148]. This outcome is however compatible with the presence of a signal at the 1.4σ level. The corresponding measurement of the total cross section is illustrated in Fig. 11.7(left). The CMS analysis in this channel is also inclusive and uses additional kinematic discriminants to reach a sensitivity of 3.4σ [149]. CMS observes an excess with a significance of 2.5σ. In this channel, CMS also measures a fiducial cross section as shown in Fig. 11.7(right). The ATLAS experiment has also performed a combination of the total cross sections in these two channel at 7, 8 and 13 TeV [150]. The results of these combinations are shown in Fig. 11.7(left).

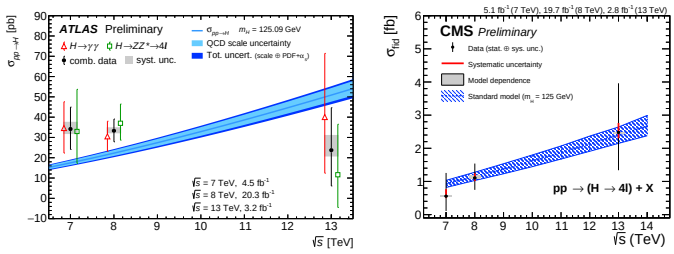

Figure 11.7: (Left) Total cross sections measured by ATLAS at 7, 8 and 13 TeV in the $H \to \gamma\gamma$ and $H \to ZZ^*$ channels and their combinations. (Right) The fiducial cross section measured in the $H \to ZZ^*$ channel by CMS at 7, 8 and 13 TeV.

The CMS experiment has investigated two additional channels. The first is the $H \to WW^* \to \ell\nu\ell\nu$ in categories of up to one jet, with a sensitivity of 2σ [151] and has observed only a very mild excess of 0.7σ. The second is the $H \to b\bar{b}$ decay mode in the VBF production sensitive only to approximately twice the SM production rate. The observation in this channel is compatible both with the background and the background in presence of a SM signal [152].

III.6. Higgs production in association with top quarks or in top decays

III.6.1. The associated production with top quark pairs

As discussed in Section II, the coupling of the Higgs particle to top quarks plays a special role in the electroweak breaking mechanism and in its possible extensions. Substantial indirect evidence of this coupling is provided by the compatibility of observed rates of the Higgs boson in the principal discovery channels, given that the main production process – the gluon fusion – is dominated by a top quark loop. Direct evidence of this coupling at the LHC and the future e^+e^- colliders will be mainly available through the $t\bar{t}H$ final state and will permit a clean measurement of the top quark-Higgs boson Yukawa coupling. The $t\bar{t}H$ production cross section at the LHC is tiny in comparison with the ggF or even VH production modes. The production cross section for a 125 GeV Higgs boson in pp collisions at $\sqrt{s} = 8$ TeV of about 130 fb makes it challenging to measure the $t\bar{t}H$ process with the LHC Run 1 dataset. It is thus imperative to target every accessible experimental signature. The analyses channels for such complex final states can be separated in four classes according to the decays of the Higgs boson. In each of these classes, most of the decay final states of the top quarks are considered. The topologies related to the decays of the top quarks are denoted 0L, 1L and 2L, for the fully hadronic, semi-leptonic and dilepton decay final states of the $t\bar{t}$, respectively.

The first analysis in this set is the search for $t\bar{t}H$ production in the $H \to \gamma\gamma$ channel. This analysis relies on the search for a narrow mass peak in the $m_{\gamma\gamma}$ distribution. The background is estimated from the $m_{\gamma\gamma}$ sidebands. The sensitivity in this channel is mostly limited by the available statistics. The second is the search in the $H \to b\bar{b}$ channel. This search is extremely intricate due to the large backgrounds, both physical and combinatorial in resolving the $b\bar{b}$ system related to the Higgs particle, in events with six jets and four b-tagged jets which are very hard to simulate. With the current dataset, the sensitivity of this analysis is severely impacted by the systematic uncertainties on the background predictions. The third channel is a specific search for $\tau^+\tau^-$ where the two tau leptons decay to hadrons. Finally, the W^+W^- , $\tau^+\tau^-$ and ZZ final states can be searched for inclusively in multilepton event topologies. The corresponding $t\bar{t}H$ modes can be decomposed in terms of the decays of the Higgs boson and those of the top quarks as having two b-quarks and four W bosons (or two W and two taus, or two W and two Z) in the final state.

CMS combines these four sets of measurements [153] and reports a 95% CL upper limit on the signal strength value of $\mu_{t\bar{t}H} < 4.5$. ATLAS reports [155–157] 95% CL upper limits on the signal strengths of 6.7, 6.4 and 4.7 for $H \to \gamma\gamma$, $H \to b\bar{b}$ and $H \to$ multilepton decay final states, respectively. The CMS experiment has also updated the $t\bar{t}H(\to b\bar{b})$ analysis using the matrix element method, aiming at an optimal separation between the signal and the dominant $t\bar{t}$ production in association with heavy flavor quarks in the final state [154].

III.6.2. The associated production with a single top quark

An additional production mode of the Higgs boson in association with a top quark is the single top associated production mode. There is an interesting similarity between this production mode and the $H \to \gamma\gamma$ decay mode. Both processes proceed through either the top Yukawa coupling or the interaction of the Higgs boson with the W-boson, with a negative interference between the two. Representative Feynman diagrams for this production process are shown in Fig. 11.8. Contrary to the diphoton decay channel, in this production mode the interference occurs at the tree level. This process can be used to further discriminate a negative relative sign between the couplings of the Higgs boson to fermions and its couplings to gauge bosons.

The ATLAS experiment has re-interpreted its Run 1 search of the diphoton decay channel in the ttH production in terms of tH production [155] and has produced 95% CL upper limits on the Higgs boson production cross section with respect to the rates expected for a given sign of the top Yukawa coupling. The result is not strong enough to exclude, at 95% CL, a negative top Yukawa coupling with an absolute strength equal to that of the SM. The excluded range in the ratio of the Higgs-top Yukawa coupling to that of the SM one, κ_t, at the 95% CL, is $]-\infty, -1.3] \cup [8, \infty[$.

Table 11.5: Summary of the results of searches for a Higgs boson in association with a top quark pair by the ATLAS and CMS collaborations. The results are given in terms of measured signal strength. The results of subchannels including hadronically decaying taus, which are less sensitive, are not reported in this table but can be found in the corresponding references.

	ATLAS (7 and 8 TeV)	CMS (7 and 8 TeV)	CMS (13 TeV)
$t\bar{t}(H \to \gamma\gamma)$	$1.3\ ^{+2.6}_{-1.7}\ ^{+2.5}_{-1.7}$	$1.2\ ^{+2.5}_{-1.7}\ ^{+2.6}_{-1.8}$	—

$t\bar{t}(H \to SS2\ell)$	$2.8\ ^{+1.5}_{-1.4}\ ^{+1.5}_{-1.3}$	$5.3\ ^{+2.1}_{-1.8}$	$-0.5\ ^{+1.0}_{-0.7}$
$t\bar{t}(H \to WW/\tau\tau/ZZ)$	$1.4\ \pm 0.6\ \pm 1.0$	—	$0.6\ ^{+1.4}_{-1.1}$
Combination	$1.7\ \pm 0.5\ \pm 0.8$	$2.8\ ^{+1.0}_{-0.9}$	—

The CMS experiment has produced a search with the Run 1 data exploiting a variety of Higgs boson decay modes resulting in final states with photons, bottom quarks, and multiple charged leptons, including tau leptons. The analysis is optimized for the opposite sign of the top Yukawa coupling with respect to that in the SM, and corresponding to a large enhancement of the signal cross section. The expected sensitivity of this analysis in terms of exclusion of the ratio of the cross section to the expected SM cross section is 2 for $\kappa_t = -1$, while the observed exclusion limit is 2.8.

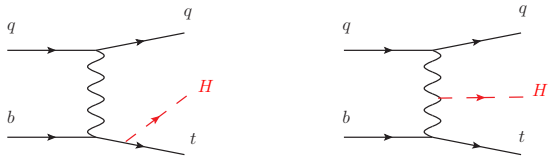

Figure 11.8: Feynman diagrams contributing to the Higgs production in association with a single top-quark through the top Yukawa coupling (left) and through the Higgs coupling to the W gauge boson (right).

III.6.3. Flavor changing neutral current decays of the top quark

The discovery of the Higgs boson at a mass smaller than the top quark mass opened a new decay channel for the top quark. The decays of the top quark to a Higgs boson and a charm or an up quark proceed through a Flavor Changing Neutral Current (FCNC) which are forbidden at the tree level and suppressed at higher orders through the Glashow–Iliopoulos–Maiani (GIM) mechanism [3]. The SM prediction for these branching fractions is $\mathrm{BR}(t \to Hc) = 10^{-15}$ and two orders of magnitude less for the Hu final state. These decay channels of the top quark are, however, very interesting to probe possible FCNC interactions in the Higgs Yukawa couplings to the quark sector.

The ATLAS experiment has searched for FCNC top decays specifically in channels involving a Higgs boson with subsequent decays to two photons [158] and a pair of b-quarks [159]. It has also reinterpreted a search for the ttH production in the multilepton final state (discussed in Section III.6.1) [157]. The latter channel covers Higgs boson decays to a pair of W-bosons and a pair of

taus. No significant excess was observed in any of the specific channels (as discussed in Section III.6.1, a slight excess is observed in the ttH multilepton channel) and 95% CL upper limits are set on BR($t \to Hc$) < 0.46% with an expected sensitivity of 0.25% and BR($t \to Hu$) < 0.45% with an expected sensitivity of 0.29%. The CMS experiment has performed a search for these FCNC top decays in the diphoton and multilepton channels [160], yielding a 95% CL upper limit on BR($t \to Hc$) < 0.56% with an expected sensitivity of 0.65%.

From these limits on branching fractions, constraints on non flavor-diagonal Yukawa couplings of a FCNC sector Lagrangian of the form:

$$\mathcal{L}_{FCNC} = \lambda_{tcH}\bar{t}Hc + \lambda_{tuH}\bar{t}Hu + h.c.$$

can be derived. The 95% CL observed (expected) upper limits from ATLAS on the $|\lambda_{tcH}|$ and $|\lambda_{tuH}|$ couplings are 0.13 (0.10) and 0.13 (0.10), respectively.

III.7. Searches for other rare production modes

III.7.1. Searches for Higgs boson pair production

Higgs boson pair production in the SM is rare. It is however a very interesting final state to search in two specific modes: (i) the search for non-resonant production of the Higgs boson pair and (ii) the search for resonant production of two Higgs bosons in the decay of a heavier particle.

Non-resonant Higgs pair production is an interesting milestone in the study of prospects for constraining Higgs self-couplings. In the SM the main non-resonant production mode of two Higgs bosons in the final state proceeds through a loop (mainly of top quarks) (Fig. 11.9a). Another production mode is via the trilinear coupling of the Higgs boson (Fig. 11.9b), whose amplitude is not negligible compared to the former. These diagrams interfere negatively making the overall production rate smaller than what would be expected in the absence of a trilinear coupling. The sensitivity to the trilinear coupling will be discussed in Section III.7.1.ii.

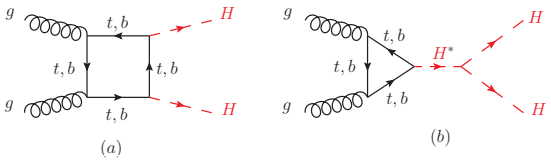

Figure 11.9: Feynman diagrams contributing to Higgs boson pair production through (a) a top- and b-quark loop and (b) through the self couplings of the Higgs boson.

(i) Searches for Higgs boson pair production

The searches for Higgs boson pair production both resonant and non-resonant are very interesting probes for a variety of theories beyond the SM, and can be done in a large number of Higgs boson decay channels. The ATLAS collaboration has searched both for resonant and non resonant Higgs boson pair production in the following channels: (i) $HH \to b\bar{b}\gamma\gamma$ [161]; (ii) $HH \to b\bar{b}\tau^+\tau^-$ [162]; (iii) $HH \to b\bar{b}b\bar{b}$ [163]; and (iv) $HH \to WW^*\gamma\gamma$ [162]. The CMS collaboration has only performed searches for resonant Higgs boson pair production in a large variety of decay modes: (i) in final states containing multiple leptons (electrons or muons) covering the WW^*WW^*, WW^*ZZ^*, ZZ^*ZZ^*, $ZZ^*\tau^+\tau^-$, $WW^*\tau^+\tau^-$, $ZZ^*b\bar{b}$, $\tau^+\tau^-\tau^+\tau^-$ channels [164]; (ii) in final states with a di-photon pair compatible with being produced in the decay of the Higgs boson and one lepton covering the $\gamma\gamma WW^*$, $\gamma\gamma ZZ^*$, $\gamma\gamma\tau^+\tau^-$ channels [164]; (iii) in the $b\bar{b}\tau^+\tau^-$ channel [165]; and (iv) in the $b\bar{b}b\bar{b}$ channel [166]. A summary of the channels searched for at the LHC is given in Table 11.6. The results and interpretation of the search for resonant Higgs boson pair production are discussed in Section VII.8.i.d.

Table 11.6: Summary of the final states investigated in the search for Higgs boson pair production by ATLAS (A) and CMS (C).

(ii) Measuring Higgs self couplings

The Higgs boson self coupling is an extremely important direct probe of the Higgs potential. The measurement of the quartic coupling in HHH final states is essentially deemed to be impossible at the HL-LHC. The possibility of measuring the trilinear coupling of the Higgs boson at the LHC in HH final states is studied in detail.

In the SM the Higgs boson pair production through the trilinear Higgs has an on-shell component and a large off-shell component. The on-shell $H \to H^*H^*$ is strongly disfavored, requiring two off-shell Higgs bosons in the final state. The sensitivity region to the trilinear coupling production as in Fig. 11.9-b, is mainly in the kinematic region where the two Higgs boson in the final state are on-shell and the Higgs boson acts as a propagator (off-shell). As discussed in the introduction to this section, this process interferes negatively with the background Higgs boson pair production (Fig. 11.9a). In the SM hypothesis sensitivity to the trilinear coupling requires the measurement of a deficit in the Higgs boson pair production, in a similar way as the off-shell couplings measurement as explained in Section V.2. Given the current sensitivity of Higgs boson pair production measurements discussed in the previous Section III.7.1.i, only projections for the high Luminosity LHC are considered with an integrated luminosity of $3\,\text{ab}^{-1}$ and therefore in high pile-up conditions. Three channels have been investigated: (i) the $HH \to b\bar{b}\gamma\gamma$; (ii) the $HH \to b\bar{b}\tau^+\tau^-$; and (iii) the $HH \to b\bar{b}W^+W^-$. The prospects in channel (i) have been studied by both the ATLAS [167] and the CMS [168] collaborations, yielding a sensitivity of 1.3σ and 1.6σ respectively to overall Higgs boson pair production. The ATLAS and CMS collaborations have studied the channel (ii) yielding a sensitivity of 0.6σ [169] and 0.9σ [168] to Higgs boson pair production respectively. Only the CMS collaboration has studied the channel (iii) showing its low sensitivity [168]. It should be noted that there is a large uncertainty on these projections related both to the modeling of signal and the backgrounds, the very difficult high pile-up environment (both for reconstruction and trigger) and the design of the upgraded detectors. As discussed in Section III.7.1.i, more channels are possible and deserve to be studied in detail.

The measurements of the trilinear coupling requires to separate the contributions to the overall Higgs boson pair production and in particular measure the deficit expected in the case of SM couplings. The ATLAS collaboration has estimated the sensitivity to the trilinear λ_{HHH} coupling to exclusion regions of $\lambda_{HHH}/\lambda_{HHH}^{SM}$ at 95% CL of $]-\infty,-1.3] \cup [8.6,\infty[$ with the $b\bar{b}\gamma\gamma$ channel [167] and $]-\infty,-1.4] \cup [12.0,\infty[$ with the $b\bar{b}\tau^+\tau^-$ channel [169]. Measuring the Higgs boson trilinear coupling will be very difficult at the High Luminosity LHC.

III.8. Searches for rare decays of the Higgs boson

III.8.1. $H \to Z\gamma$

The search for $H \to Z\gamma$ is performed in the final states where the Z boson decays into opposite sign and same flavor leptons ($\ell^+\ell^-$), ℓ here refers to e or μ. While the branching fraction for $H \to Z\gamma$ is comparable to $H \to \gamma\gamma$ (about 10^{-3}) at $m_H = 125\,\text{GeV}$, the observable signal yield is brought down by the small branching ratio of $Z \to (e^+e^- + \mu^+\mu^-) = 6.7 \times 10^{-2}$. In these channels, the $m_{\ell\ell\gamma}$ mass resolution is excellent (1-3%) so the analyses search for a narrow mass peak over a continuous background. The major backgrounds arise from the $Z + \gamma$ final state radiation in Drell–Yan decays and $Z +$ jets processes where a jet is misidentified as a photon. The ratio of signal over background in this channel is typically of the order of 0.5%. In

a narrow window of a few GeV around125 GeV, several hundreds of events are expected.

Events are divided into mutually exclusive categories on the basis of the expected $m_{Z\gamma}$ resolution and the signal-to-background ratio. A VBF category is formed for $H \to Z\gamma$ candidates which are accompanied by two energetic jets separated by a large pseudorapidity. While this category contains only about 2% of the total event count, the signal-to-noise is about an order of magnitude higher. The search for a Higgs boson is conducted independently in each category and the results from all categories are then combined.

No excess of events is observed in either ATLAS or CMS experiments. The CMS expected and observed 95% CL upper limits for $m_H = 125\,\text{GeV}$ [170] on the signal strength μ are 10 and 9.5 respectively. The ATLAS expected and observed upper limits [171] on the signal strength μ are 9 and 11 respectively for a SM $m_H = 125.5\,\text{GeV}$.

III.8.2. $H \to \mu^+\mu^-$

$H \to \mu^+\mu^-$ is the only channel where the Higgs coupling to second generation fermions can be measured at the LHC. The branching fraction in this channel for a 125 GeV SM Higgs boson is 2.2×10^{-4}, about ten times smaller than that for $H \to \gamma\gamma$. The dominant and irreducible background arises from the $Z/\gamma^* \to \mu^+\mu^-$ process which has a rate several orders of magnitude larger than that from the SM Higgs boson signal. Due to the precise muon momentum measurement achieved by ATLAS and CMS, the $m_{\mu^+\mu^-}$ mass resolution is excellent ($\approx 2-3\%$). A search is performed for a narrow peak over a large but smoothly falling background. For optimal search sensitivity, events are divided into several categories. To take advantage of the superior muon momentum measurement in the central region, the two experiments subdivide events by the pseudorapidity of the muons. To suppress the Drell–Yan background, ATLAS requires $p_T^{\mu^+\mu^-} > 15\,\text{GeV}$ while CMS separates them into two $p_T^{\mu^+\mu^-}$ based categories. CMS further categorizes events by the number and the topology of additional energetic jets in the event.

No excess in the $m_{\mu^+\mu^-}$ spectrum is observed near 125 GeV. From an analysis of their Run 1 data, ATLAS sets [172] an observed (expected) 95% CL upper limit on the signal strength $\mu < 7.0$ (7.2). The CMS analysis [173] of their 7 and 8 TeV data sets an observed (expected) limit of $\mu < 7.4$ (6.5).

III.8.3. $H \to e^+e^-$

A search similar to the $H \to \mu^+\mu^-$, is performed by CMS in the di-electron channel [173]. In this search channel there the contribution from the peaking background from Higgs boson decays to diphoton mis-identified as di-electrons (when mostly converted photons are faking electrons) needs to be assessed. The sensitivity to the SM Higgs decays is negligible given the extremely small branching fraction to e^+e^-, approximately 40,000 times smaller than the branching fraction to dimuons. It is nevertheless interesting to probe this decay channel to search for potential large anomalous couplings. Assuming a SM Higgs boson production cross section, the observed limit on the branching fraction at the 95% CL is 0.0019 [173], five orders of magnitude larger than the expected SM prediction.

III.8.4. Lepton flavor violating (LFV) Higgs boson decays

Given the Yukawa suppression of the couplings of the Higgs boson to quarks and leptons of the first two generations and the small total width of the Higgs boson, new physics contributions could easily have sizable branching fractions. One very interesting possibility is the Lepton Flavor Violating (LFV) decays of the Higgs boson, in particular in the $\tau\mu$ and τe modes. These decays are suppressed in the SM but could be enhanced in theories such as two-Higgs-doublet models (discussed in Section VII).

There are already fairly strong constraints on LFV Yukawa couplings $|Y_{\tau\mu}|$ from channels such as the $\tau \to 3\mu$ or $\tau \to \mu\gamma$, or a re-interpretation of the search for Higgs decays to $\tau^+\tau^-$. A direct search at the LHC however complements these indirect limits. The search for LFV decays in the $\tau\mu$ channel have been done with the Run 1 dataset in several channels according to the subsequent decay of the τ. The results from CMS [174] and for ATLAS for the hadronic [175], the leptonic [176] decays of the tau, and their combination [176] are reported in Table 11.7. It is interesting to note that the analysis strategies for the di-lepton $\tau_{lep}\mu$ channel are very different between the ATLAS [176] and CMS [174].

	ATLAS $\tau_{\text{had}}\mu$	ATLAS $\tau_{\text{lep}}\mu$	ATLAS $\tau\mu$	CMS $\tau\mu$
BR($H \to \tau\mu$)	$(0.77 \pm 0.62)\%$	$(0.03^{+0.88}_{-0.86})\%$	$(0.53 \pm 0.51)\%$	$(0.84^{+0.39}_{-0.37})\%$
95% CL Expected	1.24%	1.73%	1.01%	0.75%
95% CL Observed	1.85%	1.79%	1.43%	1.51%

Table 11.7: Summary of the results of searches for lepton flavor violating decays of the Higgs boson in the $\tau\mu$ channel from ATLAS and CMS.

As shown in Table 11.7 a small excess in this channel is observed by CMS with a significance of 2.5σ, while in ATLAS the excess is smaller and of the order of 1σ.

The ATLAS collaboration has also reported results on the search for the LFV Higgs boson decays in the τe channel [176], yielding an observed (expected) limit of 1.04% (1.21%).

III.8.5. Probing charm- and light-quark Yukawa couplings

Probing the Yukawa couplings to quarks of the second or even the first generation is extremely challenging given the overwhelming background and the much smaller signal rates. The possibility of probing the Yukawa coupling to the charm has been discussed in [177] where indirect bounds on the charm Yukawa coupling are estimated from a combined fit to the Higgs data. The direct impact of Higgs decays to a pair of charm quarks on the direct search for $H \to b\bar{b}$ is also investigated.

Another possibility to access the Higgs Yukawa coupling has been discussed in [178], through the decays of the Higgs boson to a final state with charmonium: $H \to J/\psi\gamma$. Higgs decays in this final state have been searched for by the ATLAS collaboration [179]. The sensitivity of this analysis is however several orders of magnitude above the branching fraction estimated for the SM coupling BR($H \to J/\psi\gamma$) $= (2.8 \pm 0.2) \times 10^{-6}$ [178]. The ATLAS collaboration [179] has also searched for Higgs decays to $\Upsilon(nS)\gamma$ where $(n = 1, 2, 3)$, a channel with much lower sensitivity than the $H \to b\bar{b}$ to the Yukawa coupling to b-quarks.

More recently the ATLAS collaboration has searched for another quarkonia final state where the Higgs boson decays to $\phi\gamma$ [180] at the LHC Run 2 and a center-of-mass energy of 13 TeV, with a specific trigger. This channel could probe deviations from the strange-quark Yukawa coupling of the Higgs boson. Its sensitivity is several orders of magnitude above the expectation from the SM Higgs boson. Other quarkonia final states, such as the $\rho\gamma$, which could potentially probe the Yukawa coupling to light quarks, can also be searched for.

III.8.6. Rare decays outlook

Rare decays such as those described in the above sections have a clearly limited sensitivity. They however already deliver interesting messages. For example, if the coupling of the Higgs boson was as strong in the dimuon channel as it is for the top quark, this mode would have been observed already with large significance. The observed Higgs boson couplings are manifestly non-universal. Further developing these rare decay modes is an important component of the high luminosity program of the LHC to directly probe the couplings of the Higgs boson, and to potentially measure the Yukawa coupling of the Higgs boson to fermions of the second generation, in particular to muons.

III.9. Searches for non-standard model decay channels

The main decay and production properties of the observed Higgs boson are consistent with predictions of the SM. It may however have other decay channels beyond those anticipated in the SM. Among these and of great interest are the invisible decays into stable particles that interact very weakly with the detector, and that are undetected, such as Dark Matter particle candidates. Other non standard decay

Table 11.8: Summary of the channels searched for and the corresponding 95% CL limits from ATLAS and CMS on the branching fraction for the Higgs boson decay to invisible particles assuming a SM Higgs boson production cross section. The results in parentheses are the expected exclusions. [*] indicates analyses based only on 8 TeV data. When combining Run 1 results and the results from the $\approx 2\,\text{fb}^{-1}$ of 13 TeV data acquired in 2015, the CMS observed (expected) limit improves to < 32 (26) % at 95% CL.

channels that have been investigated are the decays of the Higgs particle to hidden valley or dark particles.

III.9.1. Invisible decays of the Higgs boson

The discovery of the Higgs boson immediately raised the question of its couplings to dark matter and how it could be used to reveal its existence at colliders, using the Higgs boson as a portal to dark matter (see Ref. [181] and references therein). If kinematically accessible and with a sufficiently large coupling to the Higgs boson, dark matter particles, such as, e.g., neutralinos in SUSY models, graviscalars in models with extra dimensions or heavy neutrinos in the context of four-generation fermion models, would manifest themselves as invisible decays of the Higgs boson, thus strongly motivating searches for the invisible decays of the Higgs boson.

To identify an invisibly decaying Higgs boson at the LHC, it must be produced in association with other particles. Searches for invisible decays of the Higgs particle at the LHC have been carried out in three associated production modes of the Higgs boson with the highest SM cross sections and target events with large missing energy.

The ggF production mode has the largest SM cross section but it usually results in the Higgs boson being created alone and hence leaving no characteristic signature in the detector of its invisible decay. One way to search for invisible decays in ggF production mode is to look for events with the "monojet" topology arising from initial state gluon radiation and containing missing energy. The major irreducible background in such searches stems from Z + jets events where the Z boson decays into a pair of neutrinos. The analysis with the best sensitivity targets the VBF production topology but suffers from large backgrounds arising from events with two jets and large missing energy. The VH mode has much smaller cross section but the presence of a W or Z boson allows a variety of final states that can be tagged with relatively low background.

ATLAS [182–185], and CMS [186–189] have searched for such final states but have observed no significant excess over predicted backgrounds. Table 11.8 summarizes the 95% CL limits on the invisible decays of the Higgs boson assuming SM Higgs boson production cross section and corresponding detector acceptances.

III.9.2. Exotic Higgs boson decays

The 125 GeV Higgs boson not only serves as a probe for potential dark matter candidates, but also to search for other exotic particles arising from fields associated with a low-mass hidden sector. Such hidden sectors are composed of fields that are singlets under the SM group $\text{SU}(3) \times \text{SU}(2) \times U(1)$. These models are referred to as hidden valley models [190, 191]. Since a light Higgs boson is a particle with a narrow width, even modest couplings to new states can give rise to a significant modification of Higgs phenomenology through exotic decays. Simple hidden valley models exist in which the Higgs boson decays to an invisible fundamental particle, which has a long lifetime to decay back to SM particles through small mixings with the SM Higgs boson; Ref. [191] describes an example. The Higgs boson may also decay to a pair of hidden valley "v-quarks," which subsequently hadronize in the hidden sector, forming "v-mesons." These mesons often prefer to decay to the heaviest state kinematically available, so that a possible signature is $H \to 4b$. Some of the v-mesons may be stable, implying a mixed missing energy plus heavy flavor final state. In other cases, the v-mesons may decay to leptons, implying the presence of low mass lepton resonances in high- H_T events [192]. Other scenarios have been studied [193] in which Higgs bosons decay predominantly into light hidden sector particles, either directly, or through light SUSY states, and with subsequent cascades that increase the multiplicity of hidden sector particles. In such scenarios, the high multiplicity hidden sector particles, after decaying back into the SM, appear in the detector as clusters of collimated leptons known as lepton jets.

A variety of models have been investigated searching for final states involving dark photons and hidden valley scalars. The resulting topologies searched for are prompt electron jets in the WH production process [194], displaced muonic jets [195], four muons final state, and long lived weakly interacting particles [196]. The latter occur not only in hidden valley scenarios, but also in gauge-mediated extensions of the minimal supersymmetric standard model (MSSM), the MSSM with R-parity violation, and inelastic dark matter [197]. Finally the CMS collaboration has performed a search for pair production of light bosons [198]. Such a scenario can occur in supersymmetric models with additional hidden (or dark) valleys.

IV. Combining the main channels

As described in Section II, there are five main production modes of a SM Higgs boson at the LHC. In the LHC Run 1 dataset the predicted numbers of SM Higgs bosons produced per experiment are approximately 0.5 million, 40,000, 20,000 and 3,000 in the gluon fusion, vector boson fusion, the associated VH and $t\bar{t}H$ production modes respectively[3]. There are also five main decay channels: the $\gamma\gamma$, ZZ, WW, $\tau^+\tau^-$ and $b\bar{b}$. Analyses using exclusive categories according to production modes have been designed to maximize the sensitivity of the analyses to the presence of a signal using known characteristic features of these modes. These categories can also be used to further separate production modes for each decay channel. The typical number of events selected eventually in each decay channel ranges from a fraction of an event to O(100) events per experiment.

The analysis strategy used by the LHC and Tevatron experiments to perform the searches for the Higgs boson has been based on the Higgs decay modes. It is a natural choice given that it focusses on the decay products of the object searched for. However, for each channel, exclusive subchannels have been defined according to the Higgs production processes and in the results presented these subchannels have been combined. The natural extension of this approach in order to probe further the production and decay modes of the Higgs boson is to combine the analysis channels together. Such a combination is also used in Section VI to further measure the coupling properties of the Higgs boson.

At the LHC or the Tevatron, the total cross section cannot be measured in any of the production modes. As a consequence, neither the absolute branching fractions nor the total natural width of the Higgs boson can be directly measured. However, a combined measurement of the large variety of categories described in Section III, with different sensitivities to various production and decay modes permits a wide variety of measurements of the production, decay or in general coupling properties. These measurements require, in general, a limited but nevertheless restrictive number of assumptions.

In this section, results will be given combining not only different channels, but also the ATLAS and CMS results together [141]. These

[3] Similarly at the Tevatron where the CDF and D0 experiments have gathered approximately $10\,\text{fb}^{-1}$ of data at 1.96 TeV, the predicted numbers of SM Higgs boson events produced per experiment are approximately 10,000 and 2,000 events in the gluon fusion and VH associated production, respectively.

Table 11.9: Summary of the main production categories used in the analysis channels involved in the combined measurement of the coupling properties of the Higgs boson. (A) and (C) indicate respectively when ATLAS and CMS include the specific exclusive category in the combination. For the ttH channel, note that the number of leptons (ℓ) indicates typically the type of decay of the two top quarks.

	$\gamma\gamma$	ZZ (4ℓ)	WW ($\ell\nu\ell\nu$)	$\tau^+\tau^-$	$b\bar{b}$

results were derived by the two collaborations, taking rigorously into account all correlations in the systematic uncertainties and in the large number of channels and their categories. This combination has led the two collaborations to a more precise experimental portrait of the Higgs boson. This work also concludes and synthesizes the analyses of the main production and decay channels of the Higgs boson at the Run 1 of the LHC.

In this section, only the results on the main Higgs boson production and decay modes will be discussed. The combination framework described herein will also be used in Section VI, to discuss the measurements of the coupling properties of the Higgs boson.

IV.1. Principles of the combination

The combination of the Higgs boson analysis channels in each experiment and for the two experiments together is done using a fit of a signal and background model to the data. As described above the data is made of a large number of categories, aiming at reconstructing exclusive production and decay modes. In the combination of ATLAS and CMS [141] there are approximately 600 categories. The combination is a simultaneous fit to all these categories, using a reduced number of parameters of interest and a Higgs boson mass fixed at its measured value (see Section III.2). A synoptic view of the main production categories is illustrated in Table 11.9. The much larger number of categories present in the ATLAS and CMS combination [141], is due to additional separation in terms of finer exclusive production regions, decay channels of the Z and the W bosons, and taus, control regions where little-to-no signal is present, and different center-of-mass energies. It should be noted that the individual combination performed by ATLAS [199] included two additional decay channels: the $\mu^+\mu^-$ and $Z\gamma$, for the sake of simplicity these channels were omitted in the ATLAS-CMS combination. In addition, a $H \to b\bar{b}$ analysis performed by CMS [13] and included in its own combination, has been omitted from the ATLAS-CMS combination.

The key to understanding how the combination of channels works relies on the combination master formula, which expresses for each category, indexed by c, of a given channel (typically a category covers mostly one decay mode, but possibly various production modes), the measured number of signal events n_s^c as a function of a limited number of parameters as follows:

$$n_s^c = (\sum_{i,f} \mu_i \, \sigma_i^{SM} \times A_{if}^c \times \varepsilon_{if}^c \times \mu_f \, \mathrm{BR}_f^{SM}) \times \mathcal{L}^c \qquad (11.13)$$

The production index is defined as $i \in \{ggH, VBF, VH, ttH\}$ and the decay index is defined as $f \in \{\gamma\gamma, WW, ZZ, bb, \tau\tau\}$ while σ_i^{SM} and BR_f^{SM} are the corresponding production cross sections and decay branching fractions, estimated as described in Section II, assuming that the Higgs boson is that of the SM. A_{if}^c and ε_{if}^c are the signal acceptance and the reconstruction efficiency for given production and decay modes in the category c. $\mathcal{L}^c$ is the integrated luminosity used for that specific category. For the purpose of this review, these parameters can be considered as fixed[4].

The parameters of interest in the master formula are the signal strength parameters μ_i and μ_f. It is important to note that the formula relies on the factorization of the production cross section and decay branching fraction, which assumes the narrow width approximation. The width of the Higgs boson will be discussed in Section V, however for the precision needed here, the fact that the Higgs boson has been observed in decay channels with high mass resolution as a resonance is sufficient to validate this hypothesis. It is also manifest in the above equation that the ten parameters for the production modes (μ_i) and decay modes (μ_f) cannot be determined simultaneously. This illustrates that total cross sections or branching fractions cannot be measured without further assumptions in this fit.

The master formula also illustrates an important caveat to the measurement of signal strength parameters. In case these are interpreted as scale factors of the production cross sections or branching fractions, then all the other quantities such as the acceptances and efficiencies, A_{if}^c and ε_{if}^c, need to be assumed as independent and fixed to their estimated values for the SM Higgs boson. An additional important caveat to note concerning these combined results is that only the normalizations are varied, while the discriminating variables for the signal are not modified and are still used in the fit. These caveats are of particular importance in the use of the combination to measure the coupling properties of the Higgs boson as discussed in Section VI. For relatively small perturbations of the couplings of the Higgs boson from the SM values, this hypothesis is valid.

However the 25 products, $\mu_i \times \mu_f$, can be considered as free parameters and in principle measurable (if there is sufficient sensitivity from specific categories). Measuring the products of signal strengths can be viewed as the measurements of the cross sections times the branching fraction, $\sigma \cdot \mathrm{BR}$. The results are reported in Table 11.10 for the combination of ATLAS and CMS and they are illustrated in Fig. 11.10.

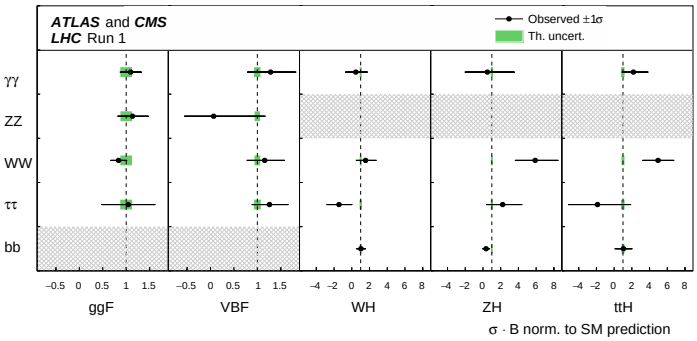

Figure 11.10: Combined measurements of the products $\sigma \cdot \mathrm{BR}$ for the five main production and five main decay modes.

[4] In the combination performed by the ATLAS and CMS experiments the systematic uncertainties on these parameters are taken into account by allowing these parameters to vary in the fit.

It is remarkable that of the 25 possible combinations of production and decay modes in the main channels, the fit to ATLAS and CMS data allows the measurement of 20. A coherent picture emerges with an excellent consistency between the observation in each channel and the expectation for a SM Higgs boson.

This 20 parameter fit quantifies, with very little theoretical input, the current experimental knowledge of the main production and decays modes. It is also a very useful tool to further understand the influential channels in the measurements of the Higgs couplings. Without a loss of independence of the theoretical predictions, a less general fit allowing for further interpretations concerning production cross sections and branching fractions is possible. In this fit a reference process, measured with high precision and significance, is used to parametrize all the other processes. In the ATLAS-CMS combination [141] the gluon fusion production mechanism in the $H \to ZZ$ decay mode is chosen. Then, the master formula applies with the following parameters for all i and f indices except when both $i = ggF$ and $f = ZZ$

$$\begin{aligned} \mu_i &= \frac{\sigma_i}{\sigma_{ggF}\sigma_i^{SM}} \times \mu_{gg\to H\to ZZ} \\ \mu_f &= \frac{\mathrm{BR}_i}{\mathrm{BR}_{ZZ}\mathrm{BR}_i^{SM}} \\ \mu_{gg\to H\to ZZ} &= \mu_{ggF} \times \mu_{ZZ} \times \sigma_i^{SM} \times \mathrm{BR}_f^{SM} \end{aligned} \qquad (11.14)$$

The result of the combination with these 9 parameters is illustrated in Fig. 11.11. It allows interesting conclusions on the production and decay properties of the Higgs boson. It shows that the ratio of the decay rates to Z and W bosons is as expected from the SM, a direct illustration of the custodial symmetry, and also quantifies the relative precision at which the ttH coupling is currently measured. It also shows that with the improved precision stemming from the combination, no significant deviations from the SM is observed.

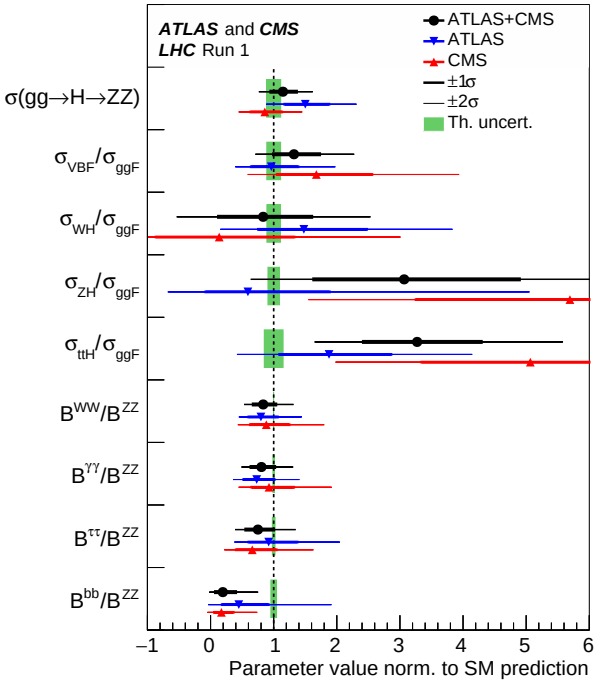

Figure 11.11: Measurement of the $\sigma(gg \to H \to ZZ)$ cross section and of the ratios of cross sections and branching fractions from the combination of the ATLAS and CMS measurements. The results from each experiment are also shown. The results are normalised to the SM predictions for the various parameters. The shaded bands indicate the theoretical uncertainties in these predictions.

Finally, the most constrained fit in this combination, and historically the first made, allows for only one single parameter to vary *i.e.* $\forall(i,f), \mu_i = \mu_f = \mu$. This global signal strength model provides the most precise and simple probe of the compatibility of the signal with the SM Higgs boson. This model is sensitive to any deviation from the SM Higgs boson couplings provided that these deviations do not cancel overall. The combined global signal strength is

$$\mu = 1.09 \pm 0.07\ (\mathrm{stat}) \ \pm 0.04\ (\mathrm{expt}) \ \pm 0.03\ (\mathrm{th.\,bkg}) \ \pm 0.07\ (\mathrm{th.\,sig})$$

This overall signal strength is fully compatible with the SM expectation of 1, with a precision of 10%. It is interesting to note that the major uncertainties in this first measurement arises from the limited precision in the theoretical predictions for the signal production processes.

IV.2. Characterization of the main decay modes and observation of Higgs decays to taus

Despite the large number of decay channels, since the cross sections cannot be independently measured, from the measurements described in this section it is impossible to measure decay branching fractions without a loss of generality. The simplest assumption that can be made is that the production cross sections are those of the SM Higgs boson, which is equivalent to assuming that for all i indices $\mu_i = 1$. All branching fractions μ_f can then be measured in a simple 5 parameter fit. The result of this fit is illustrated in Fig. 11.12, and the measured signal strengths are reported in Table 11.11.

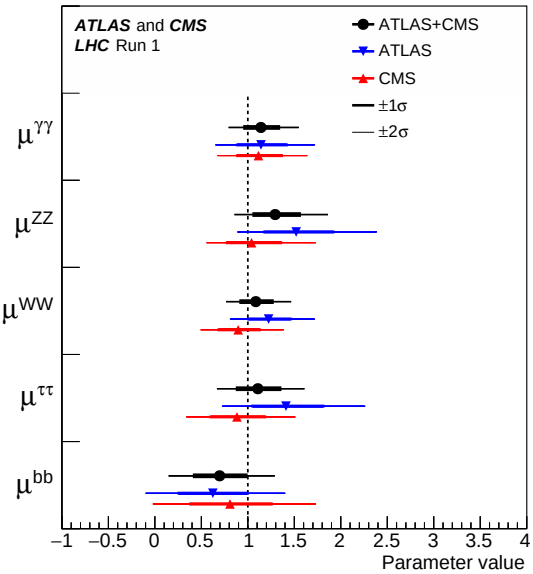

Figure 11.12: The signal strengths μ measured by the ATLAS and CMS experiments [141] for the five principal Higgs boson decay channels assuming that the production cross sections are those of the SM.

Table 11.11 also reports the results of a similar combination by each experiment from their data. For the main discovery modes $\gamma\gamma$, ZZ and WW, the combined significance is not computed as these decay modes have been firmly established by each experiment independently. However for the $\tau^+\tau^-$ and $b\bar{b}$ decay modes these results shed new combined light on the observation significance in these channels.

For the $\tau^+\tau^-$ channel, ATLAS and CMS are both sensitive and have observed excesses in their data. The individual results are not sufficiently significant to claim an observation, but combined they are. This conclusion can be made also in a more generic manner using the ratio of branching fractions model described above. It should be noted that in the search for $H \to \tau\tau$ decay, the most sensitive production mode is the VBF process, the experimental evidence for which is discussed in Section IV.3.

Table 11.11: Summary of the significances of the excesses observed for the main decay processes. The $\gamma\gamma$, ZZ, and W^+W^- decay modes have been established at more than 5σ by both the ATLAS and CMS experiments individually, the combined observation significance therefore exceeds 5σ and is not reported here.

	Expected Z	Observed Z
$\gamma\gamma$	4.6σ (ATLAS) 5.3σ (CMS)	5.2σ (ATLAS) 4.6σ (CMS)
ZZ	6.2σ (ATLAS) 6.3σ (CMS)	8.1σ (ATLAS) 6.5σ (CMS)
WW	5.9σ (ATLAS) 5.4σ (CMS)	6.5σ (ATLAS) 4.7σ (CMS)
$\tau^+\tau^-$	3.4σ (ATLAS) 3.9σ (CMS)	4.5σ (ATLAS) 3.8σ (CMS)
$b\bar{b}$	2.6σ (ATLAS) 2.5σ (CMS)	1.4σ (ATLAS) 2.1σ (CMS)
$\tau^+\tau^-$ (Comb.)	5.0σ	5.5σ
$b\bar{b}$ (Combined)	3.7σ	2.6σ

Table 11.12: Summary of the combined significance of observation for the main production processes. The ggF process has been established at more than 5σ by both the ATLAS and CMS experiments individually, the combined observation significance far exceeds 5σ and is not reported here.

	Expected Z		Observed Z	
ggF	Ind.	Obs.	Ind.	Obs.
VBF	4.6σ		5.4σ	
WH	2.7σ		2.4σ	
ZH	2.9σ		2.3σ	
VH	4.2σ		3.5σ	
ttH	2.0σ		4.4σ	

As illustrated in Table 11.11, ATLAS and CMS are both much less sensitive to the $H \to b\bar{b}$ decay mode. The available sensitivity comes mostly from the VH process, as discussed earlier in this section. The combined significance of 3.7σ is sufficient to suggest evidence, however ATLAS and CMS observations are both low with respect to the rate expected for the SM Higgs boson. With the increased production cross sections at 13 TeV and the much larger dataset expected, this channel will undoubtedly be followed with great attention at the Run 2 of the LHC.

IV.3. Characterization of the main production modes and evidence for VBF production

As discussed earlier, most analysis channels are divided into several exclusive categories allowing for an increased overall sensitivity and to measure the various Higgs production modes. The cross sections of the main production modes can be measured assuming that the branching fractions are those of the SM Higgs boson, *i.e.* for all f indices $\mu_f = 1$. These assumptions lead to a 5 parameter combination. The result is illustrated in Fig. 11.13 for the ATLAS-CMS combination [141]. The significance of observation of the production modes are reported in Table 11.12.

The gluon fusion production process is the dominant production mode. Although no numerical estimate of combined significance of observation for this process has been given by the experiments, it is considered as established due to the overwhelming evidence from the three main discovery channels. None of the other production modes have been firmly established by the experiments individually. These show that for the VBF mode, the combination has a large sensitivity and produced a combined observation of 5.4σ, establishing this process with a rate compatible with that expected from the SM Higgs boson. A similar conclusion can be reached but with assumptions from the fit to the ratio $\sigma_{VBF}/\sigma_{ggF}$ discussed earlier in this section.

It is interesting to note that despite the low sensitivity to the ttH production mode, the excesses observed in several ttH channels (discussed in Section III.6.1), lead to a significance of direct observation for ttH production in excess of 4σ. The compatibility of this observation with the SM production rate is at the 2.3σ level. Given the increased sensitivity expected at the higher center-of-mass energy of 13 TeV, a great attention will undoubtedly be devoted to this channel.

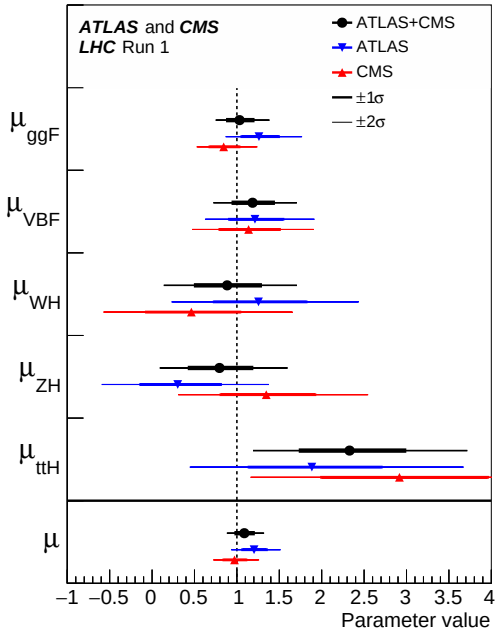

Figure 11.13: The signal strengths μ measured by the ATLAS and CMS experiments [141] in the five principal production modes and their combination, assuming that the decay branching fractions are those of the SM Higgs boson.

One can further reduce the number of parameters of interest by grouping the ggF and ttH production modes together, as they both originate in the SM from the Yukawa coupling to the top quark and the VH and VBF processes together as they both originate from the coupling of the Higgs boson to massive vector bosons. Grouping here means that the two production cross sections are scaled by a single parameter of interest, which is equivalent to fixing their ratio to the expected ratio for a SM Higgs boson. The 2-dimensional profile of the likelihood for each main decay channel individually is shown in Fig. 11.14, illustrating the relative constraint that each decay channel is imposing on the production process and the correlation between the grouped processes. This correlation stems from the cross contamination of the exclusive categories with processes from the two groups. Concerning the VBF production mode, these results show its manifest predominance in the $\tau^+\tau^-$ channel and the importance of the $\gamma\gamma$ and WW channels in constraining it. While in most cases the $ggF + ttH$ group is mostly constrained by the indirect gluon fusion process, in the case of the $b\bar{b}$ channel, the bulk of the constraint comes from the ttH process.

V. Main quantum numbers and width of the Higgs boson

V.1. Main quantum numbers J^{PC}

Probing the Higgs boson quantum numbers is essential to further unveiling its coupling properties. The measurements of the signal event yields of the observed new state in all the channels discussed in Sections III and IV and their compatibility with the SM Higgs boson predictions, give a qualitative, but nonetheless compelling indication of its nature. This qualitative picture is further complemented by the implications of the observation of the particle in the diphoton channel. According to the Landau–Yang theorem [200], the observation made

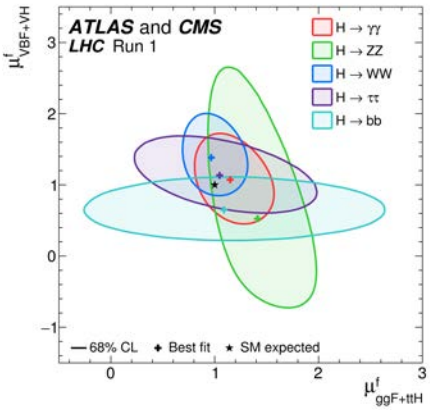

Figure 11.14: Two dimensional likelihood contours for individual production signal strengths for the $VBF+VH$ versus $ggF+ttH$ processes for various Higgs boson decay modes for the ATLAS and CMS experiment combination.

in the diphoton channel excludes the spin-1 hypothesis and restricts possibilities for the spin of the observed particle to 0 or 2.

The Landau–Yang theorem does not apply if the observed state is not decaying to a pair of photons but to a pair of scalars subsequently decaying to two very collimated pairs of photons (as for example in the case of $H \to a_1 a_1 \to 4\gamma$). This possibility has not been rigorously excluded but is not experimentally favored since tight selection criteria are applied on the electromagnetic shower shapes of the reconstructed photons. A more systematic analysis of shower shapes and the fraction of conversions could be performed to further discriminate between the single prompt photon and the two overlapping photons hypotheses. There are also potential theoretical loopholes concerning the applicability of the Landau–Yang theorem [200], such as off-shell vector boson decays. However, for the observed particle not to be of spin 0 and +1 parity would require an improbable conspiracy of effects. It is nevertheless important that this hypothesis be independently tested, in particular since the measurements of coupling properties of the Higgs boson assume that the observed state is CP-even.

V.1.1. Charge conjugation

The charge conjugation quantum number is multiplicative, therefore given that the Higgs-like particle is observed in the $H \to \gamma\gamma$ channel, and given that photons are C-odd eigenstates, assuming C conservation, the observed neutral particle should be C-even.

V.1.2. Spin and parity

To probe the spin and parity quantum numbers of the discovered particle, a systematic analysis of its production and decay processes is performed in several analyses, designed to be independent of the event yields measured and relying instead on the production and the decay angles, and on the threshold distributions as long as a significant signal is observed (*i.e.* an excess over the expected background that can be used to further discriminate between signal hypotheses) of the produced particle. These analyses are based on probing various alternative models of spin and parity. These models can be expressed in terms of an effective Lagrangian [201] or in terms of helicity amplitudes [202, 203]. The two approaches are equivalent. In the following, the effective Lagrangian formalism is chosen to describe the models considered and a restricted number of models are discussed [201]. In the analysis performed by CMS [202] a larger number of models have been investigated, however the main channels studied by both experiments are essentially the same and the main conclusions are similar and fully consistent.

(i) Spin-0 model

The interaction Lagrangian relevant for the analysis of spin-0 particle interaction with a pair of W- or Z-boson with either fixed or mixed SM and BSM CP-even couplings or CP-odd couplings, is the following:

$$\begin{aligned}\mathcal{L}_0^{W,Z} \supset \Big\{ & \cos(\alpha)\kappa_{SM}\left[\frac{1}{2} g_{HZZ} Z_\mu Z^\mu + g_{HWW} W^+_\mu W^{-\mu}\right] \\ & - \frac{1}{4\Lambda}\left[\cos(\alpha)\kappa_{HZZ} Z_{\mu\nu} Z^{\mu\nu} + \sin(\alpha)\kappa_{AZZ} Z_{\mu\nu}\tilde{Z}^{\mu\nu}\right] \\ & - \frac{1}{2\Lambda}\left[\cos(\alpha)\kappa_{HWW} W^+_{\mu\nu} W^{-\mu\nu} + \sin(\alpha)\kappa_{AWW} W^+_{\mu\nu}\tilde{W}^{-\mu\nu}\right]\Big\} H_0\end{aligned} \tag{11.15}$$

Where $V^\mu = Z^\mu, W^{+\mu}$ are the vector boson fields, $V^{\pm\mu\nu}$ are the reduced field tensors and $\tilde{V}^{\pm\mu\nu} = 1/2\,\varepsilon^{\mu\nu\rho\sigma} V_{\rho\sigma}$ are the dual tensor fields. Here, Λ defines an effective theory energy scale. The factors $\kappa_{SM}, \kappa_{HZZ}, \kappa_{HWW}, \kappa_{AZZ}, \kappa_{AWW}$ denote the coupling constants corresponding of the coupling of the SM, BSM CP-even and CP-odd components of the Higgs field H_0 to the W and Z fields. The mixing angle α allows for the production of CP-mixed state and the CP-symmetry is broken when $\alpha \neq 0, \pi$.

This formalism can be used to probe both CP-mixing for a spin-0 state or specific alternative hypotheses such as a pure CP-odd state ($J^P = 0^-$) corresponding to $\alpha = \pi/2$, $\kappa_{SM} = \kappa_{HVV} = 0$ and $\kappa_{AVV} = 1$. A BSM CP-even state $J^P = 0^+_h$ corresponds to $\alpha = 0$, $\kappa_{SM} = \kappa_{AVV} = 0$ and $\kappa_{HVV} = 1$. These hypotheses are compared to the SM Higgs boson hypothesis corresponding to $\alpha = 0$ and $\kappa_{HVV} = \kappa_{AVV} = 0$ and $\kappa_{SM} = 1$.

(ii) Spin-2 model

The graviton inspired interaction Lagrangian for a spin-2 boson $X^{\mu\nu}$ for a color, weak and electromagnetic singlet spin-2 resonance uniquely interacting with the energy momentum tensor $\mathcal{T}^{V,f}$ of vector bosons V or fermions f, can be written as follows [204]:

$$\mathcal{L}_2 \supset \frac{1}{\Lambda}\left[\sum_V \xi_V \mathcal{T}^V_{\mu\nu} X^{\mu\nu} + \sum_f \xi_f \mathcal{T}^f_{\mu\nu} X^{\mu\nu}\right]$$

Where the strength of the interaction is determined by the couplings ξ_V and ξ_f. The simplest scenario, referred to as the universal couplings (UC), corresponds to $\xi_V = \xi_f$. These models predict a large branching ratio to photons (of approximately 5%) and negligible couplings to massive gauge bosons (W and Z). Such scenarios are therefore disfavored and other models are investigated where the couplings of the W, Z and γ are assumed to be independent. Universality of the couplings refers to $\xi_g = \xi_q$. Two other scenarios are considered with low light-quark fraction where $\xi_q = 0$ and the low gluon-fraction where $\xi_q = 2\xi_g$. In these scenarios a large enhancement of the tail of the transverse momentum of the spin-2 state is expected and requires a further selection requirement in order to probe the models within the range of validity of the effective field theory. Two requirements are considered, $p_T^X < 300\,\text{GeV}$ and $p_T^X < 125\,\text{GeV}$ [201].

V.1.3. Probing fixed J^P scenarios

At the LHC, the determination of the spin and CP properties of the Higgs boson is done independently from the total rates measurement, it uses a global angular helicity analysis and, when applicable, the study of threshold effects. The channels used for this analysis, $H \to \gamma\gamma$, $H \to W^{(*)}W^{(*)} \to \ell\nu\ell\nu$ and $H \to Z^{(*)}Z^{(*)} \to 4\ell$, are those where the observation of a signal is unambiguous.

At the Tevatron, an analysis using the threshold distribution of the production of the discovered state [205] in the associated production mode VH with subsequent decay to a pair of b-quarks was performed by the D0 collaboration.

(i) The VH production at D0

The mass of the VH system is a powerful discriminant to distinguish a $J^P = 0^+_m$, with a threshold behavior in $d\sigma/dM^2 \sim \beta$ from 0^- or 2^+ with threshold behaviors respectively in $\sim \beta^3$ and $\sim \beta^5$ (for a graviton like spin 2) [205]. The VH mass observable, not only discriminates signal hypotheses, but also has an increased separation between the 0^- and 2^+ hypotheses with respect to the backgrounds, thus allowing, with a small and not yet significant signal yield, to exclude that the observed state is 0^- at 98% CL [206] and 2^+ at the 99.9% CL [207].

(ii) The $\gamma\gamma$ channel at the LHC

In the $H \to \gamma\gamma$ channel, the analysis is performed inclusively using the production angle $\cos\theta^*_{CS}$ and the transverse momentum of the diphoton pair [201]. The definition chosen for the polar angle in the rest frame is the Collins–Soper frame, which is defined as the bisector axis of the momenta of the incoming protons in the diphoton rest frame. The SM Higgs signal distribution is expected to be uniform with a cutoff due to the selection requirements on the photons transverse momentum. The $H \to \gamma\gamma$ channel is mostly sensitive to the gluon-initiated spin-2 production scenarios, which yield a $\cos\theta^*_{CS}$ distribution peaking at values close to 1. The limits are derived from a fit of the signal in bins of $\cos\theta^*_{CS}$ and diphoton transverse momentum and are summarized in Fig. 11.15 for ATLAS, only combined results are shown. The data shows a good compatibility with the SM 0^+ hypothesis and contributes strongly to the exclusion of several Spin-2 scenarios. The conclusions are the same from CMS results [202].

(iii) The $H \to W^{(*)}W^{(*)} \to \ell\nu\ell\nu$ channel at the LHC

In the $H \to W^{(*)}W^{(*)} \to \ell\nu\ell\nu$ channel, the production and decay angles cannot be easily reconstructed due to the presence of neutrinos in the final state, however sensitivity arises from the V-A structure of the decay of the W bosons. A scalar state thus yields a clear spin correlation pattern that implies that the charged leptons e or μ from the decays of the W bosons are produced close to one another in the transverse plane. This feature, which impacts observables such as the azimuthal angle between the two leptons $\Delta\Phi_{\ell\ell}$ or their invariant mass $M_{\ell\ell}$ in addition of the threshold behavior of the decay which is used in kinematic variables such as the transverse mass defined in Section III, can be used to discriminate between various spin and parity hypotheses. The approach adopted by ATLAS uses a multivariate discriminant, whereas CMS uses a 2D-fit of the dilepton mass and the transverse mass. The results of the $H \to W^{(*)}W^{(*)} \to \ell\nu\ell\nu$ analyses alone are summarized in Fig. 11.15 for ATLAS and in combination with other channels. Spin-1 hypotheses (1^+ and 1^-) have also been tested with this channel by ATLAS and CMS. ATLAS and CMS exclude the 1^+ and 1^- hypotheses at more than 95% CL.

(iv) The $H \to Z^{(*)}Z^{(*)} \to 4\ell$ channel at the LHC

The $H \to Z^{(*)}Z^{(*)} \to 4\ell$ coupling analysis, as described in Section III, also uses a discriminant based on the 0^+ nature of the Higgs boson to further discriminate the signal from the background. In this analysis this feature is used to discriminate between signal hypotheses. The observables sensitive to the spin and parity are [208] the masses of the two Z bosons (due to the threshold dependence of the mass of the off-shell Z boson), two production angle θ^* and ϕ_1, and three decay angles, ϕ, θ_1 and θ_2. The production and decay angles defined as:

– θ_1 and θ_2, the angles between the negative final state lepton and the direction of flight of Z_1 and Z_2 in the rest frame.

– ϕ, the angle between the decay planes of the four final state leptons expressed in the four lepton rest frame.

– ϕ_1, the angle defined between the decay plane of the leading lepton pair and a plane defined by the vector of the Z_1 in the four lepton rest frame and the positive direction of the proton axis.

– θ^*, the production angle of the Z_1 defined in the four lepton rest frame with respect to the proton axis.

These angles are illustrated in Fig. 11.15. There are two approaches to this analysis. The first, used by CMS, is a matrix element likelihood approach where a kinematic discriminant is defined based on the ratio of the signal and background probabilities. These probabilities are defined using the leading-order matrix elements. A similar approach is also performed by ATLAS as a cross check of their main result. The main approach adopted by ATLAS is the combination of sensitive observables with a Boosted Decision Tree. These analyses are sensitive to various J^P hypotheses and in particular discriminate the 0^+ hypothesis from the 0^-. In all scenarios investigated and for both the ATLAS and CMS experiments, the data are compatible with the 0^+ hypothesis. ATLAS [203] and CMS [202] exclude a pseudoscalar nature of the observed boson at CL_S levels of 98% and 99.8%.

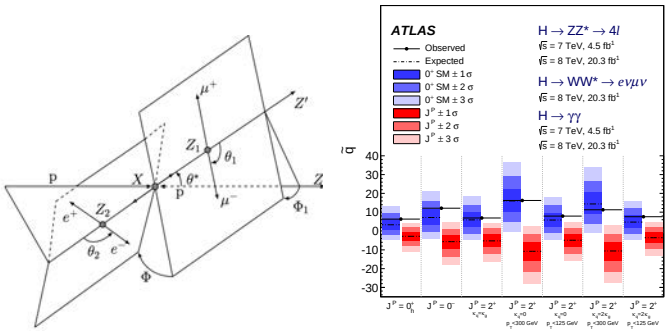

Figure 11.15: (Left) Definition of the production and decay angles defined for the $H \to Z^{(*)}Z^{(*)} \to 4\ell$ final state [202]. Expected distributions of the test statistic for the SM hypothesis (in blue) and several alternative spin and parity hypotheses (in red).

V.1.4. Probing anomalous HVV couplings

The careful study of the kinematic properties of the events observed in the $H \to Z^{(*)}Z^{(*)} \to 4\ell$ and $H \to W^{(*)}W^{(*)} \to \ell\nu\ell\nu$ channel, and in particular the angular distributions described above, allows one to further probe the HVV coupling beyond testing fixed hypotheses. Assuming that the observed particle is a spin-0 state, and using several discriminating observables in the $H \to Z^{(*)}Z^{(*)} \to 4\ell$ and $H \to W^{(*)}W^{(*)} \to \ell\nu\ell\nu$ channels, the anomalous terms in the formalism of Eq. (11.15) can be probed. In the approach of helicity amplitudes used by CMS [202], all terms are essentially equivalent, except for one additional phase which is neglected in Eq. (11.15).

Results are derived in terms of the parameters $\tilde{\kappa}_{HVV} = v/\Lambda\,\kappa_{HVV}$ and $\tilde{\kappa}_{AVV} = v/\Lambda\,\kappa_{AVV}$, and more precisely as measurements of $\tilde{\kappa}_{HVV}/\kappa_{SM}$ and $\tan\alpha\,.\,\tilde{\kappa}_{AVV}/\kappa_{SM}$ as shown in Fig. 11.16. These parameters can be interpreted as mixing parameters of a tensor anomalous CP-even coupling and a CP-odd component. The measurements are made in the $H \to Z^{(*)}Z^{(*)} \to 4\ell$ and $H \to W^{(*)}W^{(*)} \to \ell\nu\ell\nu$ channels independently and then combined assuming that the $\tilde{\kappa}_{HVV}/\kappa_{SM}$ and $\tan\alpha\,.\,\tilde{\kappa}_{AVV}/\kappa_{SM}$ are the same for the W and Z vector bosons. Only the combination of the WW and ZZ channels is shown in Fig. 11.16. The asymmetric shape of the likelihood as a function of $\tilde{\kappa}_{HWW,HZZ}/\kappa_{SM}$ is mainly due to the interference between the BSM and the SM contributions that give a maximal deviation from the SM predictions for negative relative values of the BSM couplings. In Fig. 11.16 the expected likelihood profiles for a SM Higgs boson are also displayed. While no significant deviation from the SM Higgs boson expectation is observed, the precision of the measurements of the mixing parameters is fairly low. The results from the CMS measurements [202] are very similar and the conclusions the same.

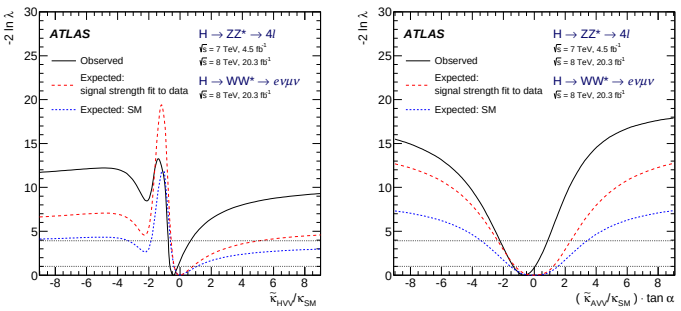

Figure 11.16: Likelihood profiles for the $\tilde{\kappa}_{HVV}$ and $\tilde{\kappa}_{AVV}\,.\,\tan\alpha$ parameters, representing respectively CP-even and CP-odd anomalous couplings of the Higgs boson.

V.2. Off-shell couplings of the Higgs boson

In the dominant gluon fusion production mode, the production cross section of a off-shell Higgs boson is known to be sizable. This follows as a consequence of the enhanced couplings of the Higgs boson to the longitudinal polarizations of the massive vector bosons at high energy.

The off-shell to on-shell cross section ratio is approximately 8% in the SM. Still the Higgs contribution to VV production at large invariant mass remains small compared to the background. It is nevertheless interesting to probe Higgs production in this regime as it is sensitive to new physics beyond the SM.

The difficulty in the off-shell VV analysis, beyond the small signal-to-background ratio, is due to a large negative interference between the signal and the $gg \to VV$ background. boson signal in the far off-shell domain results in a deficit of events with respect to the expectation from background only events. It is only when the off-shell couplings of the Higgs boson are larger than expected in the SM that the presence of a signal appears as an excess over the background expectation. One additional intricacy arises from the precision in the prediction of the rate for $gg \to VV$, a loop process at lowest order, and its interference with the signal. At the time of the publications of the results from the ATLAS [209] and CMS [210] a full NLO prediction had not been computed.

It is interesting to note that in this regime the Higgs boson is studied as a propagator and not as a particle. The measurement of its off-shell couplings is therefore absolute and does not rely on the knowledge of the total Higgs boson width. The off-shell couplings constraints can then be used to indirectly constrain the natural width of the Higgs boson, under specific assumptions detailed in Section V.3.3.

This measurement has been carried out in the $H \to ZZ \to 4\ell$, $H \to ZZ \to \ell\ell\nu\nu$ and $H \to WW \to \ell\nu\ell\nu$ channels. To enhance the sensitivity of the analysis the knowledge of the full kinematics of the events is important. In particular the signal and the background can be further distinguished by the invariant mass of the VV system, which is more accurately accessible in the $H \to ZZ \to 4\ell$ channel. Angular distributions also play an important role in this analysis. For these reasons the $H \to Z^{(*)}Z^{(*)} \to 4\ell$ channel is significantly more sensitive than $H \to W^{(*)}W^{(*)} \to \ell\nu\ell\nu$. The CMS results in Refs. [210] and [211] include the VBF and VH processes through the selection of two additional jets in the final state. The ATLAS results do not have a specific selection for the VBF or VH production processes, but their contributions are taken into account.

Limits on the off-shell rates have been reported for the two channels by ATLAS [209] and CMS [211]. The combined results assuming that the off-shell rates in the ZZ and WW channels scale equally, are given for two different hypotheses on the VBF production rate: fixing it to its SM value or scaling it as the gluon fusion rate. The observed (expected) limits on the off-shell rate fraction with respect to its SM expectation is 6.7 (9.1) for ATLAS [209] with the VBF rate fixed to its SM value and 2.4 (6.2) for CMS [211] where no assumption is made on the relative production rates of gluon-fusion and VBF. In both cases the custodial symmetry is assumed and the ratio of the rates in the ZZ and WW decays are fixed to those of the Standard Model. Results without this assumption have also been reported in Ref.[211].

V.3. The Higgs boson width

In the SM, the Higgs boson width is very precisely predicted once the Higgs boson mass is known. For a mass of 125.1 GeV, the Higgs boson has a very narrow width of 4.2 MeV. It is dominated by the fermionic decays partial width at approximately 75%, while the vector boson modes are suppressed and contribute 25% only.

At the LHC or the Tevatron, in all production modes, only the cross sections times branching fractions can be measured. As a consequence, the total natural width of the Higgs boson cannot be inferred from measurements of Higgs boson rates. Direct constraints on the Higgs boson width are much larger than the expected natural width of the SM Higgs boson.

Table 11.13: The observed (expected) direct 95% CL constraints on the natural width of the 125 GeV resonance from fits to the $\gamma\gamma$ and ZZ mass spectra and to the 4ℓ vertex lifetime.

	$M_{\gamma\gamma}$ mass spectrum	$M_{4\ell}$ spectrum	4ℓ vertex lifetime
ATLAS	$< 5.0(6.2)$ GeV	$< 2.6(6.2)$ GeV	—
CMS	$< 2.4(3.1)$ GeV	$< 3.4(2.8)$ GeV	$> 3.5 \times 10^{-12}$ GeV

V.3.1. Direct constraints

Analysis of the reconstructed mass lineshape in the two channels with a good mass resolution, the $H \to \gamma\gamma$ and $H \to Z^{(*)}Z^{(*)} \to 4\ell$, allow for a direct measurement of the width of the SM Higgs boson. The intrinsic mass resolution in these channels is about 1-2 GeV, much larger than the expected width of the SM Higgs boson. As a result only upper limits on the Higgs boson width have been measured by ATLAS [132] and CMS [133]. The two main challenges of direct constraints on the width through the measurement of the lineshape are: (i) the modeling of resolution uncertainties and (ii) the modeling of the interference between the signal and the continuum background which can be sizable for large widths, in particular in the range where direct constraints are set. Given that these interference effects are small with respect to the individual channels sensitivity, they are neglected in deriving constraints on the total width. The combined constraints however, being more precise could be affected by the interference. ATLAS [132] has therefore not combined the constraints on the width from the two channels. The results are reported in Table 11.13. These constraints are still three orders of magnitude larger than the expected SM width and are fully compatible with the SM hypothesis.

Another direct constraint on the Higgs boson width can be obtained in the $H \to Z^{(*)}Z^{(*)} \to 4\ell$ channel, from the measurement of the average lifetime of the Higgs boson calculated from the displacement of the four-lepton vertex from the beam spot. This analysis has been carried out by CMS [210], using the measured decay length. The measured $c\tau_H$ is $2^{+25}_{-2}\,\mu$m, yielding an observed (and expected) limit at the 95% CL of $c\tau_H < 57(56)\,\mu$m. From this upper limit on the lifetime of the Higgs boson. The 95% CL lower limit on its natural width is $\Gamma_H > 3.5 \times 10^{-12}$ GeV.

V.3.2. Indirect constraints from mass shift in the diphoton channel

In the diphoton channel, it was noticed in [212], that the effect of the interference between the main signal $gg \to H \to \gamma\gamma$ and the continuum irreducible background $gg \to \gamma\gamma$, taking into account detector resolution effects, is responsible for a non negligible mass shift. The size of the mass shift depends on the total width of the Higgs boson and it was suggested that measuring this mass shift could provide a constraint on the width [212]. Comparing the mass measured in the diphoton channel with the mass measured in the four-leptons channel is subject to non negligible detector calibration systematic uncertainties, however it was further noticed that the mass shift has a dependence also on the diphoton transverse momentum. The total width of the Higgs boson could therefore be constrained using the diphoton channel alone.

Further studies were performed by the ATLAS collaboration to estimate the size of the expected mass shift [213]. The expected shift in mass in the diphoton channel is 35 ± 9 MeV for the SM Higgs boson. Very preliminary studies of the sensitivity of this method to estimate the width of the Higgs boson in the high-luminosity regime have been made by ATLAS [214] and yield an expected 95% CL upper limit on the total width of approximately 200 MeV from 3 ab^{-1} of 14 TeV data.

V.3.3. Indirect constraints from off-shell couplings

Using simultaneously on-shell and off-shell measurements in the VV channels, it was noticed [215] that the total width of the Higgs could be constrained. This can be illustrated from the parametrization of the signal strength measurements both on-shell ($\mu_{\rm on-shell}$) and off-shell ($\mu_{\rm off-shell}$) as a function of the couplings modifiers κ_g and κ_V parameterizing the main process $gg \to H \to VV$. The on-shell signal

strength can be written as:

$$\mu_{\text{on-shell}} = \frac{\kappa^2_{g,\,\text{on-shell}}\,\kappa^2_{V,\,\text{on-shell}}}{\Gamma_H/\Gamma_{SM}}$$

while in the case of the off-shell signal strength where the Higgs boson is a propagator:

$$\mu_{\text{on-shell}} = \kappa^2_{g,\,\text{off-shell}}\,\kappa^2_{V,\,\text{off-shell}}$$

Then, with the following assumption

$$\kappa^2_{g,\,\text{on-shell}}\,\kappa^2_{V,\,\text{on-shell}} \leq \kappa^2_{g,\,\text{off-shell}}\,\kappa^2_{V,\,\text{off-shell}}\,,$$

from the on-shell and off-shell constraints. This assumes that no new physics alters the Higgs boson couplings in the off-shell regime, i.e. that the running of its couplings is negligible in the off-shell regime. Both ATLAS [209] and CMS [210, 211] have used their off-shell production limits to constrain the width of the Higgs boson.

Both ATLAS and CMS analyses use the kinematic event characteristics to further gain in sensitivity to discriminate between the signal and background. The ATLAS analysis assumes that there are no anomalous couplings of the Higgs boson to vector bosons, and obtains 95% CL observed (expected) upper limit on the total width of $5.7\times\Gamma_{SM}$ ($9.0\times\Gamma_{SM}$) [209]. In the CMS approach, results are also derived allowing for anomalous couplings of the Higgs boson, therefore reducing the discriminating power of the kinematic variables used in the analysis but reducing the model dependence. When standard couplings are assumed for the Higgs boson, the observed (expected) limit on the total width is $6.2\times\Gamma_{SM}$ ($9.8\times\Gamma_{SM}$) for the ZZ channel only [210]. Without assumptions on the anomalous couplings of the Higgs boson, the observed (expected) limit on the total width is $10.9\times\Gamma_{SM}$ ($17.4\times\Gamma_{SM}$) [210].

The CMS experiment has also combined the ZZ and W^+W^- channels while keeping the gluon-fusion and VBF production processes separate. For the gluon fusion mode the observed (expected) combined upper limit at the 95% CL on the total width of the Higgs boson is $2.4\times\Gamma_{SM}$ ($6.2\times\Gamma_{SM}$) [211], while for the VBF production mode the exclusion limits are $19.3\times\Gamma_{SM}$ ($34.4\times\Gamma_{SM}$) [211].

ATLAS has also performed a study of the prospects for measuring the Higgs width in the four lepton channel alone, in the high luminosity phase of the LHC for and projects that for a LHC luminosity of $3\,\text{ab}^{-1}$, the width of the Higgs boson could be measured with the following precision [216]:

$$\Gamma_H = 4.2^{+1.5}_{-2.1}\,\text{MeV}$$

VI. Probing the coupling properties of the Higgs boson

As discussed in Section II, within the SM, all the Higgs couplings are fixed unambiguously once all the particle masses are known. Any deviation in the measurement of the couplings of the Higgs boson could therefore signal physics beyond the SM.

Measuring the Higgs couplings without relying on the SM assumption requires a general framework treating deviations from the SM coherently at the quantum level in order to provide theoretical predictions for relevant observables to be confronted with experimental data. The first attempt in that direction was the development of the so-called κ-formalism where the SM Higgs couplings are rescaled by factors κ_f, keeping the same Lorentz structure of the interactions. This formalism allows for simple interpretation of the signal strengths μ measured in the various Higgs channels and it has been used to test various physics scenarios, like the existence of additional new particles contributing to the radiative Higgs production and decays, or to probe various symmetries of the SM itself, in particular the custodial symmetry. But the κ-formalism has obvious limitations and certainly does not capture the most general deformations of the SM, even under the assumptions of heavy and decoupling new physics. A particularly acute shortcoming at the time Higgs physics is entering a precision era is the lack of proficiency of the κ's to assert the richness of kinematical distributions beyond simple signal strength measurements. Several extensions and alternative approaches are being developed as part of the activities of the Higgs cross-section working group.

The Higgs Pseudo-Observable (HPO) approach [217] is providing a particularly elegant formalism to report the data in terms of a finite set of on-shell form factors parametrizing amplitudes of physical processes subject to constraints from Lorentz invariance and other general requirements like analyticity, unitarity, and crossing symmetry. These form factors are expanded in powers of kinematical invariants of the process around the known poles of SM particles, assuming that poles from BSM particles are absent in the relevant energy regime. A set of HPOs have been proposed to characterize both the Higgs decays and the EW Higgs production channels, thus exploring different kinematical regimes. Prospective studies concluded that these HPOs can be measured/bounded at the percent level at the HL-LHC and could therefore be used to constrain some explicit models of New Physics.

Another promising approach to characterize the possible Higgs coupling deviations induced by physics beyond the SM is the use of Effective Field Theories (EFT). This approach assumes again that the new physics degrees of freedom are sufficiently heavy to be integrated out and they simply give rise to effective interactions among the light SM particles. By construction the effective Lagrangians cannot account for deviations in Higgs physics induced by light degrees of freedom, unless they are added themselves as extra fields in the effective Lagrangians. In Section VII, several examples of models with light degrees of freedom affecting Higgs production and decay rates will be presented. The main advantage of EFTs is their prowess to relate different observables in different sectors and at different energies to constrain a finite set of effective interactions among the SM degrees of freedom. In an EFT, the SM Lagrangian is extended by a set of higher-dimensional operators, and it reproduces the low-energy limit of a more fundamental UV description. It will be assumed that the Higgs boson is part of a CP-even EW doublet. This is motivated by the apparent relation between the Higgs couplings and the masses of the various particles which naturally follows under this assumption of a linear realization of the $\text{SU}(2)_L \times \text{U}(1)_Y$ symmetry of the SM. There have been some recent attempts to write the most general EFT bypassing this assumption, see for instance [218].

VI.1. Effective Lagrangian framework

The EFT has the same field content and the same linearly-realized $\text{SU}(3)_C \times \text{SU}(2)_L \times \text{U}(1)_Y$ local symmetry as the SM. The difference is the presence of operators with canonical dimension D larger than 4. These are organized in a systematic expansion in D, where each consecutive term is suppressed by a larger power of a high mass scale. Assuming baryon and lepton number conservation, the most general Lagrangian takes the form

$$\mathcal{L}_{\text{eff}} = \mathcal{L}_{\text{SM}} + \sum_i c_i^{(6)}\mathcal{O}_i^{(6)} \; + \sum_j c_j^{(8)}\mathcal{O}_j^{(8)} + \cdots\,. \tag{11.16}$$

The list of dimension-6 operators was first classified in a systematic way in Ref. [219] after the works of Ref. [220]. Subsequent analyses pointed out the presence of redundant operators, and a minimal and complete list of operators was finally provided in Ref. [221][5]. For a single family of fermions, there are 76 real ways to deform the SM generated by 59 independent operators (with the 3 families of fermions of the SM, flavor indices can be added to these 59 operators, and furthermore, new operator structures, that have been dismissed by means of Fierz transformations in the single family case, have to be considered, for a total of 2499 real deformations [223]). Of particular interest are the 17 CP-invariant operators, in addition to 8 dipole operators, that affect, at tree-level, the Higgs production and decay rates [224–226]. A convenient list of these operators can be found in

[5] Complete classifications of D=8 operators have recently appeared in the literature, see Ref. [222]. Still, in this review, the EFT Lagrangians will be truncated at the level of dimension-6 operators.

Table 11.14: List of 17 CP-even operators affecting, at tree-level, only Higgs production and decay rates (left) as well as EW observables (right). See text for notations.

Operators affecting Higgs physics only	Operators affecting Higgs and EW physics
$\mathcal{O}_r = \lvert\Phi\rvert^2 \lvert D_\mu\Phi\rvert^2$	$\mathcal{O}_W = \frac{ig}{2}\left(\Phi^\dagger\sigma^i \overleftrightarrow{D^\mu}\Phi\right)(D^\nu W_{\mu\nu})^i$
$\mathcal{O}_6 = \lambda\lvert\Phi\rvert^6$	$\mathcal{O}_B = \frac{ig'}{2}\left(\Phi^\dagger \overleftrightarrow{D^\mu}\Phi\right)(\partial^\nu B_{\mu\nu})$
$\mathcal{O}_{BB} = \frac{g'^2}{4}\lvert\Phi\rvert^2 B_{\mu\nu}B^{\mu\nu}$	$\mathcal{O}_T = \frac{1}{2}\left(\Phi^\dagger \overleftrightarrow{D^\mu}\Phi\right)^2$
$\mathcal{O}_{WW} = \frac{g^2}{4}\lvert\Phi\rvert^2 W^i_{\mu\nu}W^{i\,\mu\nu}$	$\mathcal{O}_{HB} = ig'\left(D^\mu\Phi\right)^\dagger(D^\nu\Phi)B_{\mu\nu}$

$\mathcal{O}_{dG} = g_S\left(\bar{q}_L\Phi\sigma^{\mu\nu}t^A d_R\right)G^A_{\mu\nu}$
$\mathcal{O}_{lB} = g'\left(\bar{L}_L\Phi\sigma^{\mu\nu}l_R\right)B_{\mu\nu}$
$\mathcal{O}_{lW} = g\left(\bar{L}_L\sigma^i\Phi\sigma^{\mu\nu}l_R\right)W^i_{\mu\nu}$

Table 11.14, and Table 11.15. The other operators completing the basis of dimension-6 operators can be found in Ref. [226].

The SM gauge couplings are denoted by g', g, g_S while $y_{u,d,e}$ are the SM Yukawa couplings (in the mass eigenstate basis that diagonalizes the general Yukawa coupling matrices $Y_{u,d,l}$) and λ is the SM Higgs quartic coupling. We denote by $i\Phi^\dagger \overleftrightarrow{D}^\mu\Phi$ the Hermitian derivative $i\Phi^\dagger(D^\mu\Phi) - i(D^\mu\Phi)^\dagger\Phi$, $\sigma^{\mu\nu} \equiv i[\gamma^\mu,\gamma^\nu]/2$ and $\tilde{\Phi}$ is the Higgs charge-conjugate doublet: $\tilde{\Phi} = i\sigma^2\Phi^*$. Each operator $\mathcal{O}_{yu,yd,ye}$ is further assumed to be flavor-aligned with the corresponding fermion mass term, as required in order to avoid large Flavor-Changing Neutral Currents (FCNC) mediated by the tree-level exchange of the Higgs boson. This implies one coefficient for the up-type quarks (c_{yu}), one for down-type quarks (c_{yd}), and one for the charged leptons (c_{ye}), i.e. the $c_{yu,ud,ye}$ matrices should be proportional to the identity matrix in flavor space.

The choice of the basis of operators is not unique and using the equations of motion, i.e., performing field redefinitions, different dimension-6 operators can be obtained as linear combinations of the operators in the previous tables and of four-fermion operators. Some relations between common bases of operators can be found for instance in Refs. [225, 223]. Different bases have different advantages. For instance the so-called SILH basis [224] better captures the low-energy effects of universal theories in which new physics couples to SM bosons only. The Warsaw basis [221] on the other hand mostly includes vertex corrections and easily connects operators to observables [226]. The basis defined in Table 11.14, and Table 11.15 is particularly well suited for an analysis of the Higgs data. The reason is that the eight operators of the left-hand side of Table 11.14, in the vacuum with $|\Phi|^2 = v^2/2$, merely redefine the SM input parameters and therefore were left unconstrained at tree-level before Higgs data are considered. These eight operators modify the physical Higgs vertices and can be probed via the decay processes $H \to \gamma\gamma, Z\gamma, \bar{b}b, \bar{\tau}\tau$ and the production channels $gg \to H, VV \to H, pp \to \bar{t}tH$ and $gg \to HH$. Section VI.2 illustrates how the Higgs data accumulated at the LHC can (partially) constrain these eight operators, following the initial phenomenological study of Ref. [226]. The other nine operators of Table 11.14 are tightly constrained by the LEP EW precision measurements (the measurements of the Z-boson couplings to quarks and leptons on the Z-pole) and by diboson production.[6]

The minimal flavor violation assumption imposes Yukawa dependences in the eight dipole operators. For the light generations of fermions, this dependence lowers the induced deviations in the Higgs rates below the experimental sensitivity reachable in any foreseeable future. The corresponding operators in the top sector are not suppressed but they are already constrained by the limit of the top dipole operators imposed by the bounds on the neutron electric dipole moment, on the $b \to s\gamma$ and $b \to s\ell^+\ell^-$ rates and on the $t\bar{t}$ cross section [229, 225].

Automatic tools [225, 204] are being developed to analyze the experimental data within an EFT framework.

VI.2. Probing coupling properties

As described in Section III a framework was developed by the ATLAS and CMS collaboration [141], individually and together, to combine the very large number of exclusive categories aimed at reconstructing the five main decay modes and the five main production modes of the Higgs boson. The general conclusions of this combination in terms of production cross sections and decay modes, illustrating the compatibility of the observation with the expectation from the SM Higgs boson is given in Section III. The same framework with its master formula Eq. (11.13) can be used to further measure coupling properties of the Higgs boson under specific additional assumptions.

VI.2.1. Combined measurements of the coupling properties of H

(i) From effective Lagrangians to Higgs observables

All 8 operators of the effective Lagrangian that were unconstrained before the Higgs data induce, at tree-level, deviations in the Higgs couplings that either respect the Lorentz structure of the SM interactions, or generate simple new interactions of the Higgs boson to the W and Z field strengths, or induce some contact interactions of the Higgs boson to photons (and to a photon and a Z boson) and gluons that take the form of the ones that are generated by integrating out the top quark. In other words, the Higgs couplings are described, in the unitary gauge, by the following effective Lagrangian [230, 44]

$$\begin{aligned}\mathcal{L} = {} & \kappa_3\frac{m_H^2}{2v}H^3 + \kappa_Z\frac{m_Z^2}{v}Z_\mu Z^\mu H + \kappa_W\frac{2m_W^2}{v}W^+_\mu W^{-\mu}H \\ & + \kappa_g\frac{\alpha_s}{12\pi v}G^a_{\mu\nu}G^{a\mu\nu}H + \kappa_\gamma\frac{\alpha}{2\pi v}A_{\mu\nu}A^{\mu\nu}H + \kappa_{Z\gamma}\frac{\alpha}{\pi v}A_{\mu\nu}Z^{\mu\nu}H \\ & + \kappa_{VV}\frac{\alpha}{2\pi v}\left(\cos^2\theta_W Z_{\mu\nu}Z^{\mu\nu} + 2\,W^+_{\mu\nu}W^{-\mu\nu}\right)H \\ & - \left(\kappa_t\sum_{f=u,c,t}\frac{m_f}{v}f\overline{f} + \kappa_b\sum_{f=d,s,b}\frac{m_f}{v}f\overline{f} + \kappa_\tau\sum_{f=e,\mu,\tau}\frac{m_f}{v}f\overline{f}\right)H. \end{aligned} \tag{11.17}$$

The correspondence between the effective coefficients of the dimension-6 operators and the κ's can be found for instance in Ref. [45]. In the SM, the Higgs boson does not couple to massless gauge bosons at tree level, hence $\kappa_g = \kappa_\gamma = \kappa_{Z\gamma} = 0$. Nonetheless, the contact operators are generated radiatively by SM particles loops. In particular, the top quark gives a contribution to the 3 coefficients $\kappa_g, \kappa_\gamma, \kappa_{Z\gamma}$ that does not decouple in the infinite top mass limit. For instance, in that limit $\kappa_\gamma = \kappa_g = 1$ [24, 25, 231].

The coefficient for the contact interactions of the Higgs boson to the W and Z field strengths is not independent but obeys the relation

$$(1 - \cos^4\theta_W)\kappa_{VV} = \sin 2\theta_W\kappa_{Z\gamma} + \sin^2\theta_W\kappa_{\gamma\gamma}. \tag{11.18}$$

This relation is a general consequence of the custodial symmetry [225], which also imposes $\kappa_Z = \kappa_W$ at leading order ($\kappa_Z/\kappa_W - 1$ is a measure

[6] There remains an accidental flat direction [227] in the fit of anomalous gauge boson couplings using LEP2 data on diboson production alone. This flat direction can be lifted when LHC Higgs data are considered [228].

of custodial symmetry breaking and as such is already constrained by electroweak precision data and the bounds on anomalous gauge couplings). When the Higgs boson is part of an $SU(2)_L$ doublet, the custodial symmetry could only be broken by the $\mathcal{O}_T = \frac{1}{2}\left(\Phi^\dagger \overleftrightarrow{D}^\mu \Phi\right)^2$ operator at the level of dimension-6 operators and it is accidentally realized among the interactions with four derivatives, like the contact interactions considered.

The coefficient κ_3 can be accessed directly only through double Higgs production processes, hence it will remain largely unconstrained at the LHC. The LHC will also have a limited sensitivity on the coefficient κ_τ since the lepton contribution to the Higgs production cross section remains subdominant and the only way to access the Higgs coupling is via the $H \to \tau^+\tau^-$ and possibly $H \to \mu^+\mu^-$ channels. Until the associated production of a Higgs with a pair of top quarks is observed, the Higgs coupling to the top quark is only probed indirectly via the one-loop gluon fusion production or the radiative decay into two photons. However, these two processes are only sensitive to the combinations of couplings $(\kappa_t + \kappa_g)$ and $(\kappa_t + \kappa_\gamma)$ and not to the individual couplings. Therefore a deviation in the Higgs coupling to the top quark can in principle always be masked by new contact interactions to photons and gluons (and this is precisely what is happening in minimal incarnations of composite Higgs models). The current limited sensitivity in the $t\bar{t}H$ channel leaves elongated ellipses in the direction $\kappa_g = \kappa_\gamma = 1 - \kappa_t$.

The operators already bounded by EW precision data and the limits on anomalous gauge couplings modify in general the Lorentz structure of the Higgs couplings and hence induce some modifications of the kinematical differential distributions [232, 233]. A promising way to have a direct access to the effective coefficients of these operators in Higgs physics is to study the VH associated production with a W or a Z at large invariant mass of the VH system [232, 234]. It has not been estimated yet whether the sensitivity on the determination of the effective coefficients in these measurements can compete with the one derived for the study of anomalous gauge couplings. In any case, these differential distributions could also be a way to directly test the hypothesis that the Higgs boson belongs to an $SU(2)_L$ doublet together with the longitudinal components of the massive electroweak gauge bosons.

(ii) Interpretations of the experimental data

The measurements of the coupling properties of the Higgs boson are entirely based on the formalism of the effective Lagrangian described in Section V.6.2.i. Measurements of coupling properties in this framework means measurements of the parameters of the model Eq. (11.17) or combinations of these parameters with different sets of assumptions.

These measurements are carried out with the combination framework described in Section IV where the μ_i and μ_f signal strength parameters are further interpreted in terms of modifiers of the SM couplings κ_k where $k \in \{Z, W, f, g, \gamma, Z\gamma\}$ as in Eq. (11.17). These coupling modifiers κ are fully motivated as leading order coupling scale factors defined such that the cross sections σ_j and the partial decay widths Γ_j associated with the SM particle j scale with the factor κ_j^2 when compared to the corresponding SM prediction. The number of signal events per category for the various production modes are typically estimated at higher orders in the analyses but are scaled by these single LO-inspired factors, thus not taking into account possible intricacies and correlations of these parameters through the higher order corrections. This approximation is valid within the level of precision of current results and their compatibility with the SM expectation.

In this formalism further assumptions are explicitly made: (i) the signals observed in the different search channels originate from a single narrow resonance with a mass of 125 GeV; (ii) similarly to the combination described in Section IV the narrow width approximation is assumed (to allow the decomposition of signal yields); (iii) the tensor structure of the couplings is assumed to be the same as that of a SM Higgs boson. This means in particular that the observed state is assumed to be a CP-even scalar as in the SM.

Loop-level couplings such as the $gg \to H$, $H \to \gamma\gamma$ and $H \to Z\gamma$ can either be treated effectively, with The κ_g, κ_γ and $\kappa_{Z\gamma}$ as free parameters in the fit or these parameters can be expressed in terms of the know SM field content and as a function of the SM coupling modifiers, in the following way:

$$\begin{aligned}
\kappa_g^2(\kappa_t, \kappa_b) &= 1.06\,\kappa_t^2 - 0.07\,\kappa_t\kappa_b + 0.01\,\kappa_b^2 \\
\kappa_\gamma^2(\kappa_F, \kappa_V) &= 1.59\,\kappa_V^2 - 0.66\,\kappa_V\kappa_F + 0.07\,\kappa_F^2 \\
\kappa_{Z\gamma}^2(\kappa_F, \kappa_V) &= 1.12\,\kappa_V^2 - 0.15\,\kappa_V\kappa_F + 0.03\,\kappa_F^2
\end{aligned} \tag{11.19}$$

The $\kappa_{Z\gamma}$ parametrization is used only in the ATLAS combined measurements of the coupling properties of the Higgs boson [199]. Neither the $Z\gamma$ nor the $\mu^+\mu^-$ channels are included in the CMS [133] and the ATLAS-CMS combinations [141], which therefore do not use the $\kappa_{Z\gamma}$ or κ_μ parameters explicitly. The parametrizations are given for a Higgs boson mass hypothesis of 125.09 GeV (and in the last two expressions, all the Higgs-fermion couplings are assumed to be rescaled by an universal multiplicative factor κ_F). It can be noted from the expression of κ_γ that the coupling of the Higgs boson to photons is dominated by the loop of W bosons, and it is affected by the top quark loop mostly through its interference with the W loop. The sensitivity of the current measurements to the relative sign of the fermion and vector boson couplings to the Higgs boson is due to this large negative interference term. The κ_g parameter is expressed in terms of the scaling of production cross sections and therefore also depends on the pp collisions centre-of-mass energy. The parametrizations of κ_γ and $\kappa_{Z\gamma}$ are obtained from the scaling of partial widths and are only dependent on the Higgs boson mass hypothesis. Experiments use a more complete parametrization with the contributions from the b-quarks, τ-leptons in the loop [230, 44].

The global fit is then performed expressing the μ_i and μ_f parameters in terms of a limited number of κ_k parameters or their ratios, under various assumptions. The parametrization for the main production modes are: $\mu_{ggF} = \kappa_g^2$ for the gluon fusion and an effective coupling of the Higgs boson to the gluons; $\mu_{VBF,VH} = \kappa_V^2$ for the VBF and VH processes when the W and Z couplings are assumed to scale equally, and the following expression for the VBF production mode is used:

$$\mu_{VBF}^2(\kappa_W, \kappa_Z) = \frac{\kappa_W^2\sigma_{WWH} + \kappa_Z^2\sigma_{ZZH}}{\sigma_{WWH} + \sigma_{ZZH}} \tag{11.20}$$

when the couplings to the W and Z bosons are varied independently (σ_{WWH} and σ_{ZZH} denote the VBF cross sections via the fusion of a W and a Z boson respectively, the small interference term is neglected); $\mu_{ttH} = \kappa_t^2$ for the $t\bar{t}$H production mode. Numerically the production modes signal strengths as a function of the coupling modifiers to the SM fields are:

$$\begin{aligned}
\mu_{ggF} &= 1.06\kappa_t^2 + 0.01\kappa_b^2 - 0.07\kappa_t\kappa_b \\
\mu_{VBFF} &= 0.74\kappa_W^2 + 0.26\kappa_Z^2
\end{aligned}$$

The decay mode signal strengths are parametrized as $\mu_k = \kappa_k^2/\kappa_H^2$ where $k \in \{Z, W, f, g, \gamma, Z\gamma\}$ denotes the decay mode and κ_H the overall modifier of the total width. Similarly to the combinations reported in Section IV, when parametrizing signal yields per categories using the combination master formula, it is again manifest that parametrizations as a function of coupling modifiers (κ) cannot be obtained is κ_H is considered effective, since it is a common factor to all signal yields. However, κ_H can also be treated as an effective parameter or expressed in terms of the coupling modifiers to the SM field content. Its general expression as a function of the Standard Model field content is:

$$\begin{aligned}
\kappa_H^2 =& 0.57\kappa_b^2 + 0.06\kappa_\tau^2 + 0.03\kappa_c^2 \\
&+ 0.22\kappa_W^2 + 0.03\kappa_Z^2 + 0.09\kappa_g^2 + 0.0023\kappa_\gamma^2
\end{aligned} \tag{11.21}$$

The general expression of the total width of the Higgs boson can be written as follows:

$$\Gamma_H = \frac{\kappa_H^2\Gamma_H^{SM}}{1 - \mathrm{BR}_{\mathrm{BSM}}}$$

where Γ_H^{SM} is the total width of the SM Higgs boson and $\mathrm{BR}_{\mathrm{BSM}}$ is the branching fraction of the Higgs boson to new particles beyond the SM.

Specific parametrizations will be made in order to address the following aspects of the coupling properties of the Higgs boson under different assumptions: (i) the relative couplings of the Higgs boson to fermions and bosons; (ii) the potential impact of the presence of new particles beyond the SM either in the loops or both in the loops and the decay of the H; and (iii) also, more general models either of coupling modifiers or their ratios, under different assumptions.

(iii) Relative couplings to bosons and fermions

As will be discussed in Section VII.6.3, it is interesting to probe a model where no additional field content is considered in the decay width of the Higgs boson and where the relative couplings of the Higgs boson to W- and Z-bosons is fixed to its SM value and where all Yukawa couplings scale with one coupling modifier. In this model only SM particles are assumed to contribute to the gluon fusion and the diphoton loops, all fermion couplings modifiers are required to scale simultaneously with a unique factor κ_F and all vector boson couplings modifiers must scale simultaneously with a unique factor κ_V. This parametrization assumes that no new particles affect the direct decays or the loops. It is a two parameters fit with κ_V and κ_F as parameters of interest. The ATLAS-CMS combined results for each channel independently, the combinations of all channels for the two experiments separately and the results and the overall combination are shown in Fig. 11.17.

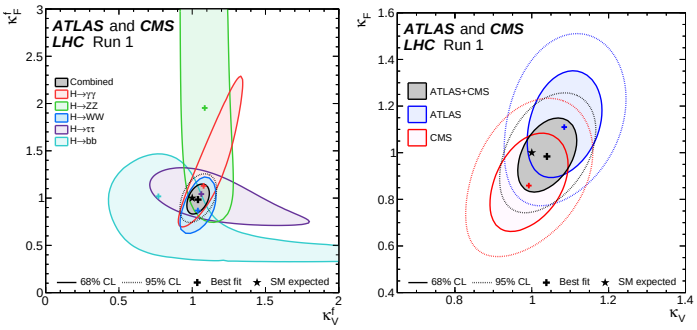

Figure 11.17: Likelihood contours in the (κ_F, κ_V) plane for the ATLAS-CMS combination for the main decay channels separately (left) and for the individual combination of all channels for ATLAS and CMS separately and the complete combined contour (right) [141].

The global fit is only sensitive to the relative sign of κ_V and κ_F. By convention negative values of κ_F can be considered. Such values are not excluded a priori, but would imply the existence of new physics at a light scale and would also raise questions about the stability of such a vacuum [235]. Among the five low mass Higgs channels, only the $\gamma\gamma$ is sensitive to the sign of κ_F through the interference of the W and t loops as shown in Eq. (11.19). The current global fit disfavors a negative value of κ_F at more than five standard deviations. A specific analysis for the Higgs boson production in association with a single top quark has been proposed [236, 237] in order to more directly probe the sign of κ_F. All available experimental data show a fair agreement of the SM prediction of the couplings of the Higgs boson to fermions and gauge bosons. The results shown in Fig. 11.17 assume that $\kappa_F \geq 0$, however in Ref. [141], a similar combination is done without this assumption. The combined sensitivity to the exclusion of a negative relative sign, is approximately 5σ in this model. It is interesting to note that although none of the channels have a significant sensitivity to resolve the sign ambiguity, the combination can, mainly through the $W-t$ interference in the $H \to \gamma\gamma$ channel and the $H \to W^+W^-$ channel. The observed exclusion is fully compatible with the expectation [141]. The combined measurements of these parameters:

$$\kappa_V = 1.04 \pm 0.05$$
$$\kappa_F = 0.98^{+0.11}_{-0.10}$$

Is already at the 5% level for the κ_V parameter with the Run 1 dataset.

(iv) Coupling measurements and probing new physics beyond the SM in loops and in the decay

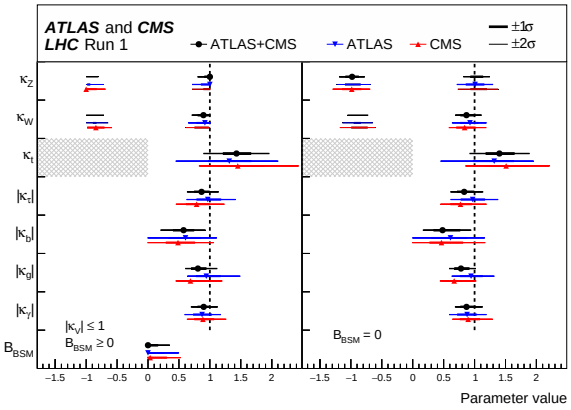

Figure 11.18: ATLAS-CMS combined measurements of coupling modifiers.

In the model described above in Section VI.2.1.iii the assumption is that no new fields distort in a perceptible way the loop contributions in the couplings of the H to gluons and photons and the total width, its couplings to known SM particles are then probed. In a first approach to simultaneously probe new physics beyond the SM in the loops and not in the decay and the couplings of the Higgs boson to SM particles, only one assumption is needed *i.e.* that $\mathrm{BR}_{\mathrm{BSM}} = 0$. In this model the coupling of the H to photons and gluons is effective and κ_Z, κ_W, κ_t, $|\kappa_\tau|$, and $|\kappa_b|$ are measured simultaneously. The absolute value of certain coupling modifiers only indicates the complete degeneracy of combined likelihood for the two signs. It can be noted that when the coupling to gluons is not considered effective, there is some sensitivity to the sign of κ_b through the interference between the top and bottom quarks loops in the gluon fusion process. In this model it is interesting to note that the constraints on the top quark Yukawa coupling comes from the ttH direct search channels. The expected precision on κ_t is approximately 40%. As discussed in Section III the excesses observed in the ttH channel yield a large value of $\kappa_t = 1.40^{+0.24}_{-0.21}$. The complete set of results from this model is given in Fig. 11.18.

This model, which assumes that no new particles enter the decay of the Higgs boson, also yields very interesting constraints on new physics in the loops through the effective coupling modifiers κ_g and κ_γ. The measured values of these parameters:

$$\kappa_g = 0.78^{+0.13}_{-0.10}$$
$$\kappa_\gamma = 0.87^{+0.14}_{-0.09}$$

are fully compatible with the expectation for the SM Higgs boson.

A more constrained model fully focussing on BSM scenarios with new heavy particles contributing to the loops (and not directly in the decays *i.e.* $\mathrm{BR}_{\mathrm{BSM}} = 0$) and where all couplings to the SM particles are assumed to be the same as in the Standard Model ($\kappa_W = \kappa_Z = \kappa_t = \kappa_b = \kappa_\tau = 1$) is also used to constrain the κ_g and κ_γ parameters only. The contours of the combined likelihood in the $(\kappa_\gamma, \kappa_g)$ plane for the ATLAS and CMS experiments and their combination are shown in Fig. 11.19.

This general model requires the strong assumption that the the Higgs boson decays only to SM particles. This assumption is necessary due to the degeneracy of solutions given that κ_H is a common factor to all measured signals. The degeneracy can however be resolved

using a constraint on the width of the Higgs boson as the one from the Off-Shell couplings measurements. This approach was used by the ATLAS experiment [199], thus yielding a absolute measurement of the couplings of the Higgs boson.

Another well motivated constraint to resolve the aforementioned degeneracy is unitarity. Simply requiring that $\kappa_V \leq 1$ allows to free the $\mathrm{BR_{BSM}}$ parameter and further probe new physics in the decay of the Higgs boson. An intuitive understanding of how this constraint works can be given by a simple example *e.g.* VBF $H \to W^+W^-$ production where the number of signal events will be parametrized by $(1 - \mathrm{BR_{BSM}})\kappa_W^4/\kappa_H^2$, where for a number of signal events observed close to the SM expectation, large values of $\mathrm{BR_{BSM}}$ cannot be compensated by a large value of κ_W and is thus limited. Or in other terms, if $\kappa_W \sim 1$ is preferred from other channels, a low signal in the VBF $H \to W^+W^-$ channel would be a sign of the presence of new physics beyond the SM in the Higgs decays. From this general model all the above parameters can be measured in addition to $\mathrm{BR_{BSM}}$. The results of this combination are shown in Fig. 11.18. The results for all parameters do not change significantly with respect to the previous model. A limit can however be set on the beyond the SM branching fraction of the Higgs boson at the 95% CL:

$$\mathrm{BR_{BSM}} < 34\%$$

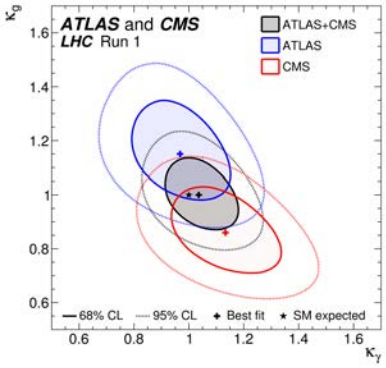

Figure 11.19: Likelihood contours of the global in the $(\kappa_g, \kappa_\gamma)$ plane for the ATLAS-CMS combination for the individual combination of all channels for ATLAS and CMS separately and the complete combined contour [141].

In the second approach, new physics is considered also in the decay thus affecting the total width of the H through decays to particles which are either "invisible" and escape detection in the experiments, or "undetected" which are not distinctive enough to be seen in the current analyses. This approach is complementary to the direct search for invisible decays of the Higgs boson described in Section III. The two approaches can be combined assuming that the undetected branching fraction is negligible. this combination was performed by the ATLAS experiment [238] and yields a limit on the invisible decays of the Higgs boson of $\mathrm{BR}_{inv} < 25\%$ at the 95% CL.

This constraint can then be further used to probe Higgs portal models to Dark Matter [239], where an additional weakly interacting particle χ with mass typically lower than $m_H/2$ is introduced as Dark Matter candidate and where the Higgs boson is considered as the only mediator between the SM particles and Dark Matter. In this model it is interesting to express the limit on the invisible branching fraction in terms of strength of interaction of Dark Matter with standard matter, *i.e.* in terms of it interaction cross section with nucleons $\sigma_{\chi-N}$. In this model the couplings of the Higgs boson to SM particles are assumed to be those of the SM and the interaction of the Higgs boson with the nucleon is parametrized in Higgs-Nucleon form factor estimated using lattice QCD calculations [239]. The exclusion limits from the constraints on invisible Higgs decays, both direct and indirect from the measurement of the coupling properties of the Higgs boson can be compared to direct detection experiments. For comparison the limit at 90% CL on the invisible branching fraction of $\mathrm{BR}_{inv} < 22\%$ [238] is used and converted into limits on $\sigma_{\chi-N}$ under several hypotheses on the nature of Dark Matter particles depending mainly on their spin (scalar-, vector- or fermion-like). These results are shown in Fig. 11.20.

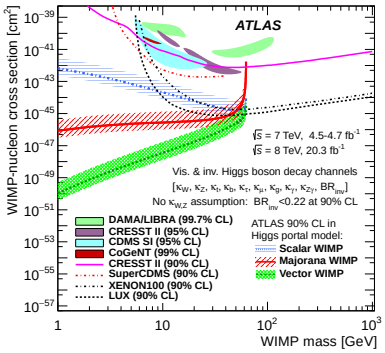

Figure 11.20: 90% CL upper limits on the WIMP-nucleon scattering cross section as a function of the Dark Matter particle mass. Spin-independent results excluded and favored regions from direct detection experiments are also shown.

(v) Generic measurement of the H couplings to fermions and gauge bosons

Measuring the couplings of the Higgs boson with requires additional input on constraints on its natural width, or further assumptions. A more generic approach to avoid the degeneracy in the measurement of the coupling modifiers is to probe the coupling properties of the Higgs boson through ratio of couplings. This model, is inspired by the generic model of ratios of cross sections and branching ratios discussed in Section III, where the cross section times branching fraction of the $gg \to H \to ZZ$ process is parametrized as a function of a single coupling modifier:

$$\kappa_{gZ} = \kappa_g \times \frac{\kappa_Z}{\kappa_H}$$

Then all combination signals can be parametrized with the following ratios of coupling modifiers: (i) the $\lambda_{Zg} = \kappa_Z/\kappa_g$ ratio which is mainly probed by the measurements of the VBF and ZH production; (ii) the $\lambda_{tg} = \kappa_t/\kappa_g$ ratio constrained by the ttH production process; (iii) the $\lambda_{WZ} = \kappa_W/\kappa_Z$ ratio mainly probed by the WW and ZZ decay modes; (iv) the $\lambda_{\tau Z} = \kappa_\tau/\kappa_Z$ ratio constrained by the $\tau^+\tau^-$ channel; (v) the $\lambda_{bZ} = \kappa_b/\kappa_Z$ ratio probed mainly by the $VH(b\bar{b})$ channels; and (vi) the $\lambda_{\gamma Z} = \kappa_\gamma/\kappa_Z$ ratio constrained by the diphoton channel. In this parametrization the ZZ channels plays an important normalization role. This model is very general, as it makes neither assumptions on the total width of the Higgs boson or the content of the loops. The results of the combination for this general model are illustrated in Fig. 11.21.

This general model summarizes the status of a flurry of measurements of the Higgs boson that have been carried out at Run 1, in five main production and five main decay modes. Reaching unprecedented level of complexity in a combination with approximately 600 categories and several thousands of parameters for systematic uncertainties. It summarizes the legacy of the measurements of Run 1 and their main conclusions on the coupling properties of the Higgs boson, which can be summarized as follows: (i) the κ_{gZ} parameters shows that the Higgs boson has been firmly observed in a direct ZZ decay mode; (ii) the λ_{WZ} parameter illustrates the firm observation of the Higgs boson direct decays to the W-boson and measures directly the ratio of the coupling to the W- and Z-bosons a direct probe of the custodial symmetry, already very accurately measured with electroweak precision data; (iii) the $\lambda\gamma Z$ parameters shows that the coupling of the Higgs boson to photons is compatible with the SM

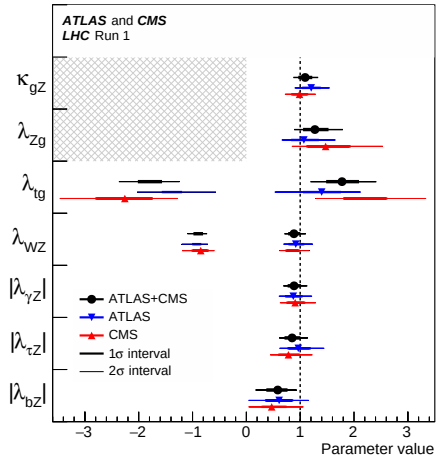

Figure 11.21: ATLAS-CMS combined measurements of ratios of coupling modifiers.

expectation, thus providing a probe of new physics in the decay loop of the Higgs boson to two photons; (iv) the $\lambda_{\tau Z}$ parameters indicates the evidence in the direct decay of the Higgs boson to a pair of taus of the Yukawa coupling of the Higgs boson to fermions (and in particular to taus); (v) the λ_{bZ} parameter indicates that more data is needed to further establish the Yukawa coupling of the Higgs boson to b-quarks; and (vi) the λ_{tZ} similarly indicates that the more data is needed to further directly constrain the Yukawa coupling of the Higgs boson to top quarks. Each measurement is consistent with the prediction within less than 2σ, except for λ_{bZ} and λ_{tZ} which show similar disagreements to those discussed in Section IV. However the probability of the overall compatibility of these measurements with the SM expectation is estimated to be 13%.

VI.2.2. Differential cross sections

To further characterize the production and decay properties of H, first measurements of fiducial and differential cross sections have been carried out by the ATLAS collaboration [240], with the 8 TeV dataset of pp collision at LHC, corresponding to an integrated luminosity of $20.3\,\text{fb}^{-1}$, in the diphoton channel. The selection criteria to define the fiducial volume are the following: the two highest transverse momentum (E_T), isolated final state photons, within $|\eta| < 2.37$ and with $105\,\text{GeV} < M_{\gamma\gamma} < 160\,\text{GeV}$ are selected (the transition region between the barrel and endcap calorimeters is not removed); after the pair is selected, the same cut on $E_T/M_{\gamma\gamma}$ as in the event selection *i.e.* in excess of 0.35 (0.25) for the two photons is applied. Several observables have been studied: the transverse momentum rapidity of the diphoton system, the production angle in the Collins–Soper frame, the jet multiplicity, the jet veto fractions for a given jet multiplicity, and the transverse momentum distribution of the leading jet. The following additional observables: the difference in azimuthal angle between the leading and the subleading jets, and the transverse component of the vector sum of the momenta of the Higgs boson and dijet system, have also been measured in two jet events. To minimize the model dependence the differential cross sections are given within a specific fiducial region of the two photons. The observables were chosen to probe the production properties and the spin and parity of the H. The differential cross section in H transverse momentum is given in Fig. 11.22.

VI.2.3. Constraints on non-SM Higgs boson interactions in an effective Lagrangian

An example of the possible use of differential cross sections in constraining non-SM Higgs boson couplings in an EFT is given by the ATLAS collaboration [241]. In this analysis, differential cross section measured in the diphoton channel are used to constrain an effective Lagrangian where the SM is supplemented by dimension six CP-even operators of the Strongly Interacting Light Higgs (SILH) formulation and corresponding CP-odd operators. The diphoton differential cross

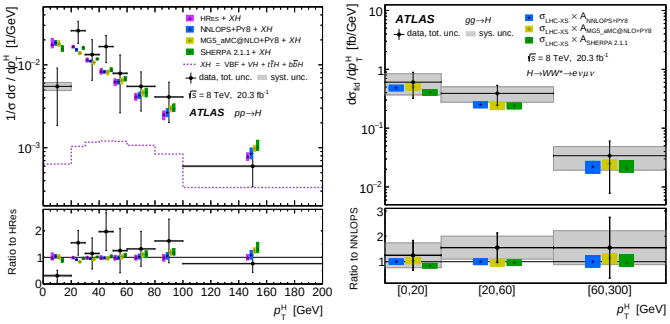

Figure 11.22: Observed differential cross sections in transverse momentum of the H in the diphoton channel, compared to the prediction of the ggF process [240].

sections are mainly sensitive to the operators that affect the Higgs boson interactions with gauge bosons and the relevant terms in the effective Lagrangian can be parameterized as:

$$\begin{aligned}\mathcal{L}_{eff} =& \bar{c}_\gamma \mathcal{O}_\gamma + \bar{c}_g \mathcal{O}_g + \bar{c}_{HW} \mathcal{O}_{HW} + \bar{c}_{HB} \mathcal{O}_{HB} + \\ & \tilde{c}_\gamma \tilde{\mathcal{O}}_\gamma + \tilde{c}_g \tilde{\mathcal{O}}_g + \tilde{c}_{HW} \tilde{\mathcal{O}}_{HW} + \tilde{c}_{HB} \tilde{\mathcal{O}}_{HB}\end{aligned} \tag{11.22}$$

Where $\bar{c}_i$ and $\tilde{c}_i$ are the effective coefficients corresponding to the CP-even and CP-odd interactions, respectively.

The differential distributions used in this combination are: (i) the transverse momentum of the Higgs boson, (ii) the number of reconstructed jets produced in association with the diphoton pair, (iii) the invariant mass of the diphoton system and (iv) the difference in azimuthal angle of the leading and sub-leading jets in events with two or more jets.

This analysis shows how differential information significantly improves the sensitivity to operators that modify the Higgs boson interaction to photons, gluons and vector bosons both from the main gluon fusion and the vector boson fusion production modes.

VII. New physics models of EWSB in the light of the Higgs boson discovery

A main theoretical motivation to add a Higgs boson to the SM is that, without it, the longitudinal components of the massive EW gauge bosons would form a strongly coupled system as their scattering amplitude would have grown with their energy, destroying all the predictive power of the model above $4\pi v \sim 3\,\text{TeV}$. The discovery of a light scalar with couplings to gauge bosons and fermions that are apparently consistent with SM predictions and the slow running of the Higgs self-coupling at high energies allows one to consider the SM as a valid perturbative description of nature all the way to the Planck scale. This picture is admittedly very attractive, but it posits that the Higgs boson is an elementary scalar field, which comes with an intrinsic instability of its mass under radiative corrections. This Higgs naturalness problem calls for new physics around the TeV scale. Supersymmetric models are the most elegant solution to maintain the perturbativity of the SM while alleviating the instability issue. Another possibility is that the Higgs boson itself has a finite size and is composite and thus never feels the UV degrees of freedom that would drag its mass to much higher scales. Both classes of models predict specific modifications from the SM Higgs properties.

The realization of supersymmetry at low energies has many good qualities that render it attractive as a model of new physics. First of all since for every fermion there is a boson of equal mass and effective coupling to the SM-like Higgs, in the case of exact supersymmetry it yields an automatic cancellation of loop corrections to the Higgs mass parameter: (analogous to Eq. (11.2)) $\delta m^2 = 0$ [9, 11]. In practice, it is known that SUSY must be broken in nature since no superpartners of the SM particles have been observed so far. The mass difference between the boson and fermion degrees of freedom is governed by the soft supersymmetry breaking parameters, generically called M_{SUSY}. Therefore, independently of the precise value of any of the particle

masses and that of its corresponding superpartner, all corrections are proportional to M^2_{SUSY} times the logarithmic dependence of the ratio of energy scales as in Eq. (11.2). Hence, provided that $M_{SUSY} \simeq \mathcal{O}(<\text{few})$ TeV, the fine-tuning problem is solved, in the sense that the low energy mass parameters of the Higgs sector become insensitive to physics at the GUT or Planck scale. Another interesting feature of SUSY theories is related to the dynamical generation of EWSB [242]. In the SM a negative Higgs mass parameter, m^2, needs to be inserted by hand to induce EWSB. In SUSY, instead, even if the relevant Higgs mass parameter is positive in the ultraviolet, it may become negative and induce electroweak symmetry breaking radiatively through the strong effect of the top quark-Higgs boson coupling in its renormalization group evolution.

In the following, the Higgs sector will be explored in specific SUSY models. In all of them there is one neutral Higgs boson with properties that resemble those of the SM Higgs boson, whereas additional neutral and charged Higgs bosons are also predicted and are intensively being sought for at the LHC (see Section VII.8). In the simplest SUSY model the lightest Higgs boson mass, that usually plays the role of the SM-like Higgs, is predicted to be less than 135 GeV for stops in the TeV to few TeV range [243] whereas, larger values of the SM-like Higgs boson mass – up to about 250 GeV – can be obtained in non-minimal SUSY extensions of the SM [243]. In general, accommodating a SM-like Higgs boson with mass of 125 GeV results in constraints on the supersymmetric parameter space of specific SUSY models. While naturalness dictates relatively light stops and gluinos, the first and second generation of squarks and sleptons couple weakly to the Higgs sector and may be heavy. Moreover, small values of the μ parameter and therefore light Higgsinos would be a signature of a natural realization of electroweak symmetry breaking. Such SUSY spectra, consisting of light stops and light Higgsinos, have been under intense scrutiny by the experimental collaborations [244] in order to derive model-independent bounds on the stop masses and to understand if such natural SUSY scenarios endure [243] and can explain why the Higgs boson remains light.

In the context of weakly coupled models of EWSB one can also consider multiple Higgs $\text{SU}(2)_L$ doublets as well as additional Higgs singlets, triplets or even more complicated multiplet structures, with or without low energy supersymmetry. In general for such models one needs to take into account experimental constraints from precision measurements and flavor changing neutral currents. The LHC signatures of such extended Higgs sectors are largely shaped by the role of the exotic scalar fields in EWSB.

The idea that the Higgs boson itself could be a composite bound state emerging from a new strongly-coupled sector has regained some interest. The composite Higgs idea is an interesting incarnation of EWSB via strong dynamics that smoothly interpolates between the standard Technicolor approach and the true SM limit. To avoid the usual conflict with EW data, it is sufficient if not necessary that a mass gap separates the Higgs resonance from the other resonances of the strong sector. Such a mass gap can naturally follow from dynamics if the strongly-interacting sector exhibits a global symmetry, G, broken dynamically to a subgroup H at the scale f, such that, in addition to the three Nambu–Goldstone bosons of SO(4)/SO(3) that describe the longitudinal components of the massive W and Z, the coset G/H contains a fourth Nambu–Goldstone boson that can be identified with the physical Higgs boson. Simple examples of such a coset are SU(3)/SU(2) or SO(5)/SO(4), the latter being favored since it is invariant under the custodial symmetry (it is also possible to have non-minimal custodial cosets with extra Goldstone bosons, see for instance Ref. [245]). Attempts to construct composite Higgs models in 4D have been made by Georgi and Kaplan (see for instance Ref. [246]) and modern incarnations have been recently investigated in the framework of 5D warped models where, according to the principles of the AdS/CFT correspondence, the holographic composite Higgs boson then originates from a component of a gauge field along the 5th dimension with appropriate boundary conditions.

A last crucial ingredient in the construction of viable composite Higgs models is the concept of partial compositeness [247], i.e., the idea that there are only linear mass mixings between elementary fields and composite states[7]. After diagonalization of the mass matrices, the SM particles, fermions and gauge bosons, are admixtures of elementary and composite states and thus they interact with the strong sector, and in particular with the Higgs boson, through their composite component. This setup has important consequences on the flavor properties, chiefly the suppression of large flavor changing neutral currents involving light fermions. It also plays an important role in dynamically generating a potential for the would-be Goldstone bosons. Partial compositeness also links the properties of the Higgs boson to the spectrum of the fermionic resonances, i.e. the partners of the top quark. As in the MSSM, these top partners are really the agents that trigger the EWSB and also generate the mass of the Higgs boson that otherwise would remain an exact Goldstone boson and hence massless. The bounds from the direct searches for the top partners in addition to the usual constraints from EW precision data force the minimal composite Higgs models into some rather unnatural corners of their parameter spaces [15, 249].

VII.1. Higgs bosons in the minimal supersymmetric standard model (MSSM)

The particle masses and interactions in a supersymmetric theory are uniquely defined as a function of the superpotential and the Kähler potential [250]. A fundamental theory of supersymmetry breaking, however, is unknown at this time. Nevertheless, one can parameterize the low-energy theory in terms of the most general set of soft supersymmetry-breaking operators [243]. The simplest realistic model of low-energy supersymmetry is the minimal supersymmetric extension of the SM (MSSM) [11, 250], that associates a supersymmetric partner to each gauge boson and chiral fermion of the SM, and provides a realistic model of physics at the weak scale. However, even in this minimal model with the most general set of soft supersymmetry-breaking terms more than 100 new parameters are introduced [243]. Fortunately, only a subset of these parameters impact the Higgs phenomenology either directly at tree-level or through quantum effects. Reviews of the properties and phenomenology of the Higgs bosons of the MSSM can be found for example in Refs. [40, 250, 251].

The MSSM contains the particle spectrum of a two-Higgs-doublet model (2HDM) extension of the SM and the corresponding supersymmetric partners. Two Higgs doublets,

$$\Phi_1 = \frac{1}{\sqrt{2}} \begin{pmatrix} \phi_1^0 + i a_1^0 \\ \sqrt{2}\phi_1^- \end{pmatrix}, \qquad \Phi_2 = \frac{1}{\sqrt{2}} \begin{pmatrix} \sqrt{2}\phi_2^+ \\ \phi_2^0 + i a_2^0 \end{pmatrix}, \tag{11.23}$$

with hypercharge $Y = -1$ and $Y = 1$, respectively, are required to ensure an anomaly-free SUSY extension of the SM and to generate mass for both up-type and down-type quarks and charged leptons [12]. In our notation $\Phi_{1(2)}$ gives mass to the down(up) type fermions. The Higgs potential reads

$$\begin{aligned} V = {} & m_1^2 \Phi_1^\dagger \Phi_1 + m_2^2 \Phi_2^\dagger \Phi_2 - m_3^2 (\Phi_1^T i\sigma_2 \Phi_2 + \text{h.c.}) + \frac{1}{2}\lambda_1 (\Phi_1^\dagger \Phi_1)^2 \\ & + \frac{1}{2}\lambda_2 (\Phi_2^\dagger \Phi_2)^2 + \lambda_3 (\Phi_1^\dagger \Phi_1)(\Phi_2^\dagger \Phi_2) + \lambda_4 |\Phi_1^T i\sigma_2 \Phi_2|^2 \\ & + \frac{1}{2}\lambda_5 [(\Phi_1^T i\sigma_2 \Phi_2)^2 + \text{h.c.}] \\ & + [[\lambda_6 (\Phi_1^\dagger \Phi_1) + \lambda_7 (\Phi_2^\dagger \Phi_2)] \Phi_1^T i\sigma_2 \Phi_2 + \text{h.c.}] \end{aligned} \tag{11.24}$$

where $m_i^2 = \mu^2 + m_{H_i}^2$, with μ being the supersymmetric Higgsino mass parameter and m_{H_i} (for $i = 1, 2$) the soft supersymmetric breaking mass parameters of the two Higgs doublets; $m_3^2 \equiv B\mu$ is associated to the B-term soft SUSY breaking parameter; and λ_i, for $i = 1$ to 7, are all the Higgs quartic couplings. After the spontaneous breaking of the electroweak symmetry, five physical Higgs particles are left in the spectrum: one charged Higgs pair, $H^\pm$, one CP-odd neutral

[7] For a pedagogical introduction to models of partial compositeness, see Ref. [248].

scalar, A, and two CP-even neutral states, H and h.

$$\begin{aligned} H^{\pm} &= \sin\beta\phi_1^{\pm} + \cos\beta\phi_2^{\pm}\,, \\ A &= \sin\beta\ \mathrm{Im}\phi_1^0 + \cos\beta\ \mathrm{Im}\phi_2^0\,, \\ H &= \cos\alpha(\mathrm{Re}\phi_1^0 - v_1) + \sin\alpha(\mathrm{Re}\phi_2^0 - v_2), \\ h &= -\sin\alpha(\mathrm{Re}\phi_1^0 - v_1) + \cos\alpha(\mathrm{Re}\phi_2^0 - v_2), \end{aligned} \tag{11.25}$$

where $v_i = \langle\phi_i^0\rangle$ for i=1,2 and $v^2 = v_1^2 + v_2^2 \approx (246\,\mathrm{GeV})^2$. The angle α diagonalizes the CP-even Higgs squared-mass matrix and is given in terms of the quartic couplings, while β diagonalizes both the CP-odd and charged Higgs sectors with $\tan\beta = v_2/v_1$. The h and H denote the lightest and heaviest CP-even Higgs bosons, respectively.[8]

The supersymmetric structure of the theory imposes constraints on the Higgs sector of the model. In particular, at tree level, the parameters of the Higgs self-interaction, $\lambda_{1,\ldots,4}$, are defined in terms of the electroweak gauge coupling constants, and $\lambda_{5,6,7} = 0$. As a result, the Higgs sector at tree level depends on the electroweak gauge coupling constants and the vacuum expectation value v – or equivalently the Z gauge boson mass – and is determined by only two free parameters: $\tan\beta$ and one Higgs boson mass, conventionally chosen to be the CP-odd Higgs boson mass, m_A. The other tree-level Higgs boson masses are then given in terms of these parameters. In the large $m_A \gg M_Z$ limit, also called the decoupling limit [252 [253, $\sin\alpha \to -\cos\beta$, $\cos\alpha \to \sin\beta$, hence, $\cos(\beta-\alpha) \to 0$ and this implies that the lightest CP-even Higgs h behaves as the SM Higgs. When $m_A \geq M_Z$, the condition $\cos(\beta-\alpha) \to 0$ is also called the alignment limit [253–254]. As will be discussed below, in the MSSM the alignment limit can only occur once quantum corrections to the quartic couplings have been included. The tree level value of m_h is maximized not only for $m_A \gg M_Z$ but also for $\tan\beta \gg 1$. For $m_A \gg M_Z$ it acquires a maximum value $m_h = M_Z \cos 2\beta$.

Radiative corrections have a significant impact on the values of Higgs boson masses and couplings in the MSSM. The dominant radiative effects to the SM-like Higgs mass arise from the incomplete cancellation between top and scalar-top (stop) loops and at large $\tan\beta$ also from sbottom and stau loops. The loop contributions to the tree level quartic couplings depend on the SUSY spectrum, and render $\lambda_{5,6,7}$ non zero. The stop, sbottom and stau masses and mixing angles depend on the supersymmetric Higgsino mass parameter μ and on the soft-supersymmetry-breaking parameters [11, 250]: M_Q, M_U, M_D, M_L, M_E, and A_t, A_b A_τ. The first three of these are the left-chiral and the right-chiral top and bottom scalar quark mass parameters. The next two are the left-chiral stau/sneutrino and the right-chiral stau mass parameters, and the last three are the trilinear parameters that enter in the off-diagonal squark/slepton mixing elements: $X_t \equiv A_t - \mu\cot\beta$ and $X_{b,\tau} \equiv A_{b,\tau} - \mu\tan\beta$. At the two-loop level, the masses of the gluino and the electroweak gaugino also enter in the calculations.

Radiative corrections to the Higgs boson masses have been computed using a number of techniques, with a variety of approximations; see references in Ref. [243]. For large $\tan\beta$, the stau/sbottom mixing parameters and masses are also relevant. In the large m_A (decoupling) limit and for $\tan\beta \gg 1$, the m_h value can be maximized at loop level for a specific value of X_t/M_{SUSY} For fixed X_t, the value of m_h can change by several GeV by varying M_{SUSY} within a few TeV or by varying m_t within its experimental uncertainty, as well as by varying SUSY particle parameters that enter only beyond the one-loop order. Moreover, in the large $\tan\beta$ regime light staus and/or sbottoms with sizable mixing, governed by the μ parameter, yield negative radiative corrections to the mass of the lightest Higgs boson, and can lower it by several GeV [255]. Allowing for experimental and theoretical uncertainties, one finds that for $M_{\mathrm{SUSY}} \lesssim 2\,\mathrm{TeV}$, large m_A, $\tan\beta \gg 1$ and for $X_t \simeq \sqrt{6}M_{\mathrm{SUSY}}$, the maximal value for the lightest Higgs mass is $m_h^{\max} = 135\,\mathrm{GeV}$ [256–257].

[8] Observe that in the SM sections of this review, H denotes the SM Higgs, whereas in the sections about SUSY, or extensions of the SM with two Higgs doublets, H is used for the heaviest CP-even Higgs boson, since this is the standard notation in the literature, and the 125 GeV SM-like light Higgs boson will be denoted by h.

The newly discovered SM-like Higgs boson, if interpreted as the lightest MSSM Higgs with a mass of about 125 GeV, provides information on the possible MSSM parameter space. In particular a sizable mixing in the stop sector is required ($|X_t/M_{\mathrm{SUSY}}| \geq 1.5$) for values of $M_{\mathrm{SUSY}} \simeq M_Q \simeq M_U \simeq M_D \simeq 1$ to a few TeV [255–269]. See for example Fig. 11.23. On the other hand, considering the third generation soft SUSY breaking parameters as independent inputs, $M_Q \neq M_U \neq M_D$, it follows that $m_h \simeq$125 GeV can be obtained for one stop that is as light as can be experimentally allowed [244] and the other one with a mass of the order of the stop mixing parameter. Considering both stops significantly above a few TeV, by varying/lowering the values of X_t and $\tan\beta$, the impact of higher loops in the computation of the Higgs mass becomes relevant [270–272]. For a given CP-odd Higgs mass m_A, the masses of the other two Higgs bosons, H and $H^{\pm}$, also receive radiative corrections. For a more detailed discussion of the effect of radiative corrections on the heavy Higgs masses see for example Refs. [40] and [251].

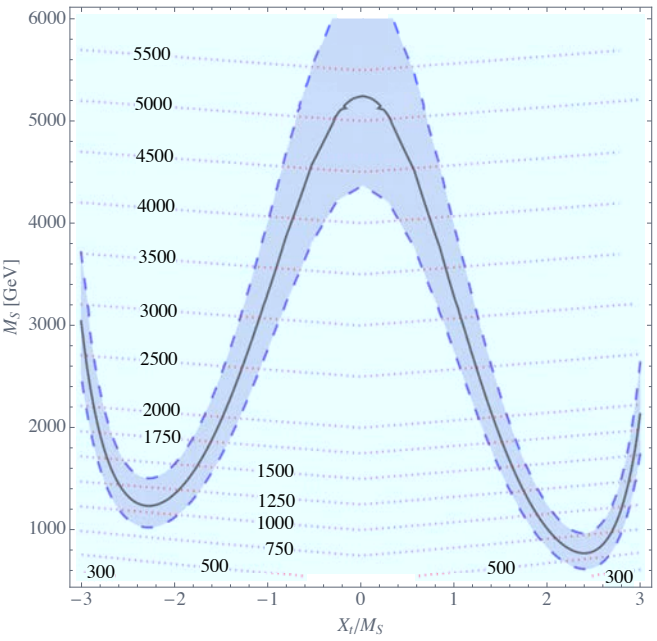

Figure 11.23: Values of the SUSY mass scale $M_{\mathrm{SUSY}} = M_S$ versus the stop mixing parameter normalized by the SUSY mass scale X_t/M_{SUSY}, for fixed $\tan\beta = 20$, $\mu = 200\,\mathrm{GeV}$ and $M_A = A_t = A_b = A_\tau = M_{\mathrm{SUSY}}$. The solid black line corresponds to $M_h = 125\,\mathrm{GeV}$ while in the grey band M_h varies by $\pm 1\,\mathrm{GeV}$. The red dotted lines are iso-values of the stop mass. This figure is based on Ref. [268].

The phenomenology of the Higgs sector depends on the couplings of the Higgs bosons to gauge bosons and fermions. The couplings of the two CP-even Higgs bosons to W and Z bosons are given in terms of the angles α and β

$$g_{hVV} = g_V m_V \sin(\beta-\alpha), \quad g_{HVV} = g_V m_V \cos(\beta-\alpha), \tag{11.26}$$

where $g_V \equiv 2m_V/v$, for $V = \mathrm{W}^{\pm}$ or Z ($g_V m_V$ is the SM hVV coupling). There are no tree-level couplings of A or $H^{\pm}$ to VV. The couplings of the Z boson to two neutral Higgs bosons, which must have opposite CP-quantum numbers, are given by $g_{\phi AZ}(p_\phi - p_A)$, where $\phi = H$ or h, the momenta p_ϕ and p_A point into the vertex, and

$$g_{hAZ} = g_Z \cos(\beta-\alpha)/2, \quad g_{HAZ} = -g_Z \sin(\beta-\alpha)/2\,. \tag{11.27}$$

Charged Higgs-W boson couplings to neutral Higgs bosons and four-point couplings of vector bosons and Higgs bosons can be found in Ref. [12].

The tree-level Higgs couplings to fermions obey the following property: the neutral components of one Higgs doublet, Φ_1, couple exclusively to down-type fermion pairs while the neutral components of the other doublet, Φ_2, couple exclusively to up-type fermion pairs [12]. This Higgs-fermion coupling structure defines the Type-II 2HDM [273]. In the MSSM, fermion masses are generated when both neutral Higgs components acquire vacuum expectation values, and the relations between Yukawa couplings and fermion masses are (in third-generation notation)

$$h_{b,\tau} = \sqrt{2}\, m_{b,\tau}/(v\cos\beta), \quad h_t = \sqrt{2}\, m_t/(v\sin\beta)\,. \tag{11.28}$$

The couplings of the neutral Higgs bosons to $f\bar{f}$ relative to the SM value, $gm_f/2M_W$, are given by

$$\begin{array}{ll} h b\bar{b}: -\sin\alpha/\cos\beta & h t\bar{t}: \cos\alpha/\sin\beta\,, \\ H b\bar{b}: \cos\alpha/\cos\beta & H t\bar{t}: \sin\alpha/\sin\beta\,, \\ A b\bar{b}: \gamma_5 \tan\beta & A t\bar{t}: \gamma_5 \cot\beta\,. \end{array} \tag{11.29}$$

In each relation above, the factor listed for $b\bar{b}$ also pertains to $\tau^+\tau^-$. The charged Higgs boson couplings to fermion pairs are given by

$$\begin{aligned} g_{H^- t\bar{b}} &= \frac{g}{\sqrt{2}M_W}\left[m_t \cot\beta \frac{1+\gamma_5}{2} + m_b \tan\beta \frac{1-\gamma_5}{2}\right], \\ g_{H^-\tau^+\nu} &= \frac{g}{\sqrt{2}M_W}\left[m_\tau \tan\beta \frac{1-\gamma_5}{2}\right]. \end{aligned} \tag{11.30}$$

The non-standard neutral Higgs bosons have significantly enhanced couplings to down-type fermions at sizeable $\tan\beta$. In the alignment limit, the lightest Higgs boson behaves like the SM one and H, A have $\tan\beta$ enhanced couplings to down type fermions, and analogous enhanced couplings are in place for the charged Higgs.

Radiative corrections can modify significantly the values of the Higgs boson couplings to fermion pairs and to vector boson pairs. In a first approximation, when radiative corrections to the quartic couplings are computed, the diagonalizing angle α is shifted from its tree-level value, and hence one may compute a "radiatively-corrected" value for $\cos(\beta-\alpha)$ [255, 274]. Additional contributions from the one-loop vertex corrections to tree-level Higgs couplings [276–283] alter significantly the Higgs-fermion Yukawa couplings at large $\tan\beta$, both in the neutral and charged Higgs sector.

VII.1.1. MSSM Higgs boson phenomenology

In the MSSM, the mass, CP properties, decay and production properties of one of the neutral Higgs bosons should agree with the LHC Higgs data. Given that present data allows only for moderate departures from the SM predictions, it implies that some degree of alignment is necessary. For sufficiently heavy non-SM-like Higgs bosons, the alignment results from decoupling. If m_A is below a few hundred GeV, radiative corrections to the angle α can result in alignment for sizable values of the Higgs mass parameter $\mu > M_{\rm SUSY}$. Such radiative corrections, being proportional to ratios of mass parameters associated to the SUSY particles, do not decouple for heavy SUSY spectra.

The SM-like branching ratios of h can be modified if decays into supersymmetric particles are kinematically allowed, and, in particular, decays into a pair of the lightest supersymmetric particles - i.e. the lightest neutralinos, $\tilde{\chi}_1^0$ - can become dominant and would be invisible if R-parity is conserved [284–286]. Moreover, if light superpartners exist that couple to photons and/or gluons, the h loop-induced coupling to gg and $\gamma\gamma$ could deviate sizably from the corresponding SM predictions [255, 287–294]

Given that some degree of alignment is necessary to agree with data, for the heavier Higgs states there are two possibilities to be considered: i) Alignment triggered by decoupling, hence $m_A \geq$ several hundred GeV: The HWW and HZZ couplings are very small. The dominant H, A decay branching ratios strongly depend on $\tan\beta$. After incorporating the leading radiative corrections to Higgs couplings, the following decay features are relevant in the MSSM: The decay modes $H, A \to b\bar{b}$, $\tau^+\tau^-$ dominate when $\tan\beta$ is large (this holds even away from decoupling). For small $\tan\beta$, the $t\bar{t}$ decay mode dominates above its kinematic threshold. For the charged Higgs boson, $H^+ \to t\bar{b}$ dominates. ii) Some degree of alignment without decoupling, hence $m_A \leq$ a few hundred GeV. The main difference with the previous case is that in the low $\tan\beta$ regime ($\tan\beta \leq 5$) additional decay channels may be allowed which involve decays into the lightest SM-like Higgs boson. For A and H, besides the $H, A \to b\bar{b}$, $\tau^+\tau^-$ decay modes, also $A \to Zh$, $H \to hh$ as well as $H \to WW/ZZ$ decay modes are available (they are suppressed in the strict alignment limit). For the charged Higgs boson, $H^+ \to \tau^+\nu_\tau$ dominates below the $t\bar{b}$ threshold, and also $H^\pm \to W^\pm h$ may be searched for. Both in i) and ii), the heavier Higgs states, H, A and $H^\pm$, are roughly mass degenerate (with masses $\pm$ 20 GeV or less apart). In cases i) and ii) the heavy Higgs boson decays into charginos, neutralinos and third-generation squarks and sleptons can be important if they are kinematically allowed [284].

The main production mechanisms for the neutral MSSM Higgs bosons at e^+e^- colliders are Higgs-strahlung ($e^+e^- \to Zh, ZH$), vector boson fusion ($e^+e^- \to \nu\bar{\nu}h, \nu\bar{\nu}H$) – with W^+W^- fusion about an order of magnitude larger than ZZ fusion – and s-channel Z boson exchange ($e^+e^- \to Ah, AH$). For the Higgs-strahlung process it is possible to reconstruct the mass and momentum of the Higgs boson recoiling against the particles from the Z boson decay, and hence sensitive searches for Higgs bosons decaying to invisible final states are possible. The main charged Higgs boson production process at e^+e^- colliders is via s-channel γ or Z boson exchange ($e^+e^- \to H^+H^-$). Charged Higgs bosons can also be produced in top quark decays via $t \to b + H^+$ if $m_H^\pm < m_t - m_b$ or via the one-loop process $e^+e^- \to W^\pm H^\mp$, which allows the production of a charged Higgs boson with $m_H^\pm > \sqrt{s}/2$, even when H^+H^- production is kinematically forbidden. Other single charged Higgs production mechanisms include $t\bar{b}H^-/\,\bar{t}bH^+$ production, $\tau^+\nu H^-/\,\tau^-\bar{\nu}H^+$ production, and a variety of processes in which $H^\pm$ is produced in association with one or two other gauge and/or Higgs bosons. For representative references on production mechanisms for the MSSM Higgs bosons at e^+e^- see [243].

At hadron colliders, the dominant neutral Higgs production mechanism at moderate values of $\tan\beta$ is gluon fusion, mediated by loops containing heavy top and bottom quarks and the corresponding supersymmetric partners [243]. The effect of light stops that may contribute to the gluon fusion production can be partially cancelled by mixing effects. Higgs boson radiation off bottom quarks becomes important for large $\tan\beta$, where at least two of the three neutral Higgs bosons have enhanced couplings to bottom-type fermions [295, 296]. In the search for non-standard neutral Higgs bosons, A and H, the production can be via either of the above channels in the final inclusive ditau mode and via radiation off bottom quarks in the 4b's final mode. The total production rates of bottom quarks and τ pairs mediated by the production of a CP-odd Higgs boson in the large $\tan\beta$ regime are approximately given by

$$\begin{aligned} \sigma_{b\bar{b}A} \times {\rm BR}(A \to b\bar{b}) &\simeq \sigma^{\rm SM}_{b\bar{b}A}\, \frac{\tan^2\beta}{(1+\Delta_b)^2} \frac{9}{(1+\Delta_b)^2+9}, \\ \sigma_{gg\to A, b\bar{b}A} \times {\rm BR}(A \to \tau^+\tau^-) &\simeq \sigma^{\rm SM}_{gg\to A, b\bar{b}A}\, \frac{\tan^2\beta}{(1+\Delta_b)^2+9}, \end{aligned} \tag{11.31}$$

where $\sigma^{\rm SM}_{b\bar{b}A}$ and $\sigma^{\rm SM}_{gg\to A, b\bar{b}A}$ denote the values of the corresponding SM Higgs boson cross sections for a SM Higgs boson mass equal to m_A. For high $\tan\beta$, the function Δ_b includes the dominant effects of the SUSY radiative corrections affecting the relation between the bottom quark mass and the bottom Yukawa coupling [259, 274, 275, 280–282], and it depends strongly on $\tan\beta$ and on the SUSY mass parameters. The production and decay rates of H, for m_A larger $m_h^{\rm max}$, are governed by formulas similar to the ones presented above, and given that A and H are nearly degenerate in mass, the total signal cross section is increased by roughly a factor of two. Detailed discussions of the impact of radiative corrections in these search modes are presented in Refs. [259, 297].

The vector boson fusion and Higgs-strahlung production of the CP-even Higgs bosons as well as the associated production of neutral Higgs bosons with top quark pairs have lower production cross sections

by at least an order of magnitude with respect to the dominant ones, depending on the precise region of MSSM parameter space [42]. Higgs pair production of non-standard MSSM Higgs bosons has been studied in Ref. [298].

Charged Higgs bosons can be produced in several different modes at hadron colliders. If $m_{H^\pm} < m_t - m_b$, the charged Higgs boson can be produced in decays of the top quark via the decay $t \to bH^+$, which would compete with the SM process $t \to bW^+$. Relevant radiative corrections to BR($t \to H^+b$) have been computed in Refs. [299–302]. For values of $m_{H^\pm}$ near m_t, width effects are important. If $m_{H^\pm} > m_t - m_b$, then charged Higgs boson production occurs mainly through radiation from a third generation quark. Charged Higgs bosons may also be produced singly in association with a top quark via the $2 \to 3$ partonic processes $pp \to H^+\bar{t}b + X$ and $pp \to H^-t\bar{b} + X$; via associated production with $W^\pm$ bosons through $b\bar{b}$ annihilation and gg fusion [303]; and in pairs via $q\bar{q}$ annihilation [304]. The inclusive H^+H^- cross section is less than the cross section for single charged Higgs associated production [304, 305]. For a more extensive discussion of charged Higgs boson production at LHC see Refs. [11 42, 306].

The additional Higgs bosons are sought for mainly via the channels

$$\begin{aligned}
&pp \to A/H \to \tau^+\tau^- \text{ (inclusive)},\\
&b\bar{b}A/H, A/H \to \tau^+\tau^- \text{ (with } b\text{−tag)},\\
&b\bar{b}A/H, A/H \to b\bar{b} \text{ (with } b\text{−tag)},\\
&pp \to t\bar{t} \to H^\pm W^\mp b\bar{b},\ H^\pm \to \tau\nu_\tau\ ,\\
&gb \to H^-t \quad \text{or} \quad g\bar{b} \to H^+\bar{t},\ H^\pm \to \tau\nu_\tau\ .
\end{aligned} \tag{11.32}$$

After the Higgs boson discovery, updated MSSM benchmarks scenarios have been defined, that highlight interesting conditions for MSSM Higgs searches [44, 258]. They include: i) a moderate mixing scenario in which the light CP-even Higgs boson can be interpreted as the newly discovered state in most of the $m_A - \tan\beta$ plane; ii) a light stop scenario with stop masses in the few to several hundred GeV range that can affect gluon fusion Higgs production; and iii) a tau-phobic scenario that exhibits variations of BR($h \to b\bar{b}$) and BR($h \to \tau^+\tau^-$) with respect to their SM values. In the above benchmarks it is also possible to have decays of $H \to hh$ in regions of moderate m_A and moderate $\tan\beta$ as far as one is away from precise alignment. Also for the previous benchmarks, the LHC reach in the traditional $A/H \to \tau^+\tau^-$ search channel varies depending on the values of μ and M_2, that may enable the A/H decays into electroweakinos. Lastly, varying the parameter μ in both sign and magnitude induces relevant variations in the possible discovery reach through the $4b$'s channel, and to a lesser extent through the inclusive ditau channel.

An alternative approach to reduce the large number of parameters relevant to the Higgs sector is to consider that, in the Higgs basis, the only important radiative corrections are those affecting the Higgs mass [307]. This approximation is called hMSSM and works well in large regions of parameter space but it breaks down for sizable values of μ and A_t, and moderate values of $\tan\beta$, for which the radiative corrections to the mixing between the two CP even eigenstates become relevant. The effect of such radiative corrections is to allow for alignment for small to intermediate values of $\tan\beta$, independent of the specific value of m_A [308]. In addition, the hMSSM assumption that the right value of the Higgs mass may be obtained for all values of m_A and $\tan\beta$ is in conflict with the MSSM predictions for the Higgs mass for small values of m_A and $\tan\beta \simeq \mathcal{O}(1)$.

Future precision measurements of the Higgs boson couplings to fermions and gauge bosons together with information on heavy Higgs searches will provide powerful information on the SUSY parameter space [309, 308–311]. If no other new states beyond the current Higgs candidate are discovered at the LHC, it becomes mandatory to understand what would be the required precision of the Higgs rate measurements to distinguish the MSSM from the SM.

Improvements in our understanding of B-physics observables put indirect constraints on additional Higgs bosons in mass ranges that would be accessible in direct LHC searches. In particular, BR($B_s \to \mu^+\mu^-$), BR($b \to s\gamma$), and BR($B_u \to \tau\nu$) play an important role within minimal flavor-violating (MFV) models [312], in which flavor effects proportional to the CKM matrix elements are induced, as in the SM. For example, see references in [243]. The supersymmetric contributions to these observables come both at the tree and loop level, and have a different parametric dependence, but share the property that they become significant for large values of $\tan\beta$, which is also the regime in which searches for non-standard MSSM Higgs bosons at hadron colliders are the most powerful.

Table 11.16: Symmetries associated to various models with singlet extensions, the corresponding terms in the superpotential that only involve Higgs and singlet fields, and the number of neutral states in the Higgs sector for the case of CP conservation.

Model	MSSM	NMSSM	nMSSM	UMSSM
Symmetry	-	Z_3	Z_5^R, Z_7^R	$U(1)'$
Superpotential	$\mu\Phi_2 \cdot \Phi_1$	$\lambda_S S\Phi_2 \cdot \Phi_1 + \frac{\kappa}{3}S^3$	$\lambda_S S\Phi_2 \cdot \Phi_1 + t_F S$	$\lambda_S S\Phi_2 \cdot \Phi_1$

A_i^0	1	2	2	1

VII.2. Higgs bosons in singlet extensions of the MSSM

In the MSSM, the Higgs mass parameter μ is a supersymmetric parameter, and as such, it should naturally be of order M_{GUT} or M_{Planck}. The fact that phenomenologically it is required that μ be at the electroweak/TeV scale is known as the μ problem [313]. Supersymmetric models with additional singlets can provide a solution to the μ problem, by promoting the μ parameter to a dynamical singlet superfield S that only interacts with the MSSM Higgs doublets through a coupling λ_S at the level of the superpotential. An effective μ is generated when the real scalar component of S acquires a vacuum expectation value $\langle S \rangle$

$$\mu_{eff} = \lambda_S \langle S \rangle. \tag{11.33}$$

After the minimization of the Higgs potential the vacuum state relates the vacuum expectation values of the three CP-even neutral scalars, ϕ_1^0, ϕ_2^0 and S, to their soft supersymmetry breaking masses, hence, one expects that these VEVs should all be of order $M_{\rm SUSY}$ and therefore the μ problem is solved.

The solution of the μ problem through the addition of a singlet superfield to the MSSM comes along with the existence of an extra global U(1) symmetry, known as the Peccei–Quinn (PQ) symmetry [314]. This PQ symmetry is broken explicitly in realistic models. For that purpose one can consider a discrete Z_3 symmetry that allows the existence of a PQ odd S^3 term in the superpotential. This model extension has been called the next-to-minimal supersymmetric SM (NMSSM) (the NMSSM was first introduced in Ref. [315], see the 2014 edition of this review for an extensive list of subsequent references). It is known however that discrete symmetries may come along with the existence of domain wall structures that imply that our universe would consist of disconnected domains with different ground states, creating unacceptably large anisotropies in the cosmic microwave background [316]. To avoid the problem of domain walls one can consider the existence of non-renormalizable operators that would lead to the preferred vacuum state. However, the same operators in turn may generate quadratically divergent tadpole contributions [243] that could shift the VEV of S to be much larger, order M_{GUT}, and ruin the singlet solution to the μ problem. To cure the problem of destabilizing tadpoles, discrete R-symmetries have been proposed that ensure that tadpoles would only appear at very high order loops and be safely suppressed. Depending on the symmetries imposed on the theory, different models with singlet extensions of the MSSM (xMSSM) have been proposed. In Table 11.16 we show the most studied examples: the NMSSM, the Nearly-Minimal Supersymmetric SM (nMSSM) [317], and the U(1)′-extended MSSM (UMSSM) [318], specifying the new parameters appearing in the superpotential and the respective symmetries. A Secluded U(1)′-extended MSSM (sMSSM) [319] contains three singlets in addition to the standard UMSSM Higgs singlet; this model is equivalent to the nMSSM in the limit that the additional singlet VEV's are large, and the trilinear singlet coupling, λ_S, is small [320].

Based on the extended models defined in Table 11.16, we write the most generic supersymmetric and soft supersymmetry breaking scalar potentials for the three scalar fields: Φ_1, Φ_2 and S:

$$V_{xMSSM} = \left|\lambda_S \Phi_2 \cdot \Phi_1 + t_F + \kappa S^2\right|^2 + |\lambda_S S|^2 \left(|\Phi_1|^2 + |\Phi_2|^2\right) + \frac{g'^2 + g^2}{8}\left(|\Phi_1|^2 - |\Phi_2|^2\right)^2 + \frac{g^2}{2}\left(|\Phi_1|^2 |\Phi_2|^2 - |\Phi_2 \cdot \Phi_1|^2\right) + \frac{g_1'^2}{2}\left(Q_{\Phi_1}|\Phi_1|^2 + Q_{\Phi_2}|\Phi_2|^2 + Q_S|S|^2\right)^2 \quad (11.34)$$

$$V_{\text{soft}} = m_{H_1}^2 |\Phi_1|^2 + m_{H_2}^2 |\Phi_2|^2 + m_s^2 |S|^2 + \left(A_s \lambda_S S H_u \cdot H_d + \frac{\kappa}{3} A_\kappa S^3 + t_S S + h.c.\right). \quad (11.35)$$

where $\Phi_2 \cdot \Phi_1 = \epsilon_{ij}\Phi_2^i \Phi_1^j$ and the couplings g', g, and g_1' are associated to the $\mathrm{U}(1)_Y$, $\mathrm{SU}(2)_L$, and $\mathrm{U}(1)'$ gauge symmetries, respectively. t_F and t_S are supersymmetric and SUSY breaking tadpole terms, respectively, m_s is a SUSY breaking mass term for the scalar component of the field S, and A_s and A_κ are the trilinear soft SUSY breaking mass parameters associated with the new terms $\lambda_S S \Phi_2 \cdot \Phi_1$ and $\kappa S^3/3$ in the superpotential, with the B-term of the MSSM expressed as $B\mu \equiv A_s \mu_{eff}$. In particular, κ and A_κ are the parameters for the NMSSM model, while t_F and t_S are those of the nMSSM. The UMSSM depends on the new coupling g_1' as well as on the $\mathrm{U}(1)'$ charges of the Higgs fields, Q_{Φ_1}, Q_{Φ_2} and Q_S, that are free parameters with the restriction that they have to add to zero for the superpotential $\lambda_3 S \Phi_2 \Phi_1$ to be gauge invariant. In a given $\mathrm{U}(1)'$ construction the charges are specified. The addition of the singlet scalar field(s) imply that additional CP-even and CP-odd Higgs bosons will appear in the spectra, whereas the charged Higgs sector remains the same as in the MSSM given that the number of Higgs doublets remains unchanged. The mixing with the extra scalar S alters the masses and properties of the physical Higgs bosons, that in general can differ significantly from the SM or the MSSM. A detailed discussion of typical mass spectra and decay properties in these models can be found for example in Refs. [321, 320]. Moreover, these models have extra neutralinos and in some cases extra neutral gauge bosons, Z'. The extra gauge boson sector is constrained by experimental data through direct Z' searches as well as the $Z - Z'$ mixing angle $\alpha_{ZZ'}$ constrained to be less that $\mathcal{O}(10^{-3})$ by precision electroweak data .

In singlet extensions of the MSSM the lightest CP-even Higgs mass at tree level, $m_{H_1}^{tree}$ receives a contribution from the singlet scalar that renders it larger than the MSSM value, in particular for small values of $\tan\beta$. The tree level upper bound reads[9]

$$m_{H_1}^{tree} \leq M_Z^2 \cos^2 2\beta + \frac{1}{2}\lambda_S^2 v^2 \sin^2 2\beta\,. \quad (11.36)$$

At the one-loop level, the top and stop loops (as well as sbottom and stau loops for large $\tan\beta$) are the dominant contributions, that are common to the MSSM and to all the singlet extensions. Gauge couplings in the UMSSM are small compared to the top quark Yukawa coupling, hence the one-loop gauge contributions are negligible. Corrections exclusive to the NMSSM and the nMSSM enter only at the two loop level. Therefore, there are no significant model-dependent contributions at one loop order, and as a result, for large $\tan\beta$ the lightest CP-even Higgs mass does not differ in any significant way from the MSSM one. In the decoupling limit, a value of the lightest SM Higgs mass of about 125 GeV is achievable in all these MSSM extensions, and this remains the case even after higher order corrections are implemented.

A singlet extended supersymmetric Higgs sector opens new avenues for discovery. Since the singlet pseudoscalar particle may be identified as the pseudo-Goldstone boson of a spontaneously broken Peccei–Quinn symmetry, it may become naturally light [322, 323]. Generally, there is mixing of the singlet sector with the MSSM Higgs sector, and for a sufficiently light, singlet dominated scalar or pseudoscalar, h_S or A_S, respectively, the SM-like Higgs boson h may decay to pairs of h_S or A_S. The light scalar and/or pseudoscalar may subsequently decay to $\tau\tau$ or $b\bar{b}$ pairs. Such cascade decays are more difficult to detect than standard searches due to the potentially soft decay products. There is also a rich phenomenology for the decays of the heavy CP-even and CP-odd doublets, A and H into two lighter Higgs bosons such as $H \to hh_S$, hh, $h_S h_S$ or $A \to A_S h_S$, $A_S h$ as well as into a light Higgs boson and a gauge boson: $H \to A_S Z$; $A \to h_S Z$, hZ. If kinematically allowed the heavy Higgs bosons decay into $t\bar{t}$. If the singlet dominated scalar or pseudoscalar are somewhat heavier, the decays $h_S \to WW$ or $A_S \to h_S Z$ will be allowed.

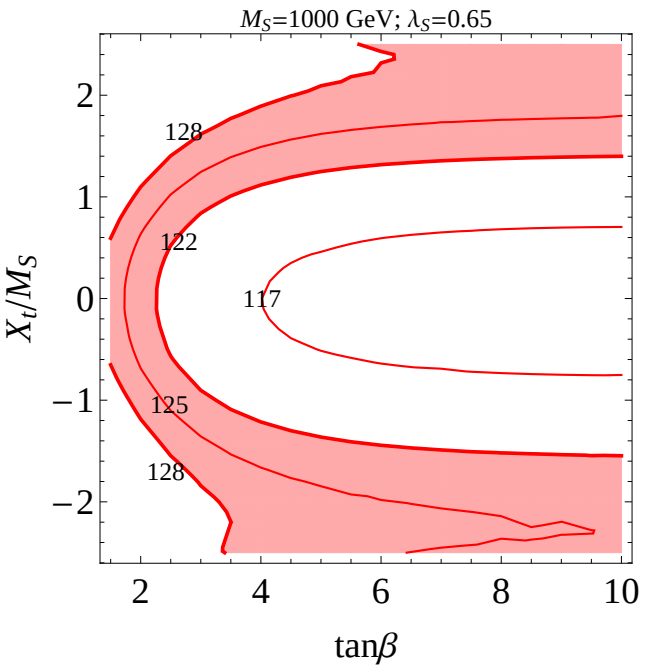

Figure 11.24: Values of the stop mixing parameter normalized to the SUSY mass scale X_t/M_{SUSY}, as a function of $\tan\beta$, for $M_{\text{SUSY}} \equiv M_S = 1000\,\text{GeV}$, $\lambda_S = 0.65$, and contours of constant values of the Higgs mass $m_h = 125 \pm 3\,\text{GeV}$ shaded in red [327].

In addition, the light singlet scenario in the NMSSM or nMSSM is typically associated with a light singlino-dominated neutralino. The recently discovered SM-like Higgs boson can then decay to pairs of this neutralino [324, 320], opening an invisible decay mode that is not excluded by present data. All of the Higgs bosons can decay into electroweakinos depending on kinematics and the singlino or higgsino composition of the electroweakinos.

In models with extended singlets, at low $\tan\beta$ it is possible to trade the requirement of a large stop mixing by a sizeable trilinear Higgs-singlet Higgs coupling λ_S, rendering more freedom on the requirements for gluon fusion production. As in the MSSM, mixing in the Higgs sector -additionally triggered by the extra new parameter λ_S - can produce variations in the Higgs–$b\bar{b}$ and Higgs–$\tau^-\tau^+$ couplings that can alter the Higgs to ZZ/WW and diphoton rates. Light charginos at low $\tan\beta$ can independently contribute to enhance the di-photon rate, without altering any other of the Higgs decay rates [290, 325].

There is much activity in exploring the NMSSM phenomenology in the light of the 125 GeV Higgs boson [326], as well as in defining benchmark scenarios with new topologies including Higgs decay chains [291]. An analytic understanding of the alignment condition in the NMSSM is presented in Ref. [292]. The NMSSM with a Higgs boson of mass 125 GeV can be compatible with stop masses of order of the electroweak scale, thereby reducing the degree of fine tuning necessary to achieve electroweak symmetry breaking (see Fig. 11.24). The alignment conditions point toward a more natural region of parameter space for electroweak symmetry breaking, while allowing for perturbativity of the theory up to the Planck scale and yielding a rich and interesting Higgs boson phenomenology at the LHC.

[9] Additional gauge interactions in the UMSSM contribute to this increase with a term of $\mathcal{O}(g_1'^2 v^2 (Q_{\phi_2}^2 \cos^2\beta + Q_{\phi_1}^2 \sin^2\beta))$.

VII.3. Supersymmetry with extended gauge sectors

In the MSSM, the tree-level value of the lightest CP-even Higgs mass originates from the D-term dependence of the scalar potential that comes from the supersymmetric kinetic terms in the Kähler potential. The D-terms lead to tree-level quartic couplings which are governed by the squares of the gauge couplings of the weak interactions, under which the Higgs has non-trivial charges and hence the lightest Higgs mass is bounded to be smaller than M_Z. If new gauge interactions were present at the TeV scale, and the Higgs bosons would have non-trivial charges under them, there would be new D-term contributions that would lead to an enhancement of the tree-level Higgs mass value. Since the low energy gauge interactions reduce to the known $\mathrm{SU}(3)_c \times \mathrm{SU}(2)_L \times \mathrm{U}(1)_Y$ ones, in order for this mechanism to work, the extended gauge and Higgs sectors should be integrated out in a non-supersymmetric way. This means that there must be supersymmetry breaking terms that are of the order of, or larger than, the new gauge boson masses. The tree-level quartic couplings would then be enhanced through their dependence on the square of the gauge couplings of the extended Higgs sector. This effect will be suppressed when the heavy gauge boson masses are larger than the supersymmetry breaking scale and will acquire its full potential only for large values of this scale.

One of the simplest possibilities is to extend the weak interactions to a $\mathrm{SU}(2)_1 \times \mathrm{SU}(2)_2$ sector, such that the known weak interactions are obtained after the spontaneous breaking of these groups to $\mathrm{SU}(2)_L$ [328]. This may be achieved by introducing a bi-doublet Σ under the two SU(2) gauge groups, which acquires a non-trivial vacuum expectation value u in the diagonal direction. The heavy gauge boson masses are therefore given by $M^2_{W'} = (g_1^2 + g_2^2)u^2/2$, and the weak coupling $g^2 = g_1^2 g_2^2/(g_1^2 + g_2^2)$. To obtain a new tree-level contribution to the Higgs potential, the Higgs bosons must be charged under the new gauge interactions. One possibility is to assume that the third generation quarks and leptons as well as the Higgs doublets have charges under the $\mathrm{SU}(2)_1$ group, while the second and first generations have charges under $\mathrm{SU}(2)_2$. This provides a natural explanation of the largeness of the third generation couplings compared to the first and second generation ones.

Under the above conditions, the D-term contributions to the neutral Higgs effective potential are given by

$$V_D = \frac{g^2\Delta + g'^2}{8}\left(|H_2^0|^2 - |H_1^0|^2\right)^2 \tag{11.37}$$

with

$$\Delta = \left(1 + \frac{4m_\Sigma^2}{g_2^2 u^2}\right)\left(1 + \frac{4m_\Sigma^2}{(g_1^2 + g_2^2)u^2}\right)^{-1}, \tag{11.38}$$

where m_Σ is the supersymmetry breaking term associated with the bi-doublet Σ. It is easy to see that while the MSSM D-term is recovered when $m_\Sigma \to 0$, it is replaced by the $\mathrm{SU}(2)_1 \times \mathrm{U}(1)_Y$ D-term when m_Σ becomes much larger than $M_{W'}$. The tree-level mass now reads

$$m_h^2|_{\mathrm{tree}} = \frac{g^2\Delta + g'^2}{4} v^2 \cos^2 2\beta, \tag{11.39}$$

and reduces to the MSSM value, $M_Z^2 \cos^2 2\beta$, for $\Delta = 1$.

Assuming $g_1 \simeq g_2$, values of $g_{1,2}$ of order one are necessary to obtain the proper value of the weak gauge coupling. In addition, if values of m_Σ of order $M_{W'}$ are assumed, enhancements of order 50 percent of the MSSM D-term contribution to the Higgs mass may be obtained. Such enhancements are sufficient to obtain the measured Higgs mass value without the need for very heavy stops or large stop mixing parameters.

The gauge extension described above leads to new, heavy gauge and Higgs bosons, as well as new neutralinos and charginos. Constraints from precision measurements put bounds of the order of a few TeV on the mass of these gauge bosons, which may be probed at the higher energy run of the LHC collider. If the new gaugino supersymmetry breaking masses are smaller than the gauge boson masses, the new electroweakinos will have masses of the order of a few TeV and therefore the weak scale phenomenology reduces to the MSSM one. Similar gauge extensions, including also new abelian gauge groups have been considered, for instance, in Ref. [329].

Gauge extensions of the MSSM can also lead to an enhancement of the Higgs mass value by modifying the renormalization group evolution of the Higgs quartic coupling to low energies. In the MSSM, the evolution of the quartic coupling is governed by the top-quark Yukawa interactions and depends on the fourth power of the top-quark Yukawa coupling. The neutralino and chargino contributions, which depend on the fourth power of the weak gauge couplings, are small due to the smallness of these couplings. Depending on the values of the soft supersymmetry breaking parameters in the gaugino and Higgsino sectors, the $\mathrm{SU}(2)_1$ gauginos may become light, with masses of the order of the weak scale. Since the $\mathrm{SU}(2)_1$ coupling may be significantly larger than the $\mathrm{SU}(2)_L$ one, for small values of the Higgsino mass parameter μ, the associated charginos and neutralinos may modify the evolution of the quartic coupling in a significant way [330]. This may lead to a significant increase of the lightest CP-even Higgs mass, even for small values of $\tan\beta \simeq 1$ for which the D-term contributions become small. In addition, under these conditions, light charginos may lead to a significant modification of the Higgs diphoton decay rate, which may be as large as 50% of the SM [330–334].

VII.4. Effects of CP violation

SUSY scenarios with CP-violation (CPV) phases are theoretically appealing, since additional CPV beyond that observed in the K, D, and B meson systems is required to explain the observed cosmic matter-antimatter asymmetry. In the MSSM, CP-violation effects in the Higgs sector appear at the quantum level, while in singlet extensions of the MSSM CP-violation effects can already be effective at tree level. In general, CP-violation effects in the Higgs sector have significant constraints from electric dipole moments data [243].

In the MSSM, the gaugino mass parameters ($M_{1,2,3}$), the Higgsino mass parameter, μ, the bilinear Higgs squared-mass parameter, m_{12}^2, and the trilinear couplings of the squark and slepton fields to the Higgs fields, A_f, may carry non-trivial phases. The two parameter combinations $\arg[\mu A_f (m_{12}^2)^*]$ and $\arg[\mu M_i (m_{12}^2)^*]$ are invariant under phase redefinitions of the MSSM fields [335, 261]. Therefore, if one of these quantities is non-zero, there would be new sources of CP-violation, which affects the Higgs sector through radiative corrections [260, 261, 336–340]. The mixing of the neutral CP-odd and CP-even Higgs boson states is no longer forbidden. Hence, m_A is no longer a physical parameter. However, the charged Higgs boson mass $m_{H^\pm}$ is still physical and can be used as an input for the computation of the neutral Higgs spectrum of the theory. For large values of $m_{H^\pm}$, corresponding to the decoupling limit, the properties of the lightest neutral Higgs boson state approach those of the SM Higgs boson. In particular, the upper bound on the lightest neutral Higgs boson mass, takes the same value as in the CP-conserving case [261]. Nevertheless, there still can be significant mixing between the two heavier neutral mass eigenstates. For a detailed study of the Higgs boson mass spectrum and parametric dependence of the associated radiative corrections, see Refs. [336, 339].

Major variations to the MSSM Higgs phenomenology occur in the presence of explicit CPV phases. In the CPV case, vector boson pairs couple to all three neutral Higgs boson mass eigenstates, H_i ($i = 1, 2, 3$), with couplings

$$g_{H_i VV} = \cos\beta \mathcal{O}_{1i} + \sin\beta \mathcal{O}_{2i}\,, \tag{11.40}$$

$$g_{H_i H_j Z} = \mathcal{O}_{3i}\left(\cos\beta \mathcal{O}_{2j} - \sin\beta \mathcal{O}_{1j}\right) - \mathcal{O}_{3j}\left(\cos\beta \mathcal{O}_{2i} - \sin\beta \mathcal{O}_{1i}\right)\,, \tag{11.41}$$

where the $g_{H_i VV}$ couplings are normalized to the analogous SM coupling and the $g_{H_i H_j Z}$ have been normalized to $g_Z^{\mathrm{SM}}/2$. The orthogonal matrix $\mathcal{O}_{ij}$ is relating the weak eigenstates to the mass eigenstates. It has non-zero off-diagonal entries mixing the CP-even and CP-odd components of the weak eigenstates. The above couplings obey the relations

$$\sum_{i=1}^{3} g_{H_i ZZ}^2 = 1 \quad \text{and} \quad g_{H_k ZZ} = \varepsilon_{ijk}\, g_{H_i H_j Z}\,, \tag{11.42}$$

where ε_{ijk} is the Levi-Civita symbol. Moreover, CPV phases imply that all neutral Higgs bosons can couple to both scalar and pseudoscalar fermion bilinear densities. The couplings of the mass eigenstates H_i to fermions depend on the loop-corrected fermion Yukawa couplings (similarly to the CPC case), on $\tan\beta$ and on the $\mathcal{O}_{ji}$ [336, 341].

The production processes of neutral MSSM Higgs bosons in the CPV scenario are similar to those in the CPC scenario. Regarding the decay properties, the lightest mass eigenstate, H_1, predominantly decays to $b\overline{b}$ if kinematically allowed, with a smaller fraction decaying to $\tau^+\tau^-$, similar to the CPC case. If kinematically allowed, a SM-like neutral Higgs boson, H_2 or H_3 can decay predominantly to H_1H_1 leading to many new interesting signals both at lepton and hadron colliders; otherwise it will decay preferentially to $b\overline{b}$.

The discovery of a 125 GeV Higgs boson has put strong constraints on the realization of the CPV scenario within the MSSM. This is partly due to the fact that the observed Higgs rates are close to the SM values, and a large CP-violating component would necessarily induce a large variation in the rate of the SM-like Higgs decay into the weak gauge bosons $W^\pm$ and Z. The measured Higgs mass imposes additional constraints on the realization of this scenario. Once all effects are considered, the CP-odd Higgs A component of the lightest Higgs tends to be smaller than about 10%. This restriction can be alleviated in the NMSSM or more general two Higgs doublet models. CP-violating effects can still be significant in the heavy Higgs sector. For instance, the Higgs bosons H_2 and H_3 may be admixtures of CP-even and CP-odd scalars, and therefore both may be able to decay into pairs of weak gauge bosons. The observation of such decays would be a clear signal of CP-violation. In the MSSM the proximity of the masses of H_2 and H_3 makes the measurement of such effect quite challenging, but in generic two Higgs doublet models, the mass splitting between the two heavy mass eigenstates may become larger, facilitating the detection of CP-violating effects at collider experiments. For a recent studies see for example [342].

VII.5. Non-supersymmetric extensions of the Higgs sector

There are many ways to extend the minimal Higgs sector of the SM. In the preceding sections the phenomenology of SUSY Higgs sectors is considered, which at tree level implies a constrained type-II 2HDM (with restrictions on the Higgs boson masses and couplings). In the following discussion, more generic 2HDM's [12, 273, 343, 344] are presented. These models are theoretically less compelling since they do not provide an explanation for the SM Higgs naturalness problem, but can lead to different patterns of Higgs-fermion couplings, hence, to different phenomenology. It is also possible to consider models with a SM Higgs boson and one or more additional scalar SU(2) doublets that acquire no VEV and hence play no role in the EWSB mechanism. These models are dubbed Inert Higgs Doublet Models (IHD) [345]. Without a VEV associated to it, a Higgs boson from an inert doublet has no tree-level coupling to gauge bosons and hence cannot decay into a pair of them. And imposing a Z_2 symmetry that prevents them from coupling to the fermions, it follows that, if the lightest inert Higgs boson is neutral, it becomes a good dark matter candidate with interesting associated collider signals. Recent studies of IHD models in the light of a 125 GeV Higgs have been performed [346], showing that there can be non-negligible enhancement or suppression of Higgs to diphotons or Higgs to $Z\gamma$. This may be due to the presence of a light charged Higgs, as light as 100 GeV, that is not in conflict with collider or flavor constraints, because it has no couplings to fermions. It is interesting to study the interplay between collider and direct dark matter detection signals in these models.

Other extensions of the Higgs sector can include [321, 347] multiple copies of $\mathrm{SU}(2)_L$ doublets, additional Higgs singlets [348], triplets or more complicated combinations of Higgs multiplets. It is also possible to enlarge the gauge symmetry beyond $\mathrm{SU}(2)_L\times\mathrm{U}(1)_Y$ along with the necessary Higgs structure to generate gauge boson and fermion masses. There are two main experimental constraints on these extensions: *(i)* precision measurements which constrain $\rho = m_W^2/(m_Z^2\cos^2\theta_W)$ to be very close to 1 and *(ii)* flavor changing neutral current (FCNC) effects. In electroweak models based on the SM gauge group, the tree-level value of ρ is determined by the Higgs multiplet structure. By suitable choices for the hypercharges, and in some cases the mass splitting between the charged and neutral Higgs sector or the vacuum expectation values of the Higgs fields, it is possible to obtain a richer combination of singlets, doublets, triplets and higher multiplets compatible with precision measurements [349]. Concerning the constraints coming from FCNC effects, the Glashow–Weinberg (GW) criterion [350] states that, in the presence of multiple Higgs doublets the tree-level FCNC's mediated by neutral Higgs bosons will be absent if all fermions of a given electric charge couple to no more than one Higgs doublet. An alternative way of suppressing FCNC in a two Higgs doublet model has been considered in Ref. [351], where it is shown that it is possible to have tree level FCNC completely fixed by the CKM matrix, as a result of an abelian symmetry.

VII.5.1. Two-Higgs-doublet models

Supersymmetry demands the existence of two Higgs doublets such that one doublet couples to up-type quarks and the other to down-type quarks and charged leptons. This Higgs-fermion coupling structure is the one identified as type-II 2HDM [273] and assures that masses for both up and down-type quarks can be generated in a supersymmetric and gauge invariant way. Two Higgs doublet models [343], however, can have a more diverse Higgs-fermion coupling structure and can be viewed as a simple extension of the SM to realize the spontaneous breakdown of $\mathrm{SU}(2)_L\times\mathrm{U}(1)_Y$ to $\mathrm{U}(1)_{\mathrm{em}}$. Quite generally, if the two Higgs doublets contain opposite hypercharges, the scalar potential will contain mixing mass parameters of the kind $m_{12}^2\Phi_1^T i\sigma_2\Phi_2 + h.c.$. In the presence of such terms, both Higgs doublets will acquire vacuum expectation values, $v_1/\sqrt{2}$ and $v_2/\sqrt{2}$, respectively, and the gauge boson masses will keep their SM expressions with the Higgs vacuum expectation value v replaced by $v = \sqrt{v_1^2+v_2^2}$. Apart from the mass terms, the most generic renormalizable and gauge invariant scalar potential contains seven quartic couplings, which are defined in Eq. (11.24).

Considering two doublets with hypercharges, with $Y_{\Phi_1} = -1$ and $Y_{\Phi_2} = 1$ as in Eq. (11.23), and the most general, renormalizable Higgs potential will be given by Eq. (11.24). Just as in the MSSM case, after electroweak symmetry breaking and in the absence of CP-violation, the physical spectrum contains a pair of charged Higgs bosons $H^\pm$, a CP-odd Higgs boson A and two neutral CP-even Higgs bosons, h and H. The angles α and β diagonalize the CP-even, and the CP-odd and Charged Higgs sectors, respectively.

The complete 2HDM is defined only after considering the interactions of the Higgs fields to fermions. Yukawa couplings of the generic form

$$-h_{ij}^a\bar{\Psi}_L^i H_a \Psi_R^j + h.c. \tag{11.43}$$

may be added to the renormalizable Lagrangian of the theory. Contrary to the SM, the two Higgs doublet structure does not ensure the alignment of the fermion mass terms $m_{ij} = h_{ij}^a v_a/\sqrt{2}$ with the Yukawa couplings h_{ij}^a. This implies that quite generally, the neutral Higgs boson will mediate flavor changing interactions between the different mass eigenstates of the fermion fields. Such flavor changing interactions should be suppressed in order to describe properly the Kaon, D and B meson phenomenology. Based on the Glashow–Weinberg criterion, it is clear that the simplest way of avoiding such transitions is to assume the existence of a symmetry that ensures the couplings of the fermions of each given quantum number (up-type and down-type quarks, charged and neutral leptons) to only one of the two Higgs doublets. Different models may be defined depending on which of these fermion fields couple to a given Higgs boson, see Table 11.17. Models of type-I [344] are those in which all SM fermions couple to a single Higgs field. In type-II models [273] down-type quarks and charged leptons couple to a common Higgs field, while the up-type quarks and neutral leptons couple to the other. In models of type-III (lepton-specific) quarks couple to one of the Higgs bosons, while leptons couple to the other. Finally, in models of type-IV (flipped), up-type quarks and charged leptons couple to one of the Higgs fields while down-quarks and neutral leptons couple to the other.

The two Higgs doublet model phenomenology depends strongly on the size of the mixing angle α and therefore on the quartic couplings.

Table 11.17: Higgs boson couplings to up, down and charged lepton-type $SU(2)_L$ singlet fermions in the four discrete types of 2HDM models that satisfy the Glashow–Weinberg criterion, from Ref. [352].

Model	2HDM I	2HDM II	2HDM III	2HDM IV
u	Φ_2	Φ_2	Φ_2	Φ_2
d	Φ_2	Φ_1	Φ_2	Φ_1
e	Φ_2	Φ_1	Φ_1	Φ_2

For large values of m_A, $\sin\alpha \to -\cos\beta$, $\cos\alpha \to \sin\beta$, $\cos(\beta-\alpha) \to 0$, and the lightest CP-even Higgs h behaves as the SM Higgs. The same behavior is obtained if the quartic couplings are such that $\mathcal{M}^2_{12}\sin\beta = -(\mathcal{M}^2_{11} - m^2_h)\cos\beta$. The latter condition represents a situation in which the coupling of h to fermions and weak gauge bosons become the same as in the SM, without decoupling the rest of the non-standard scalars and it is of particular interest due to the fact that the recently discovered Higgs boson has SM-like properties. This situation will be referred to as alignment, as in the MSSM case.

In type-II Higgs doublet models, at large values of $\tan\beta$ and moderate values of m_A, the non-standard Higgs bosons H, A and $H^\pm$ couple strongly to bottom quarks and τ leptons. Hence the decay modes of the non-standard Higgs bosons tend to be dominated by b-quark and tau-lepton modes, including top quarks or neutrinos in the case of the charged Higgs. However, for large and negative values of λ_4, the charged Higgs boson mass may be sufficiently heavy to allow on-shell decays

$$\begin{aligned} &H^\pm \to W^\pm + (H, A), \\ &\qquad g_{H^\pm W^\mp H,A} \simeq \frac{M_W}{v}\sin(\beta-\alpha)(p_{H^+} - p_{H,A})\,, \end{aligned} \tag{11.44}$$

where p_{H^+} and $p_{H,A}$ are the charged and neutral scalar Higgs momenta pointing into the vertex. On the other hand, for large and positive values of λ_5, the above charged Higgs decay into a $W^\pm$ and the CP-odd Higgs boson may be allowed, but the heavy Higgs H may be sufficiently heavy to decay into a CP-odd Higgs boson and an on-shell Z.

$$H \to Z + A, \quad g_{HZA} \simeq \frac{M_Z}{v}\sin(\beta-\alpha)(p_H - p_A). \tag{11.45}$$

The decay $H^\pm \to W^\pm + H$, on the other hand may be allowed only if $\lambda_4 < -\lambda_5$. The couplings controlling all the above decay modes are proportional to $\sin(\beta-\alpha)$ and therefore they are unsuppressed in the alignment limit. Moreover, these could still be the dominant decay modes at moderate values of $\tan\beta$, offering a way to evade the current bounds obtained assuming a dominant decay into bottom quarks or τ leptons.

The quartic couplings are restricted by the condition of stability of the effective potential as well as by the restriction of obtaining the proper value of the lightest CP-even Higgs mass. Close to the alignment limit, the lightest CP-even Higgs mass becomes approximately independent of m_A and is given by

$$\begin{aligned} m^2_h \simeq& v^2(\lambda_1\cos^4\beta + \lambda_2\sin^4\beta + 2\tilde{\lambda}_3 v^2\cos^2\beta\sin^2\beta) \\ &+ v^2(4\lambda_6\cos^3\beta\sin\beta + 4\lambda_7\sin^3\beta\cos\beta)\,, \end{aligned} \tag{11.46}$$

where $\tilde{\lambda}_3 = \lambda_3 + \lambda_4 + \lambda_5$.

The stability conditions imply the positiveness of all masses, as well as the avoidance of run-away solutions to large negative values of the fields in the scalar potential. These conditions imply

$$\begin{aligned} &\lambda_1 \geq 0, \quad \lambda_2 \geq 0, \quad \lambda_3 + \lambda_4 - |\lambda_5| \geq -\sqrt{\lambda_1\lambda_2}, \\ &\lambda_3 \geq -\sqrt{\lambda_1\lambda_2}, \quad 2|\lambda_6 + \lambda_7| < \frac{\lambda_1+\lambda_2}{2} + \tilde{\lambda}_3, \end{aligned} \tag{11.47}$$

where the first four are necessary and sufficient conditions in the case of $\lambda_6 = \lambda_7 = 0$, while the last one is a necessary condition in the case all couplings are non-zero. Therefore, to obtain the conditions that allow the decays $H^\pm \to W^\pm H, A$ and $H \to ZA$, λ_3 should take large positive values in order to compensate for the effects of λ_4 and λ_5. For recent detailed discussions about 2HDM phenomenology see Refs [309, 254, 347, 353–356, 357].

VII.5.2. Higgs triplets

Electroweak triplet scalars are the simplest non-doublet extension of the SM that can participate in the spontaneous breakdown of $\mathrm{SU}(2)_L \times \mathrm{U}(1)_Y$ to $\mathrm{U}(1)_{\rm em}$. Two types of model have been developed in enough detail to make a meaningful comparison to LHC data: the Higgs triplet model (HTM) [358, 359] and the Georgi–Machacek model [360–362].

The Higgs triplet model extends the SM by the addition of a complex $\mathrm{SU}(2)_L$ triplet scalar field Δ with hypercharge $Y = 2$, and a general gauge-invariant renormalizable potential $V(\Phi, \Delta)$ for Δ and the SM Higgs doublet Φ. The components of the triplet field can be parameterized as

$$\Delta = \frac{1}{\sqrt{2}}\begin{pmatrix} \Delta^+ & \sqrt{2}\Delta^{++} \\ v_\Delta + \delta + i\xi & -\Delta^+ \end{pmatrix}. \tag{11.48}$$

where Δ^+ is a singly-charged field, Δ^{++} is a doubly-charged field, δ is a neutral CP-even scalar, ξ is a neutral CP-odd scalar, and v_Δ is the triplet VEV. The general scalar potential mixes the doublet and triplet components. After electroweak symmetry breaking there are seven physical mass eigenstates, denoted $H^{\pm\pm}$, $H^\pm$, A, H, and h.

A distinguishing feature of the HTM is that it violates the custodial symmetry of the SM; thus the ρ parameter deviates from 1 even at tree level. Letting x denote the ratio of triplet and doublet VEVs, the tree level expression [363] is:

$$\rho = \frac{1+2x^2}{1+4x^2}\,. \tag{11.49}$$

The measured value of the ρ parameter then limits [364] the triplet VEV to be quite small, $x \lesssim 0.03$, or $v_\Delta < 8\,\mathrm{GeV}$. This constraint severely limits the role of the triplet scalar in the EWSB mechanism.

The small VEV of the Higgs triplet in the HTM is a virtue from the point of view of generating neutrino masses without the necessity for introducing right-handed neutrino fields. The gauge invariant dimension four interaction

$$h_{\nu_{ij}}\,\ell_i^T C^{-1} i\sigma_2\,\Delta\,\ell_j\,, \tag{11.50}$$

where ℓ_i are the lepton doublets, C is the charge conjugation matrix, and $h_{\nu_{ij}}$ is a complex symmetric coupling matrix, generates a Majorana mass matrix for the neutrinos:

$$m_{\nu_{ij}} = \sqrt{2}h_{\nu_{ij}}v_\Delta\,. \tag{11.51}$$

This can be combined with the usual neutrino seesaw to produce what is known as the type-II seesaw [365].

The HTM suggests the exciting possibility of measuring parameters of the neutrino mass matrix at the LHC. If the doubly-charged Higgs is light enough and/or its couplings to W^+W^+ are sufficiently suppressed, then its primary decay is into same-sign lepton pairs: $H^{++} \to \ell_i^+\ell_j^+$; from Eq. (11.50) and Eq. (11.51) it is apparent that these decays are in general lepton-flavor violating with branchings proportional to elements of the neutrino mass matrix [366].

Precision electroweak data constrain the mass spectrum as well as the triplet VEV of the HTM [363, 367, 368]. As described in Ref. [368], these constraints favor a spectrum where H^{++} is the lightest of the exotic bosons, and where the mass difference between H^+ and H^{++} is a few hundred GeV. The favored triplet VEV is a few GeV, which also favors H^{++} decays into W^+W^+ over same-sign dileptons.

The Georgi–Machacek model addresses the ρ parameter constraint directly by building in custodial symmetry. Writing the complex scalar doublet of the SM as a $(2,2)$ under $\mathrm{SU}(2)_L \times \mathrm{SU}(2)_R$, it is obvious that the next simplest construction respecting custodial symmetry is a scalar transforming like a $(3,3)$ [369]. These nine real degrees of freedom correspond to a complex electroweak triplet combined with a real triplet, with the scalar potential required to be invariant under

$SU(2)_R$. Under the custodial $SU(2)_{L+R}$, they transform as $1 \oplus 3 \oplus 5$, with a CP-even neutral scalar as the custodial singlet (thus matching the SM Higgs boson), a CP-odd neutral scalar in the custodial triplet, and another CP-even neutral scalar in the custodial 5-plet.

The scalar components can be decomposed as [370]

$$\Xi = \begin{pmatrix} \chi_3^* & \xi_1 & \chi_1 \\ -\chi_2^* & \xi_2 & \chi_2 \\ \chi_1^* & -\xi_1^* & \chi_3 \end{pmatrix}, \tag{11.52}$$

where ξ_2 is a real scalar and the others are complex scalars. Linear combinations of these account for the neutral custodial singlet, a neutral and singly-charged field making up the custodial triplet, and neutral, singly-charged, and doubly-charged fields making up the custodial 5-plet.

When combined with the usual SM doublet field Φ, the electroweak scale v is now related to the doublet and triplet VEVs by

$$v^2 = v_\Phi^2 + 8v_\Xi^2 \,. \tag{11.53}$$

Note that the GM triplets by themselves are sufficient to explain electroweak symmetry breaking and the existence of a 125 GeV neutral boson along with a custodial triplet of Goldstone bosons; the complex doublet field in the GM model is required to generate fermion masses via the usual dimension four Yukawa couplings. This raises the question of whether one can rule out the possibility that the 125 GeV boson is the neutral member of a custodial 5-plet rather than a custodial singlet, without invoking decays to fermions. A conclusive answer is given by observing that the ratio of the branching fractions to W versus Z bosons is completely determined by the custodial symmetry properties of the boson. For a custodial 5-plet, the ratio of the signal strength to WW over that to ZZ is predicted to be 1/4 that of a SM Higgs boson [369, 371], and thus already ruled out by the experimental results presented in Section VI.

Another interesting general feature of Higgs triplet models is that, after mixing, the SM-like neutral boson can have stronger couplings to WW and ZZ than predicted by the SM [362, 372]; this is in contrast to mixing with additional doublets and singlet, which can only reduce the WW and ZZ couplings versus the SM. This emphasizes that LHC Higgs data cannot extract model independent coupling strengths for the Higgs boson [230, 373].

Because of the built-in custodial symmetry, the triplet VEV in the GM model can be large compared to the doublet VEV. The custodial singlet neutral boson from the triplets mixes with the neutral boson from the doublet. Two interesting special cases are (i) the triplet VEV is small and the 125 GeV boson is SM-like except for small deviations, and (ii) the 125 GeV boson is mostly the custodial singlet neutral boson from the electroweak triplets. The phenomenology of the doubly-charged and singly-charged bosons is similar to that of the HTM. The constraints on the GM model from precision electroweak data, LEP data, and current LHC data are described in Refs. [370, 374–377].

VII.6. Composite Higgs models

Within the SM, EWSB is posited but has no dynamical origin. Furthermore, the Higgs boson appears to be unnaturally light. A scenario that remedies these two catches is to consider the Higgs boson as a bound state of new dynamics becoming strong around the weak scale. The Higgs boson can be made significantly lighter than the other resonances of the strong sector if it appears as a pseudo-Nambu–Goldstone boson, see Refs. [15, 16, 378] for recent reviews.

VII.6.1. Little Higgs models

The idea behind the Little Higgs models [379, 380] is to identify the Higgs doublet as a (pseudo) Nambu–Goldstone boson while keeping some sizable non-derivative interactions, in particular a largish Higgs quartic interaction. By analogy with QCD where the pions $\pi^{\pm,0}$ appear as Nambu–Goldstone bosons associated to the breaking of the chiral symmetry $SU(2)_L \times SU(2)_R/SU(2)$, switching on some interactions that break explicitly the global symmetry will generate masses for the would-be massless Nambu–Goldstone bosons of the order of $g\Lambda_{G/H}/(4\pi)$, where g is the coupling of the symmetry breaking interaction and $\Lambda_{G/H} = 4\pi f_{G/H}$ is the dynamical scale of the global symmetry breaking G/H. In the case of the Higgs boson, the top Yukawa interaction or the gauge interactions themselves will certainly break explicitly (part of) the global symmetry since they act non-linearly on the Higgs boson. Therefore, obtaining a Higgs mass around 100 GeV would demand a dynamical scale $\Lambda_{G/H}$ of the order of 1 TeV, which is known to lead to too large oblique corrections. Raising the strong dynamical scale by at least one order of magnitude requires an additional selection rule to ensure that a Higgs mass is generated at the 2-loop level only

$$m_H^2 = \frac{g^2}{16\pi^2}\Lambda_{G/H}^2 \to m_H^2 = \frac{g_1^2 g_2^2}{(16\pi^2)^2}\Lambda_{G/H}^2 \tag{11.54}$$

The way to enforce this selection rule is through a "collective breaking" of the global symmetry:

$$\mathcal{L} = \mathcal{L}_{G/H} + g_1\mathcal{L}_1 + g_2\mathcal{L}_2. \tag{11.55}$$

Each interaction $\mathcal{L}_1$ or $\mathcal{L}_2$ individually preserves a subset of the global symmetry such that the Higgs remains an exact Nambu–Goldstone boson whenever either g_1 or g_2 is vanishing. A mass term for the Higgs boson can be generated only by diagrams involving simultaneously both interactions. At one-loop, such diagram are not quadratically divergent, so the Higgs mass is not UV sensitive. Explicitly, the cancellation of the SM quadratic divergences is achieved by a set of new particles around the Fermi scale: gauge bosons, vector-like quarks, and extra massive scalars, which are related, by the original global symmetry, to the SM particles with the same spin. Contrary to supersymmetry, the cancellation of the quadratic divergences is achieved by same-spin particles. These new particles, with definite couplings to SM particles as dictated by the global symmetries of the theory, are perfect goals for the LHC.

The simplest incarnation of the collective breaking idea, the so-called littlest Higgs model, is based on a non-linear σ-model describing the spontaneous breaking SU(5) down to SO(5). A subgroup $SU(2)_1 \times U(1)_1 \times SU(2)_2 \times U(1)_2$ is weakly gauged. This model contains a weak doublet, that is identified with the Higgs doublet, and a complex weak triplet whose mass is not protected by collective breaking. Other popular little Higgs models are based on different coset spaces: minimal moose $(SU(3)^2/SU(3))$ [381], the simplest little Higgs $(SU(3)^2/SU(2)^2)$ [382], the bestest little Higgs $(SO(6)^2/SO(6))$ [383] *etc.* For comprehensive reviews, see Refs. [384, 385].

Generically, oblique corrections in Little Higgs models are reduced either by increasing the coupling of one of the gauge groups (in the case of product group models) or by increasing the masses of the W and Z partners, leading ultimately to a fine-tuning of the order of a few percents (see for instance Ref. [386] and references therein). The compatibility of Little Higgs models with experimental data is significantly improved when the global symmetry involves a custodial symmetry as well as a T-parity [387] under which, in analogy with R-parity in SUSY models, the SM particles are even and their partners are odd. Such Little Higgs models would therefore appear in colliders as jet(s) with missing transverse energy [388] and the ATLAS and CMS searches for squarks and gluinos [389] can be recast to obtain limits on the masses of the heavy vector-like quarks. The T-even top partner, with an expected mass below 1 TeV to cancel the top loop quadratic divergence without too much fine-tuning, would decay dominantly into a $t + Z$ pair or into a $b + W$ pair or even into $t + H$. The latest CMS and ATLAS direct searches [390] for vector-like top partners put a lower bound around 700 GeV on their mass, excluding the most natural region of the parameter space of these models, i.e., there is still fine-tuning at the per cent level.

The motivation for Little Higgs models is to solve the little hierarchy problem, i.e., to push the need for new physics (responsible for the stability of the weak scale) up to around 10 TeV. Per se, Little Higgs models are effective theories valid up to their cutoff scale $\Lambda_{G/H}$. Their UV completions could either be weakly or strongly coupled.

Table 11.18: Global symmetry breaking patterns and the corresponding Goldstone boson contents of the SM, the minimal composite Higgs model, the next to minimal composite Higgs model, and the minimal composite two Higgs doublet model. Note that the SU(3) model does not have a custodial invariance. a denotes a CP-odd scalar while h and H are CP-even scalars.

Model	Symmetry Pattern	Goldstone's
SM	SO(4)/SO(3)	W_L, Z_L
–	SU(3)/SU(2)×U(1)	W_L, Z_L, H
MCHM	SO(5)/SO(4)	W_L, Z_L, H
NMCHM	SO(6)/SO(5)	W_L, Z_L, H, a
MC2HM	SO(6)/SO(4)×SO(2)	$W_L, Z_L, h, H, H^\pm, a$

VII.6.2. Models of partial compositeness

The Higgs boson is a special object. Even in composite models, it cannot appear as a regular resonance of the strong sector without endangering the viability of the setup when confronted to data. The way out is that the Higgs appears as a pseudo Nambu–Goldstone boson: the new strongly coupled sector is supposed to be invariant under a global symmetry G spontaneously broken to a subgroup H at the scale f. To avoid conflict with EW precision measurements, it is better if the strong interactions themselves do not break the EW symmetry, hence the SM gauge symmetry itself should be contained in H. See Table 11.18 for a few examples of coset spaces.

The SM (light) fermions and gauge bosons cannot be part of the strong sector itself since LEP data have already put stringent bounds on the compositeness scale of these particles far above the TeV scale. The gauge bosons couple to the strong sector by a weak gauging of an SU(2)×U(1) subgroup of the global symmetry G. Inspiration for the construction of such models comes from the AdS/CFT correspondence: the components of a gauge field along extra warped space dimension can be interpreted as the Goldstone boson resulting from the breaking of global symmetry of the strong sector. The couplings of the SM fermions to the strong sector could a priori take two different forms: (i) a bilinear coupling of two SM fermions to a composite scalar operator, $\mathcal{O}$, of the form $\mathcal{L} = y\,\bar{q}_L u_R \mathcal{O} + \text{hc}$ in simple analogy with the SM Yukawa interactions. This is the way fermion masses were introduced in Technicolor theories and it generically comes with severe flavor problems and calls for extended model building gymnastics [391] to circumvent them; (ii) a linear mass mixing with fermionic vector-like operators: $\mathcal{L} = \lambda_L\,\bar{q}_L \mathcal{Q}_R + \lambda_R \bar{\mathcal{U}}_L u_R$. $\mathcal{Q}$ and $\mathcal{U}$ are two fermionic composite operators of mass M_Q and M_U. Being part of the composite sector, they can have a direct coupling of generic order Y_* to the Higgs boson. In analogy with the photon-ρ mixing in QCD, once the linear mixings are diagonalized, the physical states are a linear combination of elementary and composite fields. Effective Yukawa couplings are generated and read for instance for the up-type quark

$$y = Y_* \sin\theta_L \sin\theta_R \tag{11.56}$$

where $\sin\theta_i = \lambda_i/\sqrt{M_U^2+\lambda_i^2}$, $i = L, R$, measure the amount of compositeness of the SM left- and right-handed up-type quark. If the strong sector is flavor-anarchic, i.e., if the couplings of the Higgs to the composite fermions does not exhibit any particular flavor structure, the relation Eq. (11.56) implies that the light fermions are mostly elementary states ($\sin\theta_i \ll 1$), while the third generation quarks need to have a sizable degree of compositeness. The partial compositeness paradigm offers an appealing dynamical explanation of the hierarchies in the fermion masses. In fact, assuming the strong sector to be almost conformal above the confinement scale, the low-energy values of the mass-mixing parameters $\lambda_{L,R}$ are determined by the (constant) anomalous dimension of the composite operator they mix with. If the UV scale at which the linear mixings are generated is large, then $\mathcal{O}(1)$ differences in the anomalous dimensions can generate naturally large hierarchies in the fermion masses via renormalization group running [392]. While the introduction of partial compositeness greatly ameliorated the flavor problem of the original composite Higgs models, nevertheless it did not solve the issue completely, at least in the case where the strong sector is assumed to be flavor-anarchic [393]. While the partial compositeness set-up naturally emerges in models built in space-times with extra dimensions, no fully realistic microscopic realization of partial compositeness has been proposed in the literature.

Another nice aspect of the partial compositeness structure is the dynamical generation of the Higgs potential. The Higgs being a pseudo-Nambu–Goldstone boson, its mass does not receive any contribution from the strong sector itself but it is generated at the one-loop level via the couplings of the SM particles to the strong sector since these interactions are breaking the global symmetries under which the Higgs doublet transforms non-linearly. The leading contribution to the potential arises from top loops and it takes the form

$$V(H) = m_\rho^4 \frac{\sin\theta_{tL}\sin\theta_{tR}}{16\pi^2}\left(\alpha\cos(H/f) + \beta\sin^2(H/f) + \gamma\sin^4(H/f)\right), \tag{11.57}$$

where α, β, γ are numbers of order 1 subject to selection rules following the transformation properties of the top quark under the global symmetries of the strong sector[10], and $m_\rho \approx g_\rho f$ is the typical mass scale of the strong sector resonances. The gauge contribution to the potential takes the form (g denotes the SU(2) gauge coupling)

$$m_\rho^4 \frac{g^2/g_\rho^2}{16\pi^2}\sin^2(H/f), \tag{11.58}$$

which is parametrically suppressed with respect to the top contribution by $g^2/(g_\rho y_t)$. The gauge term is always positive, and cannot trigger EWSB by itself. When $\alpha = 0$, the minimization condition of the potential simply reads

$$\sin^2\frac{\langle H\rangle}{f} = -\frac{\beta}{2\gamma}, \tag{11.59}$$

which implies that the natural expectation is that the scale f is generically of the order of the weak scale. Obtaining $v \ll f$, as required phenomenologically, requires some degree of tuning, which scales like $\xi \equiv v^2/f^2$. A mild tuning of the order of 10% ($\xi \approx 0.1$) is typically enough to comply with electroweak precision constraints. This is an important point: in partial compositeness models, the entire Higgs potential is generated at one loop, therefore the separation between v and f can only be obtained at a price of a tuning. This marks a difference with respect to the Little Higgs models, which realize a parametric hierarchy between the quartic and mass terms through the collective symmetry breaking mechanism. In fact in Little Higgs models, the quartic coupling is a tree-level effect, leading to a potential

$$V(H) \approx \frac{g_{\rm SM}^2}{16\pi^2} m_\rho^2 H^2 + g_{\rm SM}^2 H^4, \tag{11.60}$$

where $g_{\rm SM}$ generically denotes the SM couplings. The minimization condition now reads $v^2/f^2 \sim g_\rho^2/(16\pi^2)$, therefore v is formally loop suppressed with respect to f. This is the major achievement of the Little Higgs constructions, which however comes at the price of the presence of sub-TeV vectors carrying EW quantum numbers and therefore giving rise generically to large oblique corrections to the propagators of the W and the Z gauge bosons.

After minimization, the potential Eq. (11.57) leads to an estimate of the Higgs mass as

$$m_H^2 \approx g_\rho^3\, y_t 2\pi^2 v^2. \tag{11.61}$$

It follows that the limit $f \to \infty$, i.e. $\xi \to 0$, is a true decoupling limit: all the resonances of the strong sector become heavy but the Higgs whose mass is protected by the symmetries of the coset G/H. When compared to the experimentally measured Higgs mass, this estimate puts an upper bound on the strength of the strong

[10] For instance in the SO(5)/SO(4) composite models, when the top quark is embedded into a spinorial representation of SO(5), then $\gamma = 0$ and when it is part of a **5**, **10** or **14** representation, $\alpha = 0$ as it can be inferred by looking at the structure of the H-dependent invariants built out of these representations [394]. The coefficient γ also generically comes with an extra power of the top compositeness fractions.

interactions: $g_\rho \lesssim 2$. In this limit of not so large coupling, the Higgs potential receives additional contributions. In particular, the fermionic resonances in the top sector which follow from the global symmetry structure of the new physics sector can help raising the Higgs mass. For instance in the minimal SO(5)/SO(4) model, using some dispersion relation techniques, one obtains [395]

$$m_H^2 \approx \frac{6}{\pi^2}\frac{m_t^2}{f^2}\frac{m_{Q_4}^2 m_{Q_1}^2}{m_{Q_1}^2 - m_{Q_4}^2}\log\left(\frac{m_{Q_1}}{m_{Q_4}}\right) \tag{11.62}$$

where Q_4 and Q_1 are fermionic color resonances transforming as a weak bi-doublet of hypercharge $Y = 1/6$ and $Y = 7/6$ and a weak singlet with hypercharge $Y = -1/3$. Therefore a 125 GeV mass can be obtained if at least one of the fermionic resonances is lighter than $\sim 1.4\, f$. As in supersymmetric scenarios, the top sector is playing a crucial role in the dynamics of EWSB and can provide the first direct signs of new physics. The direct searches for these top partners, in particular the ones with exotic electric charges 5/3, are already exploring the natural parameter spaces of these models [390, 396, 397].

The main physics properties of a pseudo Nambu–Goldstone Higgs boson can be captured in a model-independent way by a few number of higher-dimensional operators. Indeed, the strong dynamics at the origin of the composite Higgs singles out a few operators among the complete list presented earlier in Section VI: these are the operators that involve extra powers of the Higgs doublets and they are therefore generically suppressed by a factor $1/f^2$ as opposed to the operators that involve extra derivatives or gauge bosons and are suppressed by a factor $1/(g_\rho^2 f^2)$. The relevant effective Lagrangian describing a strongly interacting light Higgs is:

$$\begin{aligned}\mathcal{L}_{\rm SILH} =& \frac{c_H}{2f^2}\left(\partial_\mu\left(\Phi^\dagger\Phi\right)\right)^2 + \frac{c_T}{2f^2}\left(\Phi^\dagger \overleftrightarrow{D}^\mu \Phi\right)^2 - \frac{c_6\lambda}{f^2}\left(\Phi^\dagger\Phi\right)^3 \\ &+ \left(\sum_f \frac{c_f\, y_f}{f^2}\Phi^\dagger\Phi\bar{f}_L\Phi f_R + \text{h.c.}\right).\end{aligned} \tag{11.63}$$

Typically, these new interactions induce deviations in the Higgs couplings that scale like $\mathcal{O}(v^2/f^2)$, hence the measurements of the Higgs couplings can be translated into some constraints on the compositeness scale, $4\pi f$, of the Higgs boson. The peculiarity of these composite models is that, due to the Goldstone nature of the Higgs boson, the direct couplings to photons and gluons are further suppressed and generically the coupling modifiers defined in Section VI scale like

$$\begin{aligned}\kappa_{W,Z,f} &\sim 1 + \mathcal{O}\left(\frac{v^2}{f^2}\right), \\ \kappa_{Z\gamma} &\sim \mathcal{O}\left(\frac{v^2}{f^2}\right), \\ \kappa_{\gamma,g} &\sim \mathcal{O}\left(\frac{v^2}{f^2}\times\frac{y_t^2}{g_\rho^2}\right),\end{aligned} \tag{11.64}$$

where g_ρ denotes the typical coupling strength among the states of the strongly coupled sector and y_t is the top Yukawa coupling, the largest interaction that breaks the Goldstone symmetry. The $\kappa_{Z\gamma,\gamma,g}$ coupling modifiers are not generated by the strong coupling operators of Eq. (11.63) but some subleading form-factor operator generated by loops of heavy resonances of the strong sector. The coupling modifiers also receive additional contributions from the other resonances of the strong sector, in particular the fermionic resonances of the top sector that are required to be light to generate a 125 GeV Higgs mass. Some indirect information on the resonance spectrum could thus be inferred by a precise measurement of the Higgs coupling deviations. However, it was realized [398] that the task is actually complicated by the fact that, in the minimal models, these top partners give a contribution to both κ_t (resulting from a modification of the top Yukawa coupling) and κ_γ and κ_g (resulting from new heavy particles running into the loops) and the structure of interactions are such that the net effect vanishes for inclusive quantities like $\sigma(gg \to H)$ or $\Gamma(H \to \gamma\gamma)$ as a consequence of the Higgs low energy theorem [24, 25, 231]. So one would need to rely on differential distribution, like the Higgs p_T distribution [399], to *see* the top partner effects in Higgs data [400]. The off-shell channel $gg \to h^* \to 4\ell$ [401] and the double Higgs production $gg \to hh$ [402] can also help to resolve the gluon loop and separate the top and top-partner contributions.

VII.6.3. Minimal composite Higgs models

The minimal composite Higgs models (MCHM) are concrete examples of the partial compositeness paradigm. The Higgs doublet is described by the coset space SO(5)/SO(4) where a subgroup $\mathrm{SU}(2)_L \times \mathrm{U}(1)_Y$ is weakly gauged under which the four Goldstone bosons transform as a doublet of hypercharge 1. There is some freedom on how the global symmetry is acting on the SM fermions: in MCHM4 [394] the quarks and leptons are embedded into spinorial representations of SO(5), while in MHCM5 [403] they are part of fundamental representations (it might also be interesting phenomenologically to consider larger representations like MCHM14 [404] with the SM fermions inside a representation of dimension 14). The non-linearly realized symmetry acting on the Goldstone bosons leads to general predictions of the coupling of the Higgs boson to the EW gauge bosons. For instance, it can be shown that the quadratic terms in the W and Z bosons read

$$m_W^2(H)\left(W_\mu W^\mu + \frac{1}{2\cos^2\theta_W}Z_\mu Z^\mu\right)$$

with $m_W(H) = \dfrac{gf}{2}\sin\dfrac{H}{f}$. Expanding around the EW vacuum, the expression of the weak scale is:

$$v = f\sin(\langle H\rangle/f), \tag{11.65}$$

and the values of the modified Higgs couplings to the W and Z:

$$g_{HVV} = \frac{2m_V^2}{v}\sqrt{1 - v^2/f^2}\,, \quad g_{HHVV} = \frac{2m_V^2}{v^2}(1 - 2v^2/f^2)\,. \tag{11.66}$$

Note that the Higgs couplings to gauge bosons is always suppressed compared to the SM prediction. This is a general result [405] that holds as long as the coset space is compact.

The Higgs couplings to the fermions depend on the representation which the SM fermions are embedded into. For the most commonly used embeddings, they take the following forms

$$\begin{aligned}&\text{MCHM4}: g_{Hff} = \frac{m_f}{v}\sqrt{1 - v^2/f^2}\,, \\ &\text{MCHM5}: g_{Hff} = \frac{m_f}{v}\frac{1 - 2v^2/f^2}{\sqrt{1 - v^2/f^2}}\,, \\ &\text{MCHM14}: g_{Hff} = \frac{m_f}{v}\left(1 + A(M_{1,4,9})\frac{v^2}{f^2} + O(v^4/f^4)\right), \\ &\qquad\text{with } A(M_{1,4,9}) = \frac{3M_1M_4 - 11M_1M_9 + 8M_4M_9}{2M_9(M_1 - M_4)}\,.\end{aligned} \tag{11.67}$$

While, in MHCM4 and MCHM5, the modifications of the couplings depend only on the Higgs compositeness scale, in MCHM14 the leading corrections depend also on the mass spectrum of the resonances parametrized by M_1, M_4 and M_9 [404]. This is due to the fact that more than one SO(5) invariant gives rise to SM fermion masses. The (κ_V, κ_f) experimental fit of the Higgs couplings can be used to derive a lower bound on the Higgs compositeness scale $4\pi f \gtrsim 9$ TeV, which is less stringent than the indirect bound obtained from EW precision data, $4\pi f \gtrsim 15$ TeV [406] but more robust and less subject on assumptions [407].

VII.6.4. Twin Higgs models

In all composite models presented above, the particles responsible for canceling the quadratic divergences in the Higgs mass are charged under the SM gauge symmetries. In particular, the top partner carries color charge, implying a reasonably large minimal production cross section at the LHC. An alternative scenario, which is experimentally quite challenging and might explain the null result in various new physics searches, is the case nowadays referred to

as "neutral naturalness" [20, 21], where the particles canceling the 1-loop quadratic divergences are neutral under the SM. The canonical example for such theories is the Twin Higgs model of [20]. This is an example of a pseudo-Goldstone boson Higgs theory, with an approximate global $SU(4)$ symmetry broken to $SU(3)$. The Twin Higgs model is obtained by gauging the $SU(2)_A \times SU(2)_B$ subgroup of $SU(4)$, where $SU(2)_A$ is identified with the SM $SU(2)_L$, while $SU(2)_B$ is the twin $SU(2)$ group. Gauging this subgroup breaks the $SU(4)$ symmetry explicitly, but quadratically divergent corrections given do not involve the Higgs boson when the gauge couplings of the two SU(2) subgroups are equal, $g_A = g_B$. The $SU(4) \to SU(3)$ breaking will also result in the breaking of the twin $SU(2)_B$ group and as a result three of the seven Goldstone bosons will be eaten, leaving 4 Goldstone bosons corresponding to the SM Higgs doublet h. In fact imposing the Z_2 symmetry on the full model will ensure the cancellation of all 1-loop quadratic divergences to the Higgs mass. Logarithmically divergent terms can however arise for example from gauge loops, leading to a Higgs mass of order $g^2 f/4\pi$, which is of the order of the physical Higgs mass for $f \sim 1\,\text{TeV}$. The quadratic divergences from the top sector can be eliminated if the Z_2 protecting the Higgs mass remains unbroken by the couplings that result in the top Yukawa coupling. This can be achieved by introducing top partners charged under a twin $SU(3)_c$. In this case the quadratic divergences are cancelled by top partners that are neutral under the SM gauge symmetries.

Twin Higgs models are low-energy effective theories valid up to a cutoff scale of order $\Lambda \sim 4\pi f \sim$ 5–10 TeV, beyond which a UV completion has to be specified. The simplest such possibility is to also make the Higgs composite, and UV complete the twin-Higgs model via gauge and top partners at masses of the order of a few TeV. A concrete implementation is the holographic twin Higgs model [408], which also incorporates a custodial symmetry to protect the T-parameter from large corrections. It is based on a warped extra dimensional theory with a bulk SO(8) gauge group, which incorporates the $SU(4)$ global symmetry discussed above enlarged to contain the $\text{SU}(2)_L \times \text{SU}(2)_R$ custodial symmetry. In addition the bulk contains either a full $SU(7)$ group or an $SU(3) \times SU(3) \times U(1) \times U(1) \times Z_2$ subgroup of it to incorporate QCD, its twin, and hypercharge. The breaking on the UV brane is to the SM and the twin SM symmetries, while on the IR brane $SO(8) \to SO(7)$, giving rise to the 7 Goldstone bosons, three of which will be again eaten by the twin W, Z. The main difference compared to ordinary composite Higgs models is that in composite twin Higgs models the cancellation of the one-loop quadratic divergences is achieved by the twin partners of order 700 GeV– 1 TeV, which are uncharged under the SM gauge group. This allows the IR scale of the warped extra dimension to be raised to the multi-TeV range without reintroducing the hierarchy problem. The role of the composite partners is to UV complete the theory, rather than the cancellation of the one-loop quadratic divergences. For more details about the composite twin Higgs models, see Refs. [409].

VII.7. The Higgs boson as a dilaton

The possibility that the new particle H^0 discovered at the LHC is in fact the Goldstone boson associated to the spontaneous breaking of scale invariance at a scale f attracted some attention [18, 19] but is now challenged by the fact that all its properties are in good agreement with those predicted for the SM Higgs. And this scenario now requires rather involved model-building engineering. The first issue is the fact that the observed scalar couplings are close to their SM values. In a generic theory of spontaneously broken scale invariance, order one shifts are possible, and indeed expected in most models. Also, the apparent hierarchy between the light scalar and the cutoff of the dilaton effective theory is not reconcilable with the general walking technicolor (or Higgsless) type scenario unless a tuning is imposed.

The general couplings of a wide class of dilaton models are given (at leading order in a low-energy theorem limit for dilatons) by

$$\mathcal{L}_{dilaton} = \frac{\sigma}{f}\left[2M_W^2 W_\mu^{\pm} W^{\pm\mu} + M_Z^2 Z_\mu Z^\mu + \sum_{ij}\sqrt{m_f^i m_f^j}\,\Gamma^{ij}\bar{\psi}^i\psi^j\right] + \frac{\sigma}{f}\left[\frac{2}{e}\Delta\beta^{\text{em}}F_{\mu\nu}^2 + \frac{2}{g_3}\Delta\beta^{\text{QCD}}G_{\mu\nu}^{a\ 2}\right] \tag{11.68}$$

where Γ^{ij} is a matrix that depends upon anomalous dimensions of operators in the conformal theory that give rise to fermion masses, and the terms $\Delta\beta$ are the differences in the beta functions of electromagnetism or QCD at scales above and below the scale at which conformal symmetry is spontaneously broken. The SM low energy theorem limit for the SM Higgs is obtained from this expression by taking

$$f = v, \quad \Gamma^{ij} = I_{3\times 3}, \quad \Delta\beta^{em} = \beta_{top}^{em} + \beta_W^{em}, \quad \Delta\beta^{\text{QCD}} = \beta_{top}^{\text{QCD}}. \tag{11.69}$$

It is unclear why these relations should be approximately realized in a generic conformal field theory, as must be the case to be consistent with current data and allow for a scalar with mass of about 125 GeV. For example, in warped models of electroweak symmetry breaking (AdS/CFT duals to theories with spontaneously approximate broken conformal invariance), the ratio v/f is a function of the geometry, and is suppressed when the 5D theory is perturbative, contrary to the experimental result that the v/f ratio should be close to 1, implying that the underlying CFT may not be a large N CFT.

An additional complication is that the mass of the dilaton is expected to be, along with many other resonances, around the cutoff scale of the strongly interacting theory responsible for breaking the scale invariance spontaneously. Suppression of the dilation mass either requires a tuning of order $v^2/\Lambda^2 \sim$ percent, or a very special conformal dynamics where the beta function of the interaction leading to the scale invariance breaking remains small over a large region of couplings [410].

VII.8. Searches for signatures of extended Higgs sectors

The measurements described in Section III have established the existence of one state of the electroweak symmetry breaking sector, compatible with a SM Higgs boson, but not that it is the only one.

Various classes of models beyond the SM discussed above require extended Higgs sectors. These models, and in particular the MSSM and the NMSSM serve as guiding principle of the experimental searches for additional scalar states beyond the SM. However these searches are made as model-independent as possible and can be summarized in the following classes: (i) the search for an additional CP-even state mostly in the high mass domain decaying to vector bosons, which would correspond to the heavy CP-even state in a generic 2HDM where the light state would be the discovered H or a generic additional singlet; (ii) the search for a state in the high mass domain decaying to pairs of fermions, which would correspond a CP-odd A and the heavy CP-even state H in a generic 2HDM; (iii) the search for charged Higgs bosons, which also appear in generic 2HDMs; (iv) the search for a CP-odd state a in the low mass region which appears in the NMSSM; and (v) doubly charged Higgs which are motivated in extensions of the Higgs sector with triplets.

(i) Searches for an additional CP-even state

(a) Exclusion limits from LEP

The LEP searches for the SM Higgs boson put a lower limit of 114 GeV on its mass, but also have relevance for non-SM Higgs bosons. These searches were also interpreted as 95% CL upper bounds on the ratio of the coupling g_{HZZ} to its SM prediction as a function of the Higgs boson mass [125]. Among the MSSM new benchmarks, the low-m_H is one example which is disfavored by these searches at low mass, and nearly ruled out by current direct constraints and charged Higgs limits from LHC. Another example is the light CP-even Higgs boson of the NMSSM which is constrained to project predominantly onto the EW singlet component. An additional motivation for these

Table 11.19: Summary of references to searches for additional states from extended Higgs sectors, where (BBr) denotes the BaBar experiment, (TeV) the Tevatron experiments.

scenarios is given by the slight excess observed at LEP [125] at a Higgs boson mass hypothesis of approximately 98 GeV. The light CP-even Higgs boson h was also searched for in association with the CP-odd A, these searches are described in Section III.

(b) Searches at the LHC

The searches for the SM Higgs boson before the discovery covered a wide range of mass hypotheses. Until recently the range of investigation at LHC was from 100 GeV to 600 GeV. It has been extended to masses of up to 1 TeV. At the Tevatron this mass range was limited to up to 200 GeV. Since the discovery, the SM Higgs boson searches are reappraised to search for a heavy CP-even state. This state could be the heavy CP-even Higgs boson of a 2HDM, or a generic additional singlet. In both cases the natural width of the additional H state can be very different from that of the SM Higgs boson. To preserve unitarity of the longitudinal vector boson scattering and the longitudinal vector boson scattering into fermion pairs, the couplings of the additional CP-even Higgs boson to gauge bosons and fermions should not be too large and should constrain the natural width to be smaller than that of a unique Higgs boson at high mass with couplings to fermions and gauge bosons as predicted by the SM (and provided that trilinear and quartic couplings are not too large and that no new state affects the heavy state total width). It is therefore reasonable to consider total widths for the high mass CP-even state smaller than the equivalent SM width. For the sake of generality these searches should be done as a function of Higgs boson mass and total width. Until recently only two cases have been investigated: (i) the SM width using the complex pole scheme (CPS), and (ii) the narrow width approximation.

Searches for the Higgs boson in the $H \to \gamma\gamma$, $H \to Z\gamma$, $H \to W^{(*)}W^{(*)}$ in the $\ell\nu\ell\nu$ and $\ell\nu q\overline{q}$ channels, and the $H \to Z^{(*)}Z^{(*)}$ searches in the 4ℓ, $\ell\ell q\overline{q}$ and $\ell\ell\nu\nu$ channels have also been done, but in most cases are simple reinterpretations of the SM Higgs search in the CPS scheme. Recent references are summarized in Table 11.19.

(d) Searches for an additional resonance decaying to a pair of h

In addition to the rare and expected Higgs pair production mode, high mass CP-even Higgs bosons can be searched for in the resonant double Higgs mode. Searches for such processes, where the Higgs boson is used as a tool for searches for new phenomena beyond the SM, have been carried out in four distinct modes depending on the subsequent decays of each Higgs boson. The ATLAS and CMS Collaborations have searched for the $H \to hh \to b\overline{b}\tau\tau$ [411, 412] and $b\overline{b}\gamma\gamma$ [413, 412] final states. The ATLAS Collaboration has also searched for the $H \to hh \to 4b$ and $\gamma\gamma WW^*$ final states [412]. For masses hypotheses of an additional Higgs boson below 500 GeV, the two dominant search channels are the $b\overline{b}\gamma\gamma$ and the $b\overline{b}\tau\tau$. For masses above 500 GeV, the most powerful search channel is the $4b$ final state. The ATLAS Collaboration has also performed a combination of these search results assuming that the Higgs boson has standard decay rates [412].

(d) Searches for an additional state with the presence of h

In the post-discovery era, analyses in general need to take into account the presence of the newly discovered state. For searches with sufficiently high resolution of additional states non degenerate in mass, the strength of the observed state and limits on the signal strength of a potential additional state can be set independently, as discussed in the next section. However in some cases, such as when a channel does not have a sufficiently fine mass resolution or when the states are nearly degenerate in mass, specific analyses need to be designed. There are two examples of such analyses: (i) the search for an additional state in the $H \to W^{(*)}W^{(*)} \to \ell\nu\ell\nu$ channel in ATLAS and (ii) the search for nearly degenerate states in the $H \to \gamma\gamma$ channel with the CMS detector.

The search in the $H \to W^{(*)}W^{(*)} \to \ell\nu\ell\nu$ channel, for an additional state is done using a boosted decision tree combining several discriminating kinematic characteristics to separate the signal from the background and a high mass signal H from the lower mass state h [414]. A simultaneous fit of the two states h and H is then made to test the presence of an additional state. In this case, the usual null hypothesis of background includes including the SM signal.

The CMS search for nearly degenerate mass states decaying to a pair of photons [415] is more generic and could for instance apply to CP-odd Higgs bosons as well. It consists of a fit to the diphoton mass spectrum using two nearly degenerate mass templates.

(e) Type I 2HDM and fermiophobia

The measurements of coupling properties of H indirectly exclude that the discovered state is fermiophobic. However, the presence of an additional fermiophobic state, as predicted by Type I 2HDMs, is not excluded. Prior to the discovery, ATLAS and CMS have performed searches for a fermiophobic Higgs boson, *i.e.* produced through couplings with vector bosons only (VBF and VH) and decaying in $h_f \to \gamma\gamma$, optimized for fermiophobic signatures in the diphoton channel [416, 417]. CMS has further combined these results with searches for $h_f \to W^+W^-$ and $h_f \to ZZ$ assuming fermiophobic production and decay [418]. CMS excludes a fermiophobic Higgs boson in the range $110\,\text{GeV} < m_H < 188\,\text{GeV}$ at the 95% C.L.

(f) Interpretation benchmarks in the light of the discovered Higgs boson

Two specific benchmark scenarios driven by unitarity relations are proposed in Ref. [44], assuming the existence of an additional state h' with coupling scale factors, i.e., deviations from the couplings predicted for the SM Higgs at the same mass, denoted κ'_V and κ'_F for the couplings of h' to vector bosons and fermions respectively. The gauge boson scattering unitarity then yields the following sum rule

$$\kappa_V^2 + \kappa_V'^2 = 1 \tag{11.70}$$

and the unitarization of the gauge boson scattering to fermions yields

$$\kappa_V \cdot \kappa_F + \kappa'_V \cdot \kappa'_F = 1 \qquad (11.71)$$

The two benchmark scenarios are then defined as follows: (i) a single coupling scale factor is assumed for the gauge bosons and the fermions, with an additional parameter to take into account decays to new states; (ii) two parameters are used to describe independently the couplings to fermions and the couplings to vector bosons. A direct application of the latter can be done in the CP-even sector of the type-I 2HDM.

(ii) Searches for additional neutral states ($\phi \equiv h$, H, A) decaying to fermions

(a) Exclusion limits from LEP

In e^+e^- collisions at LEP centre-of-mass energies, the main production mechanisms of the neutral MSSM Higgs bosons were the Higgs-strahlung processes $e^+e^- \to hZ$, HZ and the pair production processes $e^+e^- \to hA$, HA, while the vector boson fusion processes played a marginal role. Higgs boson decays to $b\bar{b}$ and $\tau^+\tau^-$ were used in these searches.

The searches and limits from the four LEP experiments are described in Refs. [419, 420]. The combined LEP data did not contain any excess of events which would imply the production of a Higgs boson, and combined limits were derived [421]. For $m_A \gg M_Z$ the limit on m_h is nearly that of the SM searches, as $\sin^2(\beta-\alpha) \approx 1$. For high values of $\tan\beta$ and low m_A ($m_A \leq m_h^{max}$), the $e^+e^- \to hA$ searches become the most important, and the lightest Higgs h is non SM-like. In this region, the 95% CL mass bounds are $m_h > 92.8\,\text{GeV}$ and $m_A > 93.4\,\text{GeV}$. In the m_h-max. scenario, values of $\tan\beta$ from 0.7 to 2.0 are excluded taking $m_t = 174.3\,\text{GeV}$, while a much larger $\tan\beta$ region is excluded for other benchmark scenarios such as the no-mixing one.

A flavor-independent limit for Higgs bosons in the Higgs-strahlung process at LEP has also been set at 112 GeV [422].

Neutral Higgs bosons may also be produced by Yukawa processes $e^+e^- \to f\overline{f}\phi$, where the Higgs particle $\phi \equiv h$, H, A, is radiated off a massive fermion ($f \equiv b$ or $\tau^\pm$). These processes can be dominant at low masses, and whenever the $e^+e^- \to h\text{Z}$ and hA processes are suppressed. The corresponding ratios of the $f\overline{f}h$ and $f\overline{f}A$ couplings to the SM coupling are $\sin\alpha/\cos\beta$ and $\tan\beta$, respectively. The LEP data have been used to search for $b\overline{b}\,b\overline{b}$, $b\overline{b}\tau^+\tau^-$, and $\tau^+\tau^-\,\tau^+\tau^-$ final states [423, 424]. Regions of low mass and high enhancement factors are excluded by these searches.

The searches for the Higgs boson at LEP also included the case where it does not predominantly decay to a pair of b quarks. All four collaborations conducted dedicated searches for the Higgs boson with reduced model dependence, assuming it is produced via the Higgs-strahlung process, and not addressing its flavor of decay, a lower limit on the Higgs mass of 112.9 GeV is set by combining the data of all four experiments [422].

Using an effective Lagrangian approach and combining results sensitive to the $h\gamma\gamma$, $hZ\gamma$ and hZZ couplings, an interpretation of several searches for the Higgs boson was made and set a lower limit of 106.7 GeV on the mass of a Higgs boson that can couple anomalously to photons [422].

(b) Searches at the Tevatron and LHC

The best sensitivity is in the regime with low to moderate m_A and with large $\tan\beta$ which enhances the couplings of the Higgs bosons to down-type fermions. The corresponding limits on the Higgs boson production cross section times the branching ratio of the Higgs boson into down-type fermions can be interpreted in MSSM benchmark scenarios [259]. If $\phi = A, H$ for $m_A > m_h^{\text{max}}$, and $\phi = A, h$ for $m_A < m_h^{\text{max}}$, the most promising channels at the Tevatron are the inclusive $p\overline{p} \to \phi \to \tau^+\tau^-$ process, with contributions from both $gg \to \phi$ and $b\bar{b}\phi$ production, and $b\bar{b}\phi, \phi \to \tau^+\tau^-$ or $\phi \to b\bar{b}$, with $b\tau\tau$ or three tagged b-jets in the final state, respectively. Although Higgs boson production via gluon fusion has a higher cross section in general than via associated production, it cannot be used to study the $\phi \to b\overline{b}$ decay mode since the signal is overwhelmed by the QCD background.

The CDF and D0 collaborations have searched for neutral Higgs bosons produced in association with bottom quarks and which decay into $b\overline{b}$ [425, 426], or into $\tau^+\tau^-$ [427,428]. The most recent searches in the $b\overline{b}\phi$ channel with $\phi \to b\overline{b}$ analyze approximately $2.6\,\text{fb}^{-1}$ of data (CDF) and $5.2\,\text{fb}^{-1}$ (D0), seeking events with at least three b-tagged jets. The cross section is defined such that at least one b quark not from ϕ decay is required to have $p_T > 20\,\text{GeV}$ and $|\eta| < 5$. The invariant mass of the two leading jets as well as b-tagging variables are used to discriminate the signal from the backgrounds. The QCD background rates and shapes are inferred from data control samples, in particular, the sample with two b-tagged jets and a third, untagged jet. Separate-signal hypotheses are tested and limits are placed on $\sigma(p\overline{p} \to b\overline{b}\phi) \times \text{BR}(\phi \to b\bar{b})$. A local excess of approximately 2.5σ significance has been observed in the mass range of 130–160 GeV, but D0's search is more sensitive and sets stronger limits. The D0 result had an $\mathcal{O}(2\sigma)$ local upward fluctuation in the 110 to 125 GeV mass range. These results have been superseded by the LHC searches and the excess seen in the D0 experiment has not been confirmed elsewhere.

ATLAS and CMS also search for $\phi \to \tau^+\tau^-$ in pp collisions at $\sqrt{s} = 7\,\text{TeV}$. ATLAS seeks tau pairs in 4.7–4.8 fb^{-1} of data [429], and the search by CMS uses the full $4.9\,\text{fb}^{-1}$ of 7 TeV data $4.9\,\text{fb}^{-1}$ of 8 TeV data [430] and bb [431]. The searches are performed in categories of the decays of the two tau leptons: $e\tau_{\text{had}}$, $\mu\tau_{\text{had}}$, $e\mu$, and $\mu\mu$, where τ_{had} denotes a tau lepton which decays to one or more hadrons plus a tau neutrino, e denotes $\tau \to e\nu\nu$, and μ denotes $\tau \to \mu\nu\nu$. The dominant background comes from $Z \to \tau^+\tau^-$ decays, although $t\overline{t}$, W+jets and Z+jets events contribute as well. Separating events into categories based on the number of b-tagged jets improves the sensitivity in the MSSM. The $b\bar{b}$ annihilation process and radiation of a Higgs boson from a b quark gives rise to events in which the Higgs boson is accompanied by a $b\bar{b}$ pair in the final state. Requiring the presence of one or more b jets reduces the background from Z+jets. Data control samples are used to constrain background rates. The rates for jets to be identified as a hadronically decaying tau lepton are measured in dijet samples, and W+jets samples provide a measurement of the rate of events that, with a fake hadronic tau, can pass the signal selection requirements. Lepton fake rates are measured using samples of isolated lepton candidates and same-sign lepton candidates. Constraints from the CMS searches for $h \to \tau^+\tau^-$ and $h \to b\overline{b}$ are shown in Fig. 11.25 in the m_h-mod+ scenario defined in [258] and in the hMSSM approximation defined in [307] . The neutral Higgs boson searches consider the contributions of both the CP-odd and CP-even neutral Higgs bosons with enhanced couplings to bottom quarks, similarly as it was done for the Tevatron results. In Fig. 11.25, decays of the charged Higgs into $\tau\nu$ and of the heavy Higgs H decaying into a pair of SM-like Higgs bosons or gauge bosons, or of A decaying into hZ are also being constrained. In addition, decays of the neutral Higgs bosons into muon pairs are also being explored. Observe that in the $m_h$mod+ scenario the region of $\tan\beta$ lower than 5 does not allow for a Higgs mass m_h close to 125 GeV, as shown in the figure. For the hMSSM scenario, instead, the SM-like Higgs mass is fixed as an input and hence the requirement that it is close to 125 GeV is always fulfilled, although this may imply other limitations as discussed in section VII.1.1.

A search for $\phi \to \mu^+\mu^-$ has also been performed by the ATLAS collaboration [429]. The exclusion limits obtained are given in terms of cross section times branching fraction and combined with those of $\phi \to \tau^+\tau^-$ [429].

A search for pseudoscalar Higgs bosons at intermediate to low masses, below the Z mass (in the 25 GeV to 80 GeV mass range) has been performed by the CMS collaboration [433]. A light pseudoscalar in this mass range is excluded by current direct constraints in the MSSM but not in general 2HDMs [434]. This search is done in the decay channel where the pseudoscalar Higgs boson decays to a pair of taus and is produced in association with a pair of b-quarks.

Finally searches for a resonance decaying to a top quark pair were already done by ATLAS [435] and CMS [436]. These searches

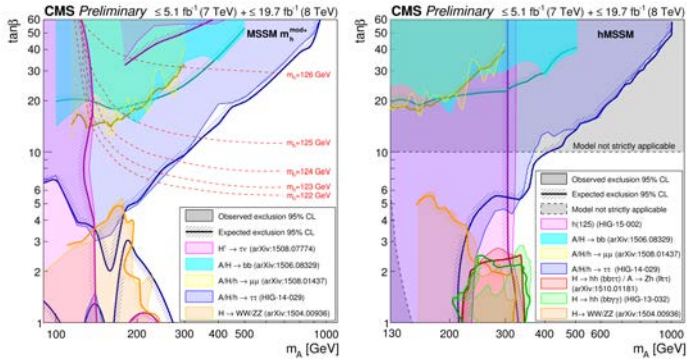

Figure 11.25: The 95% CL exclusion contours in the $(M_A, \tan\beta)$ parameter space for the hMSSM scenario (right panel) and for the m_h-mod+ scenario (left panel), for several search channels [432].

were interpreted as searches for scalar resonances by ATLAS [435], however an important missing component of these searches is an accurate treatment of the interference effects between the signal and the continuum background, that may have a non-conventional pure dip structure and can be non-negligible for a high mass state decaying to top quarks[357, 437].

The LHC has the potential to explore a broad range of SUSY parameter space through the search for non-SM-like Higgs bosons. Nevertheless, Fig. 11.25 shows a broad region with intermediate $\tan\beta$ and large values of m_A that is not tested by present neutral or charged Higgs boson searches, and which cannot be covered completely via these searches, even with much larger data sets. In this region of parameter space it is possible that only the SM-like Higgs boson can be within the LHC's reach. If no other state of the EWSB sector than H is discovered, it may be challenging to determine only from the Higgs sector whether there is a supersymmetric extension of the SM in nature.

(iii) Searches for a CP-odd state decaying to hZ

Similarly to the search for a CP-even high mass Higgs boson decaying to a pair of Higgs bosons, the search for a CP-odd states decaying hZ was carried out at the LHC by the ATLAS and CMS experiments. The ATLAS Collaboration has performed the search in three main final states corresponding to the following subsequent decays of the Higgs and Z bosons [438]: $(Z \to \ell\ell)(h \to b\bar{b})$, $(Z \to \nu\nu)(h \to b\bar{b})$ and $(Z \to \ell\ell)(h \to \tau\tau)$; and their combination assuming SM Higgs decay branching fractions. The CMS Collaboration has performed a search in the $(Z \to \ell\ell)(h \to \tau\tau)$ final state [411]. These searches have been used to constrain the parameter space of 2HDMs. In the MSSM these searches place limits on small values of $tan\beta$ for masses of A comprised between 220 GeV and 360 GeV as illustrated in Fig. 11.25.

(iv) Searches for charged Higgs bosons $H^\pm$

At e^+e^- colliders charged Higgs bosons can be pair produced in the s-channel via γ or Z boson exchange. This process is dominant in the LEP centre-of-mass energies range *i.e.* up to 209 GeV. At higher centre-of-mass energies, other processes can play an important role such as the production in top quark decays via $t \to b + H^+$ if $m_H^\pm < m_t - m_b$ or via the one-loop process $e^+e^- \to W^\pm H^\mp$ [439, 440], which allows the production of a charged Higgs boson with $m_H^\pm > \sqrt{s}/2$, even when H^+H^- production is kinematically forbidden. Other single charged Higgs production mechanisms include $t\bar{b}H^-/\,\bar{t}bH^+$ production [107], $\tau^+\nu H^-/\,\tau^-\bar{\nu}H^+$ production [441], and a variety of processes in which $H^\pm$ is produced in association with a one or two other gauge and/or Higgs bosons [442].

At hadron colliders, Charged Higgs bosons can be produced in several different modes. If $m_{H^\pm} < m_t - m_b$, the charged Higgs boson can be produced in decays of the top quark via the decay $t \to bH^\pm$. Relevant QCD and SUSY-QCD corrections to $\mathrm{BR}(t \to H^\pm b)$ have been computed [299–302]. For values of $m_{H^\pm}$ near m_t, width effects are important. In addition, the full $2 \to 3$ processes $pp/p\bar{p} \to H^+\bar{t}b + X$ and $pp/p\bar{p} \to H^-t\bar{b} + X$ must be considered. If $m_{H^\pm} > m_t - m_b$, then charged Higgs boson production occurs mainly through radiation from a third generation quark. Charged Higgs bosons may also be produced singly in association with a top quark via the $2 \to 3$ partonic processes gg, $q\bar{q} \to t\bar{b}H^-$. For charged Higgs boson production cross section predictions for the Tevatron and the LHC, see Refs. [11, 44, 43]. Charged Higgs bosons can also be produced via associated production with $W^\pm$ bosons through $b\bar{b}$ annihilation and gg-fusion [303] and in pairs via $q\bar{q}$ annihilation [304].

(a) Exclusion limits from LEP

Charged Higgs bosons have been searched for at LEP, where the combined data of the four experiments, ALEPH, DELPHI, L3, and OPAL, were sensitive to masses of up to about 90 GeV [421] in two decay channels, the $\tau\nu$ and $c\bar{s}$. The exclusion limit independent of the admixture of the two above mentioned branching fractions was 78.6 GeV.

(b) Exclusion limits from Tevatron

Compared to the mass domain covered by LEP searches, the Tevatron covered a complementary range of charged Higgs masses. The CDF and D0 collaborations have also searched for charged Higgs bosons in top quark decays with subsequent decays to $\tau\nu$ or to $c\bar{s}$ [443–445]. For the $H^+ \to c\bar{s}$ channel, the limits on $\mathrm{BR}(t \to H^+b)$ from CDF and D0 are $\approx 20\%$ in the mass range $90\,\mathrm{GeV} < m_{H^+} < 160\,\mathrm{GeV}$ and assuming a branching fraction of 100% in this specific final state. $H^+ \to \tau^+\nu_\tau$ channel, D0's limits on $\mathrm{BR}(t \to H^+b)$ are also $\approx 20\%$ in the same mass range and assuming a branching fraction of 100% in this final state. These limits are valid in general 2HDMs, and they have also been interpreted in terms of the MSSM [443–445].

(c) Exclusion limits from LHC

Similarly to the Tevatron, at the LHC light charged Higgs bosons can be searched for in the decays of top quarks. The main initial production mode for light charged Higgs bosons ($m_{H^\pm} < m_t - m_b$) is top pair production. The subsequent decay modes of the charged Higgs boson for these searches are $\tau\nu$ and $c\bar{s}$. More recently ATLAS and CMS have also searched for higher mass charged Higgs bosons ($m_{H^\pm} > m_t + m_b$) in $H^+ \to t\bar{b}$. The main production modes are the associated production of a charged Higgs boson in association with a top and a bottom quark or in association with a top quark only.

ATLAS has searched for the decay $H^+ \to \tau^+\nu_\tau$ in three final state topologies [446]: (i) lepton+jets: with $t\bar{t} \to \bar{b}WH^+ \to b\bar{b}(q\bar{q}')(\tau_{\mathrm{lep}}\nu)$, i.e., the W boson decays hadronically and the tau decays into an electron or a muon, with two neutrinos; (ii) τ +lepton: with $t\bar{t} \to \bar{b}WH^+ \to b\bar{b}(l\nu)(\tau_{\mathrm{had}}\nu)$ i.e., the W boson decays leptonically (with $\ell = e,\ \mu$) and the tau decays hadronically; (iii) τ+jets: $t\bar{t} \to \bar{b}WH^+ \to b\bar{b}(q\bar{q}')(\tau_{\mathrm{had}}\nu)$, i.e., both the W boson and the τ decay hadronically [447]. Assuming $\mathrm{BR}(H^+ \to \tau^+\nu_\tau) = 100\%$, ATLAS sets upper limits on $\mathrm{BR}(t \to H^+b)$ between 0.24% and 2.1% for charged Higgs boson masses between 90 GeV to 160 GeV. When interpreted in the context of the m_h^{max} scenario of the MSSM, these bounds exclude a large fraction of the ($m_{H^\pm}$,$\tan\beta$) plane.

The CMS collaboration has searched for the charged Higgs boson in the decay products of top quark pairs: $t\bar{t} \to H^\pm W^\mp b\bar{b}$ and $t\bar{t} \to H^+H^-b\bar{b}$ [448, 449] as well. Three types of final states with large missing transverse energy and jets originating from b-quark hadronization have been analyzed: the fully-hadronic channel with a hadronically decaying tau in association with jets, the dilepton channel with a hadronically decaying tau in association with an electron or muon and the dilepton channel with an electron-muon pair. Combining the results of these three analyses and assuming $\mathrm{BR}(H^\pm \to \tau\nu)$=1, the upper limits on $\mathrm{BR}(t \to H^+b)$ are less than 2% to 3% depending on the charged Higgs boson mass in the interval $80\,\mathrm{GeV} < m_{H^+} < 160\,\mathrm{GeV}$.

Both the ATLAS [450] and CMS [449] experiments have also searched for high mass charged Higgs bosons decaying to a top and bottom quarks. The main production mode for this search is the

associated production with one top quark (5-flavour scheme) or a top quark and and bottom quark (4-flavour scheme) in the final state. The s-channel production mode where the charged Higgs boson is produced alone in the final state at tree level is also considered. This search is particularly intricate and it is sensitive to the modeling of the top pair production background produced in association with additional partons and in particular b-quarks. No excess was found and the results are expressed in terms of exclusion limits of cross section times branching fractions. The CMS collaboration has combined the results of this search with the $H^+ \to \tau^+\nu_\tau$ search in the framework of an updated mhmax MSSM scenario [449].

ATLAS and CMS have also searched for charged Higgs bosons in top quark decays assuming $\mathrm{BR}(H^+ \to c\bar{s}) = 100\%$ [451, 452], and sets limits of $\approx 20\%$ on $\mathrm{BR}(t \to H^+ b)$ in the $90\,\mathrm{GeV} < m_{H^+} < 160\,\mathrm{GeV}$ mass range.

In two Higgs doublet models the decay of the Charged Higgs boson to a W- and a Z-boson is allowed only at loop level and is therefore suppressed. However the $H^\pm \to W^\pm Z$ decay channel is allowed in Higgs triplet models. The ATLAS experiment [453] has searched for such decays, requiring that the Charged Higgs boson is produced through the fusion of vector bosons. No excess with respect to the SM backgrounds has been observed in this channel, and the results are interpreted in the Georgi–Machacek model [360–362] discussed in Section VII.5.2.

At the LHC various other channels still remain to be explored, in particular searches involving additional neutral scalars in particular in WH, WA where A is the pseudo scalar MSSM Higgs boson, and Wa where a is the light CP-odd scalars of the NMSSM.

(v) Searches for a light CP-odd Higgs boson a

A light pseudoscalar boson a is present in any two Higgs doublet mode enhanced with an additional singlet field. A prominent example is the NMSSM. The theoretical motivations for singlet extensions of the MSSM are discussed in Section VII.2. In the NMSSM, the searches now focus on the low mass pseudo-scalar boson a region for several reasons: (i) in the NMSSM, the light pseudo-scalar a boson can, as a pseudo-Goldstone boson, be a natural candidate for an axion; (ii) scenarios where $m_a > 2m_b$ and a CP-even state h decaying to a pair of a ($m_h > 2m_a$) are excluded by direct searches at LEP in the four b channel [421, 455, 456]; (iii) in the pre-discovery era, LEP limits on a CP-even Higgs boson resulted in fine tuning MSSM constraints [457] which could be evaded through non standard decays of the Higgs to aa; (iv) an NMSSM CP-odd a boson with a mass in the range 9.2–12 GeV can also account for the difference observed between the measured anomalous muon magnetic moment and its prediction [458]. A scenario that has drawn particular attention was motivated by a small excess of events 2.3σ in the SM Higgs search at LEP at Higgs boson mass of around 98 GeV. Speculative interpretations of this excess as a signal of a Higgs boson with reduced couplings to b-quarks were given [457]. Complete reviews of the NMSSM phenomenology can be found in Refs. [459, 456].

The potential benchmark scenarios have changed in the light of the H discovery. The discovered state could be the lightest or the next-to-lightest of the three CP-even states of the NMSSM. Light pseudoscalar scenarios are still very interesting in particular for the potential axion candidate. There are three main types of direct searches for the light a boson: (i) for masses below the Υ resonance, the search is for radiative decays $\Upsilon \to a\gamma$ at B-factories; (ii) the inclusive search for in high energy pp collisions at the LHC; (iii) the search for decays of a CP-even Higgs h boson to a pair of a bosons.

Radiative decays $\Upsilon \to a\gamma$, have been searched for in various colliders, the most recent results are searches for radiative decays of the $\Upsilon(1s)$ to $a\gamma$ with a subsequent decay of the a boson to a pair of taus at CLEO [460] and the radiative decays of the $\Upsilon(1s, 2s, 3s)$ to $a\gamma$ with subsequent decays to a pair of muons or taus by the BaBar collaboration [461, 462].

Direct inclusive searches for the light pseudo scalar a boson were performed in the $a \to \mu\mu$ channel at the Tevatron by the D0 experiment [463] and by the ATLAS [464] and CMS [465] collaborations at the LHC.

Finally searches for the decays of the Higgs boson to a pair of a bosons where performed with subsequent decays to four photons by the ATLAS experiment [466], in the four muons final state by the CMS and D0 experiments [456, 467], in the two muons and two taus final state by the ATLAS [466] and D0 [456] collaborations, and in the four taus final state by the CMS [468] ALEPH collaboration at LEP [469].

No significant excess in the searches for a light CP-odd a boson were found and limits on the production times branching fractions of the a boson have been set.

(vi) Searches for doubly charged Higgs bosons $H^{\pm\pm}$

As discussed in Section VII.5, the generation of small neutrino masses via the standard EWSB mechanism described in Section II requires unnaturally small Yukawa couplings, provided that neutrinos are Dirac-type fermions. A Majorana mass term with a see-saw mechanism for neutrinos, would allow for naturally small masses and yield a framework for the appealing scenario of leptogenesis. However within the SM Majorana mass terms correspond to (non-renomalizable) dimension-5 operators. Such effective interactions can be generated via renormalizable interactions with an electroweak triplet of complex scalar fields (corresponding to a type-II see-saw mechanism). Other models such as the Zee–Babu model, with the introduction of two $\mathrm{SU}(2)_L$ singlets, also generate Majorana mass terms. The signature of such models would be the presence of doubly charged Higgs bosons $H^{\pm\pm}$.

The main production mechanisms of $H^{\pm\pm}$ bosons at hadron colliders are the pair production in the s-channel through the exchange of a Z boson or a photon and the associated production with a Charged Higgs boson through the exchange of a W boson.

VII.8.1. Searches for non-standard production processes of the Higgs boson

The discovery of the Higgs boson has also allowed for searches of BSM (beyond the SM) processes involving standard decays of the Higgs boson. One example directly pertaining to the search for additional states of the EWSB sector is the search for Higgs bosons in the cascade decay of a heavy CP-even Higgs boson decaying to charged Higgs boson and a W boson, and the charged Higgs boson subsequently decaying to H and another W boson. This search has been performed by the ATLAS collaboration in $b\overline{b}$ decays of the H particle [485].

Another example of searches for non standard processes through the presence of the H particle is the search for large flavor changing neutral current decays of the top quark to H and a charm quark. This search has been performed with the ATLAS experiment in the $H \to \gamma\gamma$ channel [486].

VII.8.2. Outlook of searches for additional states

The LHC program of searches for additional states covers a large variety of decay and production channels. Since the last review on the *Status of Higgs boson physics* [243] many new channels have been explored at the LHC, *e.g.* the searches for additional states decaying into hh or Zh. The search for charged Higgs bosons has been extended to include the WZ and the very difficult $t\overline{b}$ decay channel. There are however more channels to cover, *e.g.* the search for charged Higgs bosons in the HW and AW channels.

VIII. Summary and outlook

Summary– The discovery of the Higgs boson is an important milestone in the history of particle physics as well as an extraordinary success of the LHC machine and the ATLAS and CMS experiments. Since its discovery, substantial progress in the field of Higgs boson physics has been accomplished and a significant number of measurements probing its nature have been made. They are revealing an increasingly precise profile of the Higgs boson. All experimental measurements are consistent with the EWSB mechanism of the Standard Model (SM).

Since the last review [487], the ATLAS and CMS experiments have made a combined measurement of the mass of the Higgs boson

in the diphoton and the four-lepton channels at per mille precision, $m_H = 125.09 \pm 0.24\,\text{GeV}$. The quantum numbers of the Higgs boson have been probed in greater detail and show an excellent consistency with the $J^{PC} = 0^{++}$ hypothesis. Anomalous CP-even and CP-odd couplings have also been probed, mostly using angular distributions in diboson events. Higgs boson production and decay mechanisms have been further characterized through the measurement of various differential and fiducial cross sections.

The ATLAS and CMS collaborations have produced a detailed combined measurement of the properties of the Higgs boson. This combination establishes the direct observation of the VBF production process with a significance of 5.4σ and the observation of the $H \to \tau^+\tau^-$ with a significance of 5.5σ. This combination also provides the most precise probes of the coupling structure of the Higgs boson, with a 10%-20% accuracy. This precision could not have been reached without the rapid and profound theoretical developments on many fronts: higher order calculations, Monte Carlo simulations, and new ideas on how to extract further informations on the nature of the Higgs boson. A particularly important breakthrough has been the recent calculation at the next-to-next-to-next-to-leading order of the Higgs production by gluon fusion, the dominant production channel at the LHC. All measurements are consistent with the SM predictions and provide stringent constraints on a large number of scenarios of new physics predicting sizeable deviations in the couplings of the Higgs boson.

Without assumptions on or a measurement of the Higgs boson width, the measurements at the LHC do not provide constraints on the absolute couplings of the Higgs boson. In the SM, the total Higgs width is approximately 4.2 MeV. The direct experimental measurements using the Higgs boson mass lineshape yield an upper bound still three orders of magnitude above its SM value. However, new ideas have emerged through the study of the Higgs couplings away from its mass shell. Under the specific assumption that the running of the Higgs couplings to vector bosons and gluons is small, the total width of the Higgs boson is constrained to be smaller than 25 MeV at 95% CL. Another interesting new idea, in the diphoton channel, is the observation that the interference between the signal and the continuum background induces shifts in the mass. Constraints on the width of the Higgs boson can then be inferred from precise measurements of its mass.

Further useful information on the components of the width of the Higgs boson can also be obtained from searches for rare and exotic decay modes, including invisible decays. Insights on the couplings of the Higgs boson are also obtained from the searches for rare production modes. No significant deviation from the SM Higgs boson expectations has been found in the channels analyzed so far.

Finally, all extensions of the SM at higher energies call for an enlargement of the EWSB sector. Therefore invaluable insights can also be acquired from searches for new additional scalar states. Since the last review [487], an ample number of new searches for CP-even and CP-Odd neutral Higgs bosons, and charged Higgs bosons have been carried out. No significant deviations from the minimal SM Higgs sector has been found in the ranges of mass and couplings of the additional states that have been explored so far.

Outlook– The unitarization of the vector boson scattering (VBS) amplitudes, dominated at high energies by their longitudinal polarizations, has been the basis of the *no lose* theorem at the LHC and was one of the main motivations to build the accelerator and the detectors. It motivated the existence of a Higgs boson or the observability of manifestations of strong dynamics at TeV scale. Now that a Higgs boson has been found and that its couplings to gauge bosons comply with the SM predictions, perturbative unitarity is preserved to a large amount with the sole exchange of the Higgs boson and without the need for any additional states. It is, however, still an important channel to investigate further in order to better understand the nature of the Higgs sector and the possible completion of the SM at the TeV scale. In association with the double Higgs boson production channel by vector boson fusion, VBS could, for instance, confirm that the Higgs boson is part of a weak doublet and also establish whether it is an elementary object or a composite state that could emerge as a pseudo-Nambu–Goldstone boson from a new underlying broken symmetry.

The Higgs boson couplings are not dictated by any local gauge symmetry. Thus, in addition to a new particle, the LHC has also discovered a new force, different in nature from the other fundamental interactions since it is non-universal and distinguishes between the three families of quarks and leptons. The existence of the Higgs boson embodies the problem of an unnatural cancellation among the quantum corrections to its mass, if new physics is present at scale significantly higher than the EW scale. The non-observation of additional states which could stabilize the Higgs mass is a challenge for natural scenarios like supersymmetry or models with a new strong interaction in which the Higgs boson is not a fundamental particle. This increasingly pressing paradox starts questioning the principle of naturalness which underlies the hypothesis that phenomena at different scales do not influence each other.

The search for the Higgs boson has occupied the Particle physics community for the last 50 years. Its discovery has shaped and sharpened the physics programs of the LHC and of future accelerators. The experimental data together with the progress in theory mark the beginning of a new era of precision Higgs boson measurements.

12. THE CKM QUARK-MIXING MATRIX

Revised January 2016 by A. Ceccucci (CERN), Z. Ligeti (LBNL), and Y. Sakai (KEK).

12.1. Introduction

The masses and mixings of quarks have a common origin in the Standard Model (SM). They arise from the Yukawa interactions with the Higgs condensate,

$$\mathcal{L}_Y = -Y^d_{ij}\,\overline{Q^I_{Li}}\,\phi\,d^I_{Rj} - Y^u_{ij}\,\overline{Q^I_{Li}}\,\epsilon\,\phi^*\,u^I_{Rj} + \text{h.c.}, \tag{12.1}$$

where $Y^{u,d}$ are 3×3 complex matrices, ϕ is the Higgs field, i,j are generation labels, and ϵ is the 2×2 antisymmetric tensor. Q^I_L are left-handed quark doublets, and d^I_R and u^I_R are right-handed down- and up-type quark singlets, respectively, in the weak-eigenstate basis. When ϕ acquires a vacuum expectation value, $\langle\phi\rangle = (0, v/\sqrt{2})$, Eq. (12.1) yields mass terms for the quarks. The physical states are obtained by diagonalizing $Y^{u,d}$ by four unitary matrices, $V^{u,d}_{L,R}$, as $M^f_{\text{diag}} = V^f_L\,Y^f\,V^{f\dagger}_R(v/\sqrt{2})$, $f = u, d$. As a result, the charged-current $W^\pm$ interactions couple to the physical u_{Lj} and d_{Lk} quarks with couplings given by

$$\frac{-g}{\sqrt{2}}(\overline{u_L},\,\overline{c_L},\,\overline{t_L})\gamma^\mu\,W^+_\mu\,V_{\text{CKM}}\begin{pmatrix} d_L \\ s_L \\ b_L\end{pmatrix} + \text{h.c.},$$

$$V_{\text{CKM}} \equiv V^u_L V^{d\dagger}_L = \begin{pmatrix} V_{ud} & V_{us} & V_{ub} \\ V_{cd} & V_{cs} & V_{cb} \\ V_{td} & V_{ts} & V_{tb}\end{pmatrix}. \tag{12.2}$$

This Cabibbo-Kobayashi-Maskawa (CKM) matrix [1,2] is a 3×3 unitary matrix. It can be parameterized by three mixing angles and the CP-violating KM phase [2]. Of the many possible conventions, a standard choice has become [3]

$$\begin{aligned} V_{\text{CKM}} &= \begin{pmatrix} 1 & 0 & 0 \\ 0 & c_{23} & s_{23} \\ 0 & -s_{23} & c_{23}\end{pmatrix}\begin{pmatrix} c_{13} & 0 & s_{13}e^{-i\delta} \\ 0 & 1 & 0 \\ -s_{13}e^{i\delta} & 0 & c_{13}\end{pmatrix}\begin{pmatrix} c_{12} & s_{12} & 0 \\ -s_{12} & c_{12} & 0 \\ 0 & 0 & 1\end{pmatrix} \\ &= \begin{pmatrix} c_{12}c_{13} & s_{12}c_{13} & s_{13}e^{-i\delta} \\ -s_{12}c_{23}-c_{12}s_{23}s_{13}e^{i\delta} & c_{12}c_{23}-s_{12}s_{23}s_{13}e^{i\delta} & s_{23}c_{13} \\ s_{12}s_{23}-c_{12}c_{23}s_{13}e^{i\delta} & -c_{12}s_{23}-s_{12}c_{23}s_{13}e^{i\delta} & c_{23}c_{13}\end{pmatrix}, \end{aligned} \tag{12.3}$$

where $s_{ij} = \sin\theta_{ij}$, $c_{ij} = \cos\theta_{ij}$, and δ is the phase responsible for all CP-violating phenomena in flavor-changing processes in the SM. The angles θ_{ij} can be chosen to lie in the first quadrant, so $s_{ij}, c_{ij} \geq 0$.

It is known experimentally that $s_{13} \ll s_{23} \ll s_{12} \ll 1$, and it is convenient to exhibit this hierarchy using the Wolfenstein parameterization. We define [4–6]

$$\begin{aligned} s_{12} = \lambda = \frac{|V_{us}|}{\sqrt{|V_{ud}|^2 + |V_{us}|^2}}\,, \qquad s_{23} = A\lambda^2 = \lambda\left|\frac{V_{cb}}{V_{us}}\right|, \\ s_{13}e^{i\delta} = V^*_{ub} = A\lambda^3(\rho + i\eta) = \frac{A\lambda^3(\bar\rho + i\bar\eta)\sqrt{1 - A^2\lambda^4}}{\sqrt{1-\lambda^2}[1 - A^2\lambda^4(\bar\rho + i\bar\eta)]}\,. \end{aligned} \tag{12.4}$$

These relations ensure that $\bar\rho + i\bar\eta = -(V_{ud}V^*_{ub})/(V_{cd}V^*_{cb})$ is phase convention independent, and the CKM matrix written in terms of λ, A, $\bar\rho$, and $\bar\eta$ is unitary to all orders in λ. The definitions of $\bar\rho, \bar\eta$ reproduce all approximate results in the literature. For example, $\bar\rho = \rho(1 - \lambda^2/2 + \ldots)$ and one can write V_{CKM} to $\mathcal{O}(\lambda^4)$ either in terms of $\bar\rho, \bar\eta$ or, traditionally,

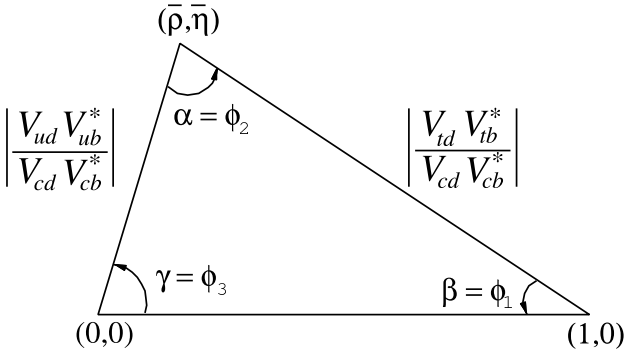

Figure 12.1: Sketch of the unitarity triangle.

$$V_{\text{CKM}} = \begin{pmatrix} 1 - \lambda^2/2 & \lambda & A\lambda^3(\rho - i\eta) \\ -\lambda & 1 - \lambda^2/2 & A\lambda^2 \\ A\lambda^3(1 - \rho - i\eta) & -A\lambda^2 & 1\end{pmatrix} + \mathcal{O}(\lambda^4)\,. \tag{12.5}$$

The CKM matrix elements are fundamental parameters of the SM, so their precise determination is important. The unitarity of the CKM matrix imposes $\sum_i V_{ij}V^*_{ik} = \delta_{jk}$ and $\sum_j V_{ij}V^*_{kj} = \delta_{ik}$. The six vanishing combinations can be represented as triangles in a complex plane, of which those obtained by taking scalar products of neighboring rows or columns are nearly degenerate. The areas of all triangles are the same, half of the Jarlskog invariant, J [7], which is a phase-convention-independent measure of CP violation, defined by $\text{Im}\big[V_{ij}V_{kl}V^*_{il}V^*_{kj}\big] = J\sum_{m,n}\varepsilon_{ikm}\varepsilon_{jln}$.

The most commonly used unitarity triangle arises from

$$V_{ud}\,V^*_{ub} + V_{cd}\,V^*_{cb} + V_{td}\,V^*_{tb} = 0\,, \tag{12.6}$$

by dividing each side by the best-known one, $V_{cd}V^*_{cb}$ (see Fig. 1). Its vertices are exactly $(0,0)$, $(1,0)$, and, due to the definition in Eq. (12.4), $(\bar\rho, \bar\eta)$. An important goal of flavor physics is to overconstrain the CKM elements, and many measurements can be conveniently displayed and compared in the $\bar\rho, \bar\eta$ plane. While the Lagrangian in Eq. (12.1) is renormalized, and the CKM matrix has a well known scale dependence above the weak scale [8], below $\mu = m_W$ the CKM elements can be treated as constants, with all μ-dependence contained in the running of quark masses and higher-dimension operators.

Unless explicitly stated otherwise, we describe all measurements assuming the SM, to extract magnitudes and phases of CKM elements in Sec. 12.2 and 12.3. Processes dominated by loop-level contributions in the SM are particularly sensitive to new physics. We give the global fit results for the CKM elements in Sec. 12.4, and discuss some implications for beyond standard model physics in Sec. 12.5.

12.2. Magnitudes of CKM elements

12.2.1. $|V_{ud}|$:

The most precise determination of $|V_{ud}|$ comes from the study of superallowed $0^+ \to 0^+$ nuclear beta decays, which are pure vector transitions. Taking the average of the fourteen most precise determinations [9] yields

$$|V_{ud}| = 0.97417 \pm 0.00021. \tag{12.7}$$

The error is dominated by theoretical uncertainties stemming from nuclear Coulomb distortions and radiative corrections. A precise determination of $|V_{ud}|$ is also obtained from the measurement of the neutron lifetime. The theoretical uncertainties are very small, but the determination is limited by the knowledge of the ratio of the axial-vector and vector couplings, $g_A = G_A/G_V$ [10]. The PIBETA experiment [11] has improved the measurement of the $\pi^+ \to \pi^0 e^+\nu$ branching ratio to 0.6%, and quotes $|V_{ud}| = 0.9728 \pm 0.0030$, in agreement with the more precise result listed above. The interest in this measurement is that the determination of $|V_{ud}|$ is very clean theoretically, because it is a pure vector transition and is free from nuclear-structure uncertainties.

12.2.2. $|V_{us}|$:

The product of $|V_{us}|$ and the form factor at $q^2 = 0$, $|V_{us}|\, f_+(0)$, has been extracted traditionally from $K^0_L \to \pi e \nu$ decays in order to avoid isospin-breaking corrections ($\pi^0 - \eta$ mixing) that affect $K^\pm$ semileptonic decay, and the complications induced by a second (scalar) form factor present in the muonic decays. The last round of measurements has lead to enough experimental constraints to justify the comparison between different decay modes. Systematic errors related to the experimental quantities, *e.g.*, the lifetime of neutral or charged kaons, and the form factor determinations for electron and muonic decays, differ among decay modes, and the consistency between different determinations enhances the confidence in the final result. For this reason, we follow the prescription [12] to average $K^0_L \to \pi e \nu$, $K^0_L \to \pi \mu \nu$, $K^\pm \to \pi^0 e^\pm \nu$, $K^\pm \to \pi^0 \mu^\pm \nu$ and $K^0_S \to \pi e \nu$. The average of these five decay modes yields $|V_{us}|\, f_+(0) = 0.2165 \pm 0.0004$. Results obtained from each decay mode, and exhaustive references to the experimental data, are listed for instance in Ref. [10]. The form factor average $f_+(0) = 0.9677 \pm 0.0037$ [13] from three-flavor lattice QCD calculations gives $|V_{us}| = 0.2237 \pm 0.0009$ [10].[1] The broadly used classic calculation of $f_+(0)$ [16] is in good agreement with this value, while other calculations [17] differ by as much as 2%.

The calculation of the ratio of the kaon and pion decay constants enables one to extract $|V_{us}/V_{ud}|$ from $K \to \mu\nu(\gamma)$ and $\pi \to \mu\nu(\gamma)$, where (γ) indicates that radiative decays are included [18]. The KLOE measurement of the $K \to \mu\nu(\gamma)$ branching ratio [19], combined with the lattice QCD result, $f_K/f_\pi = 1.1928 \pm 0.0026$ [13], leads to $|V_{us}| = 0.2254 \pm 0.0008$, where the accuracy is limited by the knowledge of the ratio of the decay constants. The average of these two determinations is quoted as [10]

$$|V_{us}| = 0.2248 \pm 0.0006. \tag{12.8}$$

The latest determination from hyperon decays can be found in Ref. [20]. The authors focus on the analysis of the vector form factor, protected from first order $SU(3)$ breaking effects by the Ademollo-Gatto theorem [21], and treat the ratio between the axial and vector form factors g_1/f_1 as experimental input, thus avoiding first order $SU(3)$ breaking effects in the axial-vector contribution. They find $|V_{us}| = 0.2250 \pm 0.0027$, although this does not include an estimate of the theoretical uncertainty due to second-order $SU(3)$ breaking, contrary to Eq. (12.8). Concerning hadronic τ decays to strange particles, averaging both inclusive and exclusive $\tau \to h\nu$ ($h = \pi$, K) decay measurements yield $|V_{us}| = 0.2204 \pm 0.0014$ [22,23].

12.2.3. $|V_{cd}|$:

The magnitude of V_{cd} can be extracted from semileptonic charm decays, using theoretical knowledge of the form factors. In semileptonic D decays, lattice QCD calculations have predicted the normalization of the $D \to \pi\ell\nu$ and $D \to K\ell\nu$ form factors [14]. The dependence on the invariant mass of the lepton pair, q^2, is determined from lattice QCD and theoretical constraints from analyticity [15]. Using three-flavor lattice QCD calculations for $D \to \pi\ell\nu$, $f_+^{D\pi}(0) = 0.666 \pm 0.029$ [14], and the average [22,24] of measurements of recent BaBar [25] and BESIII [26] as well as CLEO-c [27] and Belle [28] of $D \to \pi\ell\nu$ decays, one obtains $|V_{cd}| = 0.214 \pm 0.003 \pm 0.009$, where the first uncertainty is experimental, and the second is from the theoretical uncertainty of the form factor.

The determination of $|V_{cd}|$ is also possible from leptonic decay $D^+ \to \mu^+\nu$. Its precision has been improved by a recent BESIII measurement [29]. Averaged with earlier CLEO measurment [30] and $f_D = 209.2 \pm 3.3$ MeV [14], one obtains $|V_{cd}| = 0.219 \pm 0.005 \pm 0.003$.

Earlier determinations of $|V_{cd}|$ came from neutrino scattering data. The difference of the ratio of double-muon to single-muon production by neutrino and antineutrino beams is proportional to the charm cross section off valence d quarks, and therefore to $|V_{cd}|^2$ times the average semileptonic branching ratio of charm mesons, $\mathcal{B}_\mu$. The method was used first by CDHS [31] and then by CCFR [32,33] and CHARM II [34]. Averaging these results is complicated, because it requires assumptions about the scale of the QCD corrections, and because $\mathcal{B}_\mu$ is an effective quantity, which depends on the specific neutrino beam characteristics. Given that no recent experimental input is available, we quote the average from a past review, $\mathcal{B}_\mu |V_{cd}|^2 = (0.463 \pm 0.034) \times 10^{-2}$ [35]. Analysis cuts make these experiments insensitive to neutrino energies smaller than 30 GeV. Thus, $\mathcal{B}_\mu$ should be computed using only neutrino interactions with visible energy larger than 30 GeV. An appraisal [36] based on charm-production fractions measured in neutrino interactions [37,38] gives $\mathcal{B}_\mu = 0.088 \pm 0.006$. Data from the CHORUS experiment [39] are sufficiently precise to extract $\mathcal{B}_\mu$ directly, by comparing the number of charm decays with a muon to the total number of charmed hadrons found in the nuclear emulsions. Requiring the visible energy to be larger than 30 GeV, CHORUS finds $\mathcal{B}_\mu = 0.085 \pm 0.009 \pm 0.006$. We use the average of these two determinations, $\mathcal{B}_\mu = 0.087 \pm 0.005$, and obtain $|V_{cd}| = 0.230 \pm 0.011$. Averaging the three determinations above, we find

$$|V_{cd}| = 0.220 \pm 0.005. \tag{12.9}$$

12.2.4. $|V_{cs}|$:

The direct determination of $|V_{cs}|$ is possible from semileptonic D or leptonic D_s decays, using lattice QCD calculations of the semileptonic D form factor or the D_s decay constant. For muonic decays, the average of Belle [40], CLEO-c [41] and *BABAR* [42] is $\mathcal{B}(D_s^+ \to \mu^+\nu) = (5.56 \pm 0.24) \times 10^{-3}$ [43]. For decays to τ leptons, the average of CLEO-c [41,44,45], *BABAR* [42] and Belle [40] gives $\mathcal{B}(D_s^+ \to \tau^+\nu) = (5.56 \pm 0.22) \times 10^{-2}$ [43]. From each of these values, determinations of $|V_{cs}|$ can be obtained using the PDG values for the mass and lifetime of the D_s, the masses of the leptons, and $f_{D_s} = (248.6 \pm 2.7)$ MeV [14]. The average of these determinations gives $|V_{cs}| = 1.008 \pm 0.021$, where the error is dominated by the lattice QCD determination of f_{D_s}. In semileptonic D decays, lattice QCD calculations of the $D \to K\ell\nu$ form factor are available [14]. Using $f_+^{DK}(0) = 0.747 \pm 0.019$ and the average of CLEO-c [27], Belle [28], *BABAR* [46] and recent BESIII [26] measurements of $D \to K\ell\nu$ decays, one obtains $|V_{cs}| = 0.975 \pm 0.007 \pm 0.025$, where the first error is experimental and the second, which is dominant, is from the theoretical uncertainty of the form factor. Averaging the determinations from leptonic and semileptonic decays, we find

$$|V_{cs}| = 0.995 \pm 0.016. \tag{12.10}$$

Measurements of on-shell $W^\pm$ decays sensitive to $|V_{cs}|$ were made by LEP-2. The W branching ratios depend on the six CKM elements involving quarks lighter than m_W. The W branching ratio to each lepton flavor is $1/\mathcal{B}(W \to \ell\bar{\nu}_\ell) = 3\big[1 + \sum_{u,c,d,s,b} |V_{ij}|^2\, (1 + \alpha_s(m_W)/\pi) + \ldots\big]$. Assuming lepton universality, the measurement $\mathcal{B}(W \to \ell\bar{\nu}_\ell) = (10.83 \pm 0.07 \pm 0.07)\,\%$ [47] implies $\sum_{u,c,d,s,b} |V_{ij}|^2 = 2.002 \pm 0.027$. This is a precise test of unitarity; however, only flavor-tagged W-decays determine $|V_{cs}|$ directly, such as DELPHI's tagged $W^+ \to c\bar{s}$ analysis, yielding $|V_{cs}| = 0.94^{+0.32}_{-0.26} \pm 0.13$ [48].

12.2.5. $|V_{cb}|$:

This matrix element can be determined from exclusive and inclusive semileptonic decays of B mesons to charm. The inclusive determinations use the semileptonic decay rate measurement, together with (certain moments of) the leptonic energy and the hadronic invariant-mass spectra. The theoretical basis is the operator product expansion [49,50], which allows calculation of the decay rate and various spectra as expansions in α_s and inverse powers of the heavy-quark mass. The dependence on m_b, m_c, and the parameters that occur at subleading order is different for different moments, and a large number of measured moments overconstrains all the parameters, and tests the consistency of the determination. The precise extraction of $|V_{cb}|$ requires using a "threshold" quark mass definition [51,52]. Inclusive measurements have been performed using B mesons from Z^0 decays at LEP, and at e^+e^- machines operated at the $\Upsilon(4S)$. At LEP, the large boost of B mesons from the Z^0 allows the determination of

[1] For lattice QCD inputs, we use the averages from Ref. [14] whenever possible, unless the minireviews [10,15] choose other values. We only use unquenched lattice QCD results. Hereafter, the first error is statistical and the second is systematic, unless mentioned otherwise.

the moments throughout phase space, which is not possible otherwise, but the large statistics available at the B factories lead to more precise determinations. An average of the measurements and a compilation of the references are provided by Ref. [15]: $|V_{cb}| = (42.2 \pm 0.8) \times 10^{-3}$.

Exclusive determinations are based on semileptonic B decays to D and D^*. In the $m_{b,c} \gg \Lambda_{\rm QCD}$ limit, all form factors are given by a single Isgur-Wise function [53], which depends on the product of the four-velocities of the B and $D^{(*)}$ mesons, $w = v \cdot v'$. Heavy-quark symmetry determines the rate at $w = 1$, the maximum momentum transfer to the leptons, and $|V_{cb}|$ is obtained from an extrapolation to $w = 1$. The exclusive determination, $|V_{cb}| = (39.2 \pm 0.7) \times 10^{-3}$ [15], has a comparable precision to the inclusive one, and the main theoretical uncertainty in the form factor and the experimental uncertainty in the rate near $w = 1$ are to a large extent independent of the inclusive determination. The V_{cb} and V_{ub} minireview [15] quotes a combination with the error scaled by $\sqrt{\chi^2} = 2.9$,

$$|V_{cb}| = (40.5 \pm 1.5) \times 10^{-3}. \tag{12.11}$$

Less precise measurements of $|V_{cb}|$, not included in this average, can be obtained from $\mathcal{B}(B \to D^{(*)}\tau\bar{\nu})$. The most precise data involving τ modes are the $|V_{cb}|$-independent ratios, $\mathcal{B}(B \to D^{(*)}\tau\bar{\nu})/\mathcal{B}(B \to D^{(*)}\ell\bar{\nu})$ [54]. If the currently nearly $4\,\sigma$ hint of lepton non-universality is confirmed, the determination of $|V_{cb}|$ becomes more complicated.

12.2.6. $|V_{ub}|$:

The determination of $|V_{ub}|$ from inclusive $B \to X_u\ell\bar{\nu}$ decay is complicated due to large $B \to X_c\ell\bar{\nu}$ backgrounds. In most regions of phase space where the charm background is kinematically forbidden, the hadronic physics enters via unknown nonperturbative functions, so-called shape functions. (In contrast, the nonperturbative physics for $|V_{cb}|$ is encoded in a few parameters.) At leading order in $\Lambda_{\rm QCD}/m_b$, there is only one shape function, which can be extracted from the photon energy spectrum in $B \to X_s\gamma$ [55,56], and applied to several spectra in $B \to X_u\ell\bar{\nu}$. The subleading shape functions are modeled in the current determinations. Phase space cuts for which the rate has only subleading dependence on the shape function are also possible [57]. The measurements of both the hadronic and the leptonic systems are important for an optimal choice of phase space. A different approach is to make the measurements more inclusive by extending them deeper into the $B \to X_c\ell\bar{\nu}$ region, and thus reduce the theoretical uncertainties. Analyses of the electron-energy endpoint from CLEO [58], *BABAR* [59], and Belle [60] quote $B \to X_u e\bar{\nu}$ partial rates for $|\vec{p}_e| \geq 2.0\,\text{GeV}$ and $1.9\,\text{GeV}$, which are well below the charm endpoint. The large and pure $B\overline{B}$ samples at the B factories permit the selection of $B \to X_u\ell\bar{\nu}$ decays in events where the other B is fully reconstructed [61]. With this full-reconstruction tag method, the four-momenta of both the leptonic and the hadronic final states can be measured. It also gives access to a wider kinematic region, because of improved signal purity. Ref. [15] quotes the inclusive average, $|V_{ub}| = (4.49 \pm 0.16\,^{+0.16}_{-0.18}) \times 10^{-3}$.

To extract $|V_{ub}|$ from exclusive decays, the form factors have to be known. Experimentally, better signal-to-background ratios are offset by smaller yields. The $B \to \pi\ell\bar{\nu}$ branching ratio is now known to 5%. Lattice QCD calculations of the $B \to \pi\ell\bar{\nu}$ form factor are available [62,63] for the high q^2 region ($q^2 > 16$ or $18\,\text{GeV}^2$). A fit to the experimental partial rates and lattice results versus q^2 yields $|V_{ub}| = (3.72 \pm 0.16) \times 10^{-3}$ [63]. Light-cone QCD sum rules are supposed to be applicable for $q^2 < 12\,\text{GeV}^2$ [64]. The minireview [15] quotes a combination, $|V_{ub}| = (3.72 \pm 0.19) \times 10^{-3}$.

The uncertainties in extracting $|V_{ub}|$ from inclusive and exclusive decays are different to a large extent. A combination of the determinations is quoted [15] with the error scaled by $\sqrt{\chi^2} = 2.6$,

$$|V_{ub}| = (4.09 \pm 0.39) \times 10^{-3}. \tag{12.12}$$

A determination of $|V_{ub}|$ not included in this average can be obtained from $\mathcal{B}(B \to \tau\bar{\nu}) = (1.06 \pm 0.20) \times 10^{-4}$ [43]. Using $f_B = (190.5 \pm 4.2)\,\text{MeV}$ [14] and $\tau_{B^\pm} = (1.638 \pm 0.004)\,\text{ps}$ [65], we find $|V_{ub}| = (4.04 \pm 0.38) \times 10^{-3}$. This decay is sensitive, for example, to tree-level charged Higgs contributions, and the measured rate is consistent with the SM expectation. The recent LHCb measurement $|V_{ub}/V_{cb}| = 0.083 \pm 0.006$ [66] from the ratio of $\Lambda_b \to p^+\mu^-\bar{\nu}$ and $\Lambda_b \to \Lambda_c^+\mu^-\bar{\nu}$ in different regions of q^2, will hopefully be averaged with the above, using more than one lattice QCD inputs, by the next edition.

12.2.7. $|V_{td}|$ *and* $|V_{ts}|$:

The CKM elements $|V_{td}|$ and $|V_{ts}|$ are not likely to be precisely measurable in tree-level processes involving top quarks, so one has to rely on determinations from B–$\overline{B}$ oscillations mediated by box diagrams with top quarks, or loop-mediated rare K and B decays. Theoretical uncertainties in hadronic effects limit the accuracy of the current determinations. These can be reduced by taking ratios of processes that are equal in the flavor $SU(3)$ limit to determine $|V_{td}/V_{ts}|$.

The mixing of the two B^0 mesons was discovered by ARGUS [67], and the mass difference is precisely measured by now, $\Delta m_d = (0.5064 \pm 0.0019)\,\text{ps}^{-1}$ [68]. In the B_s^0 system, Δm_s was first measured significantly by CDF [69] and the world average, dominated by a recent LHCb measurement [70], is $\Delta m_s = (17.757 \pm 0.021)\,\text{ps}^{-1}$ [68]. Neglecting corrections suppressed by $|V_{tb}| - 1$, and using the lattice QCD results $f_{B_d}\sqrt{\widehat{B}_{B_d}} = (216 \pm 15)\,\text{MeV}$ and $f_{B_s}\sqrt{\widehat{B}_{B_s}} = (266 \pm 18)\,\text{MeV}$ [14],

$$|V_{td}| = (8.2 \pm 0.6) \times 10^{-3}, \qquad |V_{ts}| = (40.0 \pm 2.7) \times 10^{-3}. \tag{12.13}$$

The uncertainties are dominated by lattice QCD. Several uncertainties are reduced in the calculation of the ratio $\xi = \left(f_{B_s}\sqrt{\widehat{B}_{B_s}}\right)/\left(f_{B_d}\sqrt{\widehat{B}_{B_d}}\right) = 1.268 \pm 0.063$ [14] and therefore the constraint on $|V_{td}/V_{ts}|$ from $\Delta m_d/\Delta m_s$ is more reliable theoretically. These provide a theoretically clean and significantly improved constraint

$$\left|V_{td}/V_{ts}\right| = 0.215 \pm 0.001 \pm 0.011. \tag{12.14}$$

The inclusive branching ratio $\mathcal{B}(B \to X_s\gamma) = (3.43 \pm 0.22) \times 10^{-4}$ extrapolated to $E_\gamma > E_0 = 1.6\,\text{GeV}$ [71] is also sensitive to $|V_{tb}V_{ts}|$. In addition to t-quark penguins, a substantial part of the rate comes from charm contributions proportional to $V_{cb}V_{cs}^*$ via the application of 3×3 CKM unitarity (which is used here). With the NNLO calculation of $\mathcal{B}(B \to X_s\gamma)_{E_\gamma > E_0}/\mathcal{B}(B \to X_c e\bar{\nu})$ [72], we obtain $|V_{ts}/V_{cb}| = 0.99 \pm 0.05$. The $B_s \to \mu^+\mu^-$ rate is also proportional to $|V_{tb}V_{ts}|^2$ in the SM, and the observed signal $\mathcal{B}(B_s \to \mu^+\mu^-) = (2.8^{+0.7}_{-0.6}) \times 10^{-9}$ [73] is consistent with the SM, with sizable uncertainties.

A complementary determination of $|V_{td}/V_{ts}|$ is possible from the ratio of $B \to \rho\gamma$ and $K^*\gamma$ rates. The ratio of the neutral modes is theoretically cleaner than that of the charged ones, because the poorly known spectator-interaction contribution is expected to be smaller (W-exchange vs. weak annihilation). For now, because of low statistics, we average the charged and neutral rates assuming the isospin symmetry and heavy-quark limit motivated relation, $|V_{td}/V_{ts}|^2/\xi_\gamma^2 = [\Gamma(B^+ \to \rho^+\gamma) + 2\Gamma(B^0 \to \rho^0\gamma)]/[\Gamma(B^+ \to K^{*+}\gamma) + \Gamma(B^0 \to K^{*0}\gamma)] = (3.19 \pm 0.46)\%$ [71]. Here ξ_γ contains the poorly known hadronic physics. Using $\xi_\gamma = 1.2 \pm 0.2$ [74], and combining the experimental and theoretical errors in quadrature, gives $|V_{td}/V_{ts}| = 0.214 \pm 0.016 \pm 0.036$.

A theoretically clean determination of $|V_{td}V_{ts}^*|$ is possible from $K^+ \to \pi^+\nu\bar{\nu}$ decay [75]. Experimentally, only seven events have been observed [76] and the rate is consistent with the SM with large uncertainties. Much more data are needed for a precision measurement.

12.2.8. $|V_{tb}|$:

The determination of $|V_{tb}|$ from top decays uses the ratio of branching fractions $R = \mathcal{B}(t \to Wb)/\mathcal{B}(t \to Wq) = |V_{tb}|^2/(\sum_q |V_{tq}|^2) = |V_{tb}|^2$, where $q = b, s, d$. The CDF and DØ measurements performed on data collected during Run II of the Tevatron give $|V_{tb}| > 0.78$ [77] and $0.99 > |V_{tb}| > 0.90$ [78], respectively, at 95% CL. CMS measured the same quantity at 7 TeV and gives $|V_{tb}| > 0.92$ [79] at 95% CL.

The direct determination of $|V_{tb}|$, without assuming unitarity, is possible from the single top-quark-production cross section. The $(3.30^{+0.52}_{-0.40})$ pb combined cross section [80] of DØ and CDF measurements implies $|V_{tb}| = 1.02^{+0.06}_{-0.05}$. The LHC experiments, ATLAS and CMS, have measured single-top production cross sections (and extracted $|V_{tb}|$) in t-channel, Wt-channel, and s-channel at 7 TeV, 8 TeV, and 13 TeV [81]. The average of these $|V_{tb}|$ values is calculated to be $|V_{tb}| = 1.005 \pm 0.036$, where all systematic errors and theoretical errors are treated to be fully correlated. The average of Tevatron and LHC values gives

$$|V_{tb}| = 1.009 \pm 0.031\,. \tag{12.15}$$

The experimental systematic uncertainties dominate, and a dedicated combination would be welcome.

A weak constraint on $|V_{tb}|$ can be obtained from precision electroweak data, where top quarks enter in loops. The sensitivity is best in $\Gamma(Z \to b\bar{b})$ and yields $|V_{tb}| = 0.77^{+0.18}_{-0.24}$ [82].

12.3. Phases of CKM elements

As can be seen from Fig. 12.1, the angles of the unitarity triangle are

$$\begin{aligned}
\beta &= \phi_1 = \arg\left(-\frac{V_{cd}V_{cb}^*}{V_{td}V_{tb}^*}\right),\\
\alpha &= \phi_2 = \arg\left(-\frac{V_{td}V_{tb}^*}{V_{ud}V_{ub}^*}\right),\\
\gamma &= \phi_3 = \arg\left(-\frac{V_{ud}V_{ub}^*}{V_{cd}V_{cb}^*}\right).
\end{aligned} \tag{12.16}$$

Since CP violation involves phases of CKM elements, many measurements of CP-violating observables can be used to constrain these angles and the $\bar{\rho}, \bar{\eta}$ parameters.

12.3.1. ϵ and ϵ' :

The measurement of CP violation in K^0–$\overline{K}^0$ mixing, $|\epsilon| = (2.233 \pm 0.015) \times 10^{-3}$ [83], provides important information about the CKM matrix. The phase of ϵ is determined by long-distance physics, $\epsilon = \frac{1}{2}\, e^{i\phi_\epsilon} \sin\phi_\epsilon \, \arg(-M_{12}/\Gamma_{12})$, where $\phi_\epsilon = \arctan|2\Delta m_K/\Delta\Gamma_K| \simeq 43.5^\circ$. The SM prediction can be written as

$$\begin{aligned}
\epsilon = \kappa_\epsilon\, e^{i\phi_\epsilon} \frac{G_F^2 m_W^2 m_K}{12\sqrt{2}\,\pi^2 \Delta m_K} f_K^2 \widehat{B}_K \Big\{ &\eta_{tt} S(x_t)\, \mathrm{Im}[(V_{ts}V_{td}^*)^2] \\
&+ 2\eta_{ct} S(x_c, x_t)\, \mathrm{Im}(V_{cs}V_{cd}^* V_{ts}V_{td}^*) + \eta_{cc}\, x_c\, \mathrm{Im}[(V_{cs}V_{cd}^*)^2] \Big\},
\end{aligned} \tag{12.17}$$

where $\kappa_\epsilon \simeq 0.94 \pm 0.02$ [84] includes the effects of $\Delta s = 1$ operators and $\phi_\epsilon \neq \pi/4$ (see also Ref. [85]). The displayed terms are the short-distance $\Delta s = 2$ contribution to $\mathrm{Im}M_{12}$ in the usual phase convention, S is an Inami-Lim function [86], $x_q = m_q^2/m_W^2$, and η_{ij} are perturbative QCD corrections. The constraint from ϵ in the $\bar{\rho}, \bar{\eta}$ plane is bounded by approximate hyperbolas. Lattice QCD determined the bag parameter $\widehat{B}_K = 0.766 \pm 0.010$ [14], and the main uncertainties now come from $(V_{ts}V_{td}^*)^2$, which is approximately $\sigma(|V_{cb}|^4) \sim \sigma(A^4)$, the η_{ij} coefficients, and estimates of κ_ϵ.

The measurement of $6\,\mathrm{Re}(\epsilon'/\epsilon) = 1 - |\eta_{00}/\eta_{+-}|^2$, where each $\eta_{ij} = \langle\pi^i\pi^j|\mathcal{H}|K_L\rangle\,/\,\langle\pi^i\pi^j|\mathcal{H}|K_S\rangle$ violates CP, provides a qualitative test of the CKM mechanism, and strong constraints on many new physics scenarios. Its nonzero value, $\mathrm{Re}(\epsilon'/\epsilon) = (1.67 \pm 0.23) \times 10^{-3}$ [83], demonstrated the existence of direct CP violation, a prediction of the KM ansatz. While $\mathrm{Re}(\epsilon'/\epsilon) \propto \mathrm{Im}(V_{td}V_{ts}^*)$, this quantity cannot easily be used to extract CKM parameters, because the electromagnetic penguin contributions tend to cancel the gluonic penguins for large m_t [87], thus enhancing hadronic uncertainties. Most SM estimates [88–91] agree with the observed value, indicating that $\bar{\eta}$ is positive. Progress in lattice QCD [92] may eventually yield a precise SM prediction.

12.3.2. β / ϕ_1 :

12.3.2.1. *Charmonium modes:*

CP-violation measurements in B-meson decays provide direct information on the angles of the unitarity triangle, shown in Fig. 12.1. These overconstraining measurements serve to improve the determination of the CKM elements, or to reveal effects beyond the SM.

The time-dependent CP asymmetry of neutral B decays to a final state f common to B^0 and $\overline{B}^0$ is given by [93,94]

$$\mathcal{A}_f = \frac{\Gamma(\overline{B}^0(t) \to f) - \Gamma(B^0(t) \to f)}{\Gamma(\overline{B}^0(t) \to f) + \Gamma(B^0(t) \to f)} = S_f \sin(\Delta m_d\, t) - C_f \cos(\Delta m_d\, t), \tag{12.18}$$

where

$$S_f = \frac{2\,\mathrm{Im}\lambda_f}{1 + |\lambda_f|^2}\,, \qquad C_f = \frac{1 - |\lambda_f|^2}{1 + |\lambda_f|^2}\,, \qquad \lambda_f = \frac{q}{p}\frac{\bar{A}_f}{A_f}\,. \tag{12.19}$$

Here, q/p describes B^0–$\overline{B}^0$ mixing and, to a good approximation in the SM, $q/p = V_{tb}^* V_{td}/V_{tb}V_{td}^* = e^{-2i\beta + \mathcal{O}(\lambda^4)}$ in the usual phase convention. A_f ($\bar{A}_f$) is the amplitude of the $B^0 \to f$ ($\overline{B}^0 \to f$) decay. If f is a CP eigenstate, and amplitudes with one CKM phase dominate the decay, then $|A_f| = |\bar{A}_f|$, $C_f = 0$, and $S_f = \sin(\arg\lambda_f) = \eta_f \sin 2\phi$, where η_f is the CP eigenvalue of f and 2ϕ is the phase difference between the $B^0 \to f$ and $B^0 \to \overline{B}^0 \to f$ decay paths. A contribution of another amplitude to the decay with a different CKM phase makes the value of S_f sensitive to relative strong-interaction phases between the decay amplitudes (it also makes $C_f \neq 0$ possible).

The $b \to c\bar{c}s$ decays to CP eigenstates ($B^0 \to$ charmonium $K^0_{S,L}$) are the theoretically cleanest examples, measuring $S_f = -\eta_f \sin 2\beta$. The $b \to sq\bar{q}$ penguin amplitudes have dominantly the same weak phase as the $b \to c\bar{c}s$ tree amplitude. Since only λ^2-suppressed penguin amplitudes introduce a new CP-violating phase, amplitudes with a single weak phase dominate, and we expect $\big||\bar{A}_{\psi K}/A_{\psi K}| - 1\big| < 0.01$. The e^+e^- asymmetric-energy B-factory experiments, *BABAR* [95] and Belle [96], provide precise measurements. The world average including LHCb [97] and other measurements is [98]

$$\sin 2\beta = 0.691 \pm 0.017\,. \tag{12.20}$$

This measurement has a four-fold ambiguity in β, which can be resolved by a global fit as mentioned in Sec. 12.4. Experimentally, the two-fold ambiguity $\beta \to \pi/2 - \beta$ (but not $\beta \to \pi + \beta$) can be resolved by a time-dependent angular analysis of $B^0 \to J/\psi K^{*0}$ [99,100], or a time-dependent Dalitz plot analysis of $B^0 \to \overline{D}^0 h^0$ ($h^0 = \pi^0, \eta, \omega$) with $\overline{D}^0 \to K^0_S\pi^+\pi^-$ [101,102]. These results indicate that negative $\cos 2\beta$ solutions are very unlikely, in agreement with the global CKM fit result.

The $b \to c\bar{c}d$ mediated transitions, such as $B^0 \to J/\psi\pi^0$ and $B^0 \to D^{(*)+}D^{(*)-}$, also measure approximately $\sin 2\beta$. However, the dominant component of the $b \to d$ penguin amplitude has a different CKM phase ($V_{tb}^*V_{td}$) than the tree amplitude ($V_{cb}^*V_{cd}$), and its magnitudes are of the same order in λ. Therefore, the effect of penguins could be large, resulting in $S_f \neq -\eta_f \sin 2\beta$ and $C_f \neq 0$. These decay modes have also been measured by *BABAR* and Belle. The world averages [98], $S_{J/\psi\pi^0} = -0.93 \pm 0.15$, $S_{J/\psi\rho^0} = -0.66^{+0.16}_{-0.12}$, $S_{D^+D^-} = -0.98 \pm 0.17$, and $S_{D^{*+}D^{*-}} = -0.71 \pm 0.09$ ($\eta_f = +1$ for these modes), are consistent with $\sin 2\beta$ obtained from $B^0 \to$ charmonium K^0 decays, and the C_f's are consistent with zero, although the uncertainties are sizable.

The $b \to c\bar{u}d$ decays, $B^0 \to \overline{D}^0 h^0$ with $\overline{D}^0 \to CP$ eigenstates, have no penguin contributions and provide theoretically clean $\sin 2\beta$ measurements. The joint analysis of *BABAR* and Belle gives $S_{D^{(*)}h^0} = -0.66 \pm 0.12$ [103].

12.3.2.2. *Penguin-dominated modes:*

The $b \to s\bar{q}q$ penguin-dominated decays have the same CKM phase as the $b \to c\bar{c}s$ tree level decays, up to corrections suppressed by λ^2, since $V_{tb}^* V_{ts} = -V_{cb}^* V_{cs}[1 + \mathcal{O}(\lambda^2)]$. Therefore, decays such as $B^0 \to \phi K^0$ and $\eta' K^0$ provide $\sin 2\beta$ measurements in the SM. Any new physics contribution to the amplitude with a different weak phase would give rise to $S_f \neq -\eta_f \sin 2\beta$, and possibly $C_f \neq 0$. Therefore, the main interest in these modes is not simply to measure $\sin 2\beta$, but to search for new physics. Measurements of many other decay modes in this category, such as $B \to \pi^0 K_S^0$, $K_S^0 K_S^0 K_S^0$, *etc.*, have also been performed by *BABAR* and Belle. The results and their uncertainties are summarized in Fig. 12.3 and Table 12.1 of Ref. [94].

12.3.3. α / ϕ_2 :

Since α is the phase between $V_{tb}^* V_{td}$ and $V_{ub}^* V_{ud}$, only time-dependent CP asymmetries in $b \to u\bar{u}d$ decay dominated modes can directly measure $\sin 2\alpha$, in contrast to $\sin 2\beta$, where several different transitions can be used. Since $b \to d$ penguin amplitudes have a different CKM phase than $b \to u\bar{u}d$ tree amplitudes, and their magnitudes are of the same order in λ, the penguin contribution can be sizable, which makes the determination of α complicated. To date, α has been measured in $B \to \pi\pi$, $\rho\pi$ and $\rho\rho$ decay modes.

12.3.3.1. $B \to \pi\pi$*:*

It is now experimentally well established that there is a sizable contribution of $b \to d$ penguin amplitudes in $B \to \pi\pi$ decays. Thus, $S_{\pi^+\pi^-}$ in the time-dependent $B^0 \to \pi^+\pi^-$ analysis does not measure $\sin 2\alpha$, but

$$S_{\pi^+\pi^-} = \sqrt{1 - C_{\pi^+\pi^-}^2}\, \sin(2\alpha + 2\Delta\alpha), \tag{12.21}$$

where $2\Delta\alpha$ is the phase difference between $e^{2i\gamma}\bar{A}_{\pi^+\pi^-}$ and $A_{\pi^+\pi^-}$. The value of $\Delta\alpha$, hence α, can be extracted using the isospin relation among the amplitudes of $B^0 \to \pi^+\pi^-$, $B^0 \to \pi^0\pi^0$, and $B^+ \to \pi^+\pi^0$ decays [104],

$$\frac{1}{\sqrt{2}} A_{\pi^+\pi^-} + A_{\pi^0\pi^0} - A_{\pi^+\pi^0} = 0\,, \tag{12.22}$$

and a similar expression for the $\bar{A}_{\pi\pi}$'s. This method utilizes the fact that a pair of pions from $B \to \pi\pi$ decay must be in a zero angular momentum state, and, because of Bose statistics, they must have even isospin. Consequently, $\pi^0\pi^\pm$ is in a pure isospin-2 state, while the penguin amplitudes only contribute to the isospin-0 final state. The latter does not hold for the electroweak penguin amplitudes, but their effect is expected to be small. The isospin analysis uses the world averages of *BABAR*, Belle and LHCb measurements [98] $S_{\pi^+\pi^-} = -0.66 \pm 0.06$, $C_{\pi^+\pi^-} = -0.31 \pm 0.05$, the branching fractions of all three modes, and the direct CP asymmetry $C_{\pi^0\pi^0} = -0.43^{+0.25}_{-0.24}$. This analysis leads to 16 mirror solutions for $0 \leq \alpha < 2\pi$. Because of this, and the sizable experimental error of the $B^0 \to \pi^0\pi^0$ rate and CP asymmetry, only a loose constraint on α can be obtained at present [105], $0° < \alpha < 3.8°$, $86.2° < \alpha < 102.9°$, $122.1° < \alpha < 147.9°$, and $167.1° < \alpha < 180°$ at 68% CL.

12.3.3.2. $B \to \rho\rho$*:*

The decay $B^0 \to \rho^+\rho^-$ contains two vector mesons in the final state, which in general is a mixture of CP-even and CP-odd components. Therefore, it was thought that extracting α from this mode would be complicated.

However, the longitudinal polarization fractions (f_L) in $B^+ \to \rho^+\rho^0$ and $B^0 \to \rho^+\rho^-$ decays were measured to be close to unity [106], which implies that the final states are almost purely CP-even. Furthermore, $\mathcal{B}(B^0 \to \rho^0\rho^0) = (0.97 \pm 0.24) \times 10^{-6}$ is much smaller than $\mathcal{B}(B^0 \to \rho^+\rho^-) = (24.2^{+3.1}_{-3.2}) \times 10^{-6}$ and $\mathcal{B}(B^+ \to \rho^+\rho^0) = (24.0^{+1.9}_{-2.0}) \times 10^{-6}$ [22], which implies that the effect of the penguin diagrams is small. The isospin analysis using the world averages, $S_{\rho^+\rho^-} = -0.14 \pm 0.13$ and $C_{\rho^+\rho^-} = -0.00 \pm 0.09$ [22], together with the time-dependent CP asymmetry, $S_{\rho^0\rho^0} = -0.3 \pm 0.7$ and $C_{\rho^0\rho^0} = -0.2 \pm 0.9$ [107], and the above mentioned branching fractions, gives $0° < \alpha < 5.6°$, $84.4° < \alpha < 95.3°$ and $174.7° < \alpha < 180°$ at 68% CL [105], with mirror solutions at $3\pi/2 - \alpha$. A possible small violation of Eq. (12.22) due to the finite width of the ρ [108] is neglected.

12.3.3.3. $B \to \rho\pi$*:*

The final state in $B^0 \to \rho^+\pi^-$ decay is not a CP eigenstate, but this decay proceeds via the same quark-level diagrams as $B^0 \to \pi^+\pi^-$, and both B^0 and $\overline{B}^0$ can decay to $\rho^+\pi^-$. Consequently, mixing-induced CP violations can occur in four decay amplitudes, $B^0 \to \rho^\pm\pi^\mp$ and $\overline{B}^0 \to \rho^\pm\pi^\mp$. The time-dependent Dalitz plot analysis of $B^0 \to \pi^+\pi^-\pi^0$ decays permits the extraction of α with a single discrete ambiguity, $\alpha \to \alpha + \pi$, since one knows the variation of the strong phases in the interference regions of the $\rho^+\pi^-$, $\rho^-\pi^+$, and $\rho^0\pi^0$ amplitudes in the Dalitz plot [109]. The combination of Belle [110] and *BABAR* [111] measurements gives $\alpha = (54.1^{+7.7}_{-10.3})°$ and $(141.8^{+4.7}_{-5.4})°$ [105]. This constraint is still moderate.

Combining the $B \to \pi\pi$, $\rho\pi$, and $\rho\rho$ decay modes [105], α is constrained as

$$\alpha = (87.6^{+3.5}_{-3.3})°. \tag{12.23}$$

A different statistical approach [112] gives similar constraint from the combination of these measurements.

12.3.4. γ / ϕ_3 :

By virtue of Eq. (12.16), γ does not depend on CKM elements involving the top quark, so it can be measured in tree-level B decays. This is an important distinction from the measurements of α and β, and implies that the measurements of γ are unlikely to be affected by physics beyond the SM.

12.3.4.1. $B^\pm \to DK^\pm$*:*

The interference of $B^- \to D^0 K^-$ ($b \to c\bar{u}s$) and $B^- \to \overline{D}^0 K^-$ ($b \to u\bar{c}s$) transitions can be studied in final states accessible in both D^0 and $\overline{D}^0$ decays [93]. In principle, it is possible to extract the B and D decay amplitudes, the relative strong phases, and the weak phase γ from the data.

A practical complication is that the precision depends sensitively on the ratio of the interfering amplitudes

$$r_B = \left| A(B^- \to \overline{D}^0 K^-) / A(B^- \to D^0 K^-) \right|, \tag{12.24}$$

which is around 0.1−0.2. The original GLW method [113,114] considers D decays to CP eigenstates, such as $B^\pm \to D_{CP}^{(*)}(\to \pi^+\pi^-)K^{\pm(*)}$. To alleviate the smallness of r_B and make the interfering amplitudes (which are products of the B and D decay amplitudes) comparable in magnitude, the ADS method [115] considers final states where Cabibbo-allowed $\overline{D}^0$ and doubly-Cabibbo-suppressed D^0 decays interfere. Extensive measurements [98] have been made by the B factories, CDF and LHCb using both methods.

It was realized that both D^0 and $\overline{D}^0$ have large branching fractions to certain three-body final states, such as $K_S\pi^+\pi^-$, and the analysis can be optimized by studying the Dalitz plot dependence of the interferences [116,117]. The best present determination of γ comes from this method. Belle [118] and *BABAR* [119] obtained $\gamma = (78^{+11}_{-12} \pm 4 \pm 9)°$ and $\gamma = (68 \pm 14 \pm 4 \pm 3)°$, respectively, where the last uncertainty is due to the D-decay modeling. LHCb also measured $\gamma = (62^{+15}_{-14})°$ with the Dalitz model independent manner [120].) The error is sensitive to the central value of the amplitude ratio r_B (and r_B^* for the D^*K mode), for which Belle found somewhat larger central values than *BABAR* and LHCb. The same values of $r_B^{(*)}$ enter the ADS analyses, and the data can be combined to fit for $r_B^{(*)}$ and γ. The D^0–$\overline{D}^0$ mixing has been neglected in all measurements, but its effect on γ is far below the present experimental accuracy [121], unless D^0–$\overline{D}^0$ mixing is due to CP-violating new physics, in which case it can be included in the analysis [122].

Combining the GLW, ADS, and Dalitz analyses [105], γ is constrained as

$$\gamma = (73.2^{+6.3}_{-7.0})°. \tag{12.25}$$

Similar results are found in Ref. [112].

12.3.4.2. $B^0 \to D^{(*)\pm}\pi^{\mp}$*:*

The interference of $b \to u$ and $b \to c$ transitions can be studied in $\overline{B}{}^0 \to D^{(*)+}\pi^-$ ($b \to c\bar{u}d$) and $\overline{B}{}^0 \to B^0 \to D^{(*)+}\pi^-$ ($\bar{b} \to \bar{u}cd$) decays and their CP conjugates, since both B^0 and $\overline{B}{}^0$ decay to $D^{(*)\pm}\pi^{\mp}$ (or $D^{\pm}\rho^{\mp}$, *etc.*). Since there are only tree and no penguin contributions to these decays, in principle, it is possible to extract from the four time-dependent rates the magnitudes of the two hadronic amplitudes, their relative strong phase, and the weak phase between the two decay paths, which is $2\beta + \gamma$.

A complication is that the ratio of the interfering amplitudes is very small, $r_{D\pi} = A(B^0 \to D^+\pi^-)/A(\overline{B}{}^0 \to D^+\pi^-) = \mathcal{O}(0.01)$ (and similarly for $r_{D^*\pi}$ and $r_{D\rho}$), and therefore it has not been possible to measure it. To obtain $2\beta + \gamma$, $SU(3)$ flavor symmetry and dynamical assumptions have been used to relate $A(\overline{B}{}^0 \to D^-\pi^+)$ to $A(\overline{B}{}^0 \to D_s^-\pi^+)$, so this measurement is not model independent at present. Combining the $D^{\pm}\pi^{\mp}$, $D^{*\pm}\pi^{\mp}$ and $D^{\pm}\rho^{\mp}$ measurements [123] gives $\sin(2\beta+\gamma) > 0.68$ at 68% CL [105], consistent with the previously discussed results for β and γ. The amplitude ratio is much larger in the analogous $B_s^0 \to D_s^{\pm}K^{\mp}$ decays, which allows a model-independent extraction of $\gamma - 2\beta_s$ [124] (here $\beta_s = \arg(-V_{ts}V_{tb}^*/V_{cs}V_{cb}^*)$ is related to the phase of B_s mixing). Recent measurement by LHCb [125] gives $(115^{+28}_{-43})^\circ$ using a constraint on $2\beta_s$ (Sec. 12.5).

12.4. Global fit in the Standard Model

Using the independently measured CKM elements mentioned in the previous sections, the unitarity of the CKM matrix can be checked. We obtain $|V_{ud}|^2+|V_{us}|^2+|V_{ub}|^2 = 0.9996\pm0.0005$ (1st row), $|V_{cd}|^2+|V_{cs}|^2+|V_{cb}|^2 = 1.040\pm0.032$ (2nd row), $|V_{ud}|^2+|V_{cd}|^2+|V_{td}|^2 = 0.9975\pm0.0022$ (1st column), and $|V_{us}|^2+|V_{cs}|^2+|V_{ts}|^2 = 1.042\pm0.032$ (2nd column), respectively. The uncertainties in the second row and column are dominated by that of $|V_{cs}|$. For the second row, a slightly better check is obtained from the measurement of $\sum_{u,c,d,s,b}|V_{ij}|^2$ in Sec. 12.2.4 minus the sum in the first row above: $|V_{cd}|^2 + |V_{cs}|^2 + |V_{cb}|^2 = 1.002 \pm 0.027$. These provide strong tests of the unitarity of the CKM matrix. With the significantly improved direct determination of $|V_{tb}|$, the unitarity checks for the third row and column have also become fairly precise, leaving decreasing room for mixing with other states. The sum of the three angles of the unitarity triangle, $\alpha + \beta + \gamma = (183^{+7}_{-8})^\circ$, is also consistent with the SM expectation.

The CKM matrix elements can be most precisely determined using a global fit to all available measurements and imposing the SM constraints (*i.e.*, three generation unitarity). The fit must also use theory predictions for hadronic matrix elements, which sometimes have significant uncertainties. There are several approaches to combining the experimental data. CKMfitter [6,105] and Ref. [126] (which develops [127,128] further) use frequentist statistics, while UTfit [112,129] uses a Bayesian approach. These approaches provide similar results.

The constraints implied by the unitarity of the three generation CKM matrix significantly reduce the allowed range of some of the CKM elements. The fit for the Wolfenstein parameters defined in Eq. (12.4) gives

$$\begin{aligned} \lambda &= 0.22506 \pm 0.00050\,, \qquad A = 0.811 \pm 0.026\,, \\ \bar{\rho} &= 0.124^{+0.019}_{-0.018}\,, \qquad \bar{\eta} = 0.356 \pm 0.011\,. \end{aligned} \tag{12.26}$$

These values are obtained using the method of Refs. [6,105]. Using the prescription of Refs. [112,129] gives $\lambda = 0.22496 \pm 0.00048$, $A = 0.823 \pm 0.013$, $\bar{\rho} = 0.141 \pm 0.019$, $\bar{\eta} = 0.349 \pm 0.012$ [130]. The fit results for the magnitudes of all nine CKM elements are

$$V_{\rm CKM} = \begin{pmatrix} 0.97434^{+0.00011}_{-0.00012} & 0.22506 \pm 0.00050 & 0.00357 \pm 0.00015 \\ 0.22492 \pm 0.00050 & 0.97351 \pm 0.00013 & 0.0411 \pm 0.0013 \\ 0.00875^{+0.00032}_{-0.00033} & 0.0403 \pm 0.0013 & 0.99915 \pm 0.00005 \end{pmatrix}, \tag{12.27}$$

and the Jarlskog invariant is $J = (3.04^{+0.21}_{-0.20}) \times 10^{-5}$.

Figure 12.2 illustrates the constraints on the $\bar{\rho}, \bar{\eta}$ plane from various measurements and the global fit result. The shaded 95% CL regions all overlap consistently around the global fit region.

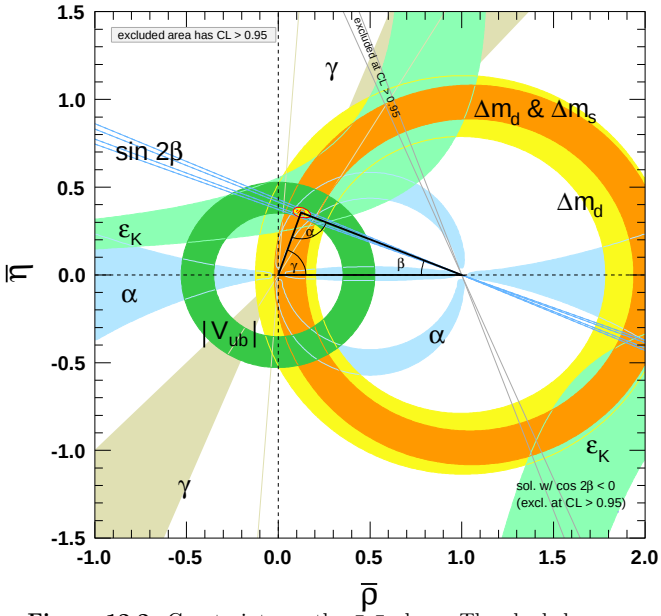

Figure 12.2: Constraints on the $\bar{\rho}, \bar{\eta}$ plane. The shaded areas have 95% CL.

12.5. Implications beyond the SM

The effects in B, B_s, K, and D decays and mixings due to high-scale physics (W, Z, t, H in the SM, and unknown heavier particles) can be parameterized by operators composed of SM fields, obeying the $SU(3) \times SU(2) \times U(1)$ gauge symmetry. Flavor-changing neutral currents, suppressed in the SM, are especially sensitive to beyond SM (BSM) contributions. Processes studied in great detail, both experimentally and theoretically, include neutral meson mixings, $B_{(s)} \to X\gamma$, $X\ell^+\ell^-$, $\ell^+\ell^-$, $K \to \pi\nu\bar{\nu}$, etc. The BSM contributions to these operators are suppressed by powers of the scale of new physics. Already at lowest order, there are many dimension-6 operators, and the observable effects of BSM interactions are encoded in their coefficients. In the SM, these coefficients are determined by just the four CKM parameters, and the W, Z, and quark masses. For example, Δm_d, $\Gamma(B \to \rho\gamma)$, $\Gamma(B \to \pi\ell^+\ell^-)$, and $\Gamma(B \to \ell^+\ell^-)$ are all proportional to $|V_{td}V_{tb}|^2$ in the SM, however, they may receive unrelated contributions from new physics. The new physics contributions may or may not obey the SM relations. (For example, the flavor sector of the MSSM contains 69 CP-conserving parameters and 41 CP-violating phases, *i.e.*, 40 new ones [131]). Thus, similar to the measurements of $\sin 2\beta$ in tree- and loop-dominated decay modes, overconstraining measurements of the magnitudes and phases of flavor-changing neutral-current amplitudes give good sensitivity to new physics.

To illustrate the level of suppression required for BSM contributions, consider a class of models in which the unitarity of the CKM matrix is maintained, and the dominant effect of new physics is to modify the neutral meson mixing amplitudes [132] by $(z_{ij}/\Lambda^2)(\overline{q}_i\gamma^\mu P_L q_j)^2$ (for recent reviews, see [133,134]). It is only known since the measurements of γ and α that the SM gives the leading contribution to $B^0 - \overline{B}{}^0$ mixing [6,135]. Nevertheless, new physics with a generic weak phase may still contribute to neutral meson mixings at a significant fraction of the SM [136,137,129]. The existing data imply that $\Lambda/|z_{ij}|^{1/2}$ has to exceed about 10^4 TeV for $K^0 - \overline{K}{}^0$ mixing, 10^3 TeV for $D^0 - \overline{D}{}^0$ mixing, 500 TeV for $B^0 - \overline{B}{}^0$ mixing, and 100 TeV for $B_s^0 - \overline{B}{}_s^0$ mixing [129,134]. (Some other operators are even better constrained [129].) The constraints are the strongest in the kaon sector, because the CKM suppression is the most severe. Thus, if there is new physics at the TeV scale, $|z_{ij}| \ll 1$ is required. Even if $|z_{ij}|$ are suppressed by a loop factor and $|V_{ti}^*V_{tj}|^2$ (in the down quark sector), similar to the SM, one expects percent-level effects, which may be observable in forthcoming flavor physics experiments. To constrain such extensions of the SM, many measurements irrelevant for the SM-CKM fit, such as the CP asymmetry in semileptonic $B_{d,s}^0$ decays,

$A_{\rm SL}^{d,s}$, are important [138]. A DØ measurement sensitive to certain linear combinations of $A_{\rm SL}^{d}$ and $A_{\rm SL}^{s}$ shows a 3.6σ hint of a deviation from the SM [139].

Many key measurements which are sensitive to BSM flavor physics are not useful to think about in terms of constraining the unitarity triangle in Fig. 12.1. For example, besides the angles in Eq. (12.16), a key quantity in the B_s system is $\beta_s = \arg(-V_{ts}V_{tb}^*/V_{cs}V_{cb}^*)$, which is the small, λ^2-suppressed, angle of a "squashed" unitarity triangle, obtained by taking the scalar product of the second and third columns. This angle can be measured via time-dependent CP violation in $B_s^0 \to J/\psi\,\phi$, similar to β in $B^0 \to J/\psi K^0$. Since the $J/\psi\,\phi$ final state is not a CP eigenstate, an angular analysis of the decay products is needed to separate the CP-even and CP-odd components, which give opposite asymmetries. In the SM, the asymmetry for the CP-even part is $2\beta_s$ (sometimes the notation $\phi_s = -2\beta_s$ plus a possible BSM contribution to the B_s mixing phase is used). Testing if the data agree with the SM prediction, $2\beta_s = 0.0363 \pm 0.0018$ [105], is another sensitive test of the SM. After the first Tevatron CP-asymmetry measurements of $B_s^0 \to J/\psi\phi$ hinted at a possible tension with the SM, the current world average, dominated by LHCb [140] including $B_s \to J/\psi\,K^+K^-$ and $J/\psi\,\pi^+\pi^-$ measurements, is $2\beta_s = 0.034 \pm 0.033$ [22]. This uncertainty is about 20 times the SM uncertainty; thus a lot will be learned from higher-precision measurements in the future.

In the kaon sector, the two measured CP-violating observables ϵ and ϵ' are tiny, so models in which all sources of CP violation are small were viable before the B-factory measurements. Since the measurement of $\sin 2\beta$, we know that CP violation can be an $\mathcal{O}(1)$ effect, and only flavor mixing is suppressed between the three quark generations. Thus, many models with spontaneous CP violation are excluded. In the kaon sector, a very clean test of the SM will come from measurements of $K^+ \to \pi^+\nu\bar{\nu}$ and $K_L^0 \to \pi^0\nu\bar{\nu}$. These loop-induced rare decays are sensitive to new physics, and will allow a determination of β, independent of its value measured in B decays [141].

The CKM elements are fundamental parameters, so they should be measured as precisely as possible. The overconstraining measurements of CP asymmetries, mixing, semileptonic, and rare decays severely constrain the magnitudes and phases of possible new physics contributions to flavor-changing interactions. If new particles are observed at the LHC, it will be important to explore their flavor parameters as precisely as possible to understand the underlying physics.

13. *CP* VIOLATION IN THE QUARK SECTOR

Revised August 2015 by T. Gershon (University of Warwick) and Y. Nir (Weizmann Institute).

The CP transformation combines charge conjugation C with parity P. Under C, particles and antiparticles are interchanged, by conjugating all internal quantum numbers, *e.g.*, $Q \to -Q$ for electromagnetic charge. Under P, the handedness of space is reversed, $\vec{x} \to -\vec{x}$. Thus, for example, a left-handed electron e^-_L is transformed under CP into a right-handed positron, e^+_R.

If CP were an exact symmetry, the laws of Nature would be the same for matter and for antimatter. We observe that most phenomena are C- and P-symmetric, and therefore, also CP-symmetric. In particular, these symmetries are respected by the gravitational, electromagnetic, and strong interactions. The weak interactions, on the other hand, violate C and P in the strongest possible way. For example, the charged W bosons couple to left-handed electrons, e^-_L, and to their CP-conjugate right-handed positrons, e^+_R, but to neither their C-conjugate left-handed positrons, e^+_L, nor their P-conjugate right-handed electrons, e^-_R. While weak interactions violate C and P separately, CP is still preserved in most weak interaction processes. The CP symmetry is, however, violated in certain rare processes, as discovered in neutral K decays in 1964 [1], and observed in recent years in B decays. A K_L meson decays more often to $\pi^- e^+ \nu_e$ than to $\pi^+ e^- \overline{\nu}_e$, thus allowing electrons and positrons to be unambiguously distinguished, but the decay-rate asymmetry is only at the 0.003 level. The CP-violating effects observed in the B system are larger: the parameter describing the CP asymmetry in the decay time distribution of $B^0/\overline{B}^0$ meson transitions to CP eigenstates like $J/\psi K_S$ is about 0.7 [2,3]. These effects are related to K^0–$\overline{K}^0$ and B^0–$\overline{B}^0$ mixing, but CP violation arising solely from decay amplitudes has also been observed, first in $K \to \pi\pi$ decays [4–6], and more recently in B^0 [7,8], B^+ [9–11], and B^0_s [12] decays. Similar effects could also occur, but have not yet been observed, in decays of b baryons. CP violation is not yet experimentally established in the D system, where the Standard Model effects are expected to be $\mathcal{O}(10^{-3})$. Moreover, CP violation has not yet been observed in processes involving the top quark, nor in flavor-conserving processes such as electric dipole moments, nor in the lepton sector; for all of these any significant observation would be a clear indication of physics beyond the Standard Model.

In addition to parity and to continuous Lorentz transformations, there is one other spacetime operation that could be a symmetry of the interactions: time reversal T, $t \to -t$. Violations of T symmetry have been observed in neutral K decays [13]. More recently, exploiting the fact that for neutral B mesons both flavor tagging and CP tagging can be used [14], T violation has been observed between states that are not CP-conjugate [15]. Moreover, T violation is expected as a corollary of CP violation if the combined CPT transformation is a fundamental symmetry of Nature [16]. All observations indicate that CPT is indeed a symmetry of Nature. Furthermore, one cannot build a locally Lorentz-invariant quantum field theory with a Hermitian Hamiltonian that violates CPT. (At several points in our discussion, we avoid assumptions about CPT, in order to identify cases where evidence for CP violation relies on assumptions about CPT.)

Within the Standard Model, CP symmetry is broken by complex phases in the Yukawa couplings (that is, the couplings of the Higgs scalar to quarks). When all manipulations to remove unphysical phases in this model are exhausted, one finds that there is a single CP-violating parameter [17]. In the basis of mass eigenstates, this single phase appears in the 3×3 unitary matrix that gives the W-boson couplings to an up-type antiquark and a down-type quark. (If the Standard Model is supplemented with Majorana mass terms for the neutrinos, the analogous mixing matrix for leptons has three CP-violating phases.) The beautifully consistent and economical Standard-Model description of CP violation in terms of Yukawa couplings, known as the Kobayashi-Maskawa (KM) mechanism [17], agrees with all measurements to date. (Some measurements are in tension with the predictions, and are discussed in more detail below. Pending verification, the results are not considered to change the overall picture of agreement with the Standard Model.) Furthermore, one can fit the data allowing new physics contributions to loop processes to compete with, or even dominate over, the Standard Model amplitudes [18,19]. Such an analysis provides model-independent proof that the KM phase is different from zero, and that the matrix of three-generation quark mixing is the dominant source of CP violation in meson decays.

The current level of experimental accuracy and the theoretical uncertainties involved in the interpretation of the various observations leave room, however, for additional subdominant sources of CP violation from new physics. Indeed, almost all extensions of the Standard Model imply that there are such additional sources. Moreover, CP violation is a necessary condition for baryogenesis, the process of dynamically generating the matter-antimatter asymmetry of the Universe [20]. Despite the phenomenological success of the KM mechanism, it fails (by several orders of magnitude) to accommodate the observed asymmetry [21]. This discrepancy strongly suggests that Nature provides additional sources of CP violation beyond the KM mechanism. The evidence for neutrino masses implies that CP can be violated also in the lepton sector. This situation makes leptogenesis [22,23], a scenario where CP-violating phases in the Yukawa couplings of the neutrinos play a crucial role in the generation of the baryon asymmetry, a very attractive possibility. The expectation of new sources motivates the large ongoing experimental effort to find deviations from the predictions of the KM mechanism.

CP violation can be experimentally searched for in a variety of processes, such as hadron decays, electric dipole moments of neutrons, electrons and nuclei, and neutrino oscillations. Hadron decays via the weak interaction probe flavor-changing CP violation. The search for electric dipole moments may find (or constrain) sources of CP violation that, unlike the KM phase, are not related to flavor-changing couplings. Following the discovery of the Higgs boson [24,25], searches for CP violation in the Higgs sector are becoming feasible. Future searches for CP violation in neutrino oscillations might provide further input on leptogenesis.

The present measurements of CP asymmetries provide some of the strongest constraints on the weak couplings of quarks. Future measurements of CP violation in K, D, B, and B^0_s meson decays will provide additional constraints on the flavor parameters of the Standard Model, and can probe new physics. In this review, we give the formalism and basic physics that are relevant to present and near future measurements of CP violation in the quark sector.

Before going into details, we list here the observables where CP violation has been observed at a level above 5σ [26–28]:

- Indirect CP violation in $K \to \pi\pi$ and $K \to \pi\ell\nu$ decays, and in the $K_L \to \pi^+\pi^- e^+ e^-$ decay, is given by

$$|\epsilon| = (2.228 \pm 0.011) \times 10^{-3}\,. \tag{13.1}$$

- Direct CP violation in $K \to \pi\pi$ decays is given by

$$\mathcal{R}e(\epsilon'/\epsilon) = (1.65 \pm 0.26) \times 10^{-3}\,. \tag{13.2}$$

- CP violation in the interference of mixing and decay in the tree-dominated $b \to c\bar{c}s$ transitions, such as $B^0 \to \psi K^0$, is given by (we use K^0 throughout to denote results that combine K_S and K_L modes, but use the sign appropriate to K_S):

$$S_{\psi K^0} = +0.691 \pm 0.017\,. \tag{13.3}$$

- CP violation in the interference of mixing and decay in modes governed by the tree-dominated $b \to c\bar{u}d$ transitions is given by

$$S_{D^{(*)}_{CP} h^0} = +0.63 \pm 0.11\,, \tag{13.4}$$

- CP violation in the interference of mixing and decay in various modes related to $b \to c\bar{c}d$ transitions is given by

$$S_{\psi\pi^0} = -0.93 \pm 0.15\,, \tag{13.5}$$

$$S_{D^+D^-} = -0.98 \pm 0.17\,. \tag{13.6}$$

$$S_{D^{*+}D^{*-}} = -0.71 \pm 0.09\,. \tag{13.7}$$

- CP violation in the interference of mixing and decay in various modes related to $b \to q\bar{q}s$ (penguin) transitions is given by

$$S_{\phi K^0} = +0.74^{+0.11}_{-0.13}\,, \tag{13.8}$$

$$S_{\eta' K^0} = +0.63 \pm 0.06\,, \tag{13.9}$$

$$S_{f_0 K^0} = +0.69^{+0.10}_{-0.12}\,, \tag{13.10}$$

$$S_{K^+K^-K_S} = +0.68^{+0.09}_{-0.10}\,, \tag{13.11}$$

- CP violation in the interference of mixing and decay in the $B^0 \to \pi^+\pi^-$ mode is given by

$$S_{\pi^+\pi^-} = -0.66 \pm 0.06\,. \tag{13.12}$$

- Direct CP violation in the $B^0 \to \pi^+\pi^-$ mode is given by

$$C_{\pi^+\pi^-} = -0.31 \pm 0.05\,. \tag{13.13}$$

- Direct CP violation in the $\overline{B}^0 \to K^-\pi^+$ mode is given by

$$\mathcal{A}_{\overline{B}^0 \to K^-\pi^+} = -0.082 \pm 0.006\,. \tag{13.14}$$

- Direct CP violation in $B^+ \to D_+ K^+$ decays (D_+ is the CP-even neutral D state) is given by

$$\mathcal{A}_{B^+ \to D_+ K^+} = +0.195 \pm 0.027\,. \tag{13.15}$$

- Direct CP violation in the $\overline{B}^0_s \to K^+\pi^-$ mode is given by

$$\mathcal{A}_{\overline{B}^0_s \to K^+\pi^-} = +0.26 \pm 0.04\,. \tag{13.16}$$

- Direct CP violation in $B^+ \to K^+K^-\pi^+$ decays is given by

$$\mathcal{A}_{B^+ \to K^+K^-\pi^+} = -0.118 \pm 0.022\,. \tag{13.17}$$

In addition, large CP violation effects have recently been observed in certain regions of the phase space of $B^+ \to K^+K^-K^+$, $\pi^+\pi^-K^+$, $\pi^+\pi^-\pi^+$ and $K^+K^-\pi^+$ decays.

13.1. Formalism

The phenomenology of CP violation for neutral flavored mesons is particularly interesting, since many of the observables can be cleanly interpreted. Although the phenomenology is superficially different for K^0, D^0, B^0, and B^0_s decays, this is primarily because each of these systems is governed by a different balance between decay rates, oscillations, and lifetime splitting. However, the general considerations presented in this section are identical for all flavored neutral pseudoscalar mesons. The phenomenology of CP violation for neutral mesons that do not carry flavor quantum numbers (such as the $\eta^{(\prime)}$ state) is quite different: such states are their own antiparticles and have definite CP eigenvalues, so the signature of CP violation is simply the decay to a final state with the opposite CP. Such decays are mediated by the electromagnetic or (OZI-suppressed) strong interaction, where CP violation is not expected and has not yet been observed. In the remainder of this review, we restrict ourselves to considerations of weakly decaying hadrons.

In this section, we present a general formalism for, and classification of, CP violation in the decay of a weakly decaying hadron, denoted M. We pay particular attention to the case that M is a K^0, D^0, B^0, or B^0_s meson. Subsequent sections describe the CP-violating phenomenology, approximations, and alternative formalisms that are specific to each system.

13.1.1. *Charged- and neutral-hadron decays* :

We define decay amplitudes of M (which could be charged or neutral) and its CP conjugate $\overline{M}$ to a multi-particle final state f and its CP conjugate $\overline{f}$ as

$$\begin{aligned} A_f &= \langle f\,|\mathcal{H}|\,M\rangle\,, \quad \overline{A}_f = \langle f\,|\mathcal{H}|\,\overline{M}\rangle\,, \\ A_{\overline{f}} &= \langle \overline{f}\,|\mathcal{H}|\,M\rangle\,, \quad \overline{A}_{\overline{f}} = \langle \overline{f}\,|\mathcal{H}|\,\overline{M}\rangle\,, \end{aligned} \tag{13.18}$$

where $\mathcal{H}$ is the Hamiltonian governing weak interactions. The action of CP on these states introduces phases ξ_M and ξ_f that depend on their flavor content, according to

$$CP|M\rangle = e^{+i\xi_M}\,|\overline{M}\rangle\,, \quad CP|f\rangle = e^{+i\xi_f}\,|\overline{f}\rangle\,, \tag{13.19}$$

with

$$CP|\overline{M}\rangle = e^{-i\xi_M}\,|M\rangle\,, \quad CP|\overline{f}\rangle = e^{-i\xi_f}\,|f\rangle \tag{13.20}$$

so that $(CP)^2 = 1$. The phases ξ_M and ξ_f are arbitrary and unobservable because of the flavor symmetry of the strong interaction. If CP is conserved by the dynamics, $[CP, \mathcal{H}] = 0$, then A_f and $\overline{A}_{\overline{f}}$ have the same magnitude and an arbitrary unphysical relative phase

$$\overline{A}_{\overline{f}} = e^{i(\xi_f - \xi_M)}\,A_f\,. \tag{13.21}$$

13.1.2. *Neutral-meson mixing* :

A state that is initially a superposition of M^0 and $\overline{M}^0$, say

$$|\psi(0)\rangle = a(0)|M^0\rangle + b(0)|\overline{M}^0\rangle\,, \tag{13.22}$$

will evolve in time acquiring components that describe all possible decay final states $\{f_1, f_2, \ldots\}$, that is,

$$|\psi(t)\rangle = a(t)|M^0\rangle + b(t)|\overline{M}^0\rangle + c_1(t)|f_1\rangle + c_2(t)|f_2\rangle + \cdots\,. \tag{13.23}$$

If we are interested in computing only the values of $a(t)$ and $b(t)$ (and not the values of all $c_i(t)$), and if the times t in which we are interested are much larger than the typical strong interaction scale, then we can use a much simplified formalism [29]. The simplified time evolution is determined by a 2×2 effective Hamiltonian $\mathbf{H}$ that is not Hermitian, since otherwise the mesons would only oscillate and not decay. Any complex matrix, such as $\mathbf{H}$, can be written in terms of Hermitian matrices $\mathbf{M}$ and $\mathbf{\Gamma}$ as

$$\mathbf{H} = \mathbf{M} - \frac{i}{2}\mathbf{\Gamma}\,. \tag{13.24}$$

$\mathbf{M}$ and $\mathbf{\Gamma}$ are associated with $(M^0, \overline{M}^0) \leftrightarrow (M^0, \overline{M}^0)$ transitions via off-shell (dispersive), and on-shell (absorptive) intermediate states, respectively. Diagonal elements of $\mathbf{M}$ and $\mathbf{\Gamma}$ are associated with the flavor-conserving transitions $M^0 \to M^0$ and $\overline{M}^0 \to \overline{M}^0$, while off-diagonal elements are associated with flavor-changing transitions $M^0 \leftrightarrow \overline{M}^0$.

The eigenvectors of $\mathbf{H}$ have well-defined masses and decay widths. To specify the components of the strong interaction eigenstates, M^0 and $\overline{M}^0$, in the light (M_L) and heavy (M_H) mass eigenstates, we introduce three complex parameters: p, q, and, for the case that both CP and CPT are violated in mixing, z:

$$\begin{aligned} |M_L\rangle &\propto p\sqrt{1-z}\,|M^0\rangle + q\sqrt{1+z}\,|\overline{M}^0\rangle \\ |M_H\rangle &\propto p\sqrt{1+z}\,|M^0\rangle - q\sqrt{1-z}\,|\overline{M}^0\rangle\,, \end{aligned} \tag{13.25}$$

with the normalization $|q|^2 + |p|^2 = 1$ when $z = 0$. (Another possible choice, which is in standard usage for K mesons, defines the mass eigenstates according to their lifetimes: K_S for the short-lived and K_L for the long-lived state. The K_L is experimentally found to be the heavier state. Yet another choice is often used for the D mesons [30]: the eigenstates are labelled according to their dominant CP content.)

The real and imaginary parts of the eigenvalues $\omega_{L,H}$ corresponding to $|M_{L,H}\rangle$ represent their masses and decay widths, respectively. The mass and width splittings are

$$\begin{aligned} \Delta m &\equiv m_H - m_L = \mathcal{R}e(\omega_H - \omega_L)\,, \\ \Delta\Gamma &\equiv \Gamma_H - \Gamma_L = -2\,\mathcal{I}m(\omega_H - \omega_L)\,. \end{aligned} \tag{13.26}$$

Note that here Δm is positive by definition, while the sign of $\Delta\Gamma$ must be experimentally determined. The sign of $\Delta\Gamma$ has not yet been established for B^0 mesons, while $\Delta\Gamma < 0$ is established for K and B_s^0 mesons. The Standard Model predicts $\Delta\Gamma < 0$ also for $B_{(s)}^0$ mesons (for this reason, $\Delta\Gamma = \Gamma_L - \Gamma_H$, which is still a signed quantity, is often used in the B^0 and B_s^0 literature and is the convention used in the PDG experimental summaries).

Solving the eigenvalue problem for $\mathbf{H}$ yields

$$\left(\frac{q}{p}\right)^2 = \frac{\mathbf{M}_{12}^* - (i/2)\mathbf{\Gamma}_{12}^*}{\mathbf{M}_{12} - (i/2)\mathbf{\Gamma}_{12}} \tag{13.27}$$

and

$$z \equiv \frac{\delta m - (i/2)\delta\Gamma}{\Delta m - (i/2)\Delta\Gamma} \,, \tag{13.28}$$

where

$$\delta m \equiv \mathbf{M}_{11} - \mathbf{M}_{22} \,, \quad \delta\Gamma \equiv \mathbf{\Gamma}_{11} - \mathbf{\Gamma}_{22} \tag{13.29}$$

are the differences in effective mass and decay-rate expectation values for the strong interaction states M^0 and $\overline{M}^0$.

If either CP or CPT is a symmetry of $\mathbf{H}$ (independently of whether T is conserved or violated), then the values of δm and $\delta\Gamma$ are both zero, and hence $z = 0$. We also find that

$$\omega_H - \omega_L = 2\sqrt{\left(\mathbf{M}_{12} - \frac{i}{2}\mathbf{\Gamma}_{12}\right)\left(\mathbf{M}_{12}^* - \frac{i}{2}\mathbf{\Gamma}_{12}^*\right)} \,. \tag{13.30}$$

If either CP or T is a symmetry of $\mathbf{H}$ (independently of whether CPT is conserved or violated), then $\mathbf{\Gamma}_{12}/\mathbf{M}_{12}$ is real, leading to

$$\left(\frac{q}{p}\right)^2 = e^{2i\xi_M} \quad \Rightarrow \quad \left|\frac{q}{p}\right| = 1 \,, \tag{13.31}$$

where ξ_M is the arbitrary unphysical phase introduced in Eq. (13.20). If, and only if, CP is a symmetry of $\mathbf{H}$ (independently of CPT and T), then both of the above conditions hold, with the result that the mass eigenstates are orthogonal

$$\langle M_H | M_L \rangle = |p|^2 - |q|^2 = 0 \,. \tag{13.32}$$

13.1.3. *CP-violating observables* :

All CP-violating observables in M and $\overline{M}$ decays to final states f and $\overline{f}$ can be expressed in terms of phase-convention-independent combinations of A_f, $\overline{A}_f$, $A_{\overline{f}}$, and $\overline{A}_{\overline{f}}$, together with, for neutral meson decays only, q/p. CP violation in charged meson and all baryon decays depends only on the combination $|\overline{A}_{\overline{f}}/A_f|$, while CP violation in flavored neutral meson decays is complicated by $M^0 \leftrightarrow \overline{M}^0$ oscillations, and depends, additionally, on $|q/p|$ and on $\lambda_f \equiv (q/p)(\overline{A}_f/A_f)$.

The decay rates of the two neutral kaon mass eigenstates, K_S and K_L, are different enough ($\Gamma_S/\Gamma_L \sim 500$) that one can, in most cases, actually study their decays independently. For D^0, B^0, and B_s^0 mesons, however, values of $\Delta\Gamma/\Gamma$ (where $\Gamma \equiv (\Gamma_H + \Gamma_L)/2$) are relatively small, and so both mass eigenstates must be considered in their evolution. We denote the state of an initially pure $|M^0\rangle$ or $|\overline{M}^0\rangle$ after an elapsed proper time t as $|M^0_{\rm phys}(t)\rangle$ or $|\overline{M}^0_{\rm phys}(t)\rangle$, respectively. Using the effective Hamiltonian approximation, but not assuming CPT is a good symmetry, we obtain

$$\begin{aligned} |M^0_{\rm phys}(t)\rangle &= (g_+(t) + z\, g_-(t))\,|M^0\rangle - \sqrt{1-z^2}\,\frac{q}{p}\,g_-(t)|\overline{M}^0\rangle \,, \\ |\overline{M}^0_{\rm phys}(t)\rangle &= (g_+(t) - z\, g_-(t))\,|\overline{M}^0\rangle - \sqrt{1-z^2}\,\frac{p}{q}\,g_-(t)|M^0\rangle \,, \end{aligned} \tag{13.33}$$

where

$$g_\pm(t) \equiv \frac{1}{2}\left(e^{-im_H t - \frac{1}{2}\Gamma_H t} \pm e^{-im_L t - \frac{1}{2}\Gamma_L t}\right) \tag{13.34}$$

and $z = 0$ if either CPT or CP is conserved.

Defining $x \equiv \Delta m/\Gamma$ and $y \equiv \Delta\Gamma/(2\Gamma)$, and assuming $z = 0$, one obtains the following time-dependent decay rates:

$$\begin{aligned} &\frac{d\Gamma\left[M^0_{\rm phys}(t) \to f\right]/dt}{e^{-\Gamma t}\mathcal{N}_f} = \\ &\quad \left(|A_f|^2 + |(q/p)\overline{A}_f|^2\right)\cosh(y\Gamma t) + \left(|A_f|^2 - |(q/p)\overline{A}_f|^2\right)\cos(x\Gamma t) \\ &\quad + 2\,\mathcal{R}e((q/p)A_f^*\overline{A}_f)\sinh(y\Gamma t) - 2\,\mathcal{I}m((q/p)A_f^*\overline{A}_f)\sin(x\Gamma t) \,, \end{aligned} \tag{13.35}$$

$$\begin{aligned} &\frac{d\Gamma\left[\overline{M}^0_{\rm phys}(t) \to f\right]/dt}{e^{-\Gamma t}\mathcal{N}_f} = \\ &\quad \left(|(p/q)A_f|^2 + |\overline{A}_f|^2\right)\cosh(y\Gamma t) - \left(|(p/q)A_f|^2 - |\overline{A}_f|^2\right)\cos(x\Gamma t) \\ &\quad + 2\,\mathcal{R}e((p/q)A_f\overline{A}_f^*)\sinh(y\Gamma t) - 2\,\mathcal{I}m((p/q)A_f\overline{A}_f^*)\sin(x\Gamma t) \,, \end{aligned} \tag{13.36}$$

where $\mathcal{N}_f$ is a common, time-independent, normalization factor that can be determined bearing in mind that the range of t is $0 < t < \infty$. Decay rates to the CP-conjugate final state $\overline{f}$ are obtained analogously, with $\mathcal{N}_f = \mathcal{N}_{\overline{f}}$ and the substitutions $A_f \to A_{\overline{f}}$ and $\overline{A}_f \to \overline{A}_{\overline{f}}$ in Eqs. (13.35, 13.36). Terms proportional to $|A_f|^2$ or $|\overline{A}_f|^2$ are associated with decays that occur without any net $M^0 \leftrightarrow \overline{M}^0$ oscillation, while terms proportional to $|(q/p)\overline{A}_f|^2$ or $|(p/q)A_f|^2$ are associated with decays following a net oscillation. The $\sinh(y\Gamma t)$ and $\sin(x\Gamma t)$ terms of Eqs. (13.35, 13.36) are associated with the interference between these two cases. Note that, in multi-body decays, amplitudes are functions of phase-space variables. Interference may be present in some regions but not others, and is strongly influenced by resonant substructure.

When neutral pseudoscalar mesons are produced coherently in pairs from the decay of a vector resonance, $V \to M^0\overline{M}^0$ (for example, $\Upsilon(4S) \to B^0\overline{B}^0$ or $\phi \to K^0\overline{K}^0$), the time-dependence of their subsequent decays to final states f_1 and f_2 has a similar form to Eqs. (13.35, 13.36):

$$\begin{aligned} &\frac{d\Gamma\left[V_{\rm phys}(t_1,t_2) \to f_1 f_2\right]/d(\Delta t)}{e^{-\Gamma|\Delta t|}\mathcal{N}_{f_1 f_2}} = \\ &\quad \left(|a_+|^2 + |a_-|^2\right)\cosh(y\Gamma\Delta t) + \left(|a_+|^2 - |a_-|^2\right)\cos(x\Gamma\Delta t) \\ &\quad - 2\,\mathcal{R}e(a_+^* a_-)\sinh(y\Gamma\Delta t) + 2\,\mathcal{I}m(a_+^* a_-)\sin(x\Gamma\Delta t) \,, \end{aligned} \tag{13.37}$$

where $\Delta t \equiv t_2 - t_1$ is the difference in the production times, t_1 and t_2, of f_1 and f_2, respectively, and the dependence on the average decay time and on decay angles has been integrated out. The normalisation factor $\mathcal{N}_{f_1 f_2}$ can be evaluated, noting that the range of Δt is $-\infty < \Delta t < \infty$. The coefficients in Eq. (13.37) are determined by the amplitudes for no net oscillation from $t_1 \to t_2$, $\overline{A}_{f_1}A_{f_2}$, and $A_{f_1}\overline{A}_{f_2}$, and for a net oscillation, $(q/p)\overline{A}_{f_1}\overline{A}_{f_2}$ and $(p/q)A_{f_1}A_{f_2}$, via

$$a_+ \equiv \overline{A}_{f_1}A_{f_2} - A_{f_1}\overline{A}_{f_2} \,, \tag{13.38}$$

$$a_- \equiv -\sqrt{1-z^2}\left(\frac{q}{p}\overline{A}_{f_1}\overline{A}_{f_2} - \frac{p}{q}A_{f_1}A_{f_2}\right) + z\left(\overline{A}_{f_1}A_{f_2} + A_{f_1}\overline{A}_{f_2}\right) \,.$$

Assuming CPT conservation, $z = 0$, and identifying $\Delta t \to t$ and $f_2 \to f$, we find that Eqs. (13.37, 13.38) reduce essentially to Eq. (13.35) with $A_{f_1} = 0$, $\overline{A}_{f_1} = 1$, or to Eq. (13.36) with $\overline{A}_{f_1} = 0$, $A_{f_1} = 1$. Indeed, such a situation plays an important role in experiments that exploit the coherence of $V \to M^0\overline{M}^0$ (for example $\psi(3770) \to D^0\overline{D}^0$ or $\Upsilon(4S) \to B^0\overline{B}^0$) production. Final states f_1 with $A_{f_1} = 0$ or $\overline{A}_{f_1} = 0$ are called tagging states, because they identify the decaying pseudoscalar meson as, respectively, $\overline{M}^0$ or M^0. Before one of M^0 or $\overline{M}^0$ decays, they evolve in phase, so that there is always one M^0 and one $\overline{M}^0$ present. A tagging decay of one meson sets the clock for the time evolution of the other: it starts at t_1 as purely M^0 or $\overline{M}^0$, with time evolution that depends only on $t_2 - t_1$.

When f_1 is a state that both M^0 and $\overline{M}^0$ can decay into, then Eq. (13.37) contains interference terms proportional to $A_{f_1}\overline{A}_{f_1} \neq 0$ that are not present in Eqs. (13.35, 13.36). Even when f_1 is dominantly produced by M^0 decays rather than $\overline{M}^0$ decays, or vice versa, $A_{f_1}\overline{A}_{f_1}$ can be non-zero owing to doubly-CKM-suppressed decays (with amplitudes suppressed by at least two powers of λ relative to the dominant amplitude, in the language of Section 13.3), and these terms should be considered for precision studies of CP violation in coherent $V \to M^0\overline{M}^0$ decays [31]. The correlations in $V \to M^0\overline{M}^0$ decays can also be exploited to determine strong phase differences between favored and suppressed decay amplitudes [32].

13.1.4. *Classification of CP-violating effects* :

We distinguish three types of CP-violating effects that can occur in the quark sector:

I. CP violation in decay is defined by

$$|\overline{A}_{\overline{f}}/A_f| \neq 1 \,. \tag{13.39}$$

In charged meson (and all baryon) decays, where mixing effects are absent, this is the only possible source of CP asymmetries:

$$\mathcal{A}_{f^\pm} \equiv \frac{\Gamma(M^- \to f^-) - \Gamma(M^+ \to f^+)}{\Gamma(M^- \to f^-) + \Gamma(M^+ \to f^+)} = \frac{|\overline{A}_{f^-}/A_{f^+}|^2 - 1}{|\overline{A}_{f^-}/A_{f^+}|^2 + 1} \,. \tag{13.40}$$

Note that the usual sign convention for CP asymmetries of hadrons is for the difference between the rate involving the particle that contains a heavy quark and that which contains an antiquark. Hence Eq. (13.40) corresponds to the definition for $B^\pm$ mesons, but the opposite sign is used for $D^\pm_{(s)}$ decays.

II. CP (and T) violation in mixing is defined by

$$|q/p| \neq 1 \,. \tag{13.41}$$

In charged-current semileptonic neutral meson decays $M, \overline{M} \to \ell^\pm X$ (taking $|A_{\ell^+X}| = |\overline{A}_{\ell^-X}|$ and $A_{\ell^-X} = \overline{A}_{\ell^+X} = 0$, as is the case in the Standard Model, to lowest order in G_F, and in most of its reasonable extensions), this is the only source of CP violation, and can be measured via the asymmetry of "wrong-sign" decays induced by oscillations:

$$\mathcal{A}_{\rm SL}(t) \equiv \frac{d\Gamma/dt\big[\overline{M}^0_{\rm phys}(t) \to \ell^+X\big] - d\Gamma/dt\big[M^0_{\rm phys}(t) \to \ell^-X\big]}{d\Gamma/dt\big[\overline{M}^0_{\rm phys}(t) \to \ell^+X\big] + d\Gamma/dt\big[M^0_{\rm phys}(t) \to \ell^-X\big]}$$
$$= \frac{1 - |q/p|^4}{1 + |q/p|^4}. \tag{13.42}$$

Note that this asymmetry of time-dependent decay rates is actually time-independent.

III. CP violation in interference between a decay without mixing, $M^0 \to f$, and a decay with mixing, $M^0 \to \overline{M}^0 \to f$ (such an effect occurs only in decays to final states that are common to M^0 and $\overline{M}^0$, including all CP eigenstates), is defined by

$$\arg(\lambda_f) + \arg(\lambda_{\overline{f}}) \neq 0 \,, \tag{13.43}$$

with

$$\lambda_f \equiv \frac{q}{p}\frac{\overline{A}_f}{A_f} \,. \tag{13.44}$$

For final CP eigenstates, f_{CP}, the condition Eq. (13.43) simplifies to

$$\mathcal{I}m(\lambda_{f_{CP}}) \neq 0 \,, \tag{13.45}$$

This form of CP violation can be observed, for example, using the asymmetry of neutral meson decays into CP eigenstates

$$\mathcal{A}_{f_{CP}}(t) \equiv \frac{d\Gamma/dt\big[\overline{M}^0_{\rm phys}(t) \to f_{CP}\big] - d\Gamma/dt\big[M^0_{\rm phys}(t) \to f_{CP}\big]}{d\Gamma/dt\big[\overline{M}^0_{\rm phys}(t) \to f_{CP}\big] + d\Gamma/dt\big[M^0_{\rm phys}(t) \to f_{CP}\big]} \,. \tag{13.46}$$

If $\Delta\Gamma = 0$, as expected to a good approximation for B^0 mesons, but not for K^0 and B^0_s mesons, and $|q/p| = 1$, then $\mathcal{A}_{f_{CP}}$ has a particularly simple form (see Eq. (13.91), below). If, in addition, the decay amplitudes fulfill $|\overline{A}_{f_{CP}}| = |A_{f_{CP}}|$, the interference between decays with and without mixing is the only source of the asymmetry and $\mathcal{A}_{f_{CP}}(t) = \mathcal{I}m(\lambda_{f_{CP}})\sin(x\Gamma t)$.

Examples of these three types of CP violation will be given in Sections 13.4, 13.5, and 13.6.

13.2. Theoretical Interpretation: General Considerations

Consider the $M \to f$ decay amplitude A_f, and the CP conjugate process, $\overline{M} \to \overline{f}$, with decay amplitude $\overline{A}_{\overline{f}}$. There are two types of phases that may appear in these decay amplitudes. Complex parameters in any Lagrangian term that contributes to the amplitude will appear in complex conjugate form in the CP-conjugate amplitude. Thus, their phases appear in A_f and $\overline{A}_{\overline{f}}$ with opposite signs. In the Standard Model, these phases occur only in the couplings of the $W^\pm$ bosons, and hence, are often called "weak phases." The weak phase of any single term is convention-dependent. However, the difference between the weak phases in two different terms in A_f is convention-independent. A second type of phase can appear in scattering or decay amplitudes, even when the Lagrangian is real. This phase originates from the possible contribution from intermediate on-shell states in the decay process. Since such phases are generated by CP-invariant interactions, they are the same in A_f and $\overline{A}_{\overline{f}}$. Usually the dominant rescattering is due to strong interactions; hence the designation "strong phases" for the phase shifts so induced. Again, only the relative strong phases between different terms in the amplitude are physically meaningful.

The "weak" and "strong" phases discussed here appear in addition to the spurious CP-transformation phases of Eq. (13.21). Those spurious phases are due to an arbitrary choice of phase convention, and do not originate from any dynamics or induce any CP violation. For simplicity, we set them to zero from here on.

It is useful to write each contribution a_i to A_f in three parts: its magnitude $|a_i|$, its weak phase ϕ_i, and its strong phase δ_i. If, for example, there are two such contributions, $A_f = a_1 + a_2$, we have

$$A_f = |a_1|e^{i(\delta_1+\phi_1)} + |a_2|e^{i(\delta_2+\phi_2)},$$
$$\overline{A}_{\overline{f}} = |a_1|e^{i(\delta_1-\phi_1)} + |a_2|e^{i(\delta_2-\phi_2)}. \tag{13.47}$$

Similarly, for neutral mesons, it is useful to write

$$\mathbf{M}_{12} = |\mathbf{M}_{12}|e^{i\phi_M} \,, \quad \mathbf{\Gamma}_{12} = |\mathbf{\Gamma}_{12}|e^{i\phi_\Gamma} \,. \tag{13.48}$$

Each of the phases appearing in Eqs. (13.47, 13.48) is convention-dependent, but combinations such as $\delta_1 - \delta_2$, $\phi_1 - \phi_2$, $\phi_M - \phi_\Gamma$, and $\phi_M + \phi_1 - \overline{\phi}_1$ (where $\overline{\phi}_1$ is a weak phase contributing to $\overline{A}_f$) are physical.

It is now straightforward to evaluate the various asymmetries in terms of the theoretical parameters introduced here. We will do so with approximations that are often relevant to the most interesting measured asymmetries.

1. The CP asymmetry in charged meson and all baryon decays [Eq. (13.40)] is given by

$$\mathcal{A}_f = -\frac{2|a_1a_2|\sin(\delta_2-\delta_1)\sin(\phi_2-\phi_1)}{|a_1|^2 + |a_2|^2 + 2|a_1a_2|\cos(\delta_2-\delta_1)\cos(\phi_2-\phi_1)} \,. \tag{13.49}$$

The quantity of most interest to theory is the weak phase difference $\phi_2 - \phi_1$. Its extraction from the asymmetry requires, however, that the amplitude ratio $|a_2/a_1|$ and the strong phase difference $\delta_2 - \delta_1$ are known. Both quantities depend on non-perturbative hadronic parameters that are difficult to calculate, but in some cases can be obtained from experiment.

2. In the approximation that $|\mathbf{\Gamma}_{12}/\mathbf{M}_{12}| \ll 1$ (valid for B^0 and B^0_s mesons), the CP asymmetry in semileptonic neutral-meson decays [Eq. (13.42)] is given by

$$\mathcal{A}_{\rm SL} = -\left|\frac{\mathbf{\Gamma}_{12}}{\mathbf{M}_{12}}\right|\sin(\phi_M - \phi_\Gamma) \,. \tag{13.50}$$

The quantity of most interest to theory is the weak phase $\phi_M - \phi_\Gamma$. Its extraction from the asymmetry requires, however, that $|\mathbf{\Gamma}_{12}/\mathbf{M}_{12}|$

is known. This quantity depends on long-distance physics that is difficult to calculate.

3. In the approximations that only a single weak phase contributes to decay, $A_f = |a_f| e^{i(\delta_f + \phi_f)}$, and that $|\mathbf{\Gamma}_{12}/\mathbf{M}_{12}| = 0$, we obtain $|\lambda_f| = 1$, and the CP asymmetries in decays to a final CP eigenstate f [Eq. (13.46)] with eigenvalue $\eta_f = \pm 1$ are given by

$$\mathcal{A}_{f_{CP}}(t) = \mathcal{I}m(\lambda_f)\ \sin(\Delta m t) \quad \text{with} \quad \mathcal{I}m(\lambda_f) = \eta_f \sin(\phi_M + 2\phi_f)\,. \tag{13.51}$$

Note that the phase measured is purely a weak phase, and no hadronic parameters are involved in the extraction of its value from $\mathcal{I}m(\lambda_f)$.

The discussion above allows us to introduce another classification of CP-violating effects:

1. *Indirect CP violation* is consistent with taking $\phi_M \neq 0$ and setting all other CP violating phases to zero. CP violation in mixing (type II) belongs to this class.
2. *Direct CP violation* cannot be accounted for by just $\phi_M \neq 0$. CP violation in decay (type I) belongs to this class.

The historical significance of this classification is related to theory. In superweak models [33], CP violation appears only in diagrams that contribute to $\mathbf{M}_{12}$, hence they predict that there is no direct CP violation. In most models and, in particular, in the Standard Model, CP violation is both direct and indirect. As concerns type III CP violation, a single observation of such an effect would be consistent with indirect CP violation, but observing $\eta_{f_1}\mathcal{I}m(\lambda_{f_1}) \neq \eta_{f_2}\mathcal{I}m(\lambda_{f_2})$ (for the same decaying meson and two different final CP eigenstates f_1 and f_2) would establish direct CP violation. The experimental observation of $\epsilon' \neq 0$, which was achieved by establishing that $\mathcal{I}m(\lambda_{\pi^+\pi^-}) \neq \mathcal{I}m(\lambda_{\pi^0\pi^0})$ (see Section 13.4), excluded the superweak scenario.

13.3. Theoretical Interpretation: The KM Mechanism

Of all the Standard Model quark parameters, only the Kobayashi-Maskawa (KM) phase is CP-violating. Having a single source of CP violation, the Standard Model is very predictive for CP asymmetries: some vanish, and those that do not are correlated.

To be precise, CP could be violated also by strong interactions. The experimental upper bound on the electric-dipole moment of the neutron implies, however, that $\theta_{\rm QCD}$, the non-perturbative parameter that determines the strength of this type of CP violation, is tiny, if not zero. (The smallness of $\theta_{\rm QCD}$ constitutes a theoretical puzzle, known as "the strong CP problem.") In particular, it is irrelevant to our discussion of hadron decays.

The charged current interactions (that is, the $W^\pm$ interactions) for quarks are given by

$$-\mathcal{L}_{W^\pm} = \frac{g}{\sqrt{2}}\ \overline{u_{Li}}\ \gamma^\mu\ (V_{\rm CKM})_{ij}\ d_{Lj}\ W^+_\mu + \text{h.c.} \tag{13.52}$$

Here $i, j = 1, 2, 3$ are generation numbers. The Cabibbo-Kobayashi-Maskawa (CKM) mixing matrix for quarks is a 3×3 unitary matrix [34]. Ordering the quarks by their masses, *i.e.*, $(u_1, u_2, u_3) \to (u, c, t)$ and $(d_1, d_2, d_3) \to (d, s, b)$, the elements of $V_{\rm CKM}$ are written as follows:

$$V_{\rm CKM} = \begin{pmatrix} V_{ud} & V_{us} & V_{ub} \\ V_{cd} & V_{cs} & V_{cb} \\ V_{td} & V_{ts} & V_{tb} \end{pmatrix}\,. \tag{13.53}$$

While a general 3×3 unitary matrix depends on three real angles and six phases, the freedom to redefine the phases of the quark mass eigenstates can be used to remove five of the phases, leaving a single physical phase, the Kobayashi-Maskawa phase, that is responsible for all CP violation in the Standard Model.

The fact that one can parametrize $V_{\rm CKM}$ by three real and only one imaginary physical parameters can be made manifest by choosing an explicit parametrization. The Wolfenstein parametrization [35,36] is particularly useful:

$$V_{\rm CKM} = \begin{pmatrix} 1 - \frac{1}{2}\lambda^2 - \frac{1}{8}\lambda^4 & \lambda & A\lambda^3(\rho - i\eta) \\ -\lambda + \frac{1}{2}A^2\lambda^5[1 - 2(\rho + i\eta)] & 1 - \frac{1}{2}\lambda^2 - \frac{1}{8}\lambda^4(1 + 4A^2) & A\lambda^2 \\ A\lambda^3[1 - (1 - \frac{1}{2}\lambda^2)(\rho + i\eta)] & -A\lambda^2 + \frac{1}{2}A\lambda^4[1 - 2(\rho + i\eta)] & 1 - \frac{1}{2}A^2\lambda^4 \end{pmatrix}\,. \tag{13.54}$$

Here $\lambda \approx 0.23$ (not to be confused with λ_f), the sine of the Cabibbo angle, plays the role of an expansion parameter, and η represents the CP-violating phase. Terms of $\mathcal{O}(\lambda^6)$ have been neglected.

The unitarity of the CKM matrix, $(VV^\dagger)_{ij} = (V^\dagger V)_{ij} = \delta_{ij}$, leads to twelve distinct complex relations among the matrix elements. The six relations with $i \neq j$ can be represented geometrically as triangles in the complex plane. Two of these,

$$V_{ud}V^*_{ub} + V_{cd}V^*_{cb} + V_{td}V^*_{tb} = 0$$
$$V_{td}V^*_{ud} + V_{ts}V^*_{us} + V_{tb}V^*_{ub} = 0\,,$$

have terms of equal order, $\mathcal{O}(A\lambda^3)$, and so have corresponding triangles whose interior angles are all $\mathcal{O}(1)$ physical quantities that can be independently measured. The angles of the first triangle (see Fig. 13.1) are given by

$$\begin{aligned} \alpha \equiv \varphi_2 &\equiv \arg\left(-\frac{V_{td}V^*_{tb}}{V_{ud}V^*_{ub}}\right) \simeq \arg\left(-\frac{1-\rho-i\eta}{\rho+i\eta}\right), \\ \beta \equiv \varphi_1 &\equiv \arg\left(-\frac{V_{cd}V^*_{cb}}{V_{td}V^*_{tb}}\right) \simeq \arg\left(\frac{1}{1-\rho-i\eta}\right), \\ \gamma \equiv \varphi_3 &\equiv \arg\left(-\frac{V_{ud}V^*_{ub}}{V_{cd}V^*_{cb}}\right) \simeq \arg\left(\rho+i\eta\right). \end{aligned} \tag{13.55}$$

The angles of the second triangle are equal to (α, β, γ) up to corrections of $\mathcal{O}(\lambda^2)$. The notations (α, β, γ) and $(\varphi_1, \varphi_2, \varphi_3)$ are both in common usage but, for convenience, we only use the first convention in the following.

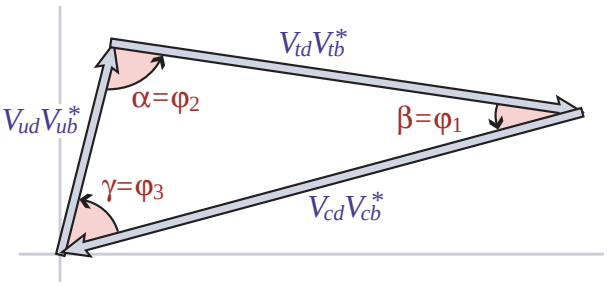

Figure 13.1: Graphical representation of the unitarity constraint $V_{ud}V^*_{ub} + V_{cd}V^*_{cb} + V_{td}V^*_{tb} = 0$ as a triangle in the complex plane.

Another relation that can be represented as a triangle,

$$V_{us}V^*_{ub} + V_{cs}V^*_{cb} + V_{ts}V^*_{tb} = 0\,, \tag{13.56}$$

and, in particular, its small angle, of $\mathcal{O}(\lambda^2)$,

$$\beta_s \equiv \arg\left(-\frac{V_{ts}V^*_{tb}}{V_{cs}V^*_{cb}}\right), \tag{13.57}$$

is convenient for analyzing CP violation in the B^0_s sector.

All unitarity triangles have the same area, commonly denoted by $J/2$ [37]. If CP is violated, J is different from zero and can be taken as the single CP-violating parameter. In the Wolfenstein parametrization of Eq. (13.54), $J \simeq \lambda^6 A^2 \eta$.

13.4. Kaons

CP violation was discovered in $K \to \pi\pi$ decays in 1964 [1]. The same mode provided the first observation of direct CP violation [4–6].

The decay amplitudes actually measured in neutral K decays refer to the mass eigenstates K_L and K_S, rather than to the K and $\overline{K}$ states referred to in Eq. (13.18). The final $\pi^+\pi^-$ and $\pi^0\pi^0$ states are CP-even. In the CP conservation limit, K_S (K_L) would be CP-even (odd), and therefore would (would not) decay to two pions. We define CP-violating amplitude ratios for two-pion final states,

$$\eta_{00} \equiv \frac{\langle\pi^0\pi^0|\mathcal{H}|K_L\rangle}{\langle\pi^0\pi^0|\mathcal{H}|K_S\rangle}\,, \quad \eta_{+-} \equiv \frac{\langle\pi^+\pi^-|\mathcal{H}|K_L\rangle}{\langle\pi^+\pi^-|\mathcal{H}|K_S\rangle}\,. \tag{13.58}$$

Another important observable is the asymmetry of time-integrated semileptonic decay rates:

$$\delta_L \equiv \frac{\Gamma(K_L \to \ell^+\nu_\ell\pi^-) - \Gamma(K_L \to \ell^-\overline{\nu}_\ell\pi^+)}{\Gamma(K_L \to \ell^+\nu_\ell\pi^-) + \Gamma(K_L \to \ell^-\overline{\nu}_\ell\pi^+)}\,. \tag{13.59}$$

CP violation has been observed as an appearance of K_L decays to two-pion final states [26],

$$|\eta_{00}| = (2.220 \pm 0.011) \times 10^{-3} \qquad |\eta_{+-}| = (2.232 \pm 0.011) \times 10^{-3} \tag{13.60}$$

$$|\eta_{00}/\eta_{+-}| = 0.9950 \pm 0.0007\,, \tag{13.61}$$

where the phase ϕ_{ij} of the amplitude ratio η_{ij} has been determined both assuming CPT invariance:

$$\phi_{00} = (43.52 \pm 0.05)^\circ\,, \qquad \phi_{+-} = (43.51 \pm 0.05)^\circ\,, \tag{13.62}$$

and without assuming CPT invariance:

$$\phi_{00} = (43.7 \pm 0.6)^\circ\,, \qquad \phi_{+-} = (43.4 \pm 0.5)^\circ\,. \tag{13.63}$$

CP violation has also been observed in semileptonic K_L decays [26]

$$\delta_L = (3.32 \pm 0.06) \times 10^{-3}\,, \tag{13.64}$$

where δ_L is a weighted average of muon and electron measurements, as well as in K_L decays to $\pi^+\pi^-\gamma$ and $\pi^+\pi^-e^+e^-$ [26]. CP violation in $K \to 3\pi$ decays has not yet been observed [26,38].

Historically, CP violation in neutral K decays has been described in terms of the complex parameters ϵ and ϵ'. The observables η_{00}, η_{+-}, and δ_L are related to these parameters, and to those of Section 13.1, by

$$\begin{aligned}
\eta_{00} &= \frac{1 - \lambda_{\pi^0\pi^0}}{1 + \lambda_{\pi^0\pi^0}} &&= \epsilon - 2\epsilon'\,, \\
\eta_{+-} &= \frac{1 - \lambda_{\pi^+\pi^-}}{1 + \lambda_{\pi^+\pi^-}} &&= \epsilon + \epsilon'\,, \\
\delta_L &= \frac{1 - |q/p|^2}{1 + |q/p|^2} &&= \frac{2\mathcal{R}e(\epsilon)}{1 + |\epsilon|^2}\,,
\end{aligned} \tag{13.65}$$

where, in the last line, we have assumed that $\left|A_{\ell^+\nu_\ell\pi^-}\right| = \left|\overline{A}_{\ell^-\overline{\nu}_\ell\pi^+}\right|$ and $\left|A_{\ell^-\overline{\nu}_\ell\pi^+}\right| = \left|\overline{A}_{\ell^+\nu_\ell\pi^-}\right| = 0$. (The convention-dependent parameter $\tilde{\epsilon} \equiv (1 - q/p)/(1 + q/p)$, sometimes used in the literature, is, in general, different from ϵ but yields a similar expression, $\delta_L = 2\mathcal{R}e(\tilde{\epsilon})/(1 + |\tilde{\epsilon}|^2)$.) A fit to the $K \to \pi\pi$ data yields [26]

$$\begin{aligned}
|\epsilon| &= (2.228 \pm 0.011) \times 10^{-3}\,, \\
\mathcal{R}e(\epsilon'/\epsilon) &= (1.66 \pm 0.23) \times 10^{-3}\,.
\end{aligned} \tag{13.66}$$

In discussing two-pion final states, it is useful to express the amplitudes $A_{\pi^0\pi^0}$ and $A_{\pi^+\pi^-}$ in terms of their isospin components via

$$\begin{aligned}
A_{\pi^0\pi^0} &= \sqrt{\frac{1}{3}}\,|A_0|\,e^{i(\delta_0+\phi_0)} - \sqrt{\frac{2}{3}}\,|A_2|\,e^{i(\delta_2+\phi_2)}, \\
A_{\pi^+\pi^-} &= \sqrt{\frac{2}{3}}\,|A_0|\,e^{i(\delta_0+\phi_0)} + \sqrt{\frac{1}{3}}\,|A_2|\,e^{i(\delta_2+\phi_2)}\,,
\end{aligned} \tag{13.67}$$

where we parameterize the amplitude $A_I(\overline{A}_I)$ for $K^0(\overline{K}^0)$ decay into two pions with total isospin $I = 0$ or 2 as

$$\begin{aligned}
A_I &\equiv \langle(\pi\pi)_I\,|\mathcal{H}|\,K^0\rangle = |A_I|\,e^{i(\delta_I+\phi_I)}\,, \\
\overline{A}_I &\equiv \langle(\pi\pi)_I\,|\mathcal{H}|\,\overline{K}^0\rangle = |A_I|\,e^{i(\delta_I-\phi_I)}\,.
\end{aligned} \tag{13.68}$$

The smallness of $|\eta_{00}|$ and $|\eta_{+-}|$ allows us to approximate

$$\epsilon \simeq \frac{1}{2}(1 - \lambda_{(\pi\pi)_{I=0}})\,, \qquad \epsilon' \simeq \frac{1}{6}\left(\lambda_{\pi^0\pi^0} - \lambda_{\pi^+\pi^-}\right)\,. \tag{13.69}$$

The parameter ϵ represents indirect CP violation, while ϵ' parameterizes direct CP violation: $\mathcal{R}e(\epsilon')$ measures CP violation in decay (type I), $\mathcal{R}e(\epsilon)$ measures CP violation in mixing (type II), and $\mathcal{I}m(\epsilon)$ and $\mathcal{I}m(\epsilon')$ measure the interference between decays with and without mixing (type III).

The following expressions for ϵ and ϵ' are useful for theoretical evaluations:

$$\epsilon \simeq \frac{e^{i\pi/4}}{\sqrt{2}}\frac{\mathcal{I}m(\mathbf{M}_{12})}{\Delta m}\,, \qquad \epsilon' = \frac{i}{\sqrt{2}}\left|\frac{A_2}{A_0}\right|e^{i(\delta_2-\delta_0)}\sin(\phi_2 - \phi_0)\,. \tag{13.70}$$

The expression for ϵ is only valid in a phase convention where $\phi_2 = 0$, corresponding to a real $V_{ud}V_{us}^*$, and in the approximation that also $\phi_0 = 0$. The phase of ϵ, $\arg(\epsilon) \approx \arctan(-2\Delta m/\Delta\Gamma)$, is independent of the electroweak model and is experimentally determined to be about $\pi/4$. The calculation of ϵ benefits from the fact that $\mathcal{I}m(\mathbf{M}_{12})$ is dominated by short distance physics. Consequently, the main sources of uncertainty in theoretical interpretations of ϵ are the values of matrix elements, such as $\langle K^0\,|(\overline{s}d)_{V-A}(\overline{s}d)_{V-A}|\,\overline{K}^0\rangle$. The expression for ϵ' is valid to first order in $|A_2/A_0| \sim 1/20$. The phase of ϵ' is experimentally determined, $\pi/2 + \delta_2 - \delta_0 \approx \pi/4$, and is independent of the electroweak model. Note that, accidentally, ϵ'/ϵ is real to a good approximation. Determination of weak phase information from the measurement of $\mathcal{R}e(\epsilon'/\epsilon)$ given in Eq. (13.66) has until now been precluded by uncertainties in the hadronic parameters, but recent advances in lattice QCD calculations [39,40] suggest that it may become possible [41].

A future measurement of much interest is that of CP violation in the rare $K \to \pi\nu\overline{\nu}$ decays. The signal for CP violation is simply observing the $K_L \to \pi^0\nu\overline{\nu}$ decay. The effect here is that of interference between decays with and without mixing (type III) [42]:

$$\frac{\Gamma(K_L \to \pi^0\nu\overline{\nu})}{\Gamma(K^+ \to \pi^+\nu\overline{\nu})} = \frac{1}{2}\left[1 + |\lambda_{\pi\nu\overline{\nu}}|^2 - 2\,\mathcal{R}e(\lambda_{\pi\nu\overline{\nu}})\right] \simeq 1 - \mathcal{R}e(\lambda_{\pi\nu\overline{\nu}}), \tag{13.71}$$

where in the last equation we neglect CP violation in decay and in mixing (expected, model-independently, to be of order 10^{-5} and 10^{-3}, respectively). Such a measurement is experimentally very challenging but would be theoretically very rewarding [43]. Similar to the CP asymmetry in $B^0 \to J/\psi K_S$, the CP violation in $K \to \pi\nu\overline{\nu}$ decay is predicted to be large (that is, the ratio in Eq. (13.71) is neither CKM- nor loop-suppressed) and can be very cleanly interpreted.

Within the Standard Model, the $K_L \to \pi^0\nu\overline{\nu}$ decay is dominated by an intermediate top quark contribution and, consequently, can be interpreted in terms of CKM parameters [44]. (For the charged mode, $K^+ \to \pi^+\nu\overline{\nu}$, the contribution from an intermediate charm quark is not negligible, and constitutes a source of hadronic uncertainty.) In particular, $\mathcal{B}(K_L \to \pi^0\nu\overline{\nu})$ provides a theoretically clean way to determine the Wolfenstein parameter η [45]:

$$\mathcal{B}(K_L \to \pi^0\nu\overline{\nu}) = \kappa_L[X(m_t^2/m_W^2)]^2A^4\eta^2\,, \tag{13.72}$$

where the hadronic parameter $\kappa_L \sim 2 \times 10^{-10}$ incorporates the value of the four-fermion matrix element which is deduced, using isospin relations, from $\mathcal{B}(K^+ \to \pi^0e^+\nu_e)$, and $X(m_t^2/m_W^2)$ is a known function of the top mass. An explicit calculation gives $\mathcal{B}(K_L \to \pi^0\nu\overline{\nu}) = (2.4 \pm 0.4) \times 10^{-11}$ [46]. The currently tightest experimental limit is $\mathcal{B}(K_L \to \pi^0\nu\overline{\nu}) < 2.6 \times 10^{-8}$ [47], which does not yet reach the bound $\mathcal{B}(K_L \to \pi^0\nu\overline{\nu}) < 4.4 \times \mathcal{B}(K^+ \to \pi^+\nu\overline{\nu})$ [42]. Significant further progress is anticipated from experiments searching for $K \to \pi\nu\overline{\nu}$ decays in the next few years [48,49].

13.5. Charm

The existence of D^0–$\overline{D}^0$ mixing has been established in recent years [50–53]. The experimental constraints read [28,54] $x \equiv \Delta m/\Gamma = (0.37 \pm 0.16) \times 10^{-2}$ and $y \equiv \Delta\Gamma/(2\Gamma) = (0.66\,^{+0.07}_{-0.10}) \times 10^{-2}$. Thus, the data clearly show that $y \neq 0$, but improved measurements are needed to be sure of the size of x. Long-distance contributions make it difficult to calculate Standard Model predictions for the D^0–$\overline{D}^0$ mixing parameters. Therefore, the goal of the search for D^0–$\overline{D}^0$ mixing is not to constrain the CKM parameters, but rather to probe new physics. Here CP violation plays an important role. Within the Standard Model, the CP-violating effects are predicted to be small, since the mixing and the relevant decays are described, to an excellent approximation, by the physics of the first two generations only. The expectation is that the Standard Model size of CP violation in D decays is $\mathcal{O}(10^{-3})$ or less, but theoretical work is ongoing to understand whether QCD effects can significantly enhance it. At present, the most sensitive searches involve the $D^0 \to K^+K^-$, $D^0 \to \pi^+\pi^-$ and $D^0 \to K^\pm\pi^\mp$ modes.

The neutral D mesons decay via a singly-Cabibbo-suppressed transition to the CP eigenstates K^+K^- and $\pi^+\pi^-$. These decays are dominated by Standard-Model tree diagrams. Thus, we can write, for $f = K^+K^-$ or $\pi^+\pi^-$,

$$A_f = A_f^T e^{+i\phi_f^T}\left[1 + r_f e^{i(\delta_f+\phi_f)}\right] ,$$
$$\bar{A}_f = A_f^T e^{-i\phi_f^T}\left[1 + r_f e^{i(\delta_f-\phi_f)}\right] , \qquad (13.73)$$

where $A_f^T e^{\pm i\phi_f^T}$ is the Standard Model tree-level contribution, ϕ_f^T and ϕ_f are weak, CP violating phases, δ_f is a strong phase difference, and r_f is the ratio between a subleading ($r_f \ll 1$) contribution with a weak phase different from ϕ_f^T and the Standard Model tree-level contribution. Neglecting r_f, λ_f is universal, and we can define an observable phase ϕ_D via

$$\lambda_f \equiv -|q/p|e^{i\phi_D} . \qquad (13.74)$$

(In the limit of CP conservation, choosing $\phi_D = 0$ is equivalent to defining the mass eigenstates by their CP eigenvalue: $|D_\mp\rangle = p|D^0\rangle \pm q|\overline{D}^0\rangle$, with D_- (D_+) being the CP-odd (CP-even) state; that is, the state that does not (does) decay into K^+K^-.)

We define the time integrated CP asymmetry for a final CP eigenstate f as follows:

$$a_f \equiv \frac{\int_0^\infty \Gamma(D^0_{\rm phys}(t) \to f)dt - \int_0^\infty \Gamma(\overline{D}^0_{\rm phys}(t) \to f)dt}{\int_0^\infty \Gamma(D^0_{\rm phys}(t) \to f)dt + \int_0^\infty \Gamma(\overline{D}^0_{\rm phys}(t) \to f)dt} . \qquad (13.75)$$

(This expression corresponds to the D meson being tagged at production, hence the integration goes from 0 to $+\infty$; measurements are also possible with $\psi(3770) \to D^0\overline{D}^0$, in which case the integration goes from $-\infty$ to $+\infty$ giving slightly different results; see the discussion in Section 13.1.3.) We take $x, y, r_f \ll 1$ and expand to leading order in these parameters. We can then separate the contribution to a_f into three parts [55],

$$a_f = a_f^d + a_f^m + a_f^i , \qquad (13.76)$$

with the following underlying mechanisms:

1. a_f^d signals CP violation in decay (similar to Eq. (13.40)):

$$a_f^d = 2r_f \sin\phi_f \sin\delta_f . \qquad (13.77)$$

2. a_f^m signals CP violation in mixing (similar to Eq. (13.50)). With our approximations, it is universal:

$$a^m = -\frac{y}{2}\left(\left|\frac{q}{p}\right| - \left|\frac{p}{q}\right|\right)\cos\phi_D . \qquad (13.78)$$

3. a_f^i signals CP violation in the interference of mixing and decay (similar to Eq. (13.51)). With our approximations, it is universal:

$$a^i = \frac{x}{2}\left(\left|\frac{q}{p}\right| + \left|\frac{p}{q}\right|\right)\sin\phi_D . \qquad (13.79)$$

One can isolate the effects of direct CP violation by taking the difference between the CP asymmetries in the K^+K^- and $\pi^+\pi^-$ modes:

$$\Delta a_{CP} \equiv a_{K^+K^-} - a_{\pi^+\pi^-} = a^d_{K^+K^-} - a^d_{\pi^+\pi^-} , \qquad (13.80)$$

where we neglected a residual, experiment-dependent, contribution from indirect CP violation due to the fact that there may be a decay time-dependent acceptance function that can be different for the K^+K^- and $\pi^+\pi^-$ channels. Recent evidence for such direct CP violation [56] has become less significant when including more data, with the current average giving [28]:

$$a^d_{K^+K^-} - a^d_{\pi^+\pi^-} = (2.6 \pm 1.0) \times 10^{-3} . \qquad (13.81)$$

One can also isolate the effects of indirect CP violation in the following way. Consider the time-dependent decay rates in Eq. (13.35) and Eq. (13.36). The mixing processes modify the time dependence from a pure exponential. However, given the small values of x and y, the time dependences can be recast, to a good approximation, into purely exponential form, but with modified decay-rate parameters [57,58] (given here for the K^+K^- final state):

$$\Gamma_{D^0\to K^+K^-} = \Gamma \times [1 + |q/p|\,(y\cos\phi_D - x\sin\phi_D)] ,$$
$$\Gamma_{\overline{D}^0\to K^+K^-} = \Gamma \times [1 + |p/q|\,(y\cos\phi_D + x\sin\phi_D)] . \qquad (13.82)$$

One can define CP-conserving and CP-violating combinations of these two observables (normalized to the true width Γ):

$$y_{CP} \equiv \frac{\Gamma_{\overline{D}^0\to K^+K^-} + \Gamma_{D^0\to K^+K^-}}{2\Gamma} - 1$$
$$= (y/2)\,(|q/p| + |p/q|)\cos\phi_D - (x/2)\,(|q/p| - |p/q|)\sin\phi_D ,$$
$$A_\Gamma \equiv \frac{\Gamma_{D^0\to K^+K^-} - \Gamma_{\overline{D}^0\to K^+K^-}}{2\Gamma}$$
$$= -(a^m + a^i) . \qquad (13.83)$$

In the limit of CP conservation (and, in particular, within the Standard Model), $y_{CP} = (\Gamma_+ - \Gamma_-)/2\Gamma = y$ (where $\Gamma_+(\Gamma_-)$ is the decay width of the CP-even (-odd) mass eigenstate) and $A_\Gamma = 0$. Indeed, present measurements imply that CP violation is small [28],

$$y_{CP} = (+0.84 \pm 0.16) \times 10^{-2} ,$$
$$A_\Gamma = (-0.06 \pm 0.04) \times 10^{-2} .$$

The $K^\pm\pi^\mp$ states are not CP eigenstates, but they are still common final states for D^0 and $\overline{D}^0$ decays. Since $D^0(\overline{D}^0) \to K^-\pi^+$ is a Cabibbo-favored (doubly-Cabibbo-suppressed) process, these processes are particularly sensitive to x and/or $y = \mathcal{O}(\lambda^2)$. Taking into account that $\left|\lambda_{K^-\pi^+}\right|, \left|\lambda^{-1}_{K^+\pi^-}\right| \ll 1$ and $x, y \ll 1$, assuming that there is no direct CP violation (these are Standard Model tree-level decays dominated by a single weak phase, and there is no contribution from penguin-like and chromomagnetic operators), and expanding the time-dependent rates for $xt, yt \lesssim \Gamma^{-1}$, one obtains

$$\Gamma[D^0_{\rm phys}(t) \to K^+\pi^-] = e^{-\Gamma t}|\overline{A}_{K^-\pi^+}|^2$$
$$\times \left[r_d^2 + r_d\left|\frac{q}{p}\right|(y'\cos\phi_D - x'\sin\phi_D)\Gamma t + \left|\frac{q}{p}\right|^2\frac{y^2+x^2}{4}(\Gamma t)^2\right] ,$$
$$\Gamma[\overline{D}^0_{\rm phys}(t) \to K^-\pi^+] = e^{-\Gamma t}|\overline{A}_{K^-\pi^+}|^2$$
$$\times \left[r_d^2 + r_d\left|\frac{p}{q}\right|(y'\cos\phi_D + x'\sin\phi_D)\Gamma t + \left|\frac{p}{q}\right|^2\frac{y^2+x^2}{4}(\Gamma t)^2\right] , \qquad (13.84)$$

where

$$y' \equiv y\cos\delta - x\sin\delta ,$$
$$x' \equiv x\cos\delta + y\sin\delta . \qquad (13.85)$$

The weak phase ϕ_D is the same as that of Eq. (13.74) (a consequence of neglecting direct CP violation) and $r_d = \mathcal{O}(\tan^2\theta_c)$ is the amplitude ratio, $r_d = \left|\overline{A}_{K^-\pi^+}/A_{K^-\pi^+}\right| = \left|A_{K^+\pi^-}/\overline{A}_{K^+\pi^-}\right|$, that

is, $\lambda_{K^-\pi^+} = r_d|q/p|e^{-i(\delta-\phi_D)}$ and $\lambda^{-1}_{K^+\pi^-} = r_d|p/q|e^{-i(\delta+\phi_D)}$. The parameter δ is a strong-phase difference for these processes, that can be obtained from measurements of quantum correlated $\psi(3770) \to D^0\overline{D}^0$ decays [59,60]. By fitting to the six coefficients of the various time-dependences, one can determine r_d, $|q/p|$, (x^2+y^2), $y'\cos\phi_D$, and $x'\sin\phi_D$. In particular, finding CP violation ($|q/p| \neq 1$ and/or $\sin\phi_D \neq 0$) at a level much higher than 10^{-3} would constitute evidence for new physics. The most stringent constraints to date on CP violation in charm mixing have been obtained with this method [61].

A fit to all data [28], including also results from time-dependent analyses of $D^0 \to K_S\pi^+\pi^-$ decays, from which x, y, $|q/p|$ and ϕ_D can be determined directly, yields no evidence for indirect CP violation:

$$1 - |q/p| = +0.09\,^{+0.08}_{-0.12}\,,$$
$$\phi_D = \left(-9\,^{+12}_{-10}\right)^\circ\,.$$

With the additional assumption of no direct CP violation in doubly-Cabibbo-suppressed D decays [62–64], tighter constraints are obtained:

$$1 - |q/p| = -0.002 \pm 0.014\,,$$
$$\phi_D = (-0.1 \pm 0.6)^\circ\,.$$

More details on various theoretical and experimental aspects of $D^0 - \overline{D}^0$ mixing can be found in Ref. [30].

Searches for CP violation in charged $D_{(s)}$ decays have been performed in many modes. Searches in decays mediated by Cabibbo-suppressed amplitudes are particularly interesting, since in other channels effects are likely to be too small to be observable in current experiments. Examples of relevant two-body modes are $D^+ \to \pi^+\pi^0$, K_SK^+, $\phi\pi^+$ and $D_s^+ \to K^+\pi^0$, $K_S\pi^+$, ϕK^+. The most precise results are $\mathcal{A}_{D^+\to K_SK^+} = -0.0003 \pm 0.0017$ and $\mathcal{A}_{D_s^+\to K_S\pi^+} = +0.0063 \pm 0.0047$ [28]. The precision of experiments is now sufficient that the effect from CP violation in the neutral kaon system can be seen in $D^+ \to K_S\pi^+$ decays [65,66].

Three-body final states provide additional possibilities to search for CP violation, since effects may vary over the phase-space. A number of methods have been proposed to exploit this feature and search for CP violation in ways that do not require modelling of the decay distribution [67–69]. Such methods are useful for analysis of charm decays since they are less sensitive to biases from production asymmetries, and are well suited to address the issue of whether or not CP violation effects are present. The results of all searches to date have been null – no significant CP violation effect has yet been observed in $D^+_{(s)}$ decays.

13.6. Beauty

13.6.1. *CP violation in mixing of B^0 and B^0_s mesons* :

The upper bound on the CP asymmetry in semileptonic B decays [27] implies that CP violation in $B^0 - \overline{B}^0$ mixing is a small effect (we use $\mathcal{A}_{\rm SL}/2 \approx 1 - |q/p|$, see Eq. (13.42)):

$$\mathcal{A}^d_{\rm SL} = (-1.5 \pm 1.7) \times 10^{-3} \implies |q/p| = 1.0007 \pm 0.0009\,. \quad (13.86)$$

The Standard Model prediction is

$$\mathcal{A}^d_{\rm SL} = \mathcal{O}\left[(m_c^2/m_t^2)\sin\beta\right] \lesssim 0.001\,. \quad (13.87)$$

An explicit calculation gives $(-4.1 \pm 0.6) \times 10^{-4}$ [70].

The experimental constraint on CP violation in $B^0_s - \overline{B}^0_s$ mixing is somewhat weaker than that in the $B^0 - \overline{B}^0$ system [27]

$$\mathcal{A}^s_{\rm SL} = (-7.5 \pm 4.1) \times 10^{-3} \implies |q/p| = 1.0038 \pm 0.0021\,. \quad (13.88)$$

The Standard Model prediction is $\mathcal{A}^s_{\rm SL} = \mathcal{O}\left[(m_c^2/m_t^2)\sin\beta_s\right] \lesssim 10^{-4}$, with an explicit calculation giving $(1.9 \pm 0.3) \times 10^{-5}$ [70]. The tension between the measurement and the prediction originates from a result from D0 for the inclusive same-sign dimuon asymmetry that deviates from the Standard Model prediction by 3.6σ [71]. As yet, this has not been confirmed by independent studies.

In models where $\mathbf{\Gamma}_{12}/\mathbf{M}_{12}$ is approximately real, such as the Standard Model, an upper bound on $\Delta\Gamma/\Delta m \approx \mathcal{R}e(\mathbf{\Gamma}_{12}/\mathbf{M}_{12})$ provides yet another upper bound on the deviation of $|q/p|$ from one. This constraint does not hold if $\mathbf{\Gamma}_{12}/\mathbf{M}_{12}$ is approximately imaginary. (An alternative parameterization uses $q/p = (1-\tilde{\epsilon}_B)/(1+\tilde{\epsilon}_B)$, leading to $\mathcal{A}_{\rm SL} \simeq 4\mathcal{R}e(\tilde{\epsilon}_B)$.)

13.6.2. *CP violation in interference of B^0 decays with and without mixing* :

The small deviation (less than one percent) of $|q/p|$ from 1 implies that, at the present level of experimental precision, CP violation in B^0 mixing is a negligible effect. Thus, for the purpose of analyzing CP asymmetries in hadronic B^0 decays, we can use

$$\lambda_f = e^{-i\phi_{M(B^0)}}(\overline{A}_f/A_f)\,, \quad (13.89)$$

where $\phi_{M(B^0)}$ refers to the phase of $\mathbf{M}_{12}$ appearing in Eq. (13.48) that is appropriate for $B^0 - \overline{B}^0$ oscillations. Within the Standard Model, the corresponding phase factor is given by

$$e^{-i\phi_{M(B^0)}} = (V^*_{tb}V_{td})/(V_{tb}V^*_{td})\,. \quad (13.90)$$

The class of CP violation effects in interference between mixing and decay is studied with final states that are common to B^0 and $\overline{B}^0$ decays [72,73]. It is convenient to rewrite Eq. (13.46) for B^0 decays as [74–76]

$$\mathcal{A}_f(t) = S_f\sin(\Delta mt) - C_f\cos(\Delta mt)\,,$$
$$S_f \equiv \frac{2\,\mathcal{I}m(\lambda_f)}{1+|\lambda_f|^2}\,, \quad C_f \equiv \frac{1-|\lambda_f|^2}{1+|\lambda_f|^2}\,, \quad (13.91)$$

where we assume that $\Delta\Gamma = 0$ and $|q/p| = 1$. An alternative notation in use is $A_f \equiv -C_f$ – this A_f should not be confused with the A_f of Eq. (13.18), but in the limit that $|q/p| = 1$ is equivalent with the $\mathcal{A}_f$ of Eq. (13.40).

A large class of interesting processes proceed via quark transitions of the form $\overline{b} \to \overline{q}q\overline{q}'$ with $q' = s$ or d. For $q = c$ or u, there are contributions from both tree (t) and penguin (p^{q_u}, where $q_u = u, c, t$ is the quark in the loop) diagrams (see Fig. 13.2) which carry different weak phases:

$$A_f = \left(V^*_{qb}V_{qq'}\right)t_f + \sum_{q_u=u,c,t}\left(V^*_{q_ub}V_{q_uq'}\right)p^{q_u}_f\,. \quad (13.92)$$

(The distinction between tree and penguin contributions is a heuristic one; the separation by the operator that enters is more precise. A detailed discussion of the more complete operator product approach, which also includes higher order QCD corrections, can be found in Ref. [77] for example.) Using CKM unitarity, these decay amplitudes can always be written in terms of just two CKM combinations. For example, for $f = \pi\pi$, which proceeds via a $\overline{b} \to \overline{u}u\overline{d}$ transition, we can write

$$A_{\pi\pi} = (V^*_{ub}V_{ud})\,T_{\pi\pi} + (V^*_{tb}V_{td})\,P^t_{\pi\pi}\,, \quad (13.93)$$

where $T_{\pi\pi} = t_{\pi\pi} + p^u_{\pi\pi} - p^c_{\pi\pi}$ and $P^t_{\pi\pi} = p^t_{\pi\pi} - p^c_{\pi\pi}$. CP-violating phases in Eq. (13.93) appear only in the CKM elements, so that

$$\frac{\overline{A}_{\pi\pi}}{A_{\pi\pi}} = \frac{\left(V_{ub}V^*_{ud}\right)T_{\pi\pi} + \left(V_{tb}V^*_{td}\right)P^t_{\pi\pi}}{\left(V^*_{ub}V_{ud}\right)T_{\pi\pi} + \left(V^*_{tb}V_{td}\right)P^t_{\pi\pi}}\,. \quad (13.94)$$

For $f = J/\psi K$, which proceeds via a $\overline{b} \to \overline{c}c\overline{s}$ transition, we can write

$$A_{\psi K} = (V^*_{cb}V_{cs})\,T_{\psi K} + (V^*_{ub}V_{us})\,P^u_{\psi K}\,, \quad (13.95)$$

where $T_{\psi K} = t_{\psi K} + p^c_{\psi K} - p^t_{\psi K}$ and $P^u_{\psi K} = p^u_{\psi K} - p^t_{\psi K}$. A subtlety arises in this decay that is related to the fact that B^0 decays into a final $J/\psi K^0$ state while $\overline{B}^0$ decays into a final $J/\psi\overline{K}^0$ state. A common final state, *e.g.*, $J/\psi K_S$, is reached only via $K^0 - \overline{K}^0$ mixing.

Consequently, the phase factor (defined in Eq. (13.48)) corresponding to neutral K mixing, $e^{-i\phi_{M(K)}} = (V_{cd}^* V_{cs})/(V_{cd} V_{cs}^*)$, plays a role:

$$\frac{\overline{A}_{\psi K_S}}{A_{\psi K_S}} = -\frac{\left(V_{cb}V_{cs}^*\right) T_{\psi K} + \left(V_{ub}V_{us}^*\right) P^u_{\psi K}}{\left(V_{cb}^*V_{cs}\right) T_{\psi K} + \left(V_{ub}^*V_{us}\right) P^u_{\psi K}} \times \frac{V_{cd}^* V_{cs}}{V_{cd} V_{cs}^*} \,. \qquad (13.96)$$

For $q = s$ or d, there are only penguin contributions to A_f, that is, $t_f = 0$ in Eq. (13.92). (The tree $\overline{b} \to \overline{u}u\overline{q}'$ transition followed by $\overline{u}u \to \overline{q}q$ rescattering is included below in the P^u terms.) Again, CKM unitarity allows us to write A_f in terms of two CKM combinations. For example, for $f = \phi K_S$, which proceeds via a $\overline{b} \to \overline{s}s\overline{s}$ transition, we can write

$$\frac{\overline{A}_{\phi K_S}}{A_{\phi K_S}} = -\frac{\left(V_{cb}V_{cs}^*\right) P^c_{\phi K} + \left(V_{ub}V_{us}^*\right) P^u_{\phi K}}{\left(V_{cb}^*V_{cs}\right) P^c_{\phi K} + \left(V_{ub}^*V_{us}\right) P^u_{\phi K}} \times \frac{V_{cd}^* V_{cs}}{V_{cd} V_{cs}^*} \,, \qquad (13.97)$$

where $P^c_{\phi K} = p^c_{\phi K} - p^t_{\phi K}$ and $P^u_{\phi K} = p^u_{\phi K} - p^t_{\phi K}$.

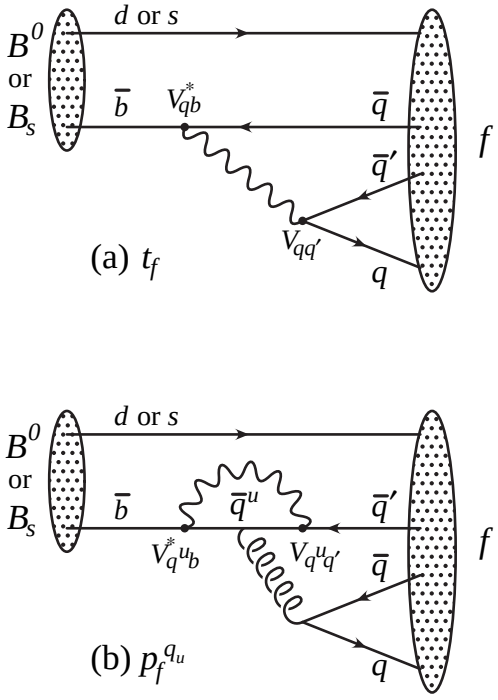

Figure 13.2: Feynman diagrams for (a) tree and (b) penguin amplitudes contributing to $B^0 \to f$ or $B_s^0 \to f$ via a $\overline{b} \to \overline{q}q\overline{q}'$ quark-level process.

Since in general the amplitude A_f involves two different weak phases, the corresponding decays can exhibit both CP violation in the interference of decays with and without mixing, $S_f \neq 0$, and CP violation in decay, $C_f \neq 0$. (At the present level of experimental precision, the contribution to C_f from CP violation in mixing is negligible, see Eq. (13.86).) If the contribution from a second weak phase is suppressed, then the interpretation of S_f in terms of Lagrangian CP-violating parameters is clean, while C_f is small. If such a second contribution is not suppressed, S_f depends on hadronic parameters and, if the relevant strong phase difference is large, C_f is large.

A summary of $\overline{b} \to \overline{q}q\overline{q}'$ modes with $q' = s$ or d is given in Table 13.1. The $\overline{b} \to \overline{d}d\overline{q}$ transitions lead to final states that are similar to those from $\overline{b} \to \overline{u}u\overline{q}$ transitions and have similar phase dependence. Final states that consist of two vector mesons ($\psi\phi$ and $\phi\phi$) are not CP eigenstates, and angular analysis is needed to separate the CP-even from the CP-odd contributions.

Table 13.1: Summary of $\overline{b} \to \overline{q}q\overline{q}'$ modes with $q' = s$ or d. The second and third columns give examples of hadronic final states (usually those which are experimentally most convenient to study). The fourth column gives the CKM dependence of the amplitude A_f, using the notation of Eqs. (13.93, 13.95, 13.97), with the dominant term first and the subdominant second. The suppression factor of the second term compared to the first is given in the last column. "Loop" refers to a penguin versus tree-suppression factor (it is mode-dependent and roughly $\mathcal{O}(0.2 - 0.3)$) and $\lambda \simeq 0.23$ is the expansion parameter of Eq. (13.54).

$\overline{b} \to \overline{q}q\overline{q}'$	$B^0 \to f$	$B_s^0 \to f$	CKM dependence of A_f	Suppression
$\bar{b} \to \bar{c}c\bar{s}$	ψK_S	$\psi\phi$	$(V_{cb}^*V_{cs})T + (V_{ub}^*V_{us})P^u$	loop $\times\, \lambda^2$
$\bar{b} \to \bar{s}s\bar{s}$	ϕK_S	$\phi\phi$	$(V_{cb}^*V_{cs})P^c + (V_{ub}^*V_{us})P^u$	λ^2
$\bar{b} \to \bar{u}u\bar{s}$	$\pi^0 K_S$	K^+K^-	$(V_{cb}^*V_{cs})P^c + (V_{ub}^*V_{us})T$	λ^2/loop
$\bar{b} \to \bar{c}c\bar{d}$	D^+D^-	ψK_S	$(V_{cb}^*V_{cd})T + (V_{tb}^*V_{td})P^t$	loop
$\bar{b} \to \bar{s}s\bar{d}$	K_SK_S	ϕK_S	$(V_{tb}^*V_{td})P^t + (V_{cb}^*V_{cd})P^c$	$\lesssim 1$
$\bar{b} \to \bar{u}u\bar{d}$	$\pi^+\pi^-$	$\rho^0 K_S$	$(V_{ub}^*V_{ud})T + (V_{tb}^*V_{td})P^t$	loop
$\bar{b} \to \bar{c}u\bar{d}$	$D_{CP}\pi^0$	$D_{CP}K_S$	$(V_{cb}^*V_{ud})T + (V_{ub}^*V_{cd})T'$	λ^2
$\bar{b} \to \bar{c}u\bar{s}$	$D_{CP}K_S$	$D_{CP}\phi$	$(V_{cb}^*V_{us})T + (V_{ub}^*V_{cs})T'$	$\lesssim 1$

The cleanliness of the theoretical interpretation of S_f can be assessed from the information in the last column of Table 13.1. In case of small uncertainties, the expression for S_f in terms of CKM phases can be deduced from the fourth column of Table 13.1 in combination with Eq. (13.90) (and, for $b \to q\overline{q}s$ decays, the example in Eq. (13.96)). Here we consider several interesting examples.

For $B^0 \to J/\psi K_S$ and other $\overline{b} \to \overline{c}c\overline{s}$ processes, we can neglect the P^u contribution to A_f, in the Standard Model, to an approximation that is better than one percent, giving:

$$\lambda_{\psi K_S} = -e^{-2i\beta} \;\Rightarrow\; S_{\psi K_S} = \sin 2\beta \,, \quad C_{\psi K_S} = 0 \,. \qquad (13.98)$$

It is important to verify experimentally the level of suppression of the penguin contribution. Methods based on flavor symmetries [78–81] allow limits to be obtained. All are currently consistent with the P^u term being negligible.

In the presence of new physics, A_f is still likely to be dominated by the T term, but the mixing amplitude might be modified. We learn that, model-independently, $C_f \approx 0$ while S_f cleanly determines the mixing phase $(\phi_M - 2\arg(V_{cb}V_{cd}^*))$. The experimental measurement [28], $S_{\psi K} = +0.691 \pm 0.017$, gave the first precision test of the Kobayashi-Maskawa mechanism, and its consistency with the predictions for $\sin 2\beta$ makes it very likely that this mechanism is indeed the dominant source of CP violation in the quark sector.

For $B^0 \to \phi K_S$ and other $\overline{b} \to \overline{s}s\overline{s}$ processes (as well as some $\overline{b} \to \overline{u}u\overline{s}$ processes), we can neglect the subdominant contributions, in the Standard Model, to an approximation that is good to the order of a few percent:

$$\lambda_{\phi K_S} = -e^{-2i\beta} \;\Rightarrow\; S_{\phi K_S} = \sin 2\beta \,, \quad C_{\phi K_S} = 0 \,. \qquad (13.99)$$

A review of explicit calculations of the effects of subleading amplitudes can be found in Ref. [82]. In the presence of new physics, both A_f and $\mathbf{M}_{12}$ can have contributions that are comparable in size to those of the Standard Model and carry new weak phases. Such a situation gives several interesting consequences for penguin-dominated $b \to q\overline{q}s$ decays ($q = u, d, s$) to a final state f:

1. The value of $-\eta_f S_f$ may be different from $S_{\psi K_S}$ by more than a few percent, where η_f is the CP eigenvalue of the final state.
2. The values of $\eta_f S_f$ for different final states f may be different from each other by more than a few percent (for example, $S_{\phi K_S} \neq S_{\eta' K_S}$).
3. The value of C_f may be different from zero by more than a few percent.

While a clear interpretation of such signals in terms of Lagrangian parameters will be difficult because, under these circumstances, hadronic parameters play a role, any of the above three options will clearly signal new physics. Fig. 13.3 summarizes the present experimental results: none of the possible signatures listed above is unambiguously established, but there is definitely still room for new physics.

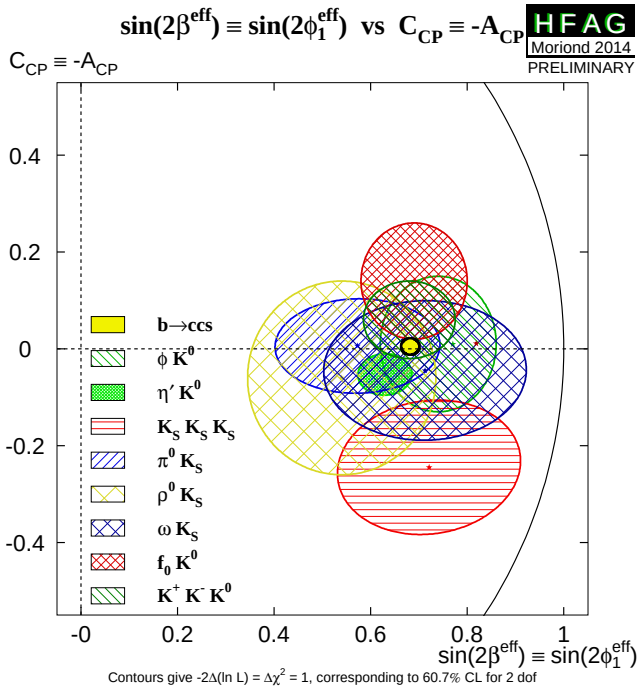

Figure 13.3: Summary of the results [28] of time-dependent analyses of $b \to q\overline{q}s$ decays, which are potentially sensitive to new physics.

For the $\overline{b} \to \overline{u}u\overline{d}$ process $B \to \pi\pi$ and other related channels, the penguin-to-tree ratio can be estimated using SU(3) relations and experimental data on related $B \to K\pi$ decays. The result (for $\pi\pi$) is that the suppression is at the level of $0.2 - 0.3$ and so cannot be neglected. The expressions for $S_{\pi\pi}$ and $C_{\pi\pi}$ to leading order in $R_{PT} \equiv (|V_{tb}V_{td}|\, P^t_{\pi\pi})/(|V_{ub}V_{ud}|\, T_{\pi\pi})$ are:

$$\lambda_{\pi\pi} = e^{2i\alpha}\left[(1 - R_{PT}e^{-i\alpha})/(1 - R_{PT}e^{+i\alpha})\right] \;\Rightarrow$$

$$S_{\pi\pi} \approx \sin 2\alpha + 2\,\mathcal{R}e(R_{PT})\cos 2\alpha \sin\alpha\;, \quad C_{\pi\pi} \approx 2\,\mathcal{I}m(R_{PT})\sin\alpha\;. \tag{13.100}$$

Note that R_{PT} is mode-dependent and, in particular, could be different for $\pi^+\pi^-$ and $\pi^0\pi^0$. If strong phases can be neglected, then R_{PT} is real, resulting in $C_{\pi\pi} = 0$. The size of $C_{\pi\pi}$ is an indicator of how large the strong phase is. The present experimental average is $C_{\pi^+\pi^-} = -0.31 \pm 0.05$ [28]. As concerns $S_{\pi\pi}$, it is clear from Eq. (13.100) that the relative size or strong phase of the penguin contribution must be known to extract α. This is the problem of penguin pollution.

The cleanest solution involves isospin relations among the $B \to \pi\pi$ amplitudes [83]:

$$\frac{1}{\sqrt{2}}A_{\pi^+\pi^-} + A_{\pi^0\pi^0} = A_{\pi^+\pi^0}\;. \tag{13.101}$$

The method exploits the fact that the penguin contribution to $P^t_{\pi\pi}$ is pure $\Delta I = 1/2$ (this is not true for the electroweak penguins which, however, are expected to be small), while the tree contribution to $T_{\pi\pi}$ contains pieces that are both $\Delta I = 1/2$ and $\Delta I = 3/2$. A simple geometric construction then allows one to find R_{PT} and extract α cleanly from $S_{\pi^+\pi^-}$. The key experimental difficulty is that one must measure accurately the separate rates for B^0 and $\overline{B}^0 \to \pi^0\pi^0$.

CP asymmetries in $B \to \rho\pi$ and $B \to \rho\rho$ can also be used to determine α. In particular, the $B \to \rho\rho$ measurements are presently very significant in constraining α. The extraction proceeds via isospin analysis similar to that of $B \to \pi\pi$. There are, however, several important differences. First, due to the finite width of the ρ mesons, a final $(\rho\rho)_{I=1}$ state is possible [84]. The effect is, however, of the order of $(\Gamma_\rho/m_\rho)^2 \sim 0.04$. Second, due to the presence of three helicity states for the two vector mesons, angular analysis is needed to separate the CP-even and CP-odd components. The theoretical expectation is that the CP-odd component is small, which is supported by experiments which find that the $\rho^+\rho^-$ and $\rho^\pm\rho^0$ modes are dominantly longitudinally polarized. Third, an important advantage of the $\rho\rho$ modes is that the penguin contribution is expected to be small due to different hadronic dynamics. This expectation is confirmed by the smallness of $\mathcal{B}(B^0 \to \rho^0\rho^0) = (0.96 \pm 0.15) \times 10^{-6}$ [28,85] compared to $\mathcal{B}(B^0 \to \rho^+\rho^-) = (24.2 \pm 3.1) \times 10^{-6}$ [28]. Thus, $S_{\rho^+\rho^-}$ is not far from $\sin 2\alpha$. Finally, both $S_{\rho^0\rho^0}$ and $C_{\rho^0\rho^0}$ are experimentally accessible, which may allow a precision determination of α. However, a full isospin analysis should allow that the fractions of longitudinal polarisation in B and $\overline{B}$ decays may differ, which has not yet been done by the experiments.

Detailed discussion of the determination of α with these methods, and the latest world average, can be found in Ref. [34]. The consistency between the range of α determined by the $B \to \pi\pi$, $\rho\pi$ and $\rho\rho$ measurements and the range allowed by CKM fits (excluding these direct determinations) provides further support to the Kobayashi-Maskawa mechanism.

All modes discussed in this Section so far have possible contributions from penguin amplitudes. As shown in Table 13.1, CP violation can also be studied with final states, typically containing charmed mesons, where no such contribution is possible. The neutral charmed meson must be reconstructed in a final state, such as a CP eigenstate, common to D^0 and $\overline{D}^0$ so that the amplitudes for the B and $\overline{B}$ meson decays interfere. Although there is a second tree amplitude with a different weak phase, the contributions of the different diagrams can in many cases be separated experimentally (for example by exploiting different decays of the $\overline{D}^0$ mesons) making these channels very clean theoretically. The first determination of $\sin(2\beta)$, with significance of CP violation over 5σ, with this method has recently been reported [86]. Moreover, the interference between the two tree diagrams gives sensitivity to γ, as will be discussed in Section 13.6.4.

13.6.3. *CP violation in interference of B^0_s decays with and without mixing*:

As discussed in Section 13.6.1, the world average for $|q/p|$ in the B^0_s system currently deviates from the Standard Model expectation due to an anomalous value of the dimuon asymmetry. Attributing the dimuon asymmetry result to a fluctuation, we again neglect the deviation of $|q/p|$ from 1, and use

$$\lambda_f = e^{-i\phi_M(B^0_s)}(\overline{A}_f/A_f)\;. \tag{13.102}$$

Within the Standard Model,

$$e^{-i\phi_{M(B^0_s)}} = (V^*_{tb}V_{ts})/(V_{tb}V^*_{ts})\;. \tag{13.103}$$

Note that $\Delta\Gamma/\Gamma = 0.122 \pm 0.009$ [28] and therefore y should not be put to zero in Eqs. (13.35, 13.36). However, $|q/p| = 1$ is expected to hold to an even better approximation than for B^0 mesons. One therefore obtains

$$\mathcal{A}_f(t) = \frac{S_f \sin(\Delta m t) - C_f \cos(\Delta m t)}{\cosh(\Delta\Gamma t/2) - A^{\Delta\Gamma}_f \sinh(\Delta\Gamma t/2)}\;,$$

$$A^{\Delta\Gamma}_f \equiv \frac{-2\,\mathcal{R}e(\lambda_f)}{1 + |\lambda_f|^2}\;. \tag{13.104}$$

The presence of the $A^{\Delta\Gamma}_f$ term implies that information on λ_f can be obtained from analyses that do not use tagging of the initial flavor, through so-called effective lifetime measurements [87].

The $B^0_s \to J/\psi\phi$ decay proceeds via the $\overline{b} \to \overline{c}c\overline{s}$ transition. The CP asymmetry in this mode thus determines (with angular analysis to

disentangle the CP-even and CP-odd components of the final state) $\sin 2\beta_s$, where β_s is defined in Eq. (13.57) [88]. The $B_s^0 \to J/\psi\pi^+\pi^-$ decay, which has a large contributions from $J/\psi f_0(980)$ and is assumed to also proceed dominantly via the $\overline{b} \to \overline{c}c\overline{s}$ transition, has also been used to determine β_s. In this case no angular analysis is necessary, since the final state has been shown to be dominated by the CP-even component [89]. A first determination of β_s with $B_s^0 \to D_s^+ D_s^-$ decays has also been made [90]. The combination of measurements yields [28]

$$-2\beta_s = 0.015 \pm 0.035\,, \tag{13.105}$$

consistent with the Standard Model prediction, $\beta_s = 0.0188 \pm 0.0004$ [18].

The experimental investigation of CP violation in the B_s^0 sector is still at a relatively early stage, and far fewer modes have been studied than in the B^0 system. First results on the $\overline{b} \to \overline{q}q\overline{s}$ decays $B_s^0 \to \phi\phi$ and K^+K^- have been reported. More channels are expected to be studied in the near future.

13.6.4. *Direct CP violation in the B system* :

An interesting class of decay modes is that of the tree-level decays $B^\pm \to D^{(*)}K^\pm$. These decays provide golden methods for a clean determination of the angle γ [91–95]. The method uses the decays $B^+ \to D^0K^+$, which proceeds via the quark transition $\overline{b} \to \overline{u}c\overline{s}$, and $B^+ \to \overline{D}^0K^+$, which proceeds via the quark transition $\overline{b} \to \overline{c}u\overline{s}$, with the D^0 and $\overline{D}^0$ decaying into a common final state. The decays into common final states, such $(\pi^0K_S)_DK^+$, involve interference effects between the two amplitudes, with sensitivity to the relative phase, $\delta + \gamma$ (δ is the relevant strong phase). The CP-conjugate processes are sensitive to $\delta - \gamma$. Measurements of branching ratios and CP asymmetries allow the determination of γ and δ from amplitude triangle relations. The method suffers from discrete ambiguities but, since all hadronic parameters can be determined from the data, has negligible theoretical uncertainty [96].

Unfortunately, the smallness of the CKM-suppressed $b \to u$ transitions makes it difficult at present to use the simplest methods [91–93] to determine γ. These difficulties are overcome (and the discrete ambiguities are removed) by performing a Dalitz plot analysis for multi-body D decays [94,95].

Constraints on γ from combinations of results on various $B \to D^{(*)}K^{(*)}$ processes have been obtained by experiments [97–99], with world averages in Refs. [18,19]. Detailed discussion of the determination of γ with these methods, and the latest world average, can be found in Ref. [34]. The consistency between the range of γ determined by the $B \to DK$ measurements and the range allowed by CKM fits (excluding these direct determinations) provides further support to the Kobayashi-Maskawa mechanism. As more data becomes available, determinations of γ from $B_s^0 \to D_s^\mp K^\pm$ [100,101] and $B^0 \to DK^{*0}$ [102–105] are expected to also give competitive measurements.

Decays to the final state $K^\mp\pi^\pm$ provided the first observations of direct CP violation in both B^0 and B_s^0 systems. The asymmetry arises due to interference between tree and penguin diagrams [106], similar to the effect discussed in Section 13.6.2. In principle, measurements of $\mathcal{A}_{\overline{B}^0 \to K^-\pi^+}$ and $\mathcal{A}_{\overline{B}_s^0 \to K^+\pi^-}$ could be used to determine the weak phase difference γ, but lack of knowledge of the relative magnitude and strong phase of the contributing amplitudes limits the achievable precision. The uncertainties on these hadronic parameters can be reduced by exploiting flavor symmetries, which predict a number of relations between asymmetries in different modes. One such relation is that the partial rate differences for B^0 and B_s^0 decays to $K^\mp\pi^\pm$ are expected to be approximately equal and opposite [107], which is consistent with current data. It is also expected that the partial rate asymmetries for $\overline{B}^0 \to K^-\pi^+$ and $B^- \to K^-\pi^0$ should be approximately equal; however, the experimental results currently show a significant discrepancy [28]:

$$\mathcal{A}_{\overline{B}^0 \to K^-\pi^+} = -0.082 \pm 0.006\,, \qquad \mathcal{A}_{B^- \to K^-\pi^0} = 0.040 \pm 0.021\,.$$

It is therefore of great interest to understand whether this originates from Standard Model QCD corrections, or whether it is a signature of new dynamics. Improved tests of a more precise relation between the partial rate differences of all four $K\pi$ final states [108–111], currently limited by knowledge of the CP asymmetry in $\overline{B}^0 \to K_S\pi^0$ decays, may help to resolve the situation.

It is also of interest to investigate whether similar patterns appear among the CP violating asymmetries in B meson decays to final states containing one pseudoscalar and one vector meson. Since the vector resonance decays to two particles, such channels can be studied through Dalitz plot analysis of the three-body final state. Model-independent analyses of $B^+ \to K^+K^-K^+$, $\pi^+\pi^-K^+$, $\pi^+\pi^-\pi^+$ and $K^+K^-\pi^+$ decays have revealed large CP violation effects in certain regions of phase space [112]. It remains to be seen whether these are associated to particular resonances or to interference effects, which will be necessary to understand the underlying dynamics.

13.7. Summary and Outlook

CP violation has been experimentally established in K and B meson decays. A full list of CP asymmetries that have been measured at a level higher than 5σ is given in the introduction to this review. In Section 13.1.4 we introduced three types of CP-violating effects. Examples of these three types include the following:

1. All three types of CP violation have been observed in $K \to \pi\pi$ decays:

$$\begin{aligned}
\mathcal{R}e(\epsilon') &= \frac{1}{6}\left(\left|\frac{\overline{A}_{\pi^0\pi^0}}{A_{\pi^0\pi^0}}\right| - \left|\frac{\overline{A}_{\pi^+\pi^-}}{A_{\pi^+\pi^-}}\right|\right) = (2.5 \pm 0.4) \times 10^{-6} && \text{(I)}\\
\mathcal{R}e(\epsilon) &= \frac{1}{2}\left(1 - \left|\frac{q}{p}\right|\right) = (1.66 \pm 0.02) \times 10^{-3} && \text{(II)}\\
\mathcal{I}m(\epsilon) &= -\frac{1}{2}\mathcal{I}m(\lambda_{(\pi\pi)_{I=0}}) = (1.57 \pm 0.02) \times 10^{-3}\,. && \text{(III)}
\end{aligned} \tag{13.106}$$

2. CP violation in decay has been observed in, for example, $B^0 \to K^+\pi^-$ transitions, while CP violation in interference of decays with and without mixing has been observed in, for example, the $B^0 \to J/\psi K_S$ channel:

$$\begin{aligned}
\mathcal{A}_{K^+\pi^-} &= \frac{|\overline{A}_{K^-\pi^+}/A_{K^+\pi^-}|^2 - 1}{|\overline{A}_{K^-\pi^+}/A_{K^+\pi^-}|^2 + 1} = -0.082 \pm 0.006 && \text{(I)}\\
S_{\psi K} &= \mathcal{I}m(\lambda_{\psi K}) = +0.691 \pm 0.017\,. && \text{(III)}
\end{aligned} \tag{13.107}$$

Based on Standard Model predictions, further observations of CP violation in B^0, B^+ and B_s^0 decays seem likely in the near future, at both LHCb and its upgrade [113,114] as well as the Belle II experiment [115]. The first observation of CP violation in b baryons is also likely to be within reach of LHCb. The same experiments have great potential to improve the sensitivity to CP violation effects in the charm sector, though uncertainty in the Standard Model predictions makes it difficult to forecast whether or not discoveries will be forthcoming. A number of upcoming experiments have potential to make significant progress on rare kaon decays. Observables that are subject to clean theoretical interpretation, such as β from $S_{\psi K_S}$, β_s from $B_s^0 \to J/\psi\phi$, $\mathcal{B}(K_L \to \pi^0\nu\overline{\nu})$ and γ from CP violation in $B \to DK$ decays, are of particular value for constraining the values of the CKM parameters and probing the flavor sector of extensions to the Standard Model. Progress in lattice QCD calculations is also needed to complement the anticipated experimental results. Other probes of CP violation now being pursued experimentally include the electric dipole moments of the neutron and electron, and the decays of tau leptons. Additional processes that are likely to play an important role in future CP studies include top-quark production and decay, Higgs boson decays and neutrino oscillations.

All measurements of CP violation to date are consistent with the predictions of the Kobayashi-Maskawa mechanism of the Standard Model. In fact, it is now established that the KM mechanism plays a major role in the CP violation measured in the quark sector.

However, a dynamically-generated matter-antimatter asymmetry of the universe requires additional sources of CP violation, and such sources are naturally generated by extensions to the Standard Model. New sources might eventually reveal themselves as small deviations from the predictions of the KM mechanism, or else might not be observable in the quark sector at all, but observable with future probes such as neutrino oscillations or electric dipole moments. The fundamental nature of CP violation demands a vigorous search.

A number of excellent reviews of CP violation are available [116–122], where the interested reader may find a detailed discussion of the various topics that are briefly reviewed here.

We thank David Kirkby for significant contributions to earlier version of this review.

14. NEUTRINO MASS, MIXING, AND OSCILLATIONS

Updated June 2016 by K. Nakamura (Kavli IPMU (WPI), U. Tokyo, KEK), and S.T. Petcov (SISSA/INFN Trieste, Kavli IPMU (WPI), U. Tokyo, Bulgarian Academy of Sciences).

The experiments with solar, atmospheric, reactor and accelerator neutrinos have provided compelling evidences for oscillations of neutrinos caused by nonzero neutrino masses and neutrino mixing. The data imply the existence of 3-neutrino mixing in vacuum. We review the theory of neutrino oscillations, the phenomenology of neutrino mixing, the problem of the nature - Dirac or Majorana, of massive neutrinos, the issue of CP violation in the lepton sector, and the current data on the neutrino masses and mixing parameters. The open questions and the main goals of future research in the field of neutrino mixing and oscillations are outlined.

14.1. Introduction: Massive neutrinos and neutrino mixing

It is a well-established experimental fact that the neutrinos and antineutrinos which take part in the standard charged current (CC) and neutral current (NC) weak interaction are of three varieties (types) or flavours: electron, ν_e and $\bar{\nu}_e$, muon, ν_μ and $\bar{\nu}_\mu$, and tauon, ν_τ and $\bar{\nu}_\tau$. The notion of neutrino type or flavour is dynamical: ν_e is the neutrino which is produced with e^+, or produces an e^-, in CC weak interaction processes; ν_μ is the neutrino which is produced with μ^+, or produces μ^-, *etc.* The flavour of a given neutrino is Lorentz invariant. Among the three different flavour neutrinos and antineutrinos, no two are identical. Correspondingly, the states which describe different flavour neutrinos must be orthogonal (within the precision of the current data): $\langle\nu_{l'}|\nu_l\rangle = \delta_{l'l}$, $\langle\bar{\nu}_{l'}|\bar{\nu}_l\rangle = \delta_{l'l}$, $\langle\bar{\nu}_{l'}|\nu_l\rangle = 0$.

It is also well-known from the existing data (all neutrino experiments were done so far with relativistic neutrinos or antineutrinos), that the flavour neutrinos ν_l (antineutrinos $\bar{\nu}_l$), are always produced in weak interaction processes in a state that is predominantly left-handed (LH) (right-handed (RH)). To account for this fact, ν_l and $\bar{\nu}_l$ are described in the Standard Model (SM) by a chiral LH flavour neutrino field $\nu_{lL}(x)$, $l = e, \mu, \tau$. For massless ν_l, the state of ν_l ($\bar{\nu}_l$) which the field $\nu_{lL}(x)$ annihilates (creates) is with helicity (-1/2) (helicity +1/2). If ν_l has a non-zero mass $m(\nu_l)$, the state of ν_l ($\bar{\nu}_l$) is a linear superposition of the helicity (-1/2) and (+1/2) states, but the helicity +1/2 state (helicity (-1/2) state) enters into the superposition with a coefficient $\propto m(\nu_l)/E$, E being the neutrino energy, and thus is strongly suppressed. Together with the LH charged lepton field $l_L(x)$, $\nu_{lL}(x)$ forms an $SU(2)_L$ doublet. In the absence of neutrino mixing and zero neutrino masses, $\nu_{lL}(x)$ and $l_L(x)$ can be assigned one unit of the additive lepton charge L_l and the three charges L_l, $l = e, \mu, \tau$, are conserved by the weak interaction.

At present there is no compelling evidence for the existence of states of relativistic neutrinos (antineutrinos), which are predominantly right-handed, ν_R (left-handed, $\bar{\nu}_L$). If RH neutrinos and LH antineutrinos exist, their interaction with matter should be much weaker than the weak interaction of the flavour LH neutrinos ν_l and RH antineutrinos $\bar{\nu}_l$, *i.e.*, ν_R ($\bar{\nu}_L$) should be "sterile" or "inert" neutrinos (antineutrinos) [1]. In the formalism of the Standard Model, the sterile ν_R and $\bar{\nu}_L$ can be described by $SU(2)_L$ singlet RH neutrino fields $\nu_R(x)$. In this case, ν_R and $\bar{\nu}_L$ will have no gauge interactions, *i.e.*, will not couple to the weak $W^\pm$ and Z^0 bosons. If present in an extension of the Standard Model, the RH neutrinos can play a crucial role i) in the generation of neutrino masses and mixing, ii) in understanding the remarkable disparity between the magnitudes of neutrino masses and the masses of the charged leptons and quarks, and iii) in the generation of the observed matter-antimatter asymmetry of the Universe (via the leptogenesis mechanism [2]) . In this scenario which is based on the see-saw theory [3], there is a link between the generation of neutrino masses and the generation of the baryon asymmetry of the Universe. The simplest hypothesis (based on symmetry considerations) is that to each LH flavour neutrino field $\nu_{lL}(x)$ there corresponds a RH neutrino field $\nu_{lR}(x)$, $l = e, \mu, \tau$, although schemes with less (more) than three RH neutrinos are also being considered.

The experiments with solar, atmospheric, reactor and accelerator neutrinos have provided compelling evidences for the existence of neutrino oscillations [4,5], transitions in flight between the different flavour neutrinos ν_e, ν_μ, ν_τ (antineutrinos $\bar{\nu}_e$, $\bar{\nu}_\mu$, $\bar{\nu}_\tau$), caused by nonzero neutrino masses and neutrino mixing. The existence of flavour neutrino oscillations implies that if a neutrino of a given flavour, say ν_μ, with energy E is produced in some weak interaction process, at a sufficiently large distance L from the ν_μ source the probability to find a neutrino of a different flavour, say ν_τ, $P(\nu_\mu \to \nu_\tau; E, L)$, is different from zero. $P(\nu_\mu \to \nu_\tau; E, L)$ is called the $\nu_\mu \to \nu_\tau$ oscillation or transition probability. If $P(\nu_\mu \to \nu_\tau; E, L) \neq 0$, the probability that ν_μ will not change into a neutrino of a different flavour, *i.e.*, the "ν_μ survival probability" $P(\nu_\mu \to \nu_\mu; E, L)$, will be smaller than one. If only muon neutrinos ν_μ are detected in a given experiment and they take part in oscillations, one would observe a "disappearance" of muon neutrinos on the way from the ν_μ source to the detector. Disappearance of the solar ν_e, reactor $\bar{\nu}_e$ and of atmospheric ν_μ and $\bar{\nu}_\mu$ due to the oscillations have been observed respectively, in the solar neutrino [6–14], KamLAND [15,16] and Super-Kamiokande [17,18] experiments. Strong evidences for ν_μ disappearance due to oscillations were obtained also in the long-baseline accelerator neutrino experiments K2K [19]. Subsequently, the MINOS [20,21] and T2K [22,23] long baseline experiments reported compelling evidence for ν_μ disappearance due to oscillations, while evidences for ν_τ appearance due to $\nu_\mu \to \nu_\tau$ oscillations were published by the Super-Kamiokande [24] and OPERA [25] collaborations. As a consequence of the results of the experiments quoted above the existence of oscillations or transitions of the solar ν_e, atmospheric ν_μ and $\bar{\nu}_\mu$, accelerator ν_μ (at $L \sim 250$ km, $L \sim 295$ km and $L \sim 730$ km) and reactor $\bar{\nu}_e$ (at $L \sim 180$ km), driven by nonzero neutrino masses and neutrino mixing, was firmly established. There are strong indications that the solar ν_e transitions are affected by the solar matter [26,27].

Further important developments took place in the period starting from June 2011. First, the T2K Collaboration reported [28] indications for $\nu_\mu \to \nu_e$ oscillations, *i.e.*, of "appearance" of ν_e in a beam of ν_μ, which had a statistical significance of 2.5σ. The MINOS [29] Collaboration also obtained data consistent with $\nu_\mu \to \nu_e$ oscillations. Subsequently, the Double Chooz Collaboration reported [30] indications for disappearance of reactor $\bar{\nu}_e$ at $L \sim 1.1$ km. Strong evidences for reactor $\bar{\nu}_e$ disappearance at $L \sim 1.65$ km and $L \sim 1.38$ km and (with statistical significance of 5.2σ and 4.9σ) were obtained respectively in the Daya Bay [31] and RENO [32] experiments. Further evidences for reactor $\bar{\nu}_e$ disappearance (at 2.9σ) and for $\nu_\mu \to \nu_e$ oscillations (at 3.1σ) were reported by the Double Chooz [33] and T2K [34] experiments, while the Daya Bay and RENO Collaborations presented updated, more precise results on reactor $\bar{\nu}_e$ disappearance [35,36,37](for the latest results of the Daya Bay [38], RENO [39], Double Chooz [40], MINOS [41] and T2K experiments [42], see Section 14.12).

Oscillations of neutrinos are a consequence of the presence of flavour neutrino mixing, or lepton mixing, in vacuum. In the formalism of local quantum field theory, used to construct the Standard Model, this means that the LH flavour neutrino fields $\nu_{lL}(x)$, which enter into the expression for the lepton current in the CC weak interaction Lagrangian, are linear combinations of the fields of three (or more) neutrinos ν_j, having masses $m_j \neq 0$:

$$\nu_{lL}(x) = \sum_j U_{lj}\, \nu_{jL}(x), \quad l = e, \mu, \tau, \tag{14.1}$$

where $\nu_{jL}(x)$ is the LH component of the field of ν_j possessing a mass m_j and U is a unitary matrix - the neutrino mixing matrix [1,4,5]. The matrix U is often called the Pontecorvo-Maki-Nakagawa-Sakata (PMNS) or Maki-Nakagawa-Sakata (MNS) mixing matrix. Obviously, Eq. (14.1) implies that the individual lepton charges L_l, $l = e, \mu, \tau$, are not conserved.

All compelling neutrino oscillation data can be described assuming 3-flavour neutrino mixing in vacuum. The data on the invisible decay width of the Z-boson is compatible with only 3 light flavour neutrinos coupled to Z [43]. The number of massive neutrinos ν_j,

n, can, in general, be bigger than 3, $n > 3$, if, for instance, there exist sterile neutrinos and they mix with the flavour neutrinos. It is firmly established on the basis of the current data that at least 3 of the neutrinos ν_j, say ν_1, ν_2, ν_3, must be light, $m_{1,2,3} \lesssim 1$ eV (Section 14.12), and must have different masses, $m_1 \neq m_2 \neq m_3$. At present there are several experimental hints for existence of one or two light sterile neutrinos at the eV scale, which mix with the flavour neutrinos, implying the presence in the neutrino mixing of additional one or two neutrinos, ν_4 or $\nu_{4,5}$, with masses m_4 ($m_{4,5}$) ~ 1 eV. These hints will be briefly discussed in Section 14.13 of the present review.

Being electrically neutral, the neutrinos with definite mass ν_j can be Dirac fermions or Majorana particles [44,45]. The first possibility is realized when there exists a lepton charge carried by the neutrinos ν_j, which is conserved by the particle interactions. This could be, *e.g.*, the total lepton charge $L = L_e + L_\mu + L_\tau$: $L(\nu_j) = 1$, $j = 1, 2, 3$. In this case the neutrino ν_j has a distinctive antiparticle $\bar{\nu}_j$: $\bar{\nu}_j$ differs from ν_j by the value of the lepton charge L it carries, $L(\bar{\nu}_j) = -1$. The massive neutrinos ν_j can be Majorana particles if no lepton charge is conserved (see, *e.g.*, Refs. [46,47]) . A massive Majorana particle χ_j is identical with its antiparticle $\bar{\chi}_j$: $\chi_j \equiv \bar{\chi}_j$. On the basis of the existing neutrino data it is impossible to determine whether the massive neutrinos are Dirac or Majorana fermions.

In the case of n neutrino flavours and n massive neutrinos, the $n \times n$ unitary neutrino mixing matrix U can be parametrized by $n(n-1)/2$ Euler angles and $n(n+1)/2$ phases. If the massive neutrinos ν_j are Dirac particles, only $(n-1)(n-2)/2$ phases are physical and can be responsible for CP violation in the lepton sector. In this respect the neutrino (lepton) mixing with Dirac massive neutrinos is similar to the quark mixing. For $n = 3$ there is just one CP violating phase in U, which is usually called "the Dirac CP violating phase." CP invariance holds if (in a certain standard convention) U is real, $U^* = U$.

If, however, the massive neutrinos are Majorana fermions, $\nu_j \equiv \chi_j$, the neutrino mixing matrix U contains $n(n-1)/2$ CP violation phases [48,49], *i.e.*, by $(n-1)$ phases more than in the Dirac neutrino case: in contrast to Dirac fields, the massive Majorana neutrino fields cannot "absorb" phases. In this case U can be cast in the form [48]

$$U = V\,P \tag{14.2}$$

where the matrix V contains the $(n-1)(n-2)/2$ Dirac CP violation phases, while P is a diagonal matrix with the additional $(n-1)$ Majorana CP violation phases α_{21}, α_{31},..., α_{n1},

$$P = diag\left(1, e^{i\frac{\alpha_{21}}{2}}, e^{i\frac{\alpha_{31}}{2}}, ..., e^{i\frac{\alpha_{n1}}{2}}\right) . \tag{14.3}$$

The Majorana phases will conserve CP if [50] $\alpha_{j1} = \pi q_j$, $q_j = 0, 1, 2$, $j = 2, 3, ..., n$. In this case $\exp[i(\alpha_{j1} - \alpha_{k1})] = \pm 1$ has a simple physical interpretation: this is the relative CP-parity of Majorana neutrinos χ_j and χ_k. The condition of CP invariance of the leptonic CC weak interaction in the case of mixing and massive Majorana neutrinos reads [46]:

$$U^*_{lj} = U_{lj}\,\rho_j\,, \quad \rho_j = \frac{1}{i}\eta_{CP}(\chi_j) = \pm 1\,, \tag{14.4}$$

where $\eta_{CP}(\chi_j) = i\rho_j = \pm i$ is the CP parity of the Majorana neutrino χ_j [50]. Thus, if CP invariance holds, the elements of U are either real or purely imaginary.

In the case of $n = 3$ there are altogether 3 CP violation phases - one Dirac and two Majorana. Even in the mixing involving only 2 massive Majorana neutrinos there is one physical CP violation Majorana phase. In contrast, the CC weak interaction is automatically CP-invariant in the case of mixing of two massive Dirac neutrinos or of two quarks.

14.2. The three neutrino mixing

All existing compelling data on neutrino oscillations can be described assuming 3-flavour neutrino mixing in vacuum. This is the minimal neutrino mixing scheme which can account for the currently available data on the oscillations of the solar (ν_e), atmospheric (ν_μ and $\bar{\nu}_\mu$), reactor ($\bar{\nu}_e$) and accelerator (ν_μ and $\bar{\nu}_\mu$) neutrinos. The (left-handed) fields of the flavour neutrinos ν_e, ν_μ and ν_τ in the expression for the weak charged lepton current in the CC weak interaction Lagrangian, are linear combinations of the LH components of the fields of three massive neutrinos ν_j:

$$\mathcal{L}_{\rm CC} = -\,\frac{g}{\sqrt{2}} \sum_{l=e,\mu,\tau} \overline{l_L}(x)\,\gamma_\alpha\,\nu_{lL}(x)\,W^{\alpha\dagger}(x) + h.c.\,,$$
$$\nu_{l\rm L}(x) = \sum_{j=1}^{3} U_{lj}\,\nu_{j\rm L}(x), \tag{14.5}$$

where U is the 3×3 unitary neutrino mixing matrix [4,5]. As we have discussed in the preceding Section, the mixing matrix U can be parameterized by 3 angles, and, depending on whether the massive neutrinos ν_j are Dirac or Majorana particles, by 1 or 3 CP violation phases [48,49]:

$$U = \begin{bmatrix} c_{12}c_{13} & s_{12}c_{13} & s_{13}e^{-i\delta} \\ -s_{12}c_{23} - c_{12}s_{23}s_{13}e^{i\delta} & c_{12}c_{23} - s_{12}s_{23}s_{13}e^{i\delta} & s_{23}c_{13} \\ s_{12}s_{23} - c_{12}c_{23}s_{13}e^{i\delta} & -c_{12}s_{23} - s_{12}c_{23}s_{13}e^{i\delta} & c_{23}c_{13} \end{bmatrix}$$
$$\times\, {\rm diag}(1,\ e^{i\frac{\alpha_{21}}{2}},\ e^{i\frac{\alpha_{31}}{2}})\ . \tag{14.6}$$

where $c_{ij} = \cos\theta_{ij}$, $s_{ij} = \sin\theta_{ij}$, the angles $\theta_{ij} = [0, \pi/2]$, $\delta = [0, 2\pi]$ is the Dirac CP violation phase and α_{21}, α_{31} are two Majorana CP violation (CPV) phases. Thus, in the case of massive Dirac neutrinos, the neutrino mixing matrix U is similar, in what concerns the number of mixing angles and CPV phases, to the CKM quark mixing matrix. The presence of two additional physical CPV phases in U if ν_j are Majorana particles is a consequence of the special properties of the latter (see, *e.g.*, Refs. [46,48]) .

As we see, the fundamental parameters characterizing the 3-neutrino mixing are: i) the 3 angles θ_{12}, θ_{23}, θ_{13}, ii) depending on the nature of massive neutrinos ν_j - 1 Dirac (δ), or 1 Dirac + 2 Majorana ($\delta, \alpha_{21}, \alpha_{31}$), CPV phases, and iii) the 3 neutrino masses, m_1, m_2, m_3. Thus, depending on whether the massive neutrinos are Dirac or Majorana particles, this makes 7 or 9 additional parameters in the minimally extended Standard Model of particle interactions with massive neutrinos.

The angles θ_{12}, θ_{23} and θ_{13} can be defined via the elements of the neutrino mixing matrix:

$$c^2_{12} \equiv \cos^2\theta_{12} = \frac{|U_{e1}|^2}{1 - |U_{e3}|^2}\,, \quad s^2_{12} \equiv \sin^2\theta_{12} = \frac{|U_{e2}|^2}{1 - |U_{e3}|^2}\,, \tag{14.7}$$

$$s^2_{13} \equiv \sin^2\theta_{13} = |U_{e3}|^2,\ \ s^2_{23} \equiv \sin^2\theta_{23} = \frac{|U_{\mu 3}|^2}{1 - |U_{e3}|^2},$$
$$c^2_{23} \equiv \cos^2\theta_{23} = \frac{|U_{\tau 3}|^2}{1 - |U_{e3}|^2}. \tag{14.8}$$

The neutrino oscillation probabilities depend (Section 14.7), in general, on the neutrino energy, E, the source-detector distance L, on the elements of U and, for relativistic neutrinos used in all neutrino experiments performed so far, on $\Delta m^2_{ij} \equiv (m^2_i - m^2_j)$, $i \neq j$. In the case of 3-neutrino mixing there are only two independent neutrino mass squared differences, say $\Delta m^2_{21} \neq 0$ and $\Delta m^2_{31} \neq 0$. The numbering of massive neutrinos ν_j is arbitrary. It proves convenient from the point of view of relating the mixing angles θ_{12}, θ_{23} and θ_{13} to observables, to identify $|\Delta m^2_{21}|$ with the smaller of the two neutrino mass squared differences, which, as it follows from the data, is responsible for the solar ν_e and, the observed by KamLAND, reactor $\bar{\nu}_e$ oscillations. We will number (just for convenience) the massive neutrinos in such a way that $m_1 < m_2$, so that $\Delta m^2_{21} > 0$. With these choices made, there are two possibilities: either $m_1 < m_2 < m_3$,

or $m_3 < m_1 < m_2$. Then the larger neutrino mass square difference $|\Delta m^2_{31}|$ or $|\Delta m^2_{32}|$, can be associated with the experimentally observed oscillations of the atmospheric and accelerator ν_μ and $\bar{\nu}_\mu$, as well as of the reactor $\bar{\nu}_e$ at $L \sim 1$ km. The effects of Δm^2_{31} or Δm^2_{32} in the oscillations of solar ν_e, and of Δm^2_{21} in the oscillations of atmospheric and accelerator ν_μ and $\bar{\nu}_\mu$ or of the reactor $\bar{\nu}_e$ at $L \sim 1$ km, are relatively small and subdominant as a consequence of the facts that i) L, E and L/E in the experiments with solar ν_e and with atmospheric and accelerator ν_μ and $\bar{\nu}_\mu$, or with reactor $\bar{\nu}_e$ and baseline $L \sim 1$ km, are very different, ii) the conditions of production and propagation (on the way to the detector) of the solar ν_e and of the atmospheric or accelerator ν_μ and $\bar{\nu}_\mu$ and of the reactor $\bar{\nu}_e$, are very different, and iii) $|\Delta m^2_{21}|$ and $|\Delta m^2_{31}|$ ($|\Delta m^2_{32}|$) in the case of $m_1 < m_2 < m_3$ ($m_3 < m_1 < m_2$), as it follows from the data, differ by approximately a factor of 30, $|\Delta m^2_{21}| \ll |\Delta m^2_{31(32)}|$, $|\Delta m^2_{21}|/|\Delta m^2_{31(32)}| \cong 0.03$. This implies that in both cases of $m_1 < m_2 < m_3$ and $m_3 < m_1 < m_2$ we have $\Delta m^2_{32} \cong \Delta m^2_{31}$ with $|\Delta m^2_{31} - \Delta m^2_{32}| = |\Delta m^2_{21}| \ll |\Delta m^2_{31,32}|$. Obviously, in the case of $m_1 < m_2 < m_3$ ($m_3 < m_1 < m_2$) we have $\Delta m^2_{31(32)} > 0$ ($\Delta m^2_{31(32)} < 0$).

It followed from the results of the Chooz experiment [51] with reactor $\bar{\nu}_e$ and from the more recent data of the Daya Bay, RENO, Double Chooz and T2K experiments (which will be discussed in Section14.12), that, in the convention we use, in which $0 < \Delta m^2_{21} < |\Delta m^2_{31(32)}|$, the element $|U_{e3}|$=$\sin\theta_{13}$ of the neutrino mixing matrix U is relatively small. This makes it possible to identify the angles θ_{12} and θ_{23} as the neutrino mixing angles associated with the solar ν_e and the dominant atmospheric ν_μ (and $\bar{\nu}_\mu$) oscillations, respectively. The angles θ_{12} and θ_{23} are sometimes called "solar" and "atmospheric" neutrino mixing angles, and are sometimes denoted as $\theta_{12} = \theta_\odot$ and $\theta_{23} = \theta_{\rm A}$ (or $\theta_{\rm atm}$), while Δm^2_{21} and Δm^2_{31} are often referred to as the "solar" and "atmospheric" neutrino mass squared differences and are often denoted as $\Delta m^2_{21} \equiv \Delta m^2_\odot$, $\Delta m^2_{31} \equiv \Delta m^2_{\rm A}$ (or $\Delta m^2_{\rm atm}$).

The solar neutrino data tell us that $\Delta m^2_{21} \cos 2\theta_{12} > 0$. In the convention employed by us we have $\Delta m^2_{21} > 0$. Correspondingly, in this convention one must have $\cos 2\theta_{12} > 0$.

Global analyses of the neutrino oscillation data [52,53,54] available by the second half of 2014 allowed us to determine the 3-neutrino oscillation parameters Δm^2_{21}, θ_{12}, $|\Delta m^2_{31}|$ ($|\Delta m^2_{32}|$), θ_{23} and θ_{13} with a relatively high precision.

The authors of the three independent analyses [52,53,54] report practically the same (within 1σ) results on Δm^2_{21}, $\sin^2\theta_{12}$, $|\Delta m^2_{31}|$ and $\sin^2\theta_{13}$. The results obtained in Ref. 52 on $\sin^2\theta_{23}$ show, in particular, that for $\Delta m^2_{31(32)} > 0$ ($\Delta m^2_{31(32)} < 0$), *i.e.*, for $m_1 < m_2 < m_3$ ($m_3 < m_1 < m_2$), the best fit value of $\sin^2\theta_{23} = 0.437$ (0.455). At the same time, the best fit values of $\sin^2\theta_{23}$ reported for $\Delta m^2_{31(32)} > 0$ ($\Delta m^2_{31(32)} < 0$) in Ref. 53 and in Ref. 54 read, respectively: $\sin^2\theta_{23} = 0.452$ (0.579) and $\sin^2\theta_{23} = 0.567$ (0.573). It should be added, however, that the global minima of the corresponding χ^2 functions in all three cases of the analyses [52,53,54] are accompanied by local minima which are less than 1σ away in the value of the χ^2 function from the corresponding global minima. Taking into account the global and the local minima of the χ^2 function found in [52,53,54] makes the results on $\sin^2\theta_{23}$ (including the 3σ allowed ranges) obtained in Refs. [52], [53] and [54] compatible. This, in particular, reflects the fact that the value of $\sin^2\theta_{23}$ is still determined experimentally with a relatively large uncertainty.

In all three analyses [52,53,54] the authors find that the best fit value of the Dirac CPV phases $\delta \cong 3\pi/2$. According to Ref. 52, the CP conserving values $\delta = 0$ (2π) and π ($\delta = 0$ (2π)) are disfavored at 1.6σ to 2.0σ (at 2.0σ) for $\Delta m^2_{31(32)} > 0$ ($\Delta m^2_{31(32)} < 0$). In the case of $\Delta m^2_{31(32)} < 0$, the value $\delta = \pi$ is statistically 1σ away from the best fit value $\delta \cong 3\pi/2$. Similar results are obtained in [53,54].

In August 2015 the first results of the NOνA neutrino oscillation experiment were announced [55,56]. These results together with the latest neutrino and the first antineutrino data from the T2K experiment [57,58] (see also Ref. 59) were included, in particular, in the latest analysis of the global neutrino oscillation data performed in Ref. 60. Thus, in Ref. 60 the authors updated the results obtained earlier in [52,53,54]. We present in Table 14.1 the best fit values and the 99.73% CL allowed ranges of the neutrino oscillation parameters found in Ref. 60 using, in particular, the more "conservative" LID NOνA data from Ref. 56. The best fit value of $\sin^2\theta_{23}$ found for $\Delta m^2_{31(32)} > 0$ ($\Delta m^2_{31(32)} < 0$) in Ref. 60 reads: $\sin^2\theta_{23} = 0.437$ (0.569). The authors of Ref. 60 also find that the hint for $\delta \cong 3\pi/2$ is strengthened by the NOνA $\nu_\mu \to \nu_e$ and T2K $\bar{\nu}_\mu \to \bar{\nu}_e$ oscillation data. The values of $\delta = \pi/2$ and $\delta = 0$ (2π) are disfavored at 3σ CL and 2σ CL, respectively, while $\delta = \pi$ is allowed at approximately 1.6σ CL (1.2σ CL) for $\Delta m^2_{31(32)} > 0$ ($\Delta m^2_{31(32)} < 0$).

Table 14.1: The best-fit values and 3σ allowed ranges of the 3-neutrino oscillation parameters, derived from a global fit of the current neutrino oscillation data (from [60]) . For the Dirac phase δ we give the best fit value and the 2σ allowed ranges; at 3σ no physical values of δ are disfavored. The values (values in brackets) correspond to $m_1 < m_2 < m_3$ ($m_3 < m_1 < m_2$). The definition of Δm^2 used is: $\Delta m^2 = m^2_3 - (m^2_2 + m^2_1)/2$. Thus, $\Delta m^2 = \Delta m^2_{31} - \Delta m^2_{21}/2 > 0$, if $m_1 < m_2 < m_3$, and $\Delta m^2 = \Delta m^2_{32} + \Delta m^2_{21}/2 < 0$ for $m_3 < m_1 < m_2$.

Parameter	best-fit	3σ
Δm^2_{21} [10^{-5} eV ^{2}]	7.37	$6.93 - 7.97$
$\lvert\Delta m^2\rvert$ [10^{-3} eV ^{2}]	2.50 (2.46)	$2.37 - 2.63$ $(2.33 - 2.60)$
$\sin^2\theta_{12}$	0.297	$0.250 - 0.354$
$\sin^2\theta_{23}$, $\Delta m^2 > 0$	0.437	$0.379 - 0.616$
$\sin^2\theta_{23}$, $\Delta m^2 < 0$	0.569	$0.383 - 0.637$
$\sin^2\theta_{13}$, $\Delta m^2 > 0$	0.0214	$0.0185 - 0.0246$
$\sin^2\theta_{13}$, $\Delta m^2 < 0$	0.0218	$0.0186 - 0.0248$
δ/π	1.35 (1.32)	$(0.92 - 1.99)$ $((0.83 - 1.99))$

It follows from the results given in Table 14.1 that θ_{23} is close to, but can be different from, $\pi/4$, $\theta_{12} \cong \pi/5.4$ and that $\theta_{13} \cong \pi/20$. Correspondingly, the pattern of neutrino mixing is drastically different from the pattern of quark mixing.

Note also that Δm^2_{21}, $\sin^2\theta_{12}$, $|\Delta m^2_{31(32)}|$, $\sin^2\theta_{23}$ and $\sin^2\theta_{13}$ are determined from the data with a 1σ uncertainty (= 1/6 of the 3σ range) of approximately 2.3%, 5.8%, 1.7%, 9.0% and 4.8%. respectively.

The existing SK atmospheric neutrino, K2K, MINOS, T2K and NOνA data do not allow to determine the sign of $\Delta m^2_{31(32)}$. Maximal solar neutrino mixing, *i.e.*, $\theta_{12} = \pi/4$, is ruled out at more than 6σ by the data. Correspondingly, one has $\cos 2\theta_{12} \geq 0.29$ (at 99.73% CL).

Apart from the hint that the Dirac phase $\delta \cong 3\pi/2$, no other experimental information on the Dirac and Majorana CPV phases in the neutrino mixing matrix is available at present. Thus, the status of CP symmetry in the lepton sector is essentially unknown. With $\theta_{13} \cong 0.15 \neq 0$, the Dirac phase δ can generate CP violating effects in neutrino oscillations [48,61,62], *i.e.*, a difference between the probabilities of the $\nu_l \to \nu_{l'}$ and $\bar{\nu}_l \to \bar{\nu}_{l'}$ oscillations, $l \neq l' = e, \mu, \tau$. The magnitude of CP violation in $\nu_l \to \nu_{l'}$ and $\bar{\nu}_l \to \bar{\nu}_{l'}$ oscillations, $l \neq l' = e, \mu, \tau$, is determined by [63] the rephasing invariant J_{CP}, associated with the Dirac CPV phase in U:

$$J_{\rm CP} = {\rm Im}\left(U_{\mu 3}\, U^*_{e3}\, U_{e2}\, U^*_{\mu 2}\right) . \qquad (14.9)$$

It is analogous to the rephasing invariant associated with the Dirac CPV phase in the CKM quark mixing matrix [64]. In the "standard" parametrization of the neutrino mixing matrix (Eq. (14.6)), $J_{\rm CP}$ has the form:

$$\begin{aligned} J_{CP} &\equiv {\rm Im}\,(U_{\mu 3}\, U^*_{e3}\, U_{e2}\, U^*_{\mu 2}) \\ &= \frac{1}{8}\cos\theta_{13}\sin 2\theta_{12}\,\sin 2\theta_{23}\,\sin 2\theta_{13}\,\sin\delta\,. \end{aligned} \qquad (14.10)$$

Thus, given the fact that $\sin 2\theta_{12}$, $\sin 2\theta_{23}$ and $\sin 2\theta_{13}$ have been determined experimentally with a relatively good precision, the size of CP violation effects in neutrino oscillations depends essentially only on the magnitude of the currently not well determined value of the Dirac phase δ. The current data implies $J_{CP} \lesssim 0.035 \sin\delta$, where we have used the 3σ ranges of $\sin^2\theta_{12}$, $\sin^2\theta_{23}$ and $\sin^2\theta_{13}$ given in Table 14.1. For the best fit values of $\sin^2\theta_{12}$, $\sin^2\theta_{23}$, $\sin^2\theta_{13}$ and δ we find in the case of $\Delta m^2_{31(2)} > 0$ ($\Delta m^2_{31(2)} < 0$): $J_{CP} \cong 0.0327 \sin\delta \cong -0.0291$ ($J_{CP} \cong 0.0327 \sin\delta \cong -0.0276$). Thus, if the indication that $\delta \cong 3\pi/2$ is confirmed by future more precise data, the CP violation effects in neutrino oscillations would be relatively large.

If the neutrinos with definite masses ν_i, $i = 1, 2, 3$, are Majorana particles, the 3-neutrino mixing matrix contains two additional Majorana CPV phases [48]. However, the flavour neutrino oscillation probabilities $P(\nu_l \to \nu_{l'})$ and $P(\bar\nu_l \to \bar\nu_{l'})$, $l, l' = e, \mu, \tau$, do not depend on the Majorana phases [48,65]. The Majorana phases can play important role, *e.g.*, in $|\Delta L| = 2$ processes like neutrinoless double beta ($(\beta\beta)_{0\nu}$-) decay $(A, Z) \to (A, Z+2) + e^- + e^-$, L being the total lepton charge, in which the Majorana nature of massive neutrinos ν_i manifests itself (see, *e.g.*, Refs. [46,66]) . Our interest in the CPV phases present in the neutrino mixing matrix is stimulated also by the intriguing possibility that the Dirac phase and/or the Majorana phases in $U_{\rm PMNS}$ can provide the CP violation necessary for the generation of the observed baryon asymmetry of the Universe [67,68].

As we have indicated, the existing data do not allow one to determine the sign of $\Delta m^2_{31(2)}$. In the case of 3-neutrino mixing, the two possible signs of $\Delta m^2_{31(2)}$ correspond to two types of neutrino mass spectrum. In the widely used conventions of numbering the neutrinos with definite mass in the two cases, the two spectra read:

– *i) spectrum with normal ordering (NO)*:

$$m_1 < m_2 < m_3, \quad \Delta m^2_{31} = \Delta m^2_{\rm A} > 0,$$
$$\Delta m^2_{21} \equiv \Delta m^2_{\odot} > 0, \;\; m_{2(3)} = (m^2_1 + \Delta m^2_{21(31)})^{\frac{1}{2}}. \qquad (14.11)$$

– *ii) spectrum with inverted ordering (IO)*:

$$m_3 < m_1 < m_2, \quad \Delta m^2_{32} = \Delta m^2_{\rm A} < 0, \quad \Delta m^2_{21} \equiv \Delta m^2_{\odot} \;\; > 0,$$
$$m_2 = (m^2_3 + \Delta m^2_{23})^{\frac{1}{2}}, \quad m_1 = (m^2_3 + \Delta m^2_{23} - \Delta m^2_{21})^{\frac{1}{2}}. \qquad (14.12)$$

Depending on the values of the lightest neutrino mass [69], $\min(m_j)$, the neutrino mass spectrum can also be:

– *Normal Hierarchical (NH)*:

$$m_1 \ll m_2 < m_3, \;\; m_2 \cong (\Delta m^2_{21})^{\frac{1}{2}} \cong 0.0086 \text{ eV},$$
$$m_3 \cong |\Delta m^2_{31}|^{\frac{1}{2}} \cong 0.0504 \text{ eV}; \text{ or} \qquad (14.13)$$

– *Inverted Hierarchical (IH)*:

$$m_3 \ll m_1 < m_2, \;\; m_{1,2} \cong |\Delta m^2_{32}|^{\frac{1}{2}} \cong 0.0500 \text{ eV}; \text{ or} \qquad (14.14)$$

– *Quasi-Degenerate (QD)*:

$$m_1 \cong m_2 \cong m_3 \cong m_0, \;\; m^2_j \gg |\Delta m^2_{31(32)}|, \;\; m_0 \gtrsim 0.10 \text{ eV}. \qquad (14.15)$$

Sometimes the determination of the neutrino mass spectrum is referred to in the literature on the subject as determination of "neutrino mass hierarchy". However, as we have seen, the neutrino mass spectrum might not be hierarchical. Therefore, determination of "neutrino mass ordering" is a more precise expression and we are going to use this expression in the present review article.

Eq. (14.11) and Eq. (14.12) suggest that, for consistency, the data on the larger neutrino mass squared difference, obtained in 3-neutrino oscillation analyses, should be presented i) either on the value of Δm^2_{32} in the case of NO spectrum and on Δm^2_{31} for IO spectrum, or ii) on the value of Δm^2_{31} for the NO spectrum and on Δm^2_{32} for IO spectrum. It would be preferable that all experimental groups which provide data on the larger neutrino mass squared difference, choose one of the indicated two possibilities to present their data - this will make straightforward the comparison of the results obtained in different experiments.

All types of neutrino mass spectrum, discussed above, are compatible with the existing constraints on the absolute scale of neutrino masses m_j. Information about the latter can be obtained, *e.g.*, by measuring the spectrum of electrons near the end point in ^{3}H β-decay experiments [70–74] and from cosmological and astrophysical data. The most stringent upper bounds on the $\bar\nu_e$ mass were obtained in the Troitzk [74,71] experiment:

$$m_{\bar\nu_e} < 2.05 \text{ eV} \quad \text{ at } 95\% \text{ CL}. \qquad (14.16)$$

Similar result was obtained in the Mainz experiment [72]: $m_{\bar\nu_e} < 2.3$ eV at 95% CL. We have $m_{\bar\nu_e} \cong m_{1,2,3}$ in the case of QD spectrum. The KATRIN experiment [73] is planned to reach sensitivity of $m_{\bar\nu_e} \sim 0.20$ eV, *i.e.*, it will probe the region of the QD spectrum.

The Cosmic Microwave Background (CMB) data of the WMAP experiment, combined with supernovae data and data on galaxy clustering can be used to obtain an upper limit on the sum of neutrinos masses (see review on Cosmological Parameters [75] and, *e.g.*, Ref. 76). Depending on the model complexity and the input data used one obtains [76]: $\sum_j m_j \lesssim (0.3 - 1.3)$ eV, 95% CL.

In March of 2013 the Planck Collaboration published their first constraints on $\sum_j m_j$ [77]. These constraints were updated in 2015 in [78]. Assuming the existence of three light massive neutrinos and the validity of the Λ CDM (Cold Dark Matter) model, and using their data on the CMB temperature power spectrum anisotropies, polarization, on gravitational lensing effects and the low l CMB polarization spectrum data (the "low P" data), the Planck Collaboration reported the following updated upper limit on the sum of the neutrino masses [78]: $\sum_j m_j < 0.57$ eV, 95% CL. Adding supernovae (light-curve) data and data on the Baryon Acoustic Oscillations (BAO) lowers the limit to [78]:

$$\sum_j m_j < 0.23 \; eV, \qquad 95\% \text{ CL}.$$

It follows from these data that neutrino masses are much smaller than the masses of charged leptons and quarks. If we take as an indicative upper limit $m_j \lesssim 0.5$ eV, we have $m_j/m_{l,q} \lesssim 10^{-6}$, $l = e, \mu, \tau$, $q = d, s, b, u, c, t$. It is natural to suppose that the remarkable smallness of neutrino masses is related to the existence of a new fundamental mass scale in particle physics, and thus to new physics beyond that predicted by the Standard Model.

14.3. Future progress

After the spectacular experimental progress made in the studies of neutrino oscillations, further understanding of the pattern of neutrino masses and neutrino mixing, of their origins and of the status of CP symmetry in the lepton sector requires an extensive and challenging program of research. The main goals of such a research program include:

- Determining the nature - Dirac or Majorana, of massive neutrinos ν_j. This is of fundamental importance for making progress in our understanding of the origin of neutrino masses and mixing and of the symmetries governing the lepton sector of particle interactions.
- Determination of the sign of Δm^2_{31} (or Δm^2_{32}), *i.e.*, the "neutrino mass ordering", or of the type of spectrum neutrino masses obey.
- Determining, or obtaining significant constraints on, the absolute scale of neutrino masses. This, in particular, would help obtain information about the detailed structure (hierarchical, quasidegenerate, etc.) of the neutrino mass spectrum.
- Determining the status of CP symmetry in the lepton sector.
- High precision measurement of θ_{13}, Δm^2_{21}, θ_{12}, $|\Delta m^2_{31}|$ and θ_{23}.
- Understanding at a fundamental level the mechanism giving rise to neutrino masses and mixing and to L_l−non-conservation. This includes understanding the origin of the patterns of ν-mixing

and ν-masses suggested by the data. Are the observed patterns of ν-mixing and of $\Delta m^2_{21,31}$ related to the existence of a new fundamental symmetry of particle interactions? Is there any relation between quark mixing and neutrino mixing, *e.g.*, does the relation $\theta_{12} + \theta_c = \pi/4$, where θ_c is the Cabibbo angle, hold? What is the physical origin of CP violation phases in the neutrino mixing matrix U? Is there any relation (correlation) between the (values of) CP violation phases and mixing angles in U? Progress in the theory of neutrino mixing might also lead to a better understanding of the mechanism of generation of baryon asymmetry of the Universe.

The high precision measurement of the value of $\sin^2 2\theta_{13}$ from the Daya Bay experiment and the subsequent results on θ_{13} obtained by the RENO, Double Chooz and T2K collaborations (see Section 1.11), have far reaching implications. The measured relatively large value of θ_{13} opened up the possibilities, in particular,

i) for searching for CP violation effects in neutrino oscillation experiments with high intensity accelerator neutrino beams, like T2K, NOνA, etc. The sensitivities of T2K and NOνA on CP violation in neutrino oscillations are discussed in, *e.g.*, Refs. [79,80].
ii) for determining the sign of Δm^2_{32}, and thus the type of neutrino mass spectrum ("neutrino mass ordering") in the long baseline neutrino oscillation experiments at accelerators (NOνA, etc.), in the experiments studying the oscillations of atmospheric neutrinos (PINGU, ORCA), as well as in experiments with reactor antineutrinos [81] (for a review see, *e.g.*, Ref. 82).

There are also long term plans extending beyond 2025 for searches for CP violation and neutrino mass spectrum (ordering) determination in long baseline neutrino oscillation experiments with accelerator neutrino beams (see, *e.g.*, Refs. [80,83,84,85]) . The successful realization of this research program would be a formidable task and would require many years of extraordinary experimental efforts aided by intensive theoretical investigations and remarkable investments.

Before reviewing in detail i) the different neutrino sources and the specific characteristics of the corresponding neutrino fluxes, which have been and are being used in neutrino oscillation experiments (Section 14.6), ii) the theory and phenomenology of neutrino oscillations (Sections 14.7 and 14.8), and iii) the compelling experimental evidences of neutrino oscillations and, more generally, the results obtained in the neutrino oscillation experiments (Sections 14.9 and 14.13), we would like to discuss briefly the problem of determination of the nature - Dirac or Majorana - of massive neutrinos as well as the (type I) seesaw mechanism of neutrino mass generation.

14.4. The nature of massive neutrinos

The experiments studying flavour neutrino oscillations cannot provide information on the nature - Dirac or Majorana, of massive neutrinos [48,65]. Establishing whether the neutrinos with definite mass ν_j are Dirac fermions possessing distinct antiparticles, or Majorana fermions, *i.e.*, spin 1/2 particles that are identical with their antiparticles, is of fundamental importance for understanding the origin of ν-masses and mixing and the underlying symmetries of particle interactions (see, *e.g.*, Ref. 86). The neutrinos with definite mass ν_j will be Dirac fermions if the particle interactions conserve some additive lepton number, *e.g.*, the total lepton charge $L = L_e + L_\mu + L_\tau$. If no lepton charge is conserved, ν_j will be Majorana fermions (see, *e.g.*, Ref. 46). The massive neutrinos are predicted to be of Majorana nature by the see-saw mechanism of neutrino mass generation [3]. The observed patterns of neutrino mixing and of neutrino mass squared differences can be related to Majorana massive neutrinos and the existence of an approximate flavour symmetry in the lepton sector (see, *e.g.*, Ref. 87). Determining the nature of massive neutrinos ν_j is one of the fundamental and most challenging problems in the future studies of neutrino mixing.

The Majorana nature of massive neutrinos ν_j manifests itself in the existence of processes in which the total lepton charge L changes by two units: $K^+ \to \pi^- + \mu^+ + \mu^+$, $\mu^- + (A,Z) \to \mu^+ + (A, Z-2)$, *etc.* Extensive studies have shown that the only feasible experiments having the potential of establishing that the massive neutrinos are Majorana

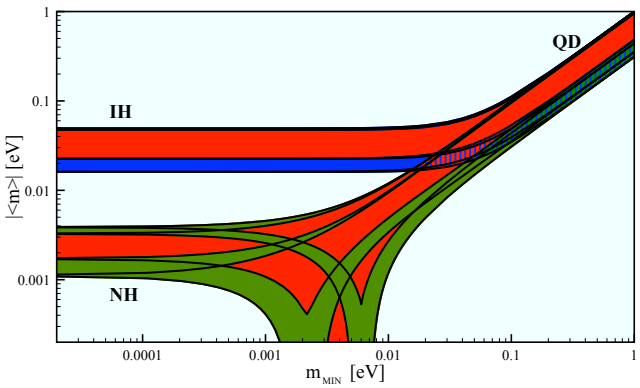

Figure 14.1: The effective Majorana mass $|<m>|$ (including a 2σ uncertainty), as a function of $\min(m_j)$. The figure is obtained using the best fit values and the 2σ ranges of allowed values of Δm^2_{21}, $\sin^2\theta_{12}$, and $|\Delta m^2_{31}| \cong |\Delta m^2_{32}|$ from Ref. 60. The phases $\alpha_{21,31}$ are varied in the interval $[0,\pi]$. The predictions for the NH, IH and QD spectra are indicated. The red regions correspond to at least one of the phases $\alpha_{21,31}$ and $(\alpha_{31} - \alpha_{21})$ having a CP violating value, while the blue and green areas correspond to $\alpha_{21,31}$ possessing CP conserving values. (Update by S. Pascoli of a figure from the one before the last article quoted in Ref. 91.)

particles are at present the experiments searching for $(\beta\beta)_{0\nu}$-decay: $(A,Z) \to (A, Z+2) + e^- + e^-$ (see, *e.g.*, Ref. 88). The observation of $(\beta\beta)_{0\nu}$-decay and the measurement of the corresponding half-life with sufficient accuracy, would not only be a proof that the total lepton charge is not conserved, but might also provide unique information on the i) type of neutrino mass spectrum (see, *e.g.*, Ref. 89), ii) Majorana phases in U [66,90] and iii) the absolute scale of neutrino masses (for details see Ref. 88 to Ref. 91 and references quoted therein).

Under the assumptions of 3-ν mixing, of massive neutrinos ν_j being Majorana particles, and of $(\beta\beta)_{0\nu}$-decay generated only by the (V-A) charged current weak interaction via the exchange of the three Majorana neutrinos ν_j having masses $m_j \lesssim$ few MeV, the $(\beta\beta)_{0\nu}$-decay amplitude has the form (see, *e.g.*, Ref. 46 and Ref. 88): $A(\beta\beta)_{0\nu} \cong <m>\, M$, where M is the corresponding nuclear matrix element which does not depend on the neutrino mixing parameters, and

$$|<m>| = \left| m_1 U^2_{e1} + m_2 U^2_{e2} + m_3 U^2_{e3} \right| = \left| \left(m_1 c^2_{12} + m_2 s^2_{12} e^{i\alpha_{21}} \right) c^2_{13} + m_3 s^2_{13} e^{i(\alpha_{31} - 2\delta)} \right|, \quad (14.17)$$

is the effective Majorana mass in $(\beta\beta)_{0\nu}$-decay. In the case of CP-invariance one has [50], $\eta_{21} \equiv e^{i\alpha_{21}} = \pm 1$, $\eta_{31} \equiv e^{i\alpha_{31}} = \pm 1$, $e^{-i2\delta} = 1$. The three neutrino masses $m_{1,2,3}$ can be expressed in terms of the two measured Δm^2_{jk} and, *e.g.*, $\min(m_j)$. Thus, given the neutrino oscillation parameters Δm^2_{21}, $\sin^2\theta_{12}$, Δm^2_{31} and $\sin^2\theta_{13}$, $|<m>|$ is a function of the lightest neutrino mass $\min(m_j)$, the Majorana (and Dirac) CP violation phases in U and of the type of neutrino mass spectrum. In the case of NH, IH and QD spectrum we have (see, *e.g.*, Ref. 66 and Ref. 91):

$$|<m>| \cong \left| \sqrt{\Delta m^2_{21}}\, s^2_{12} c^2_{13} + \sqrt{\Delta m^2_{31}}\, s^2_{13} e^{i(\alpha_{31} - \alpha_{21} - 2\delta)} \right|, \quad \text{NH}, \quad (14.18)$$

$$|<m>| \cong \tilde{m} \left(1 - \sin^2 2\theta_{12} \sin^2 \frac{\alpha_{21}}{2} \right)^{\frac{1}{2}}, \quad \text{IH (IO) and QD}, \quad (14.19)$$

where $\tilde{m} \equiv \sqrt{\Delta m^2_{23} + m^2_3}$ and $\tilde{m} \equiv m_0$ for IH (IO) and QD spectrum, respectively. In Eq. (14.19) we have exploited the fact that $\sin^2\theta_{13} \ll \cos 2\theta_{12}$. The CP conserving values of the Majorana phase α_{21} and the Majorana-Dirac phase difference $(\alpha_{31} - \alpha_{21} - 2\delta)$ determine the intervals of possible values of $|<m>|$, corresponding to the different types of neutrino mass spectrum. Using the 3σ ranges of the allowed

values of the neutrino oscillation parameters from Table 14.1 one finds that: i) 0.81×10^{-3} eV $\lesssim |<m>| \lesssim 4.43 \times 10^{-3}$ eV in the case of NH spectrum; ii) $\sqrt{\Delta m^2_{23}} \cos 2\theta_{12}\, c^2_{13} \lesssim |<m>| \lesssim \sqrt{\Delta m^2_{23}}\, c^2_{13}$, or 1.3×10^{-2} eV $\lesssim |<m>| \lesssim 5.0 \times 10^{-2}$ eV in the case of IH spectrum; 1.3×10^{-2} eV $\lesssim |<m>| \lesssim 5.0 \times 10^{-2}$ eV in the case of IH spectrum; iii) $m_0 \cos 2\theta_{12} \lesssim |<m>| \lesssim m_0$, or 2.9×10^{-2} eV $\lesssim |<m>| \lesssim m_0$ eV, $m_0 \gtrsim 0.10$ eV, in the case of QD spectrum. The difference in the ranges of $|<m>|$ in the cases of NH, IH and QD spectrum opens up the possibility to get information about the type of neutrino mass spectrum from a measurement of $|<m>|$ [89]. The predicted $(\beta\beta)_{0\nu}$-decay effective Majorana mass $|<m>|$ as a function of the lightest neutrino mass $\min(m_j)$ is shown in Fig. 14.1.

The $(\beta\beta)_{0\nu}$-decay can be generated, in principle, by a $\Delta L = 2$ mechanism other than the light Majorana neutrino exchange considered here, or by a combination of mechanisms one of which is the light Majorana neutrino exchange (for a discussion of different mechanisms which can trigger $(\beta\beta)_{0\nu}$-decay, see, *e.g.*, Refs. [92,93] and the articles quoted therein). If the $(\beta\beta)_{0\nu}$-decay will be observed, it will be of fundamental importance to determine which mechanism (or mechanisms) is (are) inducing the decay. The discussion of the problem of determining the mechanisms which possibly are operative in $(\beta\beta)_{0\nu}$-decay, including the case when more than one mechanism is involved, is out of the scope of the present article. This problem has been investigated in detail in, *e.g.*, Refs. [93,94] and we refer the reader to these articles and the articles quoted therein.

14.5. The see-saw mechanism and the baryon asymmetry of the Universe

A natural explanation of the smallness of neutrino masses is provided by the (type I) see-saw mechanism of neutrino mass generation [3]. An integral part of this rather simple mechanism [95] are the RH neutrinos ν_{lR} (RH neutrino fields $\nu_{lR}(x)$). The latter are assumed to possess a Majorana mass term as well as Yukawa type coupling $\mathcal{L}_{\rm Y}(x)$ with the Standard Model lepton and Higgs doublets, $\psi_{lL}(x)$ and $\Phi(x)$, respectively, $(\psi_{lL}(x))^T = (\nu^T_{lL}(x) \quad l^T_L(x))$, $l = e, \mu, \tau$, $(\Phi(x))^T = (\Phi^{(0)}(x) \;\; \Phi^{(-)}(x))$. In the basis in which the Majorana mass matrix of RH neutrinos is diagonal, we have:

$$\mathcal{L}_{\rm Y,M}(x) = \left(\lambda_{il}\, \overline{N_{iR}}(x)\, \Phi^\dagger(x)\, \psi_{lL}(x) + \text{h.c.}\right) - \frac{1}{2}\, M_i\, \overline{N_i}(x)\, N_i(x)\,, \tag{14.20}$$

where λ_{il} is the matrix of neutrino Yukawa couplings and N_i ($N_i(x)$) is the heavy RH Majorana neutrino (field) possessing a mass $M_i > 0$. When the electroweak symmetry is broken spontaneously, the neutrino Yukawa coupling generates a Dirac mass term: $m^D_{il}\, \overline{N_{iR}}(x)\, \nu_{lL}(x) + \text{h.c.}$, with $m^D = v\lambda$, $v = 174$ GeV being the Higgs doublet v.e.v. In the case when the elements of m^D are much smaller than M_k, $|m^D_{il}| \ll M_k$, $i, k = 1, 2, 3$, $l = e, \mu, \tau$, the interplay between the Dirac mass term and the mass term of the heavy (RH) Majorana neutrinos N_i generates an effective Majorana mass (term) for the LH flavour neutrinos [3]:

$$m^{LL}_{l'l} \cong -(m^D)^T_{l'j} M^{-1}_j m^D_{jl} = -v^2 (\lambda)^T_{l'j} M^{-1}_j \lambda_{jl}\,. \tag{14.21}$$

In grand unified theories, m^D is typically of the order of the charged fermion masses. In $SO(10)$ theories, for instance, m^D coincides with the up-quark mass matrix. Taking indicatively $m^{LL} \sim 0.1$ eV, $m^D \sim 100$ GeV, one finds $M \sim 10^{14}$ GeV, which is close to the scale of unification of the electroweak and strong interactions, $M_{GUT} \cong 2 \times 10^{16}$ GeV. In GUT theories with RH neutrinos one finds that indeed the heavy Majorana neutrinos N_j naturally obtain masses which are by few to several orders of magnitude smaller than M_{GUT}. Thus, the enormous disparity between the neutrino and charged fermion masses is explained in this approach by the huge difference between effectively the electroweak symmetry breaking scale and M_{GUT}.

An additional attractive feature of the see-saw scenario is that the generation and smallness of neutrino masses is related via the leptogenesis mechanism [2] to the generation of the baryon asymmetry of the Universe. The Yukawa coupling in Eq. (14.20), in general, is not CP conserving. Due to this CP-nonconserving coupling the heavy Majorana neutrinos undergo, *e.g.*, the decays $N_j \to l^+ + \Phi^{(-)}$, $N_j \to l^- + \Phi^{(+)}$, which have different rates: $\Gamma(N_j \to l^+ + \Phi^{(-)}) \neq \Gamma(N_j \to l^- + \Phi^{(+)})$. When these decays occur in the Early Universe at temperatures somewhat below the mass of, say, N_1, so that the latter are out of equilibrium with the rest of the particles present at that epoch, CP violating asymmetries in the individual lepton charges L_l, and in the total lepton charge L, of the Universe are generated. These lepton asymmetries are converted into a baryon asymmetry by $(B - L)$ conserving, but $(B + L)$ violating, sphaleron processes, which exist in the Standard Model and are effective at temperatures $T \sim (100 - 10^{12})$ GeV. If the heavy neutrinos N_j have hierarchical spectrum, $M_1 \ll M_2 \ll M_3$, the observed baryon asymmetry can be reproduced provided the mass of the lightest one satisfies $M_1 \gtrsim 10^9$ GeV [96]. Thus, in this scenario, the neutrino masses and mixing and the baryon asymmetry have the same origin - the neutrino Yukawa couplings and the existence of (at least two) heavy Majorana neutrinos. Moreover, quantitative studies [67] based on advances in leptogenesis theory [97] have shown that the CP violation, necessary in leptogenesis for the generation of the observed baryon asymmetry of the Universe, can be provided exclusively by the Dirac and/or Majorana phases in the neutrino mixing matrix U. This implies, in particular, that if the CP symmetry is established not to hold in the lepton sector due to U, at least some fraction (if not all) of the observed baryon asymmetry might be due to the Dirac and/or Majorana CP violation present in the neutrino mixing. More specifically, the necessary condition that the requisite CP violation for a successful leptogenesis with heirarchical in mass heavy Majorana neutrinos is due *entirely* to the Dirac CPV phase in U reads [68]: $|\sin\theta_{13} \sin\delta| \gtrsim 0.09$. This condition is comfortably compatible with the measured value of $\sin\theta_{13} \cong 0.15$ and the hint that $\delta \cong 3\pi/2$, found in the global analyses of the neutrino oscillation data.

14.6. Neutrino sources

In the experimental part of this review (Sections 14.9 - 14.13), we mainly discuss neutrino oscillation experiments using neutrinos or antineutrinos produced by the Sun, cosmic-ray interactions in the air, proton accelerators, and nuclear reactors. We call neutrinos from these sources as solar neutrinos, atmospheric neutrinos, accelerator neutrinos, and reactor (anti)neutrinos. Neutrinos (and/or antineutrinos) from each of these sources have very different properties, *e.g.*, energy spectra, flavour components, and directional distributions, at production. In the literature, neutrino flavour conversion of neutrinos from gravitationally collapsed supernova explosions (supernova neutrinos) is also discussed, but this topic is out of the scope of the present review.

Solar neutrinos and atmospheric neutrinos are naturally produced neutrinos; their fluxes as well as the distance between the (point or distributed) neutrino source and the detector cannot be controlled artificially. While the atmospheric neutrino flux involves ν_μ, $\bar\nu_\mu$, ν_e, and $\bar\nu_e$ components at production, solar neutrinos are produced as pure electron neutrinos due to thermo-nuclear fusion reactions of four protons, producing a helium nucleus. For atmospheric neutrinos with energy $\gtrsim 1$ GeV, which undergo charged-current interactions in the detector, directional correlation of the charged lepton with the parent neutrino gives the way to know, within the resolution, the distance traveled by the neutrino between the production and detection.

Accelerator neutrinos and reactor (anti)neutrinos are man-made neutrinos. In principle, it is possible to choose the distance between the neutrino source and the detector arbitrarily. Accelerator neutrinos used for neutrino oscillation experiments so far have been produced by the decay of secondary mesons (pions and kaons) produced by the collision of a primary proton beam with a nuclear target. A dominant component of the accelerator neutrino flux is ν_μ or $\bar\nu_\mu$, depending on the secondary meson's sign selection, but a wrong-sign muon neutrino component as well as ν_e and $\bar\nu_e$ components are also present. The fluxes of the accelerator neutrinos depend on a number of factors, *e.g.*, energy and intensity of the primary proton beam, material and geometry of the target, selection of the momentum and charge of

the secondary mesons that are focused, and production angle of the secondary mesons with respect to the primary beam. In other words, it is possible to control the peak energy, energy spread, and dominant neutrino flavour, of the neutrino beam.

From the nuclear reactor, almost pure electron antineutrinos are produced by β-decays of fission products of the nuclear fuel. However, experimental groups cannot control the normalization and spectrum of the $\bar{\nu}_e$ flux from commercial nuclear reactors. They are dependent on the initial fuel composition and history of the nuclear fuel burnup. These data are provided by the power plant companies.

For neutrino oscillation experiments, knowledge of the flux of each neutrino and antineutrino flavour at production is needed for planning and designing the experiment, analyzing the data, and estimating systematic errors. Basically, for all neutrino sources, flux models are constructed and validation is made by comparing various experimentally observed quantities with the model predictions. Many of the modern accelerator long baseline and reactor neutrino oscillation experiments employ a two- or multi-detector configuration. In the accelerator long baseline experiment, a "near" detector measures non-oscillated neutrino flux. In the two- or multi-baseline reactor experiments, even a near detector measures the neutrino flux with oscillations developed to some extent. However, comparing the quantities measured with different baselines, it is possible to validate the reactor flux model and measure the oscillation parameters at the same time, or to make an analysis with minimal dependence on flux models.

14.6.1. *Standard solar model predictions of the solar neutrino fluxes* :

Observation of solar neutrinos directly addresses the theory of stellar structure and evolution, which is the basis of the standard solar model (SSM). The Sun, as a well-defined neutrino source, also provides an important opportunities to investigate neutrino oscillations including matter effects, because of the wide range of matter density and the great distance from the Sun to the Earth.

The solar neutrinos are produced by some of the fusion reactions in the pp chain or CNO cycle. The combined effect of these reactions is written as

$$4p \rightarrow {}^4\mathrm{He} + 2e^+ + 2\nu_e. \qquad (14.22)$$

Table 14.2: Neutrino-producing reactions in the Sun (first column) and their abbreviations (second column). The neutrino fluxes predicted by the BPS08(GS) model [100] are listed in the third column.

Reaction	Abbr.	Flux ($\mathrm{cm}^{-2}\ \mathrm{s}^{-1}$)
$pp \rightarrow d\, e^+\, \nu$	pp	$5.97(1 \pm 0.006) \times 10^{10}$
$pe^-p \rightarrow d\, \nu$	pep	$1.41(1 \pm 0.011) \times 10^{8}$
${}^3\mathrm{He}\ p \rightarrow {}^4\mathrm{He}\ e^+\nu$	hep	$7.90(1 \pm 0.15) \times 10^{3}$
${}^7\mathrm{Be}\ e^- \rightarrow {}^7\mathrm{Li}\ \nu + (\gamma)$	^{7}Be	$5.07(1 \pm 0.06) \times 10^{9}$
${}^8\mathrm{B} \rightarrow {}^8\mathrm{Be}^*\ e^+\nu$	^{8}B	$5.94(1 \pm 0.11) \times 10^{6}$
${}^{13}\mathrm{N} \rightarrow {}^{13}\mathrm{C}\ e^+\nu$	^{13}N	$2.88(1 \pm 0.15) \times 10^{8}$
${}^{15}\mathrm{O} \rightarrow {}^{15}\mathrm{N}\ e^+\nu$	^{15}O	$2.15(1^{+0.17}_{-0.16}) \times 10^{8}$
${}^{17}\mathrm{F} \rightarrow {}^{17}\mathrm{O}\ e^+\nu$	^{17}F	$5.82(1^{+0.19}_{-0.17}) \times 10^{6}$

Positrons annihilate with electrons. Therefore, when considering the solar thermal energy generation, a relevant expression is

$$4p + 2e^- \rightarrow {}^4\mathrm{He} + 2\nu_e + 26.73\ \mathrm{MeV} - E_\nu\ , \qquad (14.23)$$

where E_ν represents the energy taken away by neutrinos, the average value being $\langle E_\nu \rangle \sim 0.6$ MeV. There have been efforts to calculate solar neutrino fluxes from these reactions on the basis of SSM. A variety of input information is needed in the evolutionary calculations. The most elaborate SSM calculations have been developed by Bahcall and his collaborators, who define their SSM as the solar model which is

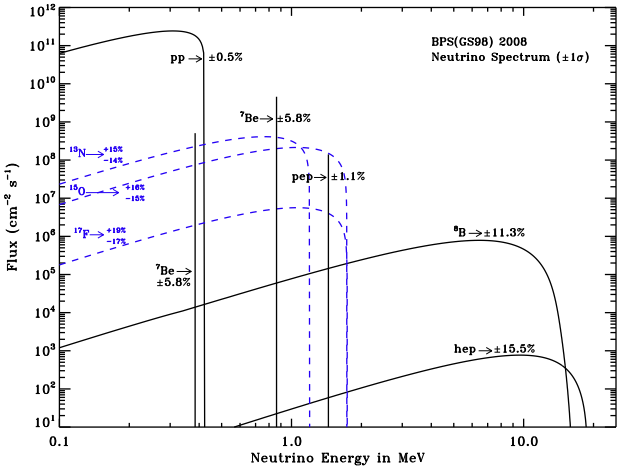

Figure 14.2: The solar neutrino spectrum predicted by the BPS08(GS) standard solar model [100]. The neutrino fluxes are given in units of $\mathrm{cm}^{-2}\mathrm{s}^{-1}\mathrm{MeV}^{-1}$ for continuous spectra and $\mathrm{cm}^{-2}\mathrm{s}^{-1}$ for line spectra. The numbers associated with the neutrino sources show theoretical errors of the fluxes. This figure is taken from Aldo Serenelli's web site, `http://www.mpa-garching.mpg.de/~aldos/`.

constructed with the best available physics and input data. Therefore, their SSM calculations have been rather frequently updated. SSM's labelled as BS05(OP) [98], BSB06(GS) and BSB06(AGS) [99], and BPS08(GS) and BPS08(AGS) [100] represent some of the relatively recent model calculations. Here, "OP" means that newly calculated radiative opacities from the "Opacity Project" are used. The later models are also calculated with OP opacities. "GS" and "AGS" refer to old and new determinations of solar abundances of heavy elements. There are significant differences between the old, higher heavy element abundances (GS) and the new, lower heavy element abundances (AGS). The models with GS are consistent with helioseismological data, but the models with AGS are not.

The prediction of the BPS08(GS) model for the fluxes from neutrino-producing reactions is given in Table 14.2. Fig. 14.2 shows the solar-neutrino spectra calculated with the BPS08(GS) model. Here we note that in Ref. 101 the authors point out that electron capture on ^{13}N, ^{15}O, and ^{17}F produces line spectra of neutrinos, which have not been considered in the SSM calculations quoted above.

In 2011, a new SSM calculations [102] have been presented by A.M. Serenelli, W.C. Haxton, and C. Peña-Garay, by adopting the newly analyzed nuclear fusion cross sections. Their high metalicity SSM is labelled as SHP11(GS). For the same solar abundances as used in Ref. 98 and Ref. 99, the most significant change is a decrease of ^{8}B flux by $\sim 5\%$.

14.6.2. *Atmospheric neutrino fluxes* :

Atmospheric neutrinos are produced by the decay of π and K mesons produced in the nuclear interactions of the primary component of cosmic rays in the atmosphere ((A) in Table 14.3). The primary cosmic ray components above 2 GeV/nucleon are protons ($\sim 95\%$), helium nuclei ($\sim 4.5\%$), and heavier nuclei. For neutrino producing hadronic interactions, a nucleus can be simply regarded as a sum of individual nucleons at high energies. Pions are dominantly produced in these interactions, and they predominantly decay according to (B1) in Table 14.3, followed by muon decay (E) in Table 14.3. The interactions in massive underground detectors of atmospheric neutrinos provide a means of studying neutrino oscillations because of the large range of distances traveled by these neutrinos ($\sim$10 to 1.27×10^4 km) to reach a detector on Earth and relatively well-understood atmospheric neutrino fluxes.

Calculation of the atmospheric neutrino fluxes requires knowledge of the primary cosmic-ray fluxes and composition, and the hadronic interactions. Atmospheric neutrinos with energy of $\sim$a few GeV are mostly produced by primary cosmic rays with energy of $\sim$100 GeV.

Table 14.3: Reactions and decays relevant to atmospheric neutrino and accelerator neutrino production. The first column shows the index of the reaction or decay, and the second column shows the reaction or decay channel. The third column shows the branching ratio [103]. (For K_L decay, sum of the branching ratios to charge conjugate modes is shown).

	Reaction/Decay	Branching ratio (%)
(A)	$p\,(n) + A \to \pi^{\pm}X,\ K^{\pm}X,\ K_L X$	
(B1)	$\pi^{\pm} \to \mu^{\pm} + \nu_\mu\,(\bar{\nu}_\mu)$	99.9877
(B2)	$\to e^{\pm} + \nu_e\,(\bar{\nu}_e)$	0.0123
(C1)	$K^{\pm} \to \mu^{\pm} + \nu_\mu\,(\bar{\nu}_\mu)$	63.55
(C2)	$\to \pi^0 + \mu^{\pm} + \nu_\mu\,(\bar{\nu}_\mu)$	3.353
(C3)	$\to \pi^0 + e^{\pm} + \nu_e\,(\bar{\nu}_e)$	5.07
(D1)	$K_L \to \pi^{\pm} + \mu^{\mp} + \bar{\nu}_\mu\,(\nu_\mu)$	27.04
(D2)	$\to \pi^{\pm} + e^{\mp} + \bar{\nu}_e\,(\nu_e)$	40.55
(E)	$\mu^{\pm} \to e^{\pm} + \bar{\nu}_\mu(\nu_\mu) + \nu_e\,(\bar{\nu}_e)$	100

For primary cosmic-rays in this energy range, a flux modulation due to the solar activity and the effects of Earth's geomagnetic fields should be taken into account. In particular, the atmospheric neutrino fluxes in the low-energy region depend on the location on the Earth. Detailed calculations of the atmospheric neutrino fluxes are performed by Honda et al. [104,105], Barr et al. [106], and Battistoni et al. [107], with a typical uncertainty of $10 \sim 20\%$.

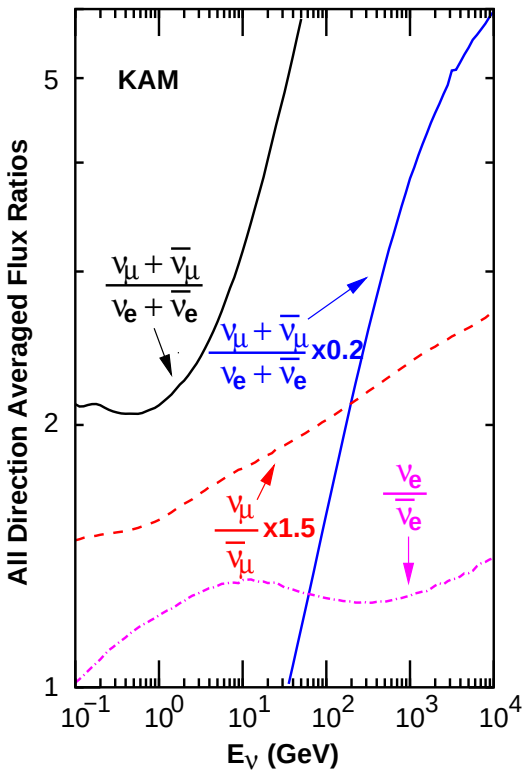

Figure 14.3: Neutrino flavour ratios calculated with the all-direction and one-year averaged atmospheric neutrino fluxes at Kamioka. This figure is provided by M. Honda, and is a part of Fig. 5 in Ref. [105], where similar plots at the INO site, the South Pole, and the Pyhäsalmi mine are also shown.

From the dominant production mechanism of the atmospheric neutrinos, we can readily understand some relations that exist between the atmospheric ν_μ, $\bar{\nu}_\mu$, ν_e, and $\bar{\nu}_e$ fluxes without detailed calculations. For the ratio of the fluxes of $(\nu_\mu + \bar{\nu}_\mu)$ and $(\nu_e + \bar{\nu}_e)$ at low energies ($\lesssim$ 1 GeV), where almost all produced muons decay before reaching the ground, we have approximately $(\nu_\mu + \bar{\nu}_\mu)/(\nu_e + \bar{\nu}_e) \approx 2$. As the neutrino energy increases, this ratio increases because an increasing fraction of muons do not decay before reaching the ground and being absorbed. We also have $\nu_\mu/\bar{\nu}_\mu \approx 1$ at low energies. Hoever, as the $\nu_e/\bar{\nu}_e$ ratio reflects the parent π^+/π^- ratio, it is expected to be slightly greater than 1 because the dominance of protons in the primary component of the cosmic rays means a π^+ excess in the secondary component. Fig. 14.3 shows these ratios at the Super-Kamiokande site, averaged over all directions and over a year, as a function of neutrino energy.

Another important feature of the atmospheric neutrino fluxes is that the zenith angle distribution for each neutrino type is up-down symmetric above $\sim$ 1 GeV, if there are no neutrino oscillations. As the neutrino energy becomes lower than $\sim$ 1 GeV, however, zenith angle distributions start to show deviations from up-down symmetric shapes due to the geomagnetic effects on primary cosmic rays.

14.6.3. *Accelerator neutrino beams* :

Conventional method to produce neutrino beams at a high-energy proton accelerator facility is to guide an intense proton beam onto a nuclear target of $1 \sim 2$ interaction lengths. For a comprehensive description of the accelerator neutrino beams, see Ref. 108. From the pA collisions, mesons are produced and their decays then produce neutrinos (see Table 14.3). In the high-energy collisions, pions are dominantly produced, with kaons produced at an order of 10% of the pion production rate. Therefore, the dominant component of the accelerator neutrinos is the muon neutrino or muon antineutrino. Mesons decay in the free space called a decay pipe or decay tunnel. This free space is evacuated or filled with helium gas.

To increase the neutrino flux, it is necessary to focus the secondary pions. Modern neutrino oscillation experiments at high-energy accelerators exploit two or three magnetic horns as an approximately point-to-parallel focusing system for this purpose. A magnetic horn is a high-current pulse magnet with toroidal magnetic fields. Therefore, the use of horns also means sign selection of the secondary hadrons that are focused, which in turn means muon neutrino sign selection. Even so, a fraction of wrong sign muon neutrinos contaminate the beam. Also, there is a small ν_e and $\bar{\nu}_e$ contamination from kaon, pion, and muon decay ((C3), (B2), and (E) in Table 14.3). Precise knowledge of ν_e and $\bar{\nu}_e$ components in the neutrino flux is important for the $\nu_\mu \to \nu_e$ ($\bar{\nu}_\mu \to \bar{\nu}_e$) appearance measurement.

With a given neutrino beam line configuration, the expected neutrino fluxes are calculated by using a simulation program tuned to that configuration. Re-interactions of the primary protons in the target and interactions of the secondary particles in the target and in the material outside the target have to be taken into account. An important input is hadron production cross sections from pA collisions for relevant target materials over wide energy and angular regions. For this purpose, some dedicated experiments such as SPY [109], HARP [110], MIPP [111], and NA61/SHINE [112] have been conducted. The data are fit to specific hadron production models to determine the model parameters.

The predicted neutrino fluxes have to be validated in some way. Modern long baseline neutrino oscillation experiments often have a two-detector configuration, with a near detector to measure an unoscillated neutrino flux immediately after the production. In the single detector experiment, the muon-neutrino flux model is calibrated by using a muon monitor which is located behind the beam dump. Since low-energy muons are absorbed in the beam dump, it is not possible to calibrate the low-energy part of the neutrino spectrum. Even in the two-detector experiments, it should be noted that the near detector does not see the same neutrino flux as the far detector sees, because the neutrino source looks like a line source for the near detector, while it looks as a point source for the far detector.

The energy E_ν of the neutrino emitted at an angle θ with respect to the parent pion direction is given by

$$E_\nu = \frac{m_\pi^2 - m_\mu^2}{2(E_\pi - p_\pi \cos\theta)}, \tag{14.24}$$

where E_π and p_π are the energy and momentum of the parent pion, m_π is the charged pion mass, m_μ is the muon mass. Suppose an ideal case that the pions are completely focused in parallel. Then, for $\theta = 0$, it can be seen from the above equation that E_ν is proportional to E_π for $E_\pi \gg m_\pi$. As the secondary pions have a wide energy spectrum, a 0 degree neutrino beam also has a wide spectrum and is called a "wide-band beam".

For a given angle θ, differentiating the above expression with respect to E_π, it can be shown that E_ν takes a maximum value $E_\nu^{\max} = (m_\pi^2 - m_\mu^2)/(2E_\pi^\circ \sin^2\theta)$ at $E_\pi^\circ = m_\pi/\sin\theta$. Numerical calculations show that a wide range of E_π, in particular that of $E_\pi \geq E_\pi^\circ$, contributes to a narrow range of $E_\nu \leq E_\nu^{\max}$ [113]. It is expected, therefore, that a narrow neutrino spectrum peaked at around $E_\nu^{\max}$ can be obtained by the off-axis beam. Fig. 14.4 shows an example of the simulated muon neutrino fluxes at $\theta = 0$ degree and 2.0° and 2.5° off-axis configurations corresponding to the T2K experiment [114]. As expected, an off-axis beam has a narrower spectrum than the 0 degree wide-band beam. Therefore, an off-axis beam is called a "narrow-band beam". This idea of an off-axis beam was proposed for BNL E889 experiment [113]. It has been employed for the T2K experiment for the first time. Currently, it is also used in the NOνA experiment [115]. For the off-axis beam, obviously the effect of a line neutrino source, namely the difference between the neutrino fluxes measured at the near and far detectors, is enhanced, and it has to be properly taken into account.

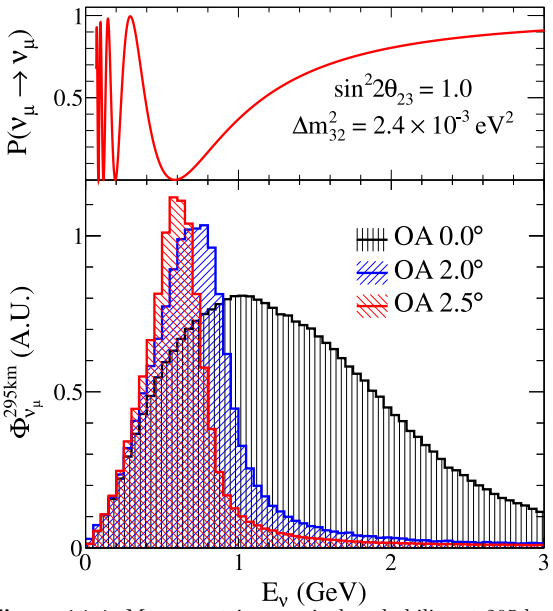

Figure 14.4: Muon neutrino survival probability at 295 km and neutrino fluxes for different off-axis angles. This figure is taken from Ref. 114.

14.6.4. *Reactor neutrino fluxes* :

In nuclear reactors, power is generated mainly by nuclear fission of four heavy isotopes, ^{235}U, ^{238}U, ^{239}Pu, and ^{241}Pu. These isotopes account for more than 99% of fissions in the reactor core. β-decays of fission products produce almost pure $\bar{\nu}_e$ flux. The rate of ν_e production is less than 10^{-5} of the rate of $\bar{\nu}_e$ production [116]. The thermal power outputs of nuclear power reactors are usually quoted in thermal GW, GW$_{\rm th}$. On the average, ~ 200 MeV and 6 electron antineutrinos are emitted per fission. With 1 GW$_{\rm th}$ output, $\sim 2 \times 10^{20}$ electron antineutrinos are produced per second and emitted isotropically. Typical power plant light-water reactors have thermal power outputs of order 3 GW$_{\rm th}$.

The total $\bar{\nu}_e$ flux $S(E_\nu)$ emitted from a reactor is given as a sum of contributions from the four fissioning isotopes, $S(E_\nu) = \sum_j f_j S_j(E_\nu)$, where f_j is the fission rate and $S_j(E_\nu)$ is the $\bar{\nu}_e$ flux per fission, of each contributing isotope. The fission rates, and therefore $S(E_\nu)$, are dependent on the thermal power output $W_{\rm th}$ from the reactor as a function of time. Using $W_{\rm th}$ and the total fission rate $F = \sum_j f_j$, $S(E_\nu)$ is rewritten as [117]

$$S(E_\nu) = \frac{W_{\rm th}}{\sum_j (f_j/F) E_j} \sum_j (f_j/F) S_j(E_\nu), \qquad (14.25)$$

where E_j is the energy release per fission by each isotope [118]. The thermal power output and fission fractions f_j/F are provided by the power plant companies.

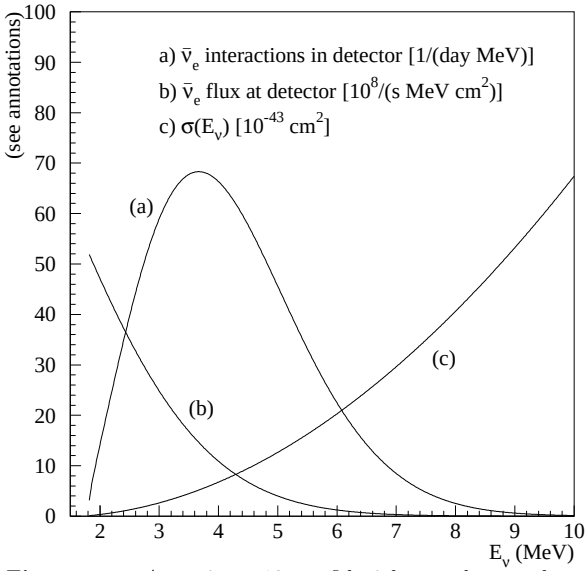

Figure 14.5: Assuming a 12-ton fiducial mass detector located 0.8 km from 12-GW$_{\rm th}$ power reactor, $\bar{\nu}_e$ interaction spectrum in the detector (curve (a)) and reactor $\bar{\nu}_e$ flux at the detector (curve (b)) are shown as a function of energy. Inverse β-decay cross section (curve (c)) is also shown. This figure is from Ref. 129.

For $S_j(E_\nu)$, a "standard" method used by most of the reactor neutrino oscillation experiments is the one called the "conversion" method [51,119,120], which uses the measured cumulative β^- spectra at ILL for ^{235}U, ^{239}Pu, and ^{241}Pu [121,122,123]. To estimate the $\bar{\nu}_e$ spectrum for each isotope, the corresponding β^- spectrum is approximated by the superposition of a set of hypothetical allowed branches. For ^{238}U, theoretical calculations [124] have been used. Recently, however, the cumulative β^- spectrum for ^{238}U has been measured at the scientific neutron source FRM II in Garching, Germany, and the converted $\bar{\nu}_e$ spectrum is given for $2.875 < E_\nu < 7.625$ MeV [125]. It is used in the recent neutrino oscillation analysis of the Double Chooz experiment [40].

While the conversion of the β spectrum to the $\bar{\nu}_e$ spectrum is trivial for a single β-decay branch, fission of the four main fuel isotopes involve > 1000 daughter isotopes and > 6000 individual β-decay branches (approximately six thousands), thus causing rather large uncertainties in both the normalization and shape of the reactor $\bar{\nu}_e$ flux. Recent detailed reactor $\bar{\nu}_e$ calculations [119,120] show a few % larger fluxes with respect to the fluxes calculated in Ref. 122. The antineutrino fluxes measured by previous short baseline reactor neutrino oscillation experiments are generally in agreement with the latter calculation. The recent reactor antineutrino flux measurement at Daya Bay [126] is also consistent with these previous measurements. This discrepancy is called the "reactor neutrino anomaly" and hints to possible oscillations involving sterile neutrinos (see Section 14.13). For the shape of the reactor $\bar{\nu}_e$ flux, all the current reactor neutrino oscillation experiments, Daya Bay [126], RENO [39,127], and Double Chooz [40], observe an excess of $\bar{\nu}_e$ flux in the energy region from 4 to 6 MeV, relative to current predictions. The excess rate is observed to

be time independent and correlated with the reactor power. Because of this, an unknown background is unlikely for its explanation. There are certain suggestions on the possible origins of this excess, but this problem is not completely solved yet [128].

Electron antineutrinos from reactors are detected via the inverse β-decay $\bar{\nu}_e + p \to e^+ + n$. This reaction has a threshold of 1.8 MeV, so that the $\bar{\nu}_e$ flux above this threshold is detected. The event rate as a function of $\bar{\nu}_e$ energy E_ν is proportional to $\sigma(E_\nu)S(E_\nu)$, where $\sigma(E_\nu)$ is the cross section of the inverse β-decay. Fig. 14.5 shows $\sigma(E_\nu)$. This figure also shows the flux and event rate for a particular detector configuration (see caption to this figure) in a reactor neutrino oscillation experiment.

14.7. Neutrino oscillations in vacuum

Neutrino oscillations are a quantum mechanical consequence of the existence of nonzero neutrino masses and neutrino (lepton) mixing, Eq. (14.1), and of the relatively small splitting between the neutrino masses. The neutrino mixing and oscillation phenomena are analogous to the $K^0 - \bar{K}^0$ and $B^0 - \bar{B}^0$ mixing and oscillations.

In what follows we will present a simplified version of the derivation of the expressions for the neutrino and antineutrino oscillation probabilities. The complete derivation would require the use of the wave packet formalism for the evolution of the massive neutrino states, or, alternatively, of the field-theoretical approach, in which one takes into account the processes of production, propagation and detection of neutrinos [130].

Suppose the flavour neutrino ν_l is produced in a CC weak interaction process and after a time T it is observed by a neutrino detector, located at a distance L from the neutrino source and capable of detecting also neutrinos $\nu_{l'}$, $l' \neq l$. We will consider the evolution of the neutrino state $|\nu_l\rangle$ in the frame in which the detector is at rest (laboratory frame). The oscillation probability, as we will see, is a Lorentz invariant quantity. If lepton mixing, Eq. (14.1), takes place and the masses m_j of all neutrinos ν_j are sufficiently small, the state of the neutrino ν_l, $|\nu_l\rangle$, will be a coherent superposition of the states $|\nu_j\rangle$ of neutrinos ν_j:

$$|\nu_l\rangle = \sum_j U^*_{lj} \, |\nu_j; \tilde{p}_j\rangle, \quad l = e, \mu, \tau \,, \tag{14.26}$$

where U is the neutrino mixing matrix and $\tilde{p}_j$ is the 4-momentum of ν_j [131].

We will consider the case of relativistic neutrinos ν_j, which corresponds to the conditions in both past and currently planned future neutrino oscillation experiments [133]. In this case the state $|\nu_j; \tilde{p}_j\rangle$ practically coincides with the helicity (-1) state $|\nu_j, L; \tilde{p}_j\rangle$ of the neutrino ν_j, the admixture of the helicity (+1) state $|\nu_j, R; \tilde{p}_j\rangle$ in $|\nu_j; \tilde{p}_j\rangle$ being suppressed due to the factor $\sim m_j/E_j$, where E_j is the energy of ν_j. If ν_j are Majorana particles, $\nu_j \equiv \chi_j$, due to the presence of the helicity (+1) state $|\chi_j, R; \tilde{p}_j\rangle$ in $|\chi_j; \tilde{p}_j\rangle$, the neutrino ν_l can produce an l^+ (instead of l^-) when it interacts, *e.g.*, with nucleons. The cross section of such a $|\Delta L_l| = 2$ process is suppressed by the factor $(m_j/E_j)^2$, which renders the process unobservable at present.

If the number n of massive neutrinos ν_j is bigger than 3 due to a mixing between the active flavour and sterile neutrinos, one will have additional relations similar to that in Eq. (14.26) for the state vectors of the (predominantly LH) sterile antineutrinos. In the case of just one RH sterile neutrino field $\nu_{sR}(x)$, for instance, we will have in addition to Eq. (14.26):

$$|\bar{\nu}_{sL}\rangle = \sum_{j=1}^{4} U^*_{sj} \, |\nu_j; \tilde{p}_j\rangle \cong \sum_{j=1}^{4} U^*_{sj} \, |\nu_j, L; \tilde{p}_j\rangle \,, \tag{14.27}$$

where the neutrino mixing matrix U is now a 4×4 unitary matrix.

For the state vector of RH flavour antineutrino $\bar{\nu}_l$, produced in a CC weak interaction process we similarly get:

$$|\bar{\nu}_l\rangle = \sum_j U_{lj} \, |\bar{\nu}_j; \tilde{p}_j\rangle \cong \sum_{j=1} U_{lj} \, |\bar{\nu}_j, R; \tilde{p}_j\rangle, \quad l = e, \mu, \tau \,, \tag{14.28}$$

where $|\bar{\nu}_j, R; \tilde{p}_j\rangle$ is the helicity (+1) state of the antineutrino $\bar{\nu}_j$ if ν_j are Dirac fermions, or the helicity (+1) state of the neutrino $\nu_j \equiv \bar{\nu}_j \equiv \chi_j$ if the massive neutrinos are Majorana particles. Thus, in the latter case we have in Eq. (14.28): $|\bar{\nu}_j; \tilde{p}_j\rangle \cong |\nu_j, R; \tilde{p}_j\rangle \equiv |\chi_j, R; \tilde{p}_j\rangle$. The presence of the matrix U in Eq. (14.28) (and not of U^*) follows directly from Eq. (14.1).

We will assume in what follows that the spectrum of masses of neutrinos is not degenerate: $m_j \neq m_k$, $j \neq k$. Then the states $|\nu_j; \tilde{p}_j\rangle$ in the linear superposition in the r.h.s. of Eq. (14.26) will have, in general, different energies and different momenta, independently of whether they are produced in a decay or interaction process: $\tilde{p}_j \neq \tilde{p}_k$, or $E_j \neq E_k$, $\mathbf{p}_j \neq \mathbf{p}_k$, $j \neq k$, where $E_j = \sqrt{p_j^2 + m_j^2}$, $p_j \equiv |\mathbf{p}_j|$. The deviations of E_j and p_j from the values for a massless neutrino E and $p = E$ are proportional to m_j^2/E_0, E_0 being a characteristic energy of the process, and are extremely small. In the case of $\pi^+ \to \mu^+ + \nu_\mu$ decay at rest, for instance, we have: $E_j = E + m_j^2/(2m_\pi)$, $p_j = E - \xi m_j^2/(2E)$, where $E = (m_\pi/2)(1 - m_\mu^2/m_\pi^2) \cong 30$ MeV, $\xi = (1 + m_\mu^2/m_\pi^2)/2 \cong 0.8$, and m_μ and m_π are the μ^+ and π^+ masses. Taking $m_j = 1$ eV we find: $E_j \cong E\,(1 + 1.2 \times 10^{-16})$ and $p_j \cong E\,(1 - 4.4 \times 10^{-16})$.

Given the uncorrelated uncertainties δE and δp in the knowledge of the neutrino energy E and momentum p, the quantum mechanical condition that neutrinos with definite mass ν_1, ν_2, ..., whose states are part of the linear superposition of states corresponding, for example, to $|\nu_l\rangle$ in Eq. (14.26), are emitted coherently when $|\nu_l$ is produced in some weak interaction process, has the form [134]:

$$\delta m^2 = \sqrt{(2E\delta E)^2 + (2p\delta p)^2} > \max(|m_i^2 - m_j^2|), \quad i, j = 1, 2, ..., n, \tag{14.29}$$

where δm^2 is the uncertainty in the square of the neutrino mass due to the uncertainties in the energy and momentum of the neutrino. Equation Eq. (14.29) follows from the well known relativistic relation $E^2 = p^2 + m^2$. In the context under discussion, δE and δp should be understood as the intrinsic quantum mechanical uncertainties in the neutrino energy and momentum for the given neutrino production and detection processes, *i.e.*, δE and δp are the minimal uncertainties with which E and p can be determined in the considered production and detection processes. Then δm^2 is the quantum mechanical uncertainty of the inferred squared neutrino mass.

Suppose that the neutrinos are observed via a CC weak interaction process and that in the detector's rest frame they are detected after time T after emission, after traveling a distance L. Then the amplitude of the probability that neutrino $\nu_{l'}$ will be observed if neutrino ν_l was produced by the neutrino source can be written as [130,132,135]:

$$A(\nu_l \to \nu_{l'}) = \sum_j U_{l'j} \, D_j \, U^\dagger_{jl} \,, \qquad l, l' = e, \mu, \tau \,, \tag{14.30}$$

where $D_j = D_j(p_j; L, T)$ describes the propagation of ν_j between the source and the detector, $U^\dagger_{jl}$ and $U_{l'j}$ are the amplitudes to find ν_j in the initial and in the final flavour neutrino state, respectively. It follows from relativistic Quantum Mechanics considerations that [130,132]

$$\begin{aligned} D_j &\equiv D_j(\tilde{p}_j; L, T) = e^{-i\tilde{p}_j\,(x_f - x_0)} = e^{-i(E_j T - p_j L)} \,, \\ p_j &\equiv |\mathbf{p}_j| \,, \end{aligned} \tag{14.31}$$

where [136] x_0 and x_f are the space-time coordinates of the points of neutrino production and detection, $T = (t_f - t_0)$ and $L = \mathbf{k}(\mathbf{x}_f - \mathbf{x}_0)$, $\mathbf{k}$ being the unit vector in the direction of neutrino momentum, $\mathbf{p}_j = \mathbf{k}\mathrm{p_j}$. What is relevant for the calculation of the probability $P(\nu_l \to \nu_{l'}) = |A(\nu_l \to \nu_{l'})|^2$ is the interference factor $D_j D_k^*$ which depends on the phase

$$\begin{aligned} \delta\varphi_{jk} = (E_j - E_k)T - (p_j - p_k)L \, &= (E_j - E_k)\left[T - \frac{E_j + E_k}{p_j + p_k}\, L\right] \\ &+ \frac{m_j^2 - m_k^2}{p_j + p_k}\, L \,. \end{aligned} \tag{14.32}$$

Some authors [137] have suggested that the distance traveled by the neutrinos L and the time interval T are related by $T = (E_j+E_k)\,L/(p_j+p_k) = L/\bar{v}$, $\bar{v} = (E_j/(E_j+E_k))v_j+(E_k/(E_j+E_k))v_k$ being the "average" velocity of ν_j and ν_k, where $v_{j,k} = p_{j,k}/E_{j,k}$. In this case the first term in the r.h.s. of Eq. (14.32) vanishes. The indicated relation has not emerged so far from any dynamical wave packet calculations. We arrive at the same conclusion concerning the term under discussion in Eq. (14.32) if one assumes [138] that $E_j = E_k = E_0$. Finally, it was proposed in Ref. 135 and Ref. 139 that the states of ν_j and $\bar{\nu}_j$ in Eq. (14.26) and Eq. (14.28) have the same 3-momentum, $p_j = p_k = p$. Under this condition the first term in the r.h.s. of Eq. (14.32) is negligible, being suppressed by the additional factor $(m_j^2+m_k^2)/p^2$ since for relativistic neutrinos $L = T$ up to terms $\sim m_{j,k}^2/p^2$. We arrive at the same conclusion if $E_j \neq E_k$, $p_j \neq p_k$, $j \neq k$, and we take into account that neutrinos are relativistic and therefore, up to corrections $\sim m_{j,k}^2/E_{j,k}^2$, we have $L \cong T$ (see, *e.g.*, C. Giunti quoted in Ref. 130).

Although the cases considered above are physically quite different, they lead to the same result for the phase difference $\delta\varphi_{jk}$. Thus, we have:

$$\delta\varphi_{jk} \cong \frac{m_j^2 - m_k^2}{2p}\,L \;= 2\pi\,\frac{L}{L^v_{jk}}\,\mathrm{sgn}(m_j^2 - m_k^2)\,, \tag{14.33}$$

where $p = (p_j + p_k)/2$ and

$$L^v_{jk} = 4\pi\frac{p}{|\Delta m^2_{jk}|} \cong 2.48\ \mathrm{m}\ \frac{p[MeV]}{|\Delta m^2_{jk}|[eV^2]} \tag{14.34}$$

is the neutrino oscillation length associated with Δm^2_{jk}. We can safely neglect the dependence of p_j and p_k on the masses m_j and m_k and consider p to be the zero neutrino mass momentum, $p = E$. The phase difference $\delta\varphi_{jk}$, Eq. (14.33), is Lorentz-invariant.

Eq. (14.31) corresponds to a plane-wave description of the propagation of neutrinos ν_j. It accounts only for the movement of the center of the wave packet describing ν_j. In the wave packet treatment of the problem, the interference between the states of ν_j and ν_k is subject to a number of conditions [130], the localization condition and the condition of overlapping of the wave packets of ν_j and ν_k at the detection point being the most important. For relativistic neutrinos, the localisation condition in space, for instance, reads: $\sigma_{xP}, \sigma_{xD} < L^v_{jk}/(2\pi)$, $\sigma_{xP(D)}$ being the spatial width of the production (detection) wave packet. Thus, the interference will not be suppressed if the spatial width of the neutrino wave packets determined by the neutrino production and detection processes is smaller than the corresponding oscillation length in vacuum. In order for the interference to be nonzero, the wave packets describing ν_j and ν_k should also overlap in the point of neutrino detection. This requires that the spatial separation between the two wave packets at the point of neutrinos detection, caused by the two wave packets having different group velocities $v_j \neq v_k$, satisfies $|(v_j - v_k)T| \ll \max(\sigma_{xP}, \sigma_{xD})$. If the interval of time T is not measured, T in the preceding condition must be replaced by the distance L between the neutrino source and the detector (for further discussion see, *e.g.*, Refs. [130,132,135]) .

For the $\nu_l \to \nu_{l'}$ and $\bar{\nu}_l \to \bar{\nu}_{l'}$ oscillation probabilities we get from Eq. (14.30), Eq. (14.31), and Eq. (14.33):

$$P(\nu_l \to \nu_{l'}) = \sum_j |U_{l'j}|^2\,|U_{lj}|^2 \;+ 2\sum_{j>k} |U_{l'j}\,U^*_{lj}\,U_{lk}\,U^*_{l'k}| \cos(\frac{\Delta m^2_{jk}}{2p}\,L - \phi_{l'l;jk})\,, \tag{14.35}$$

$$P(\bar{\nu}_l \to \bar{\nu}_{l'}) = \sum_j |U_{l'j}|^2\,|U_{lj}|^2 \;+ 2\sum_{j>k} |U_{l'j}\,U^*_{lj}\,U_{lk}\,U^*_{l'k}| \cos(\frac{\Delta m^2_{jk}}{2p}\,L + \phi_{l'l;jk})\,, \tag{14.36}$$

where $l, l' = e, \mu, \tau$ and $\phi_{l'l;jk} = \arg\left(U_{l'j}\,U^*_{lj}\,U_{lk}\,U^*_{l'k}\right)$. It follows from Eq. (14.30) - Eq. (14.32) that in order for neutrino oscillations to occur, at least two neutrinos ν_j should not be degenerate in mass and lepton mixing should take place, $U \neq \mathbf{1}$. The neutrino oscillations effects can be large if we have

$$\frac{|\Delta m^2_{jk}|}{2p}\,L = 2\pi\,\frac{L}{L^v_{jk}} \gtrsim 1\,,\ \ j \neq k\,. \tag{14.37}$$

at least for one Δm^2_{jk}. This condition has a simple physical interpretation: the neutrino oscillation length L^v_{jk} should be of the order of, or smaller, than source-detector distance L, otherwise the oscillations will not have time to develop before neutrinos reach the detector.

We see from Eq. (14.35) and Eq. (14.36) that $P(\nu_l \to \nu_{l'}) = P(\bar{\nu}_{l'} \to \bar{\nu}_l)$, $l, l' = e, \mu, \tau$. This is a consequence of CPT invariance. The conditions of CP and T invariance read [48,61,62]: $P(\nu_l \to \nu_{l'}) = P(\bar{\nu}_l \to \bar{\nu}_{l'})$, $l, l' = e, \mu, \tau$ (CP), $P(\nu_l \to \nu_{l'}) = P(\nu_{l'} \to \nu_l)$, $P(\bar{\nu}_l \to \bar{\nu}_{l'}) = P(\bar{\nu}_{l'} \to \bar{\nu}_l)$, $l, l' = e, \mu, \tau$ (T). In the case of CPT invariance, which we will assume to hold throughout this article, we get for the survival probabilities: $P(\nu_l \to \nu_l) = P(\bar{\nu}_l \to \bar{\nu}_l)$, $l, l' = e, \mu, \tau$. Thus, the study of the "disappearance" of ν_l and $\bar{\nu}_l$, caused by oscillations in vacuum, cannot be used to test whether CP invariance holds in the lepton sector. It follows from Eq. (14.35) and Eq. (14.36) that we can have CP violation effects in neutrino oscillations only if $\phi_{l'l;jk} \neq \pi q$, $q = 0, 1, 2$, *i.e.*, if $U_{l'j}\,U^*_{lj}\,U_{lk}\,U^*_{l'k}$, and therefore U itself, is not real. As a measure of CP and T violation in neutrino oscillations we can consider the asymmetries:

$$A^{(l'l)}_{\mathrm{CP}} \equiv P(\nu_l \to \nu_{l'}) - P(\bar{\nu}_l \to \bar{\nu}_{l'})\,, \quad A^{(l'l)}_{\mathrm{T}} \equiv P(\nu_l \to \nu_{l'}) - P(\nu_{l'} \to \nu_l)\,. \tag{14.38}$$

CPT invariance implies: $A^{(l'l)}_{\mathrm{CP}} = -A^{(ll')}_{\mathrm{CP}}$, $A^{(l'l)}_{\mathrm{T}} = P(\bar{\nu}_{l'} \to \bar{\nu}_l) - P(\bar{\nu}_l \to \bar{\nu}_{l'}) = A^{(l'l)}_{\mathrm{CP}}$. It follows further directly from Eq. (14.35) and Eq. (14.36) that

$$A^{(l'l)}_{\mathrm{CP}} = 4\sum_{j>k} \mathrm{Im}\left(U_{l'j}\,U^*_{lj}\,U_{lk}\,U^*_{l'k}\right) \sin\frac{\Delta m^2_{jk}}{2p}\,L\,,\ \ l, l' = e, \mu, \tau\,. \tag{14.39}$$

Eq. (14.2) and Eq. (14.35) - Eq. (14.36) imply that $P(\nu_l \to \nu_{l'})$ and $P(\bar{\nu}_l \to \bar{\nu}_{l'})$ do not depend on the Majorana CP violation phases in the neutrino mixing matrix U [48]. Thus, the experiments investigating the $\nu_l \to \nu_{l'}$ and $\bar{\nu}_l \to \bar{\nu}_{l'}$ oscillations, $l, l' = e, \mu, \tau$, cannot provide information on the nature - Dirac or Majorana, of massive neutrinos. The same conclusions hold also when the $\nu_l \to \nu_{l'}$ and $\bar{\nu}_l \to \bar{\nu}_{l'}$ oscillations take place in matter [65]. In the case of $\nu_l \leftrightarrow \nu_{l'}$ and $\bar{\nu}_l \leftrightarrow \bar{\nu}_{l'}$ oscillations in vacuum, only the Dirac phase(s) in U can cause CP violating effects leading to $P(\nu_l \to \nu_{l'}) \neq P(\bar{\nu}_l \to \bar{\nu}_{l'})$, $l \neq l'$.

In the case of 3-neutrino mixing all different $\mathrm{Im}(U_{l'j}U^*_{lj}U_{lk}U^*_{l'k}) \neq 0$, $l' \neq l = e, \mu, \tau$, $j \neq k = 1, 2, 3$, coincide up to a sign as a consequence of the unitarity of U. Therefore one has [63]:

$$A^{(\mu e)}_{\mathrm{CP}} = -\,A^{(\tau e)}_{\mathrm{CP}} = A^{(\tau\mu)}_{\mathrm{CP}} = 4\,J_{\mathrm{CP}}\,\left(\sin\frac{\Delta m^2_{32}}{2p}\,L + \sin\frac{\Delta m^2_{21}}{2p}\,L + \sin\frac{\Delta m^2_{13}}{2p}\,L\right) \tag{14.40}$$

where

$$J_{\mathrm{CP}} = \mathrm{Im}\left(U_{\mu 3}\,U^*_{e3}\,U_{e2}\,U^*_{\mu 2}\right)\,, \tag{14.41}$$

is the "rephasing invariant" associated with the Dirac CP violation phase in U. It is analogous to the rephasing invariant associated with the Dirac CP violating phase in the CKM quark mixing matrix [64]. It is clear from Eq. (14.40) that J_{CP} controls the magnitude of CP violation effects in neutrino oscillations in the case of 3-neutrino mixing. If $\sin(\Delta m^2_{ij}/(2p)L) \cong 0$ for $(ij) = (32)$, or (21), or (13), we get $A^{(l'l)}_{\mathrm{CP}} \cong 0$. Thus, if as a consequence of the production, propagation and/or detection of neutrinos, effectively oscillations due only to one non-zero neutrino mass squared difference take place, the CP violating effects will be strongly suppressed. In particular, we get $A^{(l'l)}_{\mathrm{CP}} = 0$, unless all three $\Delta m^2_{ij} \neq 0$, $(ij) = (32), (21), (13)$.

If the number of massive neutrinos n is equal to the number of neutrino flavours, $n = 3$, one has as a consequence of the unitarity of the neutrino mixing matrix: $\sum_{l'=e,\mu,\tau} P(\nu_l \to \nu_{l'}) = 1$, $l = e, \mu, \tau$, $\sum_{l=e,\mu,\tau} P(\nu_l \to \nu_{l'}) = 1, l' = e, \mu, \tau$. Similar "probability conservation" equations hold for $P(\bar{\nu}_l \to \bar{\nu}_{l'})$. If, however, the number of light massive neutrinos is bigger than the number of flavour neutrinos as a consequence, *e.g.*, of a flavour neutrino - sterile neutrino mixing, we would have $\sum_{l'=e,\mu,\tau} P(\nu_l \to \nu_{l'}) = 1 - P(\nu_l \to \bar{\nu}_{sL})$, $l = e, \mu, \tau$, where we have assumed the existence of just one sterile neutrino. Obviously, in this case $\sum_{l'=e,\mu,\tau} P(\nu_l \to \nu_{l'}) < 1$ if $P(\nu_l \to \bar{\nu}_{sL}) \neq 0$. The former inequality is used in the searches for oscillations between active and sterile neutrinos.

Consider next neutrino oscillations in the case of one neutrino mass squared difference "dominance": suppose that $|\Delta m^2_{j1}| \ll |\Delta m^2_{n1}|$, $j = 2, ..., (n-1)$, $|\Delta m^2_{n1}|\, L/(2p) \gtrsim 1$ and $|\Delta m^2_{j1}|\, L/(2p) \ll 1$, so that $\exp[i(\Delta m^2_{j1}\, L/(2p)] \cong 1$, $j = 2, ..., (n-1)$. Under these conditions we obtain from Eq. (14.35) and Eq. (14.36), keeping only the oscillating terms involving Δm^2_{n1}:

$$P(\nu_{l(l')} \to \nu_{l'(l)}) \cong P(\bar{\nu}_{l(l')} \to \bar{\nu}_{l'(l)}) \cong \delta_{ll'} - 2|U_{ln}|^2 \left[\delta_{ll'} - |U_{l'n}|^2\right] (1 - \cos \frac{\Delta m^2_{n1}}{2p} L)\,. \tag{14.42}$$

It follows from the neutrino oscillation data discussed in Section 14.2 that in the case of 3-neutrino mixing, one of the two independent neutrino mass squared differences, $\Delta m^2_{21} > 0$, is much smaller than the absolute value of the second one, $|\Delta m^2_{31}|$: $\Delta m^2_{21} \ll |\Delta m^2_{31}|$. The data, as we have seen, imply:

$$\begin{aligned} \Delta m^2_{21} &\cong 7.4 \times 10^{-5}\ \text{eV}^2\,, \\ |\Delta m^2_{31}| &\cong 2.5 \times 10^{-3}\ \text{eV}^2\,, \\ \Delta m^2_{21}/|\Delta m^2_{31}| &\cong 0.03\,. \end{aligned} \tag{14.43}$$

Neglecting the effects due to Δm^2_{21} we get from Eq. (14.42) by setting $n = 3$ and choosing, *e.g.*, i) $l = l' = e$ and ii) $l = e(\mu)$, $l' = \mu(e)$ [140]:

$$P(\nu_e \to \nu_e) = P(\bar{\nu}_e \to \bar{\nu}_e) \cong 1 - 2|U_{e3}|^2 \left(1 - |U_{e3}|^2\right) \left(1 - \cos \frac{\Delta m^2_{31}}{2p} L\right), \tag{14.44}$$

$$\begin{aligned} P(\nu_{\mu(e)} \to \nu_{e(\mu)}) &\cong 2\,|U_{\mu 3}|^2\,|U_{e3}|^2 \left(1 - \cos \frac{\Delta m^2_{31}}{2p} L\right) \\ &= \frac{|U_{\mu 3}|^2}{1 - |U_{e3}|^2}\, P^{2\nu}\left(|U_{e3}|^2, m^2_{31}\right), \end{aligned} \tag{14.45}$$

and $P(\bar{\nu}_{\mu(e)} \to \bar{\nu}_{e(\mu)}) = P(\nu_{\mu(e)} \to \nu_{e(\mu)})$. Here $P^{2\nu}\left(|U_{e3}|^2, m^2_{31}\right)$ is the probability of the 2-neutrino transition $\nu_e \to (s_{23}\nu_\mu + c_{23}\nu_\tau)$ due to Δm^2_{31} and a mixing with angle θ_{13}, where

$$\begin{aligned} \sin^2\theta_{13} = |U_{e3}|^2,\ \ s^2_{23} \equiv \sin^2\theta_{23} = \frac{|U_{\mu 3}|^2}{1 - |U_{e3}|^2}, \\ c^2_{23} \equiv \cos^2\theta_{23} = \frac{|U_{\tau 3}|^2}{1 - |U_{e3}|^2}, \end{aligned} \tag{14.46}$$

i.e., θ_{13} and θ_{23} are the angles of the standard parametrization of the neutrino mixing matrix. Eq. (14.44) describes with a relatively high precision the oscillations of reactor $\bar{\nu}_e$ on a distance $L \sim 1$ km in the case of 3-neutrino mixing. It was used in the analysis of the data of the Chooz [51], Double Chooz [30], Daya Bay [31] and RENO [32] experiments. Eq. (14.42) with $n = 3$ and $l = l' = \mu$ describes with a relatively good precision the effects of "disappearance" due to oscillations of the accelerator ν_μ, seen in the K2K [19] MINOS [20,21] and T2K [22,23] experiments. The $\nu_\mu \to \nu_\tau$ transitions due to the oscillations, which the OPERA experiment [141,142] is observing, can be described by Eq. (14.42) with $n = 3$ and $l = \mu$, $l' = \tau$. Finally, the probability Eq. (14.45) describes with a good precision the $\nu_\mu \to \nu_e$ and $\bar{\nu}_\mu \to \bar{\nu}_e$ oscillations under the conditions of the K2K experiment.

In certain cases the dimensions of the neutrino source, ΔL, are not negligible in comparison with the oscillation length. Similarly, when analyzing neutrino oscillation data one has to include the energy resolution of the detector, ΔE, *etc.* in the analysis. As can be shown [46], if $2\pi\Delta L/L^v_{jk} \gg 1$, and/or $2\pi(L/L^v_{jk})(\Delta E/E) \gg 1$, the oscillating terms in the neutrino oscillation probabilities will be strongly suppressed. In this case (as well as in the case of sufficiently large separation of the ν_j and ν_k wave packets at the detection point) the interference terms in $P(\nu_l \to \nu_{l'})$ and $P(\bar{\nu}_{l'} \to \bar{\nu}_l)$ will be negligibly small and the neutrino flavour conversion will be determined by the average probabilities:

$$\bar{P}(\nu_l \to \nu_{l'}) = \bar{P}(\bar{\nu}_l \to \bar{\nu}_{l'}) \cong \sum_j |U_{l'j}|^2\,|U_{lj}|^2\,. \tag{14.47}$$

Suppose next that in the case of 3-neutrino mixing, $|\Delta m^2_{21}|\, L/(2p) \sim 1$, while at the same time $|\Delta m^2_{31(32)}|\, L/(2p) \gg 1$, and the oscillations due to Δm^2_{31} and Δm^2_{32} are strongly suppressed (averaged out) due to integration over the region of neutrino production, the energy resolution function, *etc.* In this case we get for the ν_e and $\bar{\nu}_e$ survival probabilities:

$$P(\nu_e \to \nu_e) = P(\bar{\nu}_e \to \bar{\nu}_e) \cong |U_{e3}|^4 + \left(1 - |U_{e3}|^2\right)^2\, P^{2\nu}(\nu_e \to \nu_e)\,, \tag{14.48}$$

$$\begin{aligned} P^{2\nu}(\nu_e \to \nu_e) &= P^{2\nu}(\bar{\nu}_e \to \bar{\nu}_e) \equiv P^{2\nu}_{ee}(\theta_{12}, \Delta m^2_{21}) \\ &= 1 - \frac{1}{2}\,\sin^2 2\theta_{12}\,\left(1 - \cos \frac{\Delta m^2_{21}}{2p} L\right) \\ &= 1 - \sin^2 2\theta_{12}\,\sin^2\left(\frac{\Delta m^2_{21}}{4E} L\right) \end{aligned} \tag{14.49}$$

being the ν_e and $\bar{\nu}_e$ survival probability in the case of 2-neutrino oscillations "driven" by the angle θ_{12} and Δm^2_{21}, with θ_{12} given by

$$\cos^2\theta_{12} = \frac{|U_{e1}|^2}{1 - |U_{e3}|^2}\,, \quad \sin^2\theta_{12} = \frac{|U_{e2}|^2}{1 - |U_{e3}|^2}\,. \tag{14.50}$$

Eq. (14.48) with $P^{2\nu}(\bar{\nu}_e \to \bar{\nu}_e)$ given by Eq. (14.49) describes the effects of neutrino oscillations of reactor $\bar{\nu}_e$ observed by the KamLAND experiment.

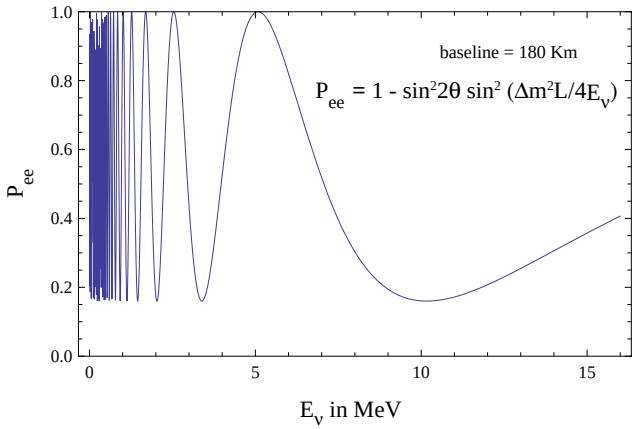

Figure 14.6: The ν_e ($\bar{\nu}_e$) survival probability $P(\nu_e \to \nu_e) = P(\bar{\nu}_e \to \bar{\nu}_e)$, Eq. (14.52), as a function of the neutrino energy for $L = 180$ km, $\Delta m^2 = 7.0 \times 10^{-5}$ eV^2 and $\sin^2 2\theta = 0.84$ (from Ref. 143).

The data of ν-oscillations experiments were often analyzed in the past, and in certain cases new data are still analyzed at present, assuming 2-neutrino mixing:

$$|\nu_l\rangle \ = |\nu_1\rangle \cos\theta + |\nu_2\rangle \sin\theta\,, \quad |\nu_x\rangle \ = -|\nu_1\rangle \sin\theta + |\nu_2\rangle \cos\theta\ , \tag{14.51}$$

where θ is the neutrino mixing angle in vacuum and ν_x is another flavour neutrino or sterile (anti-) neutrino, $x = l' \neq l$ or $\nu_x \equiv \bar{\nu}_{sL}$. In this case we have [139]:

$$P^{2\nu}(\nu_l \to \nu_l) = 1 - \frac{1}{2}\sin^2 2\theta \left(1 - \cos 2\pi \frac{L}{L^v}\right)$$
$$= 1 - \sin^2 2\theta \left(\sin^2 \frac{\Delta m^2}{4E} L\right),$$
$$P^{2\nu}(\nu_l \to \nu_x) = 1 - P^{2\nu}(\nu_l \to \nu_l), \quad (14.52)$$

where $L^v = 4\pi\, E/\Delta m^2$ ($p = E$), $\Delta m^2 = m_2^2 - m_1^2 > 0$. Combining the CPT invariance constraints with the probability conservation one obtains: $P(\nu_l \to \nu_x) = P(\bar{\nu}_l \to \bar{\nu}_x) = P(\nu_x \to \nu_l) = P(\bar{\nu}_x \to \bar{\nu}_l)$. These equalities and Eq. (14.52) with $l = \mu$ and $x = \tau$ were used, for instance, in the analysis of the Super-K atmospheric neutrino data [17], in which the first compelling evidence for oscillations of neutrinos was obtained. The probability $P^{2\nu}(\nu_l \to \nu_x)$, Eq. (14.52), depends on two factors: on $(1 - \cos 2\pi L/L^v)$, which exhibits oscillatory dependence on the distance L and on the neutrino energy $p = E$ (hence the name "neutrino oscillations"), and on $\sin^2 2\theta$, which determines the amplitude of the oscillations. In order to have $P^{2\nu}(\nu_l \to \nu_x) \cong 1$, two conditions have to be fulfilled: one should have $\sin^2 2\theta \cong 1$ and $L^v \lesssim 2\pi L$ with $\cos 2\pi L/L^v \cong -1$. If $L^v \gg 2\pi L$, the oscillations do not have enough time to develop on the way to the neutrino detector and $P(\nu_l \to \nu_x) \cong 0$, while $P(\nu_l \to \nu_l) \cong 1$. The preceding comments are illustrated in Fig. 14.6 showing the dependence of the probability $P^{2\nu}(\nu_e \to \nu_e) = P^{2\nu}(\bar{\nu}_e \to \bar{\nu}_e)$ on the neutrino energy.

Table 14.4: Sensitivity of different oscillation experiments.

Source	Type of ν	$\overline{E}$[MeV]	L[km]	min(Δm^2)[eV^2]
Reactor	$\overline{\nu}_e$	~ 1	1	$\sim 10^{-3}$
Reactor	$\overline{\nu}_e$	~ 1	100	$\sim 10^{-5}$
Accelerator	$\nu_\mu, \overline{\nu}_\mu$	$\sim 10^3$	1	~ 1
Accelerator	$\nu_\mu, \overline{\nu}_\mu$	$\sim 10^3$	1000	$\sim 10^{-3}$
Atmospheric ν's	$\nu_{\mu,e}, \overline{\nu}_{\mu,e}$	$\sim 10^3$	10^4	$\sim 10^{-4}$
Sun	ν_e	~ 1	1.5×10^8	$\sim 10^{-11}$

A given experiment searching for neutrino oscillations is specified, in particular, by the average energy of the neutrinos being studied, $\bar{E}$, and by the source-detector distance L. The requirement $L^v_{jk} \lesssim 2\pi L$ determines the minimal value of a generic neutrino mass squared difference $\Delta m^2 > 0$, to which the experiment is sensitive (figure of merit of the experiment): $\min(\Delta m^2) \sim 2\bar{E}/L$. Because of the interference nature of neutrino oscillations, experiments can probe, in general, rather small values of Δm^2 (see, *e.g.*, Ref. 135). Values of $\min(\Delta m^2)$, characterizing qualitatively the sensitivity of different experiments are given in Table 14.4. They correspond to the reactor experiments Chooz, Daya Bay, RENO, Double Chooz ($L \sim 1$ km) and KamLAND ($L \sim 100$ km), to accelerator experiments - past ($L \sim 1$ km), and current (K2K, MINOS, OPERA, T2K, NOνA [115]) , $L \sim (300 \div 1000)$ km), to the Super-Kamiokande, MINOS and IceCube-DeepCore experiments studying atmospheric neutrino oscillations, and to the solar neutrino experiments.

14.8. Matter effects in neutrino oscillations

The presence of matter can change drastically the pattern of neutrino oscillations: neutrinos can interact with the particles forming the matter. Accordingly, the Hamiltonian of the neutrino system in matter H_m, differs from the Hamiltonian in vacuum H_0, $H_m = H_0 + H_{int}$, where H_{int} describes the interaction of neutrinos with the particles of matter. When, for instance, ν_e and ν_μ propagate in matter, they can scatter (due to H_{int}) on the electrons (e^-), protons (p) and neutrons (n) present in matter. The incoherent elastic and the quasi-elastic scattering, in which the states of the initial particles change in the process (destroying the coherence between the neutrino states), are not of interest - they have a negligible effect on the solar neutrino propagation in the Sun and on the solar, atmospheric and reactor neutrino propagation in the Earth [144]: even in the center of the Sun, where the matter density is relatively high (~ 150 g/cm^3), a ν_e with energy of 1 MeV has a mean free path with respect to the indicated scattering processes $\sim 10^{10}$ km. We recall that the solar radius is much smaller: $R_\odot = 6.96 \times 10^5$ km. The oscillating ν_e and ν_μ can scatter also elastically in the forward direction on the e^-, p and n, with the momenta and the spin states of the particles remaining unchanged. In such a process the coherence of the neutrino states is preserved.

The ν_e and ν_μ coherent elastic scattering on the particles of matter generates nontrivial indices of refraction of the ν_e and ν_μ in matter [26]: $\kappa(\nu_e) \neq 1$, $\kappa(\nu_\mu) \neq 1$. Most importantly, we have $\kappa(\nu_e) \neq \kappa(\nu_\mu)$. The difference $\kappa(\nu_e) - \kappa(\nu_\mu)$ is determined essentially by the difference of the real parts of the forward $\nu_e - e^-$ and $\nu_\mu - e^-$ elastic scattering amplitudes [26] Re $[F_{\nu_e - e^-}(0)]$ − Re $[F_{\nu_\mu - e^-}(0)]$: due to the flavour symmetry of the neutrino – quark (neutrino – nucleon) neutral current interaction, the forward $\nu_e - p, n$ and $\nu_\mu - p, n$ elastic scattering amplitudes are equal and therefore do not contribute to the difference of interest [145]. The imaginary parts of the forward scattering amplitudes (responsible, in particular, for decoherence effects) are proportional to the corresponding total scattering cross-sections and in the case of interest are negligible in comparison with the real parts. The real parts of the amplitudes $F_{\nu_e - e^-}(0)$ and $F_{\nu_\mu - e^-}(0)$ can be calculated in the Standard Model. To leading order in the Fermi constant G_F, only the term in $F_{\nu_e - e^-}(0)$ due to the diagram with exchange of a virtual $W^\pm$-boson contributes to $F_{\nu_e - e^-}(0) - F_{\nu_\mu - e^-}(0)$. One finds the following result for $\kappa(\nu_e) - \kappa(\nu_\mu)$ in the rest frame of the scatters [26,146,147]:

$$\kappa(\nu_e) - \kappa(\nu_\mu) = \frac{2\pi}{p^2} \left(\text{Re } [F_{\nu_e - e^-}(0)] - \text{Re } [F_{\nu_\mu - e^-}(0)]\right)$$
$$= -\frac{1}{p}\sqrt{2} G_F N_e \ , \quad (14.53)$$

where N_e is the electron number density in matter. Given $\kappa(\nu_e) - \kappa(\nu_\mu)$, the system of evolution equations describing the $\nu_e \leftrightarrow \nu_\mu$ oscillations in matter reads [26]:

$$i\frac{d}{dt}\begin{pmatrix} A_e(t, t_0) \\ A_\mu(t, t_0) \end{pmatrix} = \begin{pmatrix} -\epsilon(t) & \epsilon' \\ \epsilon' & \epsilon(t) \end{pmatrix} \begin{pmatrix} A_e(t, t_0) \\ A_\mu(t, t_0) \end{pmatrix} \quad (14.54)$$

where $A_e(t, t_0)$ ($A_\mu(t, t_0)$) is the amplitude of the probability to find ν_e (ν_μ) at time t of the evolution of the system if at time $t_0 \leq t$ the neutrino ν_e or ν_μ has been produced and

$$\epsilon(t) = \frac{1}{2}\ [\frac{\Delta m^2}{2E}\cos 2\theta - \sqrt{2} G_F N_e(t)], \ \ \epsilon' = \frac{\Delta m^2}{4E}\sin 2\theta. \quad (14.55)$$

The term $\sqrt{2} G_F N_e(t)$ in $\epsilon(t)$ accounts for the effects of matter on neutrino oscillations. The system of evolution equations describing the oscillations of antineutrinos $\bar{\nu}_e \leftrightarrow \bar{\nu}_\mu$ in matter has exactly the same form except for the matter term in $\epsilon(t)$ which changes sign. The effect of matter in neutrino oscillations is usually called the Mikheyev, Smirnov, Wolfenstein (or MSW) effect.

Consider first the case of $\nu_e \leftrightarrow \nu_\mu$ oscillations in matter with constant density: $N_e(t) = N_e = \ const$. Due to the interaction term H_{int} in H_m, the eigenstates of the Hamiltonian of the neutrino system in vacuum, $|\nu_{1,2}\rangle$ are not eigenstates of H_m. For the eigenstates $|\nu^m_{1,2}\rangle$ of H_m, which diagonalize the evolution matrix in the r.h.s. of the system Eq. (14.54) we have:

$$|\nu_e\rangle = |\nu^m_1\rangle \cos\theta_m + |\nu^m_2\rangle \sin\theta_m \,, \qquad |\nu_\mu\rangle = -|\nu^m_1\rangle \sin\theta_m \ + |\nu^m_2\rangle \cos\theta_m \ . \quad (14.56)$$

Here θ_m is the neutrino mixing angle in matter [26],

$$\sin 2\theta_m = \frac{\tan 2\theta}{\sqrt{(1 - \frac{N_e}{N^{res}_e})^2 + \tan^2 2\theta}}, \ \cos 2\theta_m = \frac{1 - N_e/N^{res}_e}{\sqrt{(1 - \frac{N_e}{N^{res}_e})^2 + \tan^2 2\theta}}, \quad (14.57)$$

where the quantity

$$N_e^{res} = \frac{\Delta m^2 \cos 2\theta}{2E\sqrt{2}G_F} \cong 6.56 \times 10^6 \ \frac{\Delta m^2[\mathrm{eV}^2]}{E[\mathrm{MeV}]} \cos 2\theta \, \mathrm{cm}^{-3} \ \mathrm{N_A} \, , \tag{14.58}$$

is called (for $\Delta m^2 \cos 2\theta > 0$) "resonance density" [27,146], $\mathrm{N_A}$ being Avogadro's number. The "adiabatic" states $|\nu^m_{1,2}\rangle$ have energies $E^m_{1,2}$ whose difference is given by

$$E^m_2 - E^m_1 = \frac{\Delta m^2}{2E} \ \left((1 - \frac{N_e}{N_e^{res}})^2 \cos^2 2\theta + \sin^2 2\theta\right)^{\frac{1}{2}} \equiv \frac{\Delta M^2}{2E} \, . \tag{14.59}$$

The probability of $\nu_{\mu(e)} \to \nu_{e(\mu)}$ transition in matter with $N_e = const.$ has the form [26,146]

$$P^{2\nu}_m(\nu_{\mu(e)} \to \nu_{e(\mu)}) = |A_{e(\mu)}(t)|^2 = \frac{1}{2} \sin^2 2\theta_m \ [1 - \cos 2\pi \frac{L}{L_m} \ ]$$
$$L_m = 2\pi/(E^m_2 - E^m_1) \, , \tag{14.60}$$

where L_m is the oscillation length in matter. As Eq. (14.57) indicates, the dependence of $\sin^2 2\theta_m$ on N_e has a resonance character [27]. Indeed, if $\Delta m^2 \cos 2\theta > 0$, for any $\sin^2 2\theta \neq 0$ there exists a value of N_e given by N_e^{res}, such that when $N_e = N_e^{res}$ we have $\sin^2 2\theta_m = 1$ independently of the value of $\sin^2 2\theta < 1$. This implies that the presence of matter can lead to a strong enhancement of the oscillation probability $P^{2\nu}_m(\nu_{\mu(e)} \to \nu_{e(\mu)})$ even when the $\nu_{\mu(e)} \to \nu_{e(\mu)}$ oscillations in vacuum are suppressed due to a small value of $\sin^2 2\theta$. For obvious reasons

$$N_e = N_e^{res} \equiv \frac{\Delta m^2 \cos 2\theta}{2E\sqrt{2}G_F} \, , \tag{14.61}$$

is called the "resonance condition" [27,146], while the energy at which Eq. (14.61) holds for given N_e and $\Delta m^2 \cos 2\theta$, is referred to as the "resonance energy", E^{res}. The oscillation length at resonance is given by [27] $L^{res}_m = L^v / \sin 2\theta$, while the width in N_e of the resonance at half height reads $\Delta N_e^{res} = 2N_e^{res} \tan 2\theta$. Thus, if the mixing angle in vacuum is small, the resonance is narrow, $\Delta N_e^{res} \ll N_e^{res}$, and $L^{res}_m \gg L^v$. The energy difference $E^m_2 - E^m_1$ has a minimum at the resonance: $(E^m_2 - E^m_1)^{res} = \min \ (E^m_2 - E^m_1) = (\Delta m^2/(2E)) \sin 2\theta$.

It is instructive to consider two limiting cases. If $N_e \ll N_e^{res}$, we have from Eq. (14.57) and Eq. (14.59), $\theta_m \cong \theta$, $\mathrm{L_m} \cong \mathrm{L^v}$ and neutrinos oscillate practically as in vacuum. In the limit $N_e \gg N_e^{res}$, $N_e^{res} \tan^2 2\theta$, one finds $\theta_m \cong \pi/2$ ($\cos 2\theta_m \cong -1$) and the presence of matter suppres the $\nu_\mu \leftrightarrow \nu_e$ oscillations. In this case $|\nu_e\rangle \cong |\nu^m_2\rangle$, $|\nu_\mu\rangle = -|\nu^m_1\rangle$, *i.e.*, ν_e practically coincides with the heavier matter-eigenstate, while ν_μ coincides with the lighter one.

Since the neutral current weak interaction of neutrinos in the Standard Model is flavour symmetric, the formulae and results we have obtained are valid for the case of $\nu_e - \nu_\tau$ mixing and $\nu_e \leftrightarrow \nu_\tau$ oscillations in matter as well. The case of $\nu_\mu - \nu_\tau$ mixing, however, is different: to a relatively good precision we have [148] $\kappa(\nu_\mu) \cong \kappa(\nu_\tau)$ and the $\nu_\mu \leftrightarrow \nu_\tau$ oscillations in the matter of the Earth and the Sun proceed practically as in vacuum [149].

The analogs of Eq. (14.57) to Eq. (14.60) for oscillations of antineutrinos, $\bar\nu_\mu \leftrightarrow \bar\nu_e$, in matter can formally be obtained by replacing N_e with $(-N_e)$ in the indicated equations. It should be clear that depending on the sign of $\Delta m^2 \cos 2\theta$, the presence of matter can lead to resonance enhancement either of the $\nu_\mu \leftrightarrow \nu_e$ or of the $\bar\nu_\mu \leftrightarrow \bar\nu_e$ oscillations, but not of both types of oscillations [146]. For $\Delta m^2 \cos 2\theta < 0$, for instance, the matter can only suppress the $\nu_{\mu(e)} \to \nu_{e(\mu)}$ oscillations, while it can enhance the $\bar\nu_{\mu(e)} \to \bar\nu_{e(\mu)}$ transitions. The dependence of the effects of matter in $\nu_\mu \to \nu_e$ and $\bar\nu_\mu \to \bar\nu_e$ oscillations on $\mathrm{sgn}(\Delta m^2 \cos 2\theta)$ is at basis of the plans to determine the sign of $\Delta m^2_{31(32)}$, and thus the type of spectrum neutrino masses obey - with normal or inverted ordering - in long baseline neutrino oscillation experiments (NOνA, DUNE) and in atmospheric neutrino experiments with large volume detectors (PINGU, ORCA, INO, Hyper-Kamiokande, DUNE).

The discussed disparity between the behavior of neutrinos and that of antineutrinos is a consequence of the fact that the matter in the Sun or in the Earth we are interested in is not charge-symmetric (it contains e^-, p and n, but does not contain their antiparticles) and therefore the oscillations in matter are neither CP- nor CPT-invariant [65]. Thus, even in the case of 2-neutrino mixing and oscillations we have, *e.g.*, $P^{2\nu}_m(\nu_\mu \to \nu_e) \neq P^{2\nu}_m(\bar\nu_\mu \to \bar\nu_e)$ and $P^{2\nu}_m(\nu_e \to \nu_{\mu(\tau)}) \neq P^{2\nu}_m(\bar\nu_e \to \bar\nu_{\mu(\tau)})$.

The $\nu_\mu \leftrightarrow \nu_e$ ($\bar\nu_\mu \leftrightarrow \bar\nu_e$) and $\nu_e \leftrightarrow \nu_{\mu(\tau)}$ ($\bar\nu_e \leftrightarrow \bar\nu_{\mu(\tau)}$) oscillations in matter will be invariant with respect to the operation of time reversal if the N_e distribution along the neutrino path is symmetric with respect to this operation [63,150]. The latter condition is fulfilled (to a good approximation) for the N_e distribution along a path of a neutrino crossing the Earth [151].

14.8.1. *Effects of Earth matter on oscillations of neutrinos. Analytic expressions for oscillation probabilities* :

The formalism we have developed can be applied, *e.g.*, to the study of matter effects in the $\nu_e \leftrightarrow \nu_{\mu(\tau)}$ ($\nu_{\mu(\tau)} \leftrightarrow \nu_e$) and $\bar\nu_e \leftrightarrow \bar\nu_{\mu(\tau)}$ ($\bar\nu_{\mu(\tau)} \leftrightarrow \bar\nu_e$) oscillations of neutrinos which traverse the Earth [152]. Indeed, the Earth density distribution in the existing Earth models [151] is assumed to be spherically symmetric and there are two major density structures - the core and the mantle, and a certain number of substructures (shells or layers). The Earth radius is $R_\oplus = 6371$ km; the Earth core has a radius of $R_c = 3486$ km, so the Earth mantle depth is 2885 km. For a spherically symmetric Earth density distribution, the neutrino trajectory in the Earth is specified by the value of the nadir angle θ_n of the trajectory. For $\theta_n \leq 33.17^o$, or path lengths $L \geq 10660$ km, neutrinos cross the Earth core. The path length for neutrinos which cross only the Earth mantle is given by $L = 2R_\oplus \cos\theta_n$. If neutrinos cross the Earth core, the lengths of the paths in the mantle, $2L^{\mathrm{man}}$, and in the core, L^{core}, are determined by: $L^{\mathrm{man}} = R_\oplus \cos\theta_n - (R_c^2 - R_\oplus^2 \sin^2\theta_n)^{\frac{1}{2}}$, $L^{\mathrm{core}} = 2(R_c^2 - R_\oplus^2 \sin^2\theta_n)^{\frac{1}{2}}$. The mean electron number densities in the mantle and in the core according to the PREM model read [151]: $\bar N_e^{man} \cong 2.2$ cm^{-3} $\mathrm{N_A}$, $\bar N_e^c \cong 5.4$ cm^{-3} $\mathrm{N_A}$. Thus, we have $\bar N_e^c \cong 2.5 \ \bar N_e^{man}$. The change of N_e from the mantle to the core can well be approximated by a step function [151]. The electron number density N_e changes relatively little around the indicated mean values along the trajectories of neutrinos which cross a substantial part of the Earth mantle, or the mantle and the core, and the two-layer constant density approximation, $N_e^{man} = const. = \bar N_e^{man}$, $N_e^c = const. = \bar N_e^c$, $\bar N_e^{man}$ *and* $\bar N_e^c$ *being the mean densities along the given neutrino path in the Earth*, was shown to be sufficiently accurate in what concerns the calculation of neutrino oscillation probabilities [63,154,155] (and references quoted in [154,155]) in a large number of specific cases. This is related to the fact that the relatively small changes of density along the path of the neutrinos in the mantle (or in the core) take place over path lengths which are typically considerably smaller than the corresponding oscillation length in matter.

In the case of 3-neutrino mixing and for neutrino energies of $E \gtrsim 2$ GeV, the effects due to Δm^2_{21} ($|\Delta m^2_{21}| \ll |\Delta m^2_{31(23)}|$, see Eq. (14.43)) in the neutrino oscillation probabilities are sub-dominant and to leading order can be neglected: the corresponding resonance density $|N^{res}_{e21}| \lesssim 0.25 \ cm^{-3} \ N_A \ll \bar N_e^{man,c}$ and the Earth matter strongly suppresses the oscillations due to Δm^2_{21}. For oscillations in vacuum this approximation is valid in the case of NO (IO) neutrino mass spectrum (see Section 2) as long as the leading order contribution due to $\Delta m^2_{31(23)}$ in the relevant probabilities is bigger than approximately 10^{-3}. In this case the 3-neutrino $\nu_e \to \nu_{\mu(\tau)}$ ($\bar\nu_e \to \bar\nu_{\mu(\tau)}$) and $\nu_{\mu(\tau)} \to \nu_e$ ($\bar\nu_{\mu(\tau)} \to \bar\nu_e$) transition probabilities for neutrinos traversing the Earth, reduce effectively to a 2-neutrino transition probability (see, *e.g.*, Refs. [155–157]) , with $\Delta m^2_{31(23)}$ and θ_{13} playing the role of the relevant 2-neutrino vacuum oscillation parameters. We note that in the approximation of negligible Δm^2_{21} we have $\Delta m^2_{31} = \Delta m^2_{32}$. Therefore in what follows in this part of the article we will use, whenever relevant, only Δm^2_{31} in the analytic expressions.

As we have discussed in Sections 14.2 and will be discussed in greater detail in Section 14.12, the value of $\sin^2 2\theta_{13}$ has been determined with a rather high precision in the Daya Bay [38] and RENO [39] experiments. The best fit values found in the two

experiments read, respectively, $\sin^2 2\theta_{13} = 0.084$ [38] and 0.087 [39]. The 3-neutrino oscillation probabilities of the atmospheric and accelerator $\nu_{e,\mu}$ having energy $E \gtrsim 2$ GeV and crossing the Earth along a trajectory characterized by a nadir angle θ_n, for instance, have the following form in the approximation of negligible Δm^2_{21}:

$$P^{3\nu}_m(\nu_e \to \nu_e) \cong 1 - P^{2\nu}_m, \tag{14.62}$$

$$P^{3\nu}_m(\nu_e \to \nu_\mu) \cong P^{3\nu}_m(\nu_\mu \to \nu_e) \cong s^2_{23}\ P^{2\nu}_m,$$
$$P^{3\nu}_m(\nu_e \to \nu_\tau) \cong c^2_{23}\ P^{2\nu}_m, \tag{14.63}$$

$$P^{3\nu}_m(\nu_\mu \to \nu_\mu) \cong 1 - s^4_{23}\ P^{2\nu}_m - 2c^2_{23}s^2_{23}\ \left[1 - Re\ (e^{-i\kappa} A^{2\nu}_m(\nu' \to \nu'))\right], \tag{14.64}$$

$$P^{3\nu}_m(\nu_\mu \to \nu_\tau) = 1 - P^{3\nu}_m(\nu_\mu \to \nu_\mu) - P^{3\nu}_m(\nu_\mu \to \nu_e). \tag{14.65}$$

Here $P^{2\nu}_m \equiv P^{2\nu}_m(\Delta m^2_{31}, \theta_{13}; E, \theta_n)$ is the probability of the 2-neutrino $\nu_e \to \nu' \equiv (s_{23}\nu_\mu + c_{23}\nu_\tau)$ oscillations in the Earth, and κ and $A^{2\nu}_m(\nu' \to \nu') \equiv A^{2\nu}_m$ are known phase and 2-neutrino transition probability amplitude (see, *e.g.*, Refs. [155,156]). We note that Eq. (14.62) to Eq. (14.64) are based only on the assumptions that $|N^{res}_{e21}|$ is much smaller than the densities in the Earth mantle and core and that $|\Delta m^2_{21}| \ll |\Delta m^2_{31(23)}|$, and does not rely on the constant density approximation. Similar results are valid for the corresponding antineutrino oscillation probabilities: one has just to replace $P^{2\nu}_m$, κ and $A^{2\nu}_m$ in the expressions given above with the corresponding quantities for antineutrinos (the latter are obtained from those for neutrinos by changing the sign in front of N_e). Obviously, we have: $P(\nu_{e(\mu)} \to \nu_{\mu(e)}), P(\bar\nu_{e(\mu)} \to \bar\nu_{\mu(e)}) \leq \sin^2\theta_{23}$, and $P(\nu_e \to \nu_\tau), P(\bar\nu_e \to \bar\nu_\tau) \leq \cos^2\theta_{23}$. The one Δm^2 dominance approximation and correspondingly Eq. (14.62) to Eq. (14.65) were used by the Super-Kamiokande Collaboration in their 2006 neutrino oscillation analysis of the multi-GeV atmospheric neutrino data [158].

In the case of neutrinos crossing only the Earth mantle and in the constant density approximation, $P^{2\nu}_m$ is given by the r.h.s. of Eq. (14.60) with θ, Δm^2 and N_e replaced respectively by θ_{13}, Δm^2_{31} and $\tilde N^{man}_e$ (corresponding to the given θ_n) in the relevant expressions Eq. (14.57), Eq. (14.58) and Eq. (14.59) for $\sin 2\theta_m$, N^{res}_e and $(E^m_2 - E^m_1)$, while for κ and $A^{2\nu}_m$ we have (see, *e.g.*, Ref. 155):

$$\kappa \cong \frac{1}{2}[\frac{\Delta m^2_{31}}{2E}\ L + \sqrt{2}G_F \bar N^{man}_e L - \frac{\Delta M^2_{31} L}{2E}],$$
$$A^{2\nu}_m = 1 + (e^{-i\frac{\Delta M^2_{31} L}{2E}} - 1)\cos^2\theta^m_{13}\ , \tag{14.66}$$

where ΔM^2_{31} and θ^m_{13} can be obtained from Eq. (14.59) and Eq. (14.57) by setting $\theta = \theta_{13}$, $\Delta m^2 = \Delta m^2_{31} > 0$, $N^{res}_e = N^{res}_{e31} = \Delta m^2_{31}\cos 2\theta_{13}/(2E\sqrt{2}G_F)$ and $N_e = \tilde N^{man}_e(\theta_n)$. Clearly, θ^m_{13} is the mixing angle in the mantle which coincides in vacuum with θ_{13}. In the expressions for $P^{2\nu}_m \equiv P^{2\nu}_m(\Delta m^2_{31}, \theta_{13}; E, \theta_n, \bar N^{man}_e)$, κ and $A^{2\nu}_m$ in the case of oscillations in the mantle, $L = 2R_\oplus \cos\theta_n$ is the distance the neutrino travels in the mantle. The corresponding expressions for antineutrino oscillations, as we have noticed earlier, can be obtained from those derived above by making the change $\bar N^{man}_e \to -\bar N^{man}_e$.

The analytic results for $P^{2\nu}_m(\Delta m^2_{31}, \theta_{13}; E, \theta_n, \bar N^{man}_e)$, κ and $A^{2\nu}_m$, described above and obtained in the constant mantle density approximation, as we have already remarked, provide a relatively precise description of the $\nu_{\mu(e)} \to \nu_{e(\mu)}$, $\nu_e \to \nu_{e(\tau)}$, etc. oscillation probabilities in the Earth mantle if for each given trajectory of the neutrinos in the mantle, specified by the nadir angle θ_n, in the calculations one uses for $\bar N^{man}_e$ the mean value of the electron number density along that specific trajectory: $\bar N^{man}_e = \tilde N^{man}_e(\theta_n)$, where $\tilde N^{man}_e(\theta_n)$ should be calculated using the density distribution given by the existing Earth models [151].

It follows from Eq. (14.62) and Eq. (14.63) that for $\Delta m^2_{31}\cos 2\theta_{13} > 0$, the oscillation effects of interest, *e.g.*, in the $\nu_{e(\mu)} \to \nu_{\mu(e)}$ and $\nu_e \to \nu_\tau$ transitions will be maximal if $P^{2\nu}_m \cong 1$, *i.e.*, if Eq. (14.61) leading to $\sin^2 2\theta_m \cong 1$ is fulfilled, and ii) $\cos(\Delta M^2 L/(2E)) \cong -1$. Given the value of $\bar N^{man}_e$, the first condition determines the neutrino's energy, while the second determines the path length L, for which one can have $P^{2\nu}_m \cong 1$. For $\Delta m^2_{31} \cong 2.5 \times 10^{-3}$ eV^2, $\sin^2 2\theta_{13} \cong 0.090$ and $\bar N^{man}_e \cong 2.2$ N$_A$cm^{-3}, one finds that $E_{res} \cong 7.1$ GeV and $L \cong 3522/\sin 2\theta_{13}$ km $\cong 11740$ km. Since for neutrinos crossing only the mantle $L \lesssim 10660$ km, the second condition can be satisfied only if $\sin^2 2\theta_{13} \gtrsim 0.11$, which falls marginally in the 3σ range of the experimentally allowed values of $\sin^2 2\theta_{13}$. We still get a significant amplification of the probability $P^{2\nu}_m$, and therefore of $P(\nu_{e(\mu)} \to \nu_{\mu(e)})$ and $P(\nu_e \to \nu_\tau)$, even when $\cos(\Delta M^2 L/(2E)) = -0.5(-0.2)$: in this case $P^{2\nu}_m \cong 0.75$ (0.60). For $\sin^2 2\theta_{13} \cong 0.090$ we have $\cos(\Delta M^2 L/(2E)) = -0.5(-0.2)$ if $L \cong 7826$ (6622) km. Thus, for $\Delta m^2_{31} > 0$, the Earth matter effects can amplify $P^{2\nu}_m$, and therefore $P(\nu_{e(\mu)} \to \nu_{\mu(e)})$ and $P(\nu_e \to \nu_\tau)$, significantly when the neutrinos cross only the mantle, for $E \sim 7$ GeV and sufficiently large path lengths L.

If $\Delta m^2_{31} < 0$ the same considerations apply for the corresponding antineutrino oscillation probabilities $\bar P^{2\nu}_m = \bar P^{2\nu}_m(\bar\nu_e \to (s_{23}\bar\nu_\mu + c_{23}\bar\nu_\tau))$ and correspondingly for $P(\bar\nu_{e(\mu)} \to \bar\nu_{\mu(e)})$ and $P(\bar\nu_e \to \bar\nu_\tau)$. For $\Delta m^2_{31} > 0$, the $\bar\nu_{e(\mu)} \to \bar\nu_{\mu(e)}$ and $\bar\nu_e \to \bar\nu_\tau$ oscillations are suppressed by the Earth matter, while if $\Delta m^2_{31} < 0$, the same conclusion holds for the $\nu_{e(\mu)} \to \nu_{\mu(e)}$ and $\nu_e \to \nu_\tau$, oscillations. The dependence on $\mathrm{sgn}(\Delta m^2_{31})$ of the effects of Earth matter - enhancement or suppression - on the $\nu_{e(\mu)} \to \nu_{\mu(e)}$ and $\bar\nu_{e(\mu)} \to \bar\nu_{\mu(e)}$ oscillations taking place when the neutrinos traverse the Earth mantle, will be exploited in the current and planed long baseline and atmospheric neutrino oscillation experiments aiming, in particular, to determine the neutrino mass ordering (NOνA, DUNE, PINGU, ORCA, INO, Hyper-Kamiokande).

The discussed features of the Earth matter effects in the $\nu_{\mu(e)} \to \nu_{e(\mu)}$ and $\bar\nu_{\mu(e)} \to \bar\nu_{e(\mu)}$ oscillation probabilities for neutrinos with a path length in the Earth mantle of 7330 km and for $\Delta m^2_{31} > 0$, $\sin^2 2\theta_{13} = 0.10$ and $\sin^2 2\theta_{23} = 1$ are illustrated in Fig. 14.7 (taken from Ref. [159]) . The amplification of the $\nu_{\mu(e)} \to \nu_{e(\mu)}$ oscillation probability due to the Earth matter effect in the region of the resonance value of $E/\Delta m^2_{31}$ and the suppression of the $\bar\nu_{\mu(e)} \to \bar\nu_{e(\mu)}$ oscillation probability in the same region are clearly seen in the figure.

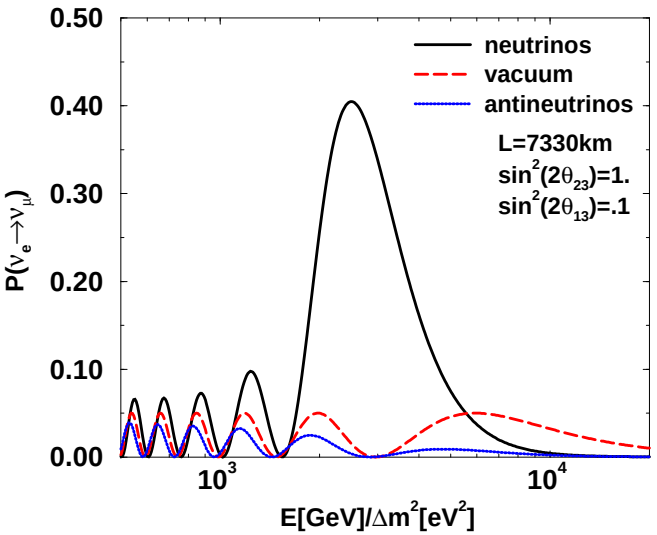

Figure 14.7: The $\nu_{e(\mu)} \to \nu_{\mu(e)}$ and $\bar\nu_{e(\mu)} \to \bar\nu_{\mu(e)}$ oscillation probabilities given in Eq. (14.63), $P(\nu_e \to \nu_\mu) = P(\nu_\mu \to \nu_e)$ (black solid line) and $P(\bar\nu_e \to \bar\nu_\mu) = P(\bar\nu_\mu \to \bar\nu_e)$ (blue solid line), as functions of $E/\Delta m^2$ for $\Delta m^2 \equiv \Delta m^2_{31} > 0$, $\sin^2 2\theta_{13} = 0.10$ and $\sin^2 2\theta_{23} = 1$. The figure is obtained for neutrinos crossing the Earth mantle along a path with length of $L = 7330$ km. The corresponding vacuum oscillation probability $P^{vac}(\nu_{e(\mu)} \to \nu_{\mu(e)}) = P^{vac}(\bar\nu_{e(\mu)} \to \bar\nu_{\mu(e)})$ is also shown (red dashed line). For $\Delta m^2 \equiv \Delta m^2_{31} < 0$, the black and blue solid lines will correspond respectively to the probabilities $P(\bar\nu_{e(\mu)} \to \bar\nu_{\mu(e)})$ and $P(\nu_{e(\mu)} \to \nu_{\mu(e)})$ (from Ref. 159).

In the case of neutrinos crossing the Earth core, new resonance-like effects become possible in the $\nu_\mu \to \nu_e$ and $\nu_e \to \nu_{\mu(\tau)}$ (or $\bar\nu_\mu \to \bar\nu_e$ and $\bar\nu_e \to \bar\nu_{\mu(\tau)}$) transitions [154–156,160–162]. For $\Delta m^2_{31} > 0$ and certain values of $\sin^2\theta_{13} \lesssim 0.05$ we can have [161] $P^{2\nu}_m(\Delta m^2_{31}, \theta_{13}) \cong 1$, and correspondingly maximal $P^{3\nu}_m(\nu_e \to \nu_\mu) = P^{3\nu}_m(\nu_\mu \to \nu_e) \cong s^2_{23}$, only due to the effect of maximal constructive interference between the amplitudes of the $\nu_e \to \nu'$ transitions in the Earth mantle and in the Earth core. The effect differs from the MSW one and the enhancement happens in the case of interest at a value of the energy between the MSW resonance energies corresponding to the density in the mantle and that of the core, or at a value of the resonance density N^{res}_e which lies between the values of N_e in the mantle and in the core [154]. In Refs. [154,155] the enhancement was called "neutrino oscillation length resonance (NOLR)", while in Refs. [156,160] the term "parametric resonance" for the same effect was used [163]. The *mantle-core enhancement effect (or NOLR)* is caused by the existence (for a given neutrino trajectory through the Earth core) of points of resonance-like maximal neutrino conversion, $P^{2\nu}_m(\Delta m^2_{31}, \theta_{13}) = 1$, in the corresponding space of neutrino oscillation parameters [161]. For $\Delta m^2_{31} < 0$ the mantle-core enhancement can take place for the antineutrino transitions, $\bar\nu_\mu \to \bar\nu_e$ and $\bar\nu_e \to \bar\nu_{\mu(\tau)}$. For neutrinos crossing the Earth core, analytic expressions for $P^{2\nu}_m(\Delta m^2_{31}, \theta_{13})$ and κ, $A^{2\nu}_m$ were derived in the two-layer constant density approximation for the Earth density distribution in [154] and [155], respectively.

A rather complete set of values of $\Delta m^2_{31}/E > 0$ and $\sin^2 2\theta_{13}$ for which $P^{2\nu}_m(\Delta m^2_{31}, \theta_{13}) = 1$ was found in Ref. 161. In the two-layer constant density approximation, the values of $\Delta m^2_{31}/E > 0$ and $\sin^2 2\theta_{13}$ at which $P^{2\nu}_m(\Delta m^2_{31}, \theta_{13}) = 1$ can be derived as solutions of the following system of equations [161]:

$$\tan\frac{\phi^{\rm man}}{2} = \pm\sqrt{\frac{-\cos 2\theta^{core}_{13}}{\cos(2\theta^{core}_{13} - 4\theta^{man}_{13})}}\,, \tag{14.67}$$

$$\tan\frac{\phi^{\rm core}}{2} = \pm\sqrt{\frac{\cos 2\theta^{man}_{13}}{-\cos(2\theta^{core}_{13})\cos(2\theta^{core}_{13} - 4\theta^{man}_{13})}}\,, \tag{14.68}$$

where the signs in the two equations are correlated, $\phi^{\rm man} = (E^m_3 - E^m_1)^{man} 2L^{man}$, $\phi^{\rm core} = (E^m_3 - E^m_1)^{core} L^{core}$, $2L^{man}$ and L^{core} are the neutrino path lengths in the Earth mantle and the core, and θ^{man}_{13} and θ^{core}_{13} are the values of the angle θ_{13} in the mantle and in the core. The expressions for $(E^m_3 - E^m_1)^{man}$ ($(E^m_3 - E^m_1)^{core}$) and θ^{man}_{13} (θ^{core}_{13}) can be obtained respectively from Eq. (14.59) and Eq. (14.57) by setting $\theta = \theta_{13}$, $\Delta m^2 = \Delta m^2_{31}$, $N^{res}_e = N^{res}_{e31} = \Delta m^2_{31}\cos 2\theta_{13}/(2E\sqrt{2}G_F)$ and $N_e = \tilde N^{man}_e(\theta_n)$ ($N_e = \tilde N^{core}_e(\theta_n)$).

The location of the points where $P^{2\nu}_m(\Delta m^2_{31}, \theta_{13}) = 1$ in the $\Delta m^2_{31}/E - \sin^2 2\theta_{13}$ plane determines the regions in the plane where $P^{2\nu}_m(\Delta m^2_{31}, \theta_{13})$ is large, $P^{2\nu}_m(\Delta m^2_{31}, \theta_{13}) \gtrsim 0.5$. These regions vary slowly with the nadir angle, being remarkably wide in the nadir angle and rather wide in the neutrino energy [161], so that the transitions of interest can produce noticeable effects in the measured observables. For $\sin^2\theta_{13} \lesssim 0.05$, there are two sets of values of $(\Delta m^2_{31}/E, \sin^2\theta_{13})$ for which $P^{2\nu}_m(\Delta m^2_{31}, \theta_{13}) = 1$, and thus two regions in $\Delta m^2_{31}/E - \sin^2 2\theta_{13}$ plane where $P^{2\nu}_m(\Delta m^2_{31}, \theta_{13}) \gtrsim 0.5$. For $\Delta m^2_{31} = 2.5 \times 10^{-3}$ eV^2 and nadir angle, *e.g.*, θ_n=0 (Earth center crossing neutrinos), we have $P^{2\nu}_m(\Delta m^2_{31}, \theta_{13}) = 1$ at $(E, \sin^2 2\theta_{13})$ =(3.4 GeV,0.034) and (5.2 GeV,0.15). At the same time for E =3.4 GeV (5.2 Gev), the probability $P^{2\nu}_m(\Delta m^2_{31}, \theta_{13}) \gtrsim 0.5$ for the values of $\sin^2 2\theta_{13}$ from the interval $0.02 \lesssim \sin^2 2\theta_{13} \lesssim 0.10$ ($0.04 \lesssim \sin^2 2\theta_{13} \lesssim 0.26$). Similar results hold for neutrinos crossing the Earth core along the trajectories with $\theta_n \neq 0$ (for further details see the last article in Ref. 161; see also the last article in Ref. 162).

The mantle-core enhancement of $P^{2\nu}_m$ (or $\bar P^{2\nu}_m$) is relevant, in particular, for the searches of sub-dominant $\nu_{e(\mu)} \to \nu_{\mu(e)}$ (or $\bar\nu_{e(\mu)} \to \bar\nu_{\mu(e)}$) oscillations of atmospheric neutrinos having energies $E \gtrsim 2$ GeV and crossing the Earth core on the way to the detector (see Ref. 154 to Ref. 162 and the references quoted therein).

The effects of Earth matter on the oscillations of atmospheric and accelerator neutrinos have not been observed so far. At present there are no compelling evidences for oscillations of the atmospheric ν_e and/or $\bar\nu_e$.

In the case of oscillations of atmospheric neutrinos in the Earth one has to take into account also the following considerations. The fluxes of atmospheric $\nu_{e,\mu}$ of energy E, which reach the detector after crossing the Earth along a given trajectory specified by the value of θ_n, $\Phi_{\nu_{e,\mu}}(E, \theta_n)$, are given by the following expressions in the case of the 3-neutrino oscillations under discussion [155,156]:

$$\Phi_{\nu_e}(E, \theta_n) \cong \Phi^0_{\nu_e}\left(1 + [s^2_{23} r - 1]\ P^{2\nu}_m\right), \tag{14.69}$$

$$\Phi_{\nu_\mu}(E, \theta_n) \cong \Phi^0_{\nu_\mu}\Big(1 + s^4_{23}[(s^2_{23}\ r)^{-1} - 1]P^{2\nu}_m - 2c^2_{23}s^2_{23}\left[1 - Re\ (e^{-i\kappa}A^{2\nu}_m(\nu_\tau \to \nu_\tau))\right]\Big)\,, \tag{14.70}$$

where $\Phi^0_{\nu_{e(\mu)}} = \Phi^0_{\nu_{e(\mu)}}(E, \theta_n)$ is the $\nu_{e(\mu)}$ flux in the absence of neutrino oscillations and

$$r \equiv r(E, \theta_n) \equiv \frac{\Phi^0_{\nu_\mu}(E, \theta_n)}{\Phi^0_{\nu_e}(E, \theta_n)}\quad . \tag{14.71}$$

It follows from the global analyses of the neutrino oscillation data that the neutrino mixing parameter s^2_{23} lies (at 3σ CL) in the interval (0.38 - 0.64). For NO (IO) neutrino mass spectrum, the three groups which performed recent global analyses, obtained the following best fit values of s^2_{23} (see Section 14.2): 0.452 (0.455) [52], 0.452 (0.579) [53] and 0.567 (0.573) [54], while in the latest analysis [60] the authors find 0.437 (0.569). For the predicted ratio $r(E, \theta_n)$ of the atmospheric ν_μ and ν_e fluxes for i) the Earth core crossing and ii) only mantle crossing neutrinos, having trajectories for which $0.3 \lesssim \cos\theta_n \leq 1.0$, one has [164] $r(E, \theta_n) \cong (2.6 \div 4.5)$ for neutrinos giving the main contribution to the multi-GeV samples, $E \cong (2 \div 10)$ GeV. Thus, for $s^2_{23} = 0.5$ (0.64) one finds for the multi-GeV neutrinos: $s^4_{23}[1 - (s^2_{23}\ r(E, \theta_z))^{-1}] \cong 0.06 - 0.14$ $(0.16 - 0.27)$ and $(s^2_{23}\ r(E, \theta_z) - 1) \cong 0.3 - 1.3$ $(0.66 - 1.9)$. Thus, the impact of the possible enhancement of $P^{2\nu}_m \cong 1$ would be largest for the flux of multi-GeV ν_e, $\Phi_{\nu_e}(E, \theta_n)$, traversing the Earth. As the preceding discussion suggests and detailed calculations show (see the first two articles quoted in Ref. 162), the sensitivity of the atmospheric neutrino experiments to the neutrino mass ordering depends strongly on the chosen value of $\sin^2\theta_{23}$ from its 3σ allowed range: it is maximal (minimal) for the maximal (minimal) allowed value of $\sin^2\theta_{23}$. In the case of the planned Hyper-Kamiokande detector and neutrino mass spectrum with normal ordering, for instance, it is estimated [165] that for $\sin^2\theta_{23} = 0.60$ it will take approximately (2-3) years to establish at 3σ CL that the spectrum is of the NO type, and approximately 10 years if $\sin^2\theta_{23} = 0.40$.

For water Cerenkov detectors, the charged current (CC) $\nu_l - N$ interaction cross section for multi-GeV neutrinos is approximately by a factor of 2 bigger than the $\bar\nu_l - N$ CC interaction cross section. Since these detectors do not distinguish between the neutrino and anti-neutrino induced CC events, determining that the neutrino mass spectrum is with inverted ordering would require roughly by a factor of 2 longer period of data acquisition than if the spectrum were with normal ordering.

The effects under discussion are larger, in general, for the multi-GeV neutrinos than for the sub-GeV neutrinos having energies $E \cong (0.1 - 1.0)$ GeV. Indeed, for the sub-GeV ν_e flux one finds in the limit of negligible θ_{13} [166]: $\Phi_{\nu_e}(E, \theta_n) \cong \Phi^0_{\nu_e}(1 + [c^2_{23}r - 1]\bar P^{2\nu}_m)$, where $\bar P^{2\nu}_m \equiv \bar P^{2\nu}_m(\Delta m^2_{21}, \theta_{12}; E, \theta_n)$ is the probability of the 2-neutrino oscillations in the Earth due to Δm^2_{21} and 2-neutrino mixing with angle θ_{12}. For the neutrinos giving contribution to the sub-GeV samples of Super-Kamiokande events one has [164] $r(E, \theta_z) \cong 2.0$. If $s^2_{23} = 0.5$ and $r(E, \theta_z) \cong 2.0$, we get $(c^2_{23}\ r(E, \theta_z) - 1) \cong 0$, and the possible effects of the $\nu_\mu \to \nu_e$ and $\nu_e \to \nu_{\mu(\tau)}$ transitions on the ν_e flux, and correspondingly in the sub-GeV $e-$like samples of events, would be rather strongly suppressed independently of the values of the corresponding transition probabilities.

The same conclusions are valid for the effects of oscillations on the fluxes of, and event rates due to, atmospheric antineutrinos $\bar\nu_e$ and $\bar\nu_\mu$.

The formulae for anti-neutrino fluxes and oscillation probabilities are analogous to those for neutrinos (see, *e.g.*, Refs. [155,156,162,166]) .

The expression for the probability of the $\nu_\mu \to \nu_e$ oscillations taking place in the Earth mantle in the case of 3-neutrino mixing, in which both neutrino mass squared differences Δm^2_{21} and Δm^2_{31} contribute and the CP violation effects due to the Dirac phase in the neutrino mixing matrix are taken into account, has the following form in the constant density approximation and keeping terms up to second order in the two small parameters $|\alpha| \equiv |\Delta m^2_{21}|/|\Delta m^2_{31}| \ll 1$ and $\sin^2\theta_{13} \ll 1$ [167]:

$$P^{3\nu\ man}_m(\nu_\mu \to \nu_e) \cong P_0 + P_{\sin\delta} + P_{\cos\delta} + P_3\,. \tag{14.72}$$

Here

$$P_0 = \sin^2\theta_{23}\,\frac{\sin^2 2\theta_{13}}{(A-1)^2}\,\sin^2[(A-1)\Delta]$$

$$P_3 = \alpha^2\,\cos^2\theta_{23}\,\frac{\sin^2 2\theta_{12}}{A^2}\,\sin^2(A\Delta)\,, \tag{14.73}$$

$$P_{\sin\delta} = -\,\alpha\,\frac{8\,J_{CP}}{A(1-A)}\,(\sin\Delta)\,(\sin A\Delta)\,(\sin[(1-A)\Delta])\;, \tag{14.74}$$

$$P_{\cos\delta} = \alpha\,\frac{8\,J_{CP}\,\cot\delta}{A(1-A)}\,(\cos\Delta)\,(\sin A\Delta)\,(\sin[(1-A)\Delta])\;, \tag{14.75}$$

where

$$\alpha = \frac{\Delta m^2_{21}}{\Delta m^2_{31}}\,,\;\; \Delta = \frac{\Delta m^2_{31}\,L}{4E}\,,\;\; A = \sqrt{2}G_{\rm F}N^{man}_e\,\frac{2E}{\Delta m^2_{31}}\,, \tag{14.76}$$

$\cot\delta = J^{-1}_{CP}{\rm Re}(U_{\mu 3}U^*_{e3}U_{e2}U^*_{\mu 2}) \propto \cos\delta$, and we recall that $J_{CP} = {\rm Im}(U_{\mu 3}U^*_{e3}U_{e2}U^*_{\mu 2})$. The analytic expression for $P^{3\nu\ man}_m(\nu_\mu \to \nu_e)$ given above is valid for [167] neutrino path lengths in the mantle ($L \leq$ 10660 km) satisfying $L \lesssim 10560$ km $\;E[{\rm GeV}]\,(7.6\times10^{-5}\ {\rm eV}^2/\Delta m^2_{21})$, and energies $E \gtrsim 0.34$ GeV$(\Delta m^2_{21}/7.6{\times}10^{-5}\ {\rm eV}^2)\,(1.4\ {\rm cm}^{-3}N_A/N^{man}_e)$. The expression for the $\bar\nu_\mu \to \bar\nu_e$ oscillation probability can be obtained formally from that for $P^{3\nu\ man}_m(\nu_\mu \to \nu_e)$ by making the changes $A \to -A$ and $J_{CP} \to -J_{CP}$, with $J_{CP}\cot\delta \equiv {\rm Re}(U_{\mu 3}U^*_{e3}U_{e2}U^*_{\mu 2})$ remaining unchanged. The term $P_{\sin\delta}$ in $P^{3\nu\ man}_m(\nu_\mu \to \nu_e)$ would be equal to zero if the Dirac phase in the neutrino mixing matrix U possesses a CP-conserving value. Even in this case, however, we have $A^{(e\mu)\ man}_{CP} \equiv (P^{3\nu\ man}_m(\nu_\mu \to \nu_e) - P^{3\nu\ man}_m(\bar\nu_\mu \to \bar\nu_e)) \neq 0$ due to the effects of the Earth matter. It will be important to experimentally disentangle the effects of the Earth matter and of J_{CP} in $A^{(e\mu)\ man}_{CP}$: this will allow to get information about the Dirac CP violation phase in U. This can be done, in principle, by studying the energy dependence of $P^{3\nu\ man}_m(\nu_\mu \to \nu_e)$ and $P^{3\nu\ man}_m(\bar\nu_\mu \to \bar\nu_e)$. Since the sign of $\Delta m^2_{31(32)}$ determines for given L whether the probability $P^{3\nu\ man}_m(\nu_\mu \to \nu_e)$ or $P^{3\nu\ man}_m(\bar\nu_\mu \to \bar\nu_e)$, as a function of energy, can be resonantly enhanced or suppressed by the matter effects, the study of the energy dependence of $P^{3\nu\ man}_m(\nu_\mu \to \nu_e)$ and/or of $P^{3\nu\ man}_m(\bar\nu_\mu \to \bar\nu_e)$ can provide also information on ${\rm sgn}(\Delta m^2_{31(32)})$. In the vacuum limit of $N^{man}_e = 0$ ($A = 0$) we have $A^{(e\mu)\ man}_{CP} = A^{(e\mu)}_{CP}$ (see Eq. (14.40)) and only the term $P_{\sin\delta}$ contributes to the asymmetry $A^{(e\mu)}_{CP}$.

The preceding remarks apply also to the probabilities $P^{3\nu\ man}_m(\nu_e \to \nu_\mu)$ and $P^{3\nu\ man}_m(\bar\nu_e \to \bar\nu_\mu)$). The probability $P^{3\nu\ man}_m(\nu_e \to \nu_\mu)$, for example, can formally be obtained from the expression for the probability $P^{3\nu\ man}_m(\nu_\mu \to \nu_e)$ by changing the sign of the term $P_{\sin\delta}$.

The expression for the probability $P^{3\nu\ man}_m(\nu_\mu \to \nu_e)$ given in Eq. (14.72) and the corresponding expression for $P^{3\nu\ man}_m(\bar\nu_\mu \to \bar\nu_e)$ can be used for the interpretation of the data of the current and the future planned long baseline oscillation experiments T2K, NOνA, MINOS+, DUNE [84] and T2HK [85].

14.8.2. *Oscillations of solar neutrinos* :

14.8.2.1. *Qualitative analysis:*

Consider next the oscillations of solar ν_e while they propagate from the central part of the Sun, where they are produced, to the surface of the Sun [27,153] (see also Ref. 26 and, *e.g.*, Ref. 168) Details concerning the production, spectrum, magnitude and particularities of the solar neutrino flux were discussed in Section 14.6, while the methods of detection of solar neutrinos, description of solar neutrino experiments and of the data they provided will be discussed in the next section (see also Ref. 169). The electron number density N_e changes considerably along the neutrino path in the Sun: it decreases monotonically from the value of ~ 100 cm^{-3} N_A in the center of the Sun to 0 at the surface of the Sun. According to the contemporary solar models (see, *e.g.*, Ref. [169,99]), N_e decreases approximately exponentially in the radial direction towards the surface of the Sun:

$$N_e(t) = N_e(t_0)\exp\left\{-\frac{t-t_0}{r_0}\right\}\;, \tag{14.77}$$

where $(t - t_0) \cong d$ is the distance traveled by the neutrino in the Sun, $N_e(t_0)$ is the electron number density at the point of ν_e production in the Sun, r_0 is the scale-height of the change of $N_e(t)$ and one has [169,99] $r_0 \sim 0.1R_\odot$.

Consider the case of 2-neutrino mixing, Eq. (14.56). Obviously, if N_e changes with t (or equivalently with the distance) along the neutrino trajectory, the matter-eigenstates, their energies, the mixing angle and the oscillation length in matter, become, through their dependence on N_e, also functions of t: $|\nu^m_{1,2}\rangle = |\nu^m_{1,2}(t)\rangle$, $E^m_{1,2} = E^m_{1,2}(t)$, $\theta_m = \theta_m(t)$ and $L_m = L_m(t)$. It is not difficult to understand qualitatively the possible behavior of the neutrino system when solar neutrinos propagate from the center to the surface of the Sun if one realizes that one is dealing effectively with a two-level system whose Hamiltonian depends on time and admits "jumps" from one level to the other (see Eq. (14.54)). Consider the case of $\Delta m^2\cos 2\theta > 0$. Let us assume first for simplicity that the electron number density at the point of a solar ν_e production in the Sun is much bigger than the resonance density, $N_e(t_0) \gg N^{res}_e$. Actually, this is one of the cases relevant to the solar neutrinos. In this case we have $\theta_m(t_0) \cong \pi/2$ and the state of the electron neutrino in the initial moment of the evolution of the system practically coincides with the heavier of the two matter-eigenstates:

$$|\nu_e\rangle \;\cong\; |\nu^m_2(t_0)\rangle\,. \tag{14.78}$$

Thus, at t_0 the neutrino system is in a state corresponding to the "level" with energy $E^m_2(t_0)$. When neutrinos propagate to the surface of the Sun they cross a layer of matter in which $N_e = N^{res}_e$: in this layer the difference between the energies of the two "levels" $(E^m_2(t) - E^m_1(t))$ has a minimal value on the neutrino trajectory (Eq. (14.59) and Eq. (14.61)). Correspondingly, the evolution of the neutrino system can proceed basically in two ways. First, the system can stay on the "level" with energy $E^m_2(t)$, *i.e.*, can continue to be in the state $|\nu^m_2(t)\rangle$ up to the final moment t_s, when the neutrino reaches the surface of the Sun. At the surface of the Sun $N_e(t_s) = 0$ and therefore $\theta_m(t_s) = \theta$, $|\nu^m_{1,2}(t_s)\rangle \equiv |\nu_{1,2}\rangle$ and $E^m_{1,2}(t_s) = E_{1,2}$. Thus, in this case the state describing the neutrino system at t_0 will evolve continuously into the state $|\nu_2\rangle$ at the surface of the Sun. Using Eq. (14.51) with $l = e$ and $x = \mu$, it is easy to obtain the probabilities to find ν_e and ν_μ at the surface of the Sun:

$$P(\nu_e \to \nu_e; t_s, t_0) \cong |\langle\nu_e|\nu_2\rangle|^2 = \sin^2\theta$$
$$P(\nu_e \to \nu_\mu; t_s, t_0) \cong |\langle\nu_\mu|\nu_2\rangle|^2 = \cos^2\theta\,. \tag{14.79}$$

It is clear that under the assumption made and if $\sin^2\theta \ll 1$, practically a total $\nu_e \to \nu_\mu$ conversion is possible. This type of evolution of the neutrino system and the $\nu_e \to \nu_\mu$ transitions taking place during the evolution, are called [27] "adiabatic." They are characterized by the fact that the probability of the "jump" from the upper "level" (having energy $E^m_2(t)$) to the lower "level" (with energy $E^m_1(t)$), P', or equivalently the probability of the $\nu^m_2(t_0) \to \nu^m_1(t_s)$

transition, $P' \equiv P'(\nu_2^m(t_0) \to \nu_1^m(t_s))$, on the whole neutrino trajectory is negligible:

$$P' \equiv P'(\nu_2^m(t_0) \to \nu_1^m(t_s)) \cong 0 \ : \ \textit{adiabatic transitions}\,. \quad (14.80)$$

The second possibility is realized if in the resonance region, where the two "levels" approach each other most, the system "jumps" from the upper "level" to the lower "level" and after that continues to be in the state $|\nu_1^m(t)\rangle$ until the neutrino reaches the surface of the Sun. Evidently, now we have $P' \equiv P'(\nu_2^m(t_0) \to \nu_1^m(t_s)) \sim 1$. In this case the neutrino system ends up in the state $|\nu_1^m(t_s)\rangle \equiv |\nu_1\rangle$ at the surface of the Sun and

$$P(\nu_e \to \nu_e; t_s, t_0) \cong |\langle \nu_e|\nu_1\rangle|^2 = \cos^2\theta$$
$$P(\nu_e \to \nu_\mu; t_s, t_0) \cong |\langle \nu_\mu|\nu_1\rangle|^2 = \sin^2\theta\,. \quad (14.81)$$

Obviously, if $\sin^2\theta \ll 1$, practically no transitions of the solar ν_e into ν_μ will occur. The considered regime of evolution of the neutrino system and the corresponding $\nu_e \to \nu_\mu$ transitions are usually referred to as "extremely nonadiabatic."

Clearly, the value of the "jump" probability P' plays a crucial role in the the $\nu_e \to \nu_\mu$ transitions: it fixes the type of the transition and determines to a large extent the $\nu_e \to \nu_\mu$ transition probability [153,170,171]. We have considered above two limiting cases. Obviously, there exists a whole spectrum of possibilities since P' can have any value from 0 to $\cos^2\theta$ [172,173]. In general, the transitions are called "nonadiabatic" if P' is non-negligible.

Numerical studies have shown [27] that solar neutrinos can undergo both adiabatic and nonadiabatic $\nu_e \to \nu_\mu$ transitions in the Sun and the matter effects can be substantial in the solar neutrino oscillations for 10^{-8} eV$^2 \lesssim \Delta m^2 \lesssim 10^{-4}$ eV^2, $10^{-4} \lesssim \sin^2 2\theta < 1.0$.

The condition of adiabaticity of the solar ν_e transitions in Sun can be written as [153,170]

$$\gamma(t) \equiv \sqrt{2} G_F \frac{(N_e^{res})^2}{|\dot{N}_e(t)|} \tan^2 2\theta \left(1 + \tan^{-2} 2\theta_m(t)\right)^{\frac{3}{2}} \gg 1$$
$$\text{adiabatic transitions}\,, \quad (14.82)$$

while if $\gamma(t) \lesssim 1$ the transitions are nonadiabatic (see also Ref. 173), where $\dot{N}_e(t) \equiv \frac{d}{dt} N_e(t)$. Condition in Eq. (14.82) implies that the $\nu_e \to \nu_{\mu(\tau)}$ transitions in the Sun will be adiabatic if $N_e(t)$ changes sufficiently slowly along the neutrino path. In order for the transitions to be adiabatic, condition in Eq. (14.82) has to be fulfilled at any point of the neutrino's path in the Sun.

14.8.2.2. *The solar ν_e survival probability:*

The system of evolution equations Eq. (14.54) can be solved exactly for N_e changing exponentially, Eq. (14.77), along the neutrino path in the Sun [172,174]. More specifically, the system in Eq. (14.54) is equivalent to one second order differential equation (with appropriate initial conditions). The latter can be shown [175] to coincide in form, in the case of N_e given by Eq. (14.77), with the Schroedinger equation for the radial part of the nonrelativistic wave function of the Hydrogen atom [176]. On the basis of the exact solution, which is expressed in terms of confluent hypergeometric functions, it was possible to derive a complete, simple and very accurate analytic description of the matter-enhanced transitions of solar neutrinos in the Sun for any values of Δm^2 and θ [26,172,173,177,178] (see also Refs. [27,153,171,179,180]) .

The probability that a ν_e, produced at time t_0 in the central part of the Sun, will not transform into $\nu_{\mu(\tau)}$ on its way to the surface of the Sun (reached at time t_s) is given by

$$P_\odot^{2\nu}(\nu_e \to \nu_e; t_s, t_0) = \bar{P}_\odot^{2\nu}(\nu_e \to \nu_e; t_s, t_0) + \ \textit{Oscillating terms}. \quad (14.83)$$

Here

$$\bar{P}_\odot^{2\nu}(\nu_e \to \nu_e; t_s, t_0) \equiv \bar{P}_\odot = \frac{1}{2} + \left(\frac{1}{2} - \mathrm{P}'\right) \cos 2\theta_m(t_0) \cos 2\theta\ , \quad (14.84)$$

is the average survival probability for ν_e having energy $\mathrm{E} \cong \mathrm{p}$ [171], where

$$P' = \frac{\exp\left[-2\pi \mathrm{r}_0 \frac{\Delta m^2}{2E} \sin^2\theta\right] - \exp\left[-2\pi \mathrm{r}_0 \frac{\Delta m^2}{2E}\right]}{1 - \exp\left[-2\pi \mathrm{r}_0 \frac{\Delta m^2}{2E}\right]}\,, \quad (14.85)$$

is [172] the "jump" probability for exponentially varying N_e, and $\theta_m(t_0)$ is the mixing angle in matter at the point of ν_e production [179]. The expression for $\bar{P}_\odot^{2\nu}(\nu_e \to \nu_e; t_s, t_0)$ with P' given by Eq. (14.85) is valid for $\Delta m^2 > 0$, but for both signs of $\cos 2\theta \neq 0$ [172,180]; it is valid for any given value of the distance along the neutrino trajectory and does not take into account the finite dimensions of the region of ν_e production in the Sun. This can be done by integrating over the different neutrino paths, *i.e.*, over the region of ν_e production.

The oscillating terms in the probability $P_\odot^{2\nu}(\nu_e \to \nu_e; t_s, t_0)$ [177,175] were shown [178] to be strongly suppressed for $\Delta m^2 \gtrsim 10^{-7}$ eV^2 by the various averagings one has to perform when analyzing the solar neutrino data. The current solar neutrino and KamLAND data suggest that $\Delta m^2 \cong 7.4 \times 10^{-5}$ eV^2. For $\Delta m^2 \gtrsim 10^{-7}$ eV^2, the averaging over the region of neutrino production in the Sun *etc.* renders negligible all interference terms which appear in the probability of ν_e survival due to the $\nu_e \leftrightarrow \nu_{\mu(\tau)}$ oscillations in vacuum taking place on the way of the neutrinos from the surface of the Sun to the surface of the Earth. Thus, the probability that ν_e will remain ν_e while it travels from the central part of the Sun to the surface of the Earth is effectively equal to the probability of survival of the ν_e while it propagates from the central part to the surface of the Sun and is given by the average probability $\bar{P}_\odot(\nu_e \to \nu_e; t_s, t_0)$ (determined by Eq. (14.84) and Eq. (14.85)).

If the solar ν_e transitions are adiabatic ($P' \cong 0$) and $\cos 2\theta_m(t_0) \cong -1$ (*i.e.*, $N_e(t_0)/|N_e^{res}| \gg 1, |\tan 2\theta|$, the ν_e are born "above" (in N_e) the resonance region), one has [27]

$$\bar{P}^{2\nu}(\nu_e \to \nu_e; t_s, t_0) \cong \frac{1}{2} - \frac{1}{2}\cos 2\theta. \quad (14.86)$$

The regime under discussion is realized for $\sin^2 2\theta \cong 0.8$ (suggested by the data, Sections 14.2 and 14.9.1), if $E/\Delta m^2$ lies approximately in the range $(2 \times 10^4 - 3 \times 10^7)$ MeV/eV^2 (see Ref. 173). This result is relevant for the interpretation of the Super-Kamiokande and SNO solar neutrino data. We see that depending on the sign of $\cos 2\theta \neq 0$, $\bar{P}^{2\nu}(\nu_e \to \nu_e)$ is either bigger or smaller than 1/2. It follows from the solar neutrino data that in the range of validity (in $E/\Delta m^2$) of Eq. (14.86) we have $\bar{P}^{2\nu}(\nu_e \to \nu_e) \cong 0.3$. Thus, the possibility of $\cos 2\theta \leq 0$ is ruled out by the data. Given the choice $\Delta m^2 > 0$ we made, the data imply that $\Delta m^2 \cos 2\theta > 0$.

If $E/\Delta m^2$ is sufficiently small so that $N_e(t_0)/|N_e^{res}| \ll 1$, we have $P' \cong 0$, $\theta_m(t_0) \cong \theta$ and the oscillations take place in the Sun as in vacuum [27]:

$$\bar{P}^{2\nu}(\nu_e \to \nu_e; t_s, t_0) \cong 1 - \frac{1}{2}\sin^2 2\theta\,, \quad (14.87)$$

which is the average two-neutrino vacuum oscillation probability. This expression describes with good precision the transitions of the solar *pp* neutrinos (Section 14.9.1). The extremely nonadiabatic ν_e transitions in the Sun, characterized by $\gamma(t) \ll 1$, are also described by the average vacuum oscillation probability (Eq. (14.87)) (for $\Delta m^2 \cos 2\theta > 0$ in this case we have (see *e.g.*, Refs. [172,173]) $\cos 2\theta_m(t_0) \cong -1$ and $P' \cong \cos^2\theta$).

The probability of ν_e survival in the case 3-neutrino mixing takes a simple form for $|\Delta m^2_{31}| \cong 2.5 \times 10^{-3}$ eV$^2 \gg |\Delta m^2_{21}|$. Indeed, for the energies of solar neutrinos $E \lesssim 10$ MeV, N^{res} corresponding to $|\Delta m^2_{31}|$ satisfies $N^{res}_{e31} \gtrsim 10^3$ cm^{-3} N$_\mathrm{A}$ and is by a factor of 10 bigger than N_e in the center of the Sun. As a consequence, the oscillations due to Δm^2_{31} proceed as in vacuum. The oscillation length associated with $|\Delta m^2_{31}|$ satisfies $L^v_{31} \lesssim 10$ km $\ll \Delta R$, ΔR being the dimension of the region of ν_e production in the Sun. We have for the different components of the solar ν_e flux [169] $\Delta R \cong (0.04 - 0.20) R_\odot$. Therefore the averaging over ΔR strongly suppresses the oscillations due to Δm^2_{31} and we get [157,181]:

$$P^{3\nu}_{\odot} \cong \sin^4\theta_{13} + \cos^4\theta_{13}\ P^{2\nu}_{\odot}(\Delta m^2_{21}, \theta_{12}; N_e \cos^2\theta_{13})\,, \qquad (14.88)$$

where $P^{2\nu}_{\odot}(\Delta m^2_{21}, \theta_{12}; N_e\cos^2\theta_{13})$ is given by Eq. (14.83) to Eq. (14.85) in which $\Delta m^2 = \Delta m^2_{21}$, $\theta = \theta_{12}$ and the solar e^- number density N_e is replaced by $N_e\cos^2\theta_{13}$. Thus, the solar ν_e transitions observed by the Super-Kamiokande and SNO experiments are described approximately by:

$$P^{3\nu}_{\odot} \cong \sin^4\theta_{13} + \cos^4\theta_{13}\ \ \sin^2\theta_{12}\,. \qquad (14.89)$$

The data show that $P^{3\nu}_{\odot} \cong 0.3$, which is a strong evidence for matter effects in the solar ν_e transitions [182] since in the case of oscillations in vacuum $P^{3\nu}_{\odot} \cong \sin^4\theta_{13} + (1 - 0.5\sin^2 2\theta_{12})\cos^4\theta_{13} \gtrsim 0.53$, where we have used $\sin^2\theta_{13} \lesssim 0.0246$ and $\sin^2 2\theta_{12} \lesssim 0.915$ (see Section 14.2).

The analytic expression for the solar ν_e survival probability, Eq. (14.88), with $P^{2\nu}_{\odot}(\Delta m^2_{21}, \theta_{12}; N_e\cos^2\theta_{13})$ given by Eq. (14.83) to Eq. (14.85) and the prescriptions described above, provides a particularly precise description of the solar ν_e survival (and transitions) in the Sun - the results differ by a few percent from those obtained by solving numerically the relevant system of evolution equations using the electron number density distribution in the Sun provided by the standard solar models - if one uses as input in the calculations a "running" value of the scale-height r_0 [173], *i.e.*, if for each given values of $E/\Delta m^2_{21}$ and θ_{12} one finds the resonance density $N^{res} = N^{res}(E/\Delta m^2_{21}, \theta_{12})$, calculates the scale-height parameter $r_0 = N_e(r)/(dN_e(r)/dr)$ at the point in the Sun where $N_e\cos^2\theta_{13} = N^{res}(E/\Delta m^2_{21}, \theta_{12})$ employing the solar electron number density distribution $N_e = N_e(r)$ given by the standard solar models [169], r being the distance from the center of the Sun.

14.8.2.3. *The day-night asymmetry:*

When the solar neutrinos reaching a detector travel through the Earth at night, a partial regeneration of the flux of the solar ν_e is possible due to the inverse Earth matter-enhanced process [183,184] $\nu_{\mu(\tau)} \to \nu_e$. This can lead to a difference between the solar neutrino induced charged current day and night event rates in the detector, R_D and R_N, *i.e.*, to a non-zero day-night asymmetry $A_{D-N} = 2(R_D - R_N)/(R_D + R_N)$. An observation of $A_{D-N} \neq 0$ will be an unambiguous proof of the presence of Earth matter effects in the transitions of solar neutrinos taking place when the neutrinos traverse the Earth: in the absence of the effects of the Earth matter we have $A_{D-N} = 0$.

In the case of two-neutrino mixing, *i.e.*, neglecting the effects of the non-zero $\sin\theta_{13}$, the probability that an electron neutrino produced in the Sun will not be converted into $\nu_{\mu(\tau)}$ when it propagates in the Sun and traverses the Earth on the way to the detector is given by the following simple expression [183]:

$$P^{2\nu}_{SE}(\nu_e \to \nu_e) = \bar{P}^{2\nu}_{\odot}(\nu_e \to \nu_e) + (1 - 2\,\bar{P}^{2\nu}_{\odot}(\nu_e \to \nu_e))\,\frac{P_{e2} - \sin^2\theta_{12}}{\cos 2\theta_{12}}\,, \qquad (14.90)$$

where $\bar{P}^{2\nu}_{\odot}(\nu_e \to \nu_e)$ is the average probability of solar ν_e survival in the Sun given in Eq. (14.84) and Eq. (14.85) (with $\theta = \theta_{12}$ and $\Delta m^2 = \Delta m^2_{21} > 0$) and $P_{e2} = |A(\nu_2 \to \nu_e)|^2$ is the probability of the $\nu_2 \to \nu_e$ transition after the ν_e have left the Sun, *i.e.*, of the $\nu_2 \to \nu_e$ transition in the Earth. For solar neutrinos crossing only the Earth mantle along a trajectory with nadir angle θ_n, the amplitude $A(\nu_2 \to \nu_e)$ in the constant density approximation, has the form:

$$A(\nu_2 \to \nu_e) = \sin\theta_{12} + (e^{-i\varphi^{man}} - 1)\cos(\theta_{12} - \theta^{man}_{12})\sin\theta^{man}_{12}\,, \qquad (14.91)$$

where $\varphi^{man} = (E^m_2 - E^m_1)^{man} 2L^{man}$, $(E^m_2 - E^m_1)^{man}$ being the relevant difference of the energies of the two matter-eigenstate neutrinos in the Earth mantle and θ^{man}_{12} is the mixing angle in the mantle which coincides in vacuum with θ_{12}. The quantities $(E^m_2 - E^m_1)^{man}$ and θ^{man}_{12} can be obtained from Eq. (14.59) and Eq. (14.57) by setting $\theta = \theta_{12}$, $\Delta m^2 = \Delta m^2_{21}$, $N^{res}_e = N^{res}_{e21} = \Delta m^2_{21}\cos 2\theta_{12}/(2E\sqrt{2}G_F)$ and $N_e = \tilde{N}^{man}_e(\theta_n)$. The two layer constnat density approximation expressions for $A(\nu_2 \to \nu_e)$ and P_{e2} for solar neutrinos crossing the Earth core at night were derived and can be found in Ref. 154.

During the day, when the neutrinos do not cross the Earth, $P_{e2} = \sin^2\theta_{12}$ and we have $P^{2\nu}_{SE}(\nu_e \to \nu_e) = \bar{P}^{2\nu}_{\odot}(\nu_e \to \nu_e)$. For Earth crossing neutrinos at night $P_{e2} \neq \sin^2\theta_{12}$ due to the Earth matter effect and $P^{2\nu}_{SE}(\nu_e \to \nu_e) \neq \bar{P}^{2\nu}_{\odot}(\nu_e \to \nu_e)$.

Detailed calculations of the day-night asymmetry $A_{D-N} \neq 0$ for the solar neutrino detectors Super-Kamiokande, SNO and BOREXINO have been performed, *e.g.*, in Refs. [185]. In Refs. [186] the effects of a $\theta_{13} \neq 0$ on the predictions for the asymmetry A_{D-N} were taken into account. The results of these calculations showed that for the experimentally determined current values of Δm^2_{21} and θ_{12}, the predicted values of the asymmetry A_{D-N} for the SNO and BOREXINO experiments are below the sensitivity of these experiments. For the Super-Kamiokande detector an asymmetry $A_{D-N} \sim -3\%$ was predicted.

14.9. Neutrino oscillation experiments

14.9.1. ***Solar neutrino experiments*** :

So far, solar neutrinos have been observed by chlorine (Homestake) [6] and gallium (SAGE [8], GALLEX [9,10], and GNO [11]) radiochemical detectors, water Cherenkov detectors using light water (Kamiokande [187,7] and Super-Kamiokande [188–191]) and heavy water (SNO [13,14,192,193]) , and liquid scintillation detectors (Borexino [194–198] and KamLAND [199,200]) .

A pioneering solar neutrino experiment by R. Davis, Jr. and collaborators at Homestake using the ^{37}Cl - ^{37}Ar method proposed by B. Pontecorvo [201] started in the late 1960s. This experiment exploited ν_e absorption on ^{37}Cl nuclei followed by the produced ^{37}Ar decay through orbital e^- capture,

$$\nu_e + {}^{37}\mathrm{Cl} \to {}^{37}\mathrm{Ar} + e^-\ \ (\text{threshold } 814 \text{ keV}). \qquad (14.92)$$

Note that ν_e absorption reactions on nuclei are CC reactions. The detector contained 615 tons of tetrachloroethylene, C_2Cl_4. The ^{37}Ar atoms produced are radioactive, with a half life ($\tau_{1/2}$) of 34.8 days. After an exposure of the detector for two to three times $\tau_{1/2}$, the reaction products were chemically extracted and introduced into a low-background proportional counter, where they were counted for a sufficiently long period to determine the exponentially decaying signal and a constant background. Solar-model calculations predict that the dominant contribution in the chlorine experiment came from ^{8}B neutrinos, the second to the dominant from ^{7}Be neutrinos, with *pep*, ^{13}N, and ^{15}O neutrinos also giving additional subdominant contributions.

Gallium experiments (GALLEX and GNO at Gran Sasso in Italy and SAGE at Baksan in Russia) utilized the reaction

$$\nu_e + {}^{71}\mathrm{Ga} \to {}^{71}\mathrm{Ge} + e^-\ \ (\text{threshold } 233 \text{ keV}), \qquad (14.93)$$

which is sensitive to the most abundant *pp* solar neutrinos. The solar-model calculations predict that more than 80% of the capture rate in gallium is due to low energy *pp* and ^{7}Be solar neutrinos with the *pp* rate being about twice the ^{7}Be rate. The ^{71}Ge atoms decay through electron capture with a half life ($\tau_{1/2}$) of 11.43 days. SAGE used approximately 50 tons of liquid gallium metal as a a target. GALLEX used 101 tons of $GaCl_3$, containing 30.3 tons of gallium. Both experiments used natural gallium, containing 39.9% of ^{71}Ga isotope. SAGE started measurement from December, 1989. GALLEX experiment had been conducted between 1991 and 1997. Since April, 1998, a newly defined collaboration, GNO (Gallium Neutrino Observatory) continued the gallium experiment at Gran Sasso until April 2003.

Both GALLEX [202] and SAGE [203] tested their detectors using intense ^{51}Cr radioactive sources with known activities. Low energy neutrinos relevant to test the gallium experiments (~ 750 keV and ~ 320 keV neutrinos) are emitted from decays of ^{51}Cr.

In 1987, the Kamiokande experiment at Kamioka in Japan succeeded in real-time solar neutrino observation, utilizing νe scattering,

$$\nu_x + e^- \to \nu_x + e^-\,, \qquad (14.94)$$

in a 3,000-ton water-Cherenkov detector. This experiment took advantage of the directional correlation between the incoming neutrino and the recoil electron. This feature greatly helps the clear separation of the solar-neutrino signal from the background. The Kamiokande result gave the first direct evidence that neutrinos come from the direction of the Sun [187]. In 1996, the high-statistics Super-Kamiokande experiment [188–191] with a 50-kton water Cherenkov detector replaced the Kamiokande experiment. Due to the high thresholds (recoil-electron total energy of 7 MeV in Kamiokande and 4 MeV at present in Super-Kamiokande) the experiments observe pure ^{8}B solar neutrinos. It should be noted that the reaction (Eq. (14.94)) is sensitive to all active neutrinos, $x = e$, μ, and τ. However, the sensitivity to ν_μ and ν_τ is smaller than the sensitivity to ν_e since $\sigma(\nu_{\mu,\tau}e) \approx 0.16\,\sigma(\nu_e e)$.

In 1999, a new real time solar-neutrino experiment, SNO (Sudbury Neutrino Observatory), in Canada started observation. This experiment used 1000 tons of ultra-pure heavy water (D_2O) contained in a spherical acrylic vessel, surrounded by an ultra-pure H_2O shield. SNO measured ^{8}B solar neutrinos via the CC and NC reactions

$$\nu_e + d \to e^- + p + p \qquad \text{(CC)}\,, \tag{14.95}$$

and

$$\nu_x + d \to \nu_x + p + n \qquad \text{(NC)}\,, \tag{14.96}$$

as well as νe scattering, (Eq. (14.94)). The CC reaction, (Eq. (14.95)), is sensitive only to ν_e, while the NC reaction, (Eq. (14.96)), is sensitive to all active neutrinos. This is a key feature to solve the solar neutrino problem. If it is caused by flavour transitions such as neutrino oscillations, the solar neutrino fluxes measured by CC and NC reactions would show a significant difference.

The Q-value of the CC reaction is -1.4 MeV and the e^- energy is strongly correlated with the ν_e energy. Thus, the CC reaction provides an accurate measure of the shape of the ^{8}B neutrino spectrum. The contributions from the CC reaction and νe scattering can be distinguished by using different $\cos\,\theta$ distributions, where θ is the angle of the e^- momentum with respect to the Sun-Earth axis. While the νe scattering events have a strong forward peak, CC events have an approximate angular distribution of $(1 - 1/3\,\cos\theta)$.

The neutrino energy threshold of the NC reaction is 2.2 MeV. In the pure D_2O [13,14], the signal of the NC reaction was neutron capture in deuterium, producing a 6.25-MeV γ-ray. In this case, the capture efficiency was low and the deposited energy was close to the detection threshold of 5 MeV. In order to enhance both the capture efficiency and the total γ-ray energy (8.6 MeV), 2 tons of NaCl was added to the heavy water in the second phase of the experiment [192]. Subsequently NaCl was removed and an array of ^{3}He neutron counters were installed for the third phase measurement [193]. These neutron counters provided independent NC measurement with different systematics from that of the second phase, and thus strengthened the reliability of the NC measurement. The SNO experiment completed data acquisition in 2006.

Another real time solar neutrino experiment, Borexino at Gran Sasso, started solar neutrino observation in 2007. This experiment measures solar neutrinos via νe scattering in 300 tons of ultra-pure liquid scintillator. With a detection threshold as low as 250 keV, the flux of monochromatic 0.862 MeV ^{7}Be solar neutrinos has been directly observed for the first time [194]. Further, Borexino measured the fluxes of monochromatic 1.44 MeV *pep* solar neutrinos [195] and pp solar neutrinos [196], both for the first time. Measurements of these low energy solar neutrinos are important not only to test the SSM further, but also to study the MSW effect over the energy region spanning from sub-MeV to 10 MeV.

KamLAND is a 1-kton ultra-pure liquid scintillator detector located at the old Kamiokande's site. Recently this experiment also measured the ^{7}Be solar neutrino flux [199]. As KamLAND is a multi-purpose experiment with one of the primary goals to be a long-baseline neutrino oscillation studies using electron antineutrinos emitted from nuclear power reactors, further description of the KamLAND experiment is given later in Section 14.9.4.

14.9.2. ***Atmospheric neutrino oscillation experiments*** :

Almost all large underground detectors can observe atmospheric neutrinos. In the early history of neutrino oscillation studies using atmospheric neutrinos, water Cherenkov detectors for Kamiokande [204,205] and IMB [206] (experiment in the US) and iron tracking calorimeters for the Frejus experiment [207] in France and the Soudan 2 experiment [208] at the Soudan mine in the US, measured atmospheric neutrinos, in particular, the $\Phi(\nu_\mu + \bar\nu_\mu)/\Phi(\nu_e + \bar\nu_e)$ ratio. The main purpose of all these experiments was search for nucleon decay, and atmospheric neutrinos were backgrounds for the main purpose. Following these initial experiments, Super-Kamiokande discovered the atmospheric neutrino oscillation [17], and a multi-purpose detector MACRO [209] at Gran Sasso obtained results consistent with neutrino oscillation. Later, the far detector of the MINOS long baseline neutrino oscillation experiment also measured atmospheric neutrinos [210], and obtained results consistent with atmospheric neutrino oscillation. This detector is a 5.4 kton iron-scintillator tracking calorimeter with toroidal magnetic field.

Atmospheric neutrino oscillations have also been observed by the neutrino telescopes for high-energy neutrino astronomy (TeV $\sim$ PeV) using Cherenkov technique, ANTARES and IceCube-DeepCore, based on the measurement of ν_μ charged-current events having an upward-going muon track to avoid contamination from atmospheric muon background. ANTARES [211] is an open water detector deployed deep under the Mediterranean Sea (depth $\sim$ 2500 m) 40 km off-shore from Toulon, France, while IceCube [212] is a detector deployed in the ice at the South Pole at the depth from 1450 m to 2450 m. Though both experiments are optimized to high-energy neutrino interactions in the TeV range, they need to measure muon neutrinos with energies as low as $\sim$ 20 GeV in order to be sensitive to atmospheric neutrino oscillations. ANTARES could reconstruct upward-going muons from ν_μ interactions down to 20 GeV [213], while IceCube used the low-energy sub-detector DeepCore, a region of denser IceCube instrumentation, to lower the muon neutrino energy threshold down to 10 GeV [214] (also see Ref. 215 with 20 GeV threshold).

All these detectors, with the exception of the MINOS far detector, cannot measure the charge of the final-state leptons, and, therefore, neutrino and antineutrino induced events cannot be discriminated; the MINOS far detector can measure the charge of the muon track, and, therefore, identify ν_μ and $\bar\nu_\mu$ charged-current events. However, all these detectors can identify the final-state leptons to be μ-like or e-like. Taking Super-Kamiokande as an example, neutrino events having their vertex in the 22.5 kton fiducial volume are classified into fully contained (FC) events and partially contained (PC) events. The FC events are required to have no activity in the anti-counter. Single-ring events have only one charged lepton which radiates Cherenkov light in the final state, and particle identification is particularly clean for single-ring FC events. A ring produced by an e-like ($e^\pm$, γ) particle exhibits a more diffuse pattern than that produced by a μ-like ($\mu^\pm$, $\pi^\pm$) particle, since an e-like particle produces an electromagnetic shower and low-energy electrons suffer considerable multiple Coulomb scattering in water. All the PC events are assumed to be μ-like since the PC events comprise a 98% pure charged-current ν_μ sample.

In the near future, Super-Kamiokande and the MINOS (now MINOS+ [216]) far detector will continue atmospheric neutrino measurements. In addition, currently several large underground detectors are proposed for construction (liquid argon detectors with a total mass of 10 - 40 kton as the far detector of the DUNE experiment [84] in the US, and a 1 Mton water Cherenkov detector, Hyper-Kamiokande [165], as the far detector of the T2HK experiment [85] in Japan) or approved (a 50 kton magnetized iron tracking calorimeter, ICAL at the INO (India-based Neutrino Observatory) [219] in the southern Indian state of Tamil Nadu).

As high-statistics atmospheric neutrino observations in the energy region of a few to $\sim$ 10 GeV are considered to be promising for the determination of the neutrino mass ordering, see Section 14.8, there are two proposed densely-instrumented neutrino telescopes PINGU (Precision IceCube Next-Generation Upgrade) [220] and ORCA (Oscillation Research with Cosmics in the Abyss) [221], both having a multi-megaton total mass. PINGU will be deployed inside

the DeepCore, and will be sensitive to > 1 GeV. ORCA is proposed as part of the second phase of the KM3NeT [222], a network of neutrino telescopes deep under the Mediterranean Sea. ORCA will have sensitivity down to a few GeV, its site being Toulon, France.

14.9.3. *Accelerator neutrino oscillation experiments* :

For earlier accelerator neutrino oscillation experiments before the discovery of the atmospheric neutrino oscillation, see, *e.g.*, Ref. 223. The $\Delta m^2 \geq 2 \times 10^{-3}$ eV^2 region can be explored by accelerator-based long-baseline experiments with typically $E \sim 1$ GeV and $L \sim$ several hundred km. With a fixed baseline distance and a narrower, well understood neutrino energy spectrum, the value of $|\Delta m^2_{31(32)}|$ and, with higher statistics, also the relevant neutrino mixing angle, are potentially better constrained in accelerator experiments than from atmospheric neutrino observations. With $\nu_\mu \to \nu_e$ appearance measurements, accelerator long-baseline experiments can measure θ_{13} within an uncertainty related, in particular, to the CP-violating phase δ. Using precise results on θ_{13} from reactor experiments, they can potentially determine or constrain δ and the neutrino mass ordering, depending on the experimental conditions such as baseline distance. K2K [19], MINOS [20,21] and MINOS+ [216], OPERA [141,142], ICARUS [224], T2K [23,22], and NOνA [55,56] are completed or currently running experiments, and DUNE [84] and T2HK [85] are proposed future experiments.

The K2K (KEK-to-Kamioka) long-baseline neutrino oscillation experiment [19] is the first accelerator-based experiment with a neutrino path length extending hundreds of kilometers. A horn-focused wide-band muon neutrino beam having an average $L/E_\nu \sim 200$ ($L = 250$ km, $\langle E_\nu \rangle \sim 1.3$ GeV), was produced by 12-GeV protons from the KEK-PS and directed to the Super-Kamiokande detector. A near detector was located 300 m downstream of the production target. K2K experiment started data-taking in 1999 and was completed in 2004.

MINOS [20,21] is the second long-baseline neutrino oscillation experiment with near and far detectors. Neutrinos are produced by the NuMI (Neutrinos at the Main Injector) facility using 120 GeV protons from the Fermilab Main Injector. The far detector is a 5.4 kton (total mass) iron-scintillator tracking calorimeter with toroidal magnetic field, located underground in the Soudan mine. The baseline distance is 735 km. The near detector, located 1.04 km downstream of the production target, is also an iron-scintillator tracking calorimeter with toroidal magnetic field, with a total mass of 0.98 kton. The NuMI neutrino beam is a horn-focused wide-band beam. Its energy spectrum can be varied by moving the target position relative to the first horn and changing the horn current. MINOS started the neutrino-beam run in 2005 and was completed in 2012. Almost all the MINOS data were taken with the low-energy beam spectrum which peaked at 3 GeV. Part of the MINOS data were taken with the $\bar{\nu}_\mu$-enhanced beam by inverting the current in magnetic horns. In September, 2013, the MINOS+ experiment [216] started with the same near and far detectors as the MINOS experiment, but with the medium-energy beam spectrum which peaks at 7 GeV. At zero degree, the NuMI medium-energy beam has much higher intensity than the NuMI low-energy beam.

The T2K experiment [22,23] is the first off-axis long-baseline neutrino oscillation experiment. The baseline distance is 295 km between the J-PARC in Tokai, Japan and Super-Kamiokande. A narrow-band ν_μ beam with a peak energy of 0.6 GeV, produced by 30 GeV protons from the J-PARC Main Ring, is directed 2.5° off-axis to SK. With this configuration, the ν_μ beam is tuned to the first oscillation minimum of the ν_μ survival probability. T2K started the first physics run in 2010.

The NOνA experiment [55,56] is an off-axis long-baseline neutrino oscillation experiment using the the NuMI medium-energy beam. Its detectors are positioned 14 mrad off-axis. With this configuration, the neutrino beam has a narrow spectrum which peaks at 2 GeV. The 14 kton far detector is located on the surface at Ash River, Minnesota, 810 km from the production target. The 0.3 kton near detector is located underground at Fermilab, approximately 1km from the target. Both detectors are fine-grained tracking calorimeters consisting of arrays of PVC cells filled with liquid scintillator. NOνA started full operation in October, 2014.

Although the atmospheric neutrino oscillations and accelerator long-baseline ν_μ disappearance data are fully consistent with the dominance of $\nu_\mu \to \nu_\tau$ oscillations for ν_μ at GeV energies, ν_τ appearance in the muon neutrino beam has to be demonstrated. As the τ production threshold is $E_\nu \sim 3.5$ GeV, a high-energy neutrino beam is needed for this purpose. The only experiment of this kind is OPERA [141,142] with a muon neutrino source at CERN and a detector at Gran Sasso with the baseline distance of 730 km. OPERA does not have a near detector. The CNGS (CERN Neutrinos to Gran Sasso) neutrino beam with $\langle E_\nu \rangle = 17$ GeV is produced by high-energy protons from the CERN SPS. OPERA received the CNGS neutrino beam between 2008 and 2012. The detector is a combination of the "Emulsion Cloud Chamber" and magnetized spectrometer, having a target mass of 1,290 tons. At Gran Sasso, another neutrino experiment, ICARUS [224], with a 600-ton liquid argon detector, was located and received the CNGS neutrino beam from 2010 to 2012. The ICARUS detector will be transported to Fermilab by 2017, and will be used in a short baseline experiment.

DUNE (Deep Underground Neutrino Experiment) [84] is a projected future experiment with a 1,300 km baseline. A $10 \sim 34$ kton liquid-argon far detector will be located deep underground at the Sanford Lab in South Dakota, the U.S. A fine-grained near neutrino detector will be installed at Fermilab. Based on the existing NuMI beamline and a MW class proton source, a wide-band, high-intensity ν_μ beam with a peak flux at 2.5 GeV is considered for this experiment. T2HK [85] is another future long baseline experiment from J-PARC to the 1 Mton water Cherenkov detector, Hyper-Kamiokande [165], which is at the proposal stage, at Kamioka. An upgrade of the J-PARC Main Ring to achieve a MW-class beam power is also proposed.

In the context of possible hints for the existence of sterile neutrinos at the eV scale, short-baseline accelerator neutrino oscillation experiments have been drawing attention. LSND [225], Karmen 2 (and Karmen 1) [226], and MiniBooNE [227,228] are completed experiments. New short-baseline experiments, MicroBooNE, SBND, and ICARUS are in preparation at Fermilab [229]. The detectors of all these new experiments use liquid-argon TPC technology.

The LSND (Liquid Scintillation Neutrino Detector) experiment [225] used the LANSE (Los Alamos Neutron Science Center, formerly known as the LAMPF) 800 MeV proton linac as a neutrino source. At this energy, kaon production is negligible. Most of the produced positive pions stop in the massive target and decay at rest, with decay muons also stop in the target and decay. Most of the produced negative pions also stop in the target and are absorbed by the target nuclei. Therefore, this neutrino source emits ν_μ, $\bar{\nu}_\mu$, and ν_e, with very small contamination of $\bar{\nu}_e$ which comes from π^- decay in flight followed by the μ^- decay at rest. Because of this small $\bar{\nu}_e$ component in the neutrino flux, LSND made a sensitive search for $\bar{\nu}_\mu \to \bar{\nu}_e$ appearance with 167 tons of diluted liquid scintillator in a tank located about 30 m from the neutrino source, using the reaction $\bar{\nu}_e + p \to e^+ + n$. Also, LSND studied $\nu_\mu \to \nu_e$ appearance above the Michel electron endpoint energy using the reaction $\nu_e + C \to e^- + N$, as the ν_e flux from μ^+ decay in flight is suppressed due to the long muon lifetime and that from π^+ decay in flight is suppressed by the small $\pi^+ \to e^+ + \nu_e$ branching ratio. The Karmen 2 experiment [226] used the 800 MeV proton synchrotron at the neutron spallation facility of the Rutherford Appleton Laboratory, also to produce low-energy $\bar{\nu}_\mu$ flux from μ^+ decay at rest. The Karmen 2 detector is a segmented liquid scintillator calorimeter located at a distance of 17.7 m from the neutrino source. MiniBooNE used a conventional horn-focused neutrino beam produced by 8 GeV protons from the Fermilab booster synchrotron. MiniBooNE investigated both ν_e [227] and $\bar{\nu}_e$ [228] appearance in ν_μ and $\bar{\nu}_\mu$ beams, respectively, with a detector containing 806 tons of mineral oil and located 541 m downstream of the production target.

14.9.4. *Reactor neutrino oscillation experiments* :

As the relevant energy range of the events detected in the reactor experiment is < 10 MeV, detection of a prompt positron signal and delayed neutron signal in coincidence is important to identify the inverse β-decay, rejecting natural backgrounds. For detecting neutrons effectively, gadolinium-loaded liquid scintillator is widely used. While neutron capture on a hydrogen produces a 2.2 MeV γ, neutron capture on Gd produces multiple γ, each having average energy of ~ 2 MeV, giving a ~ 8 MeV signal in total.

For short baseline reactor $\bar{\nu}_e$ neutrino oscillation experiments in 1980s or earlier, see, *e.g.*, Refs. [230,46]. Reactor $\bar{\nu}_e$ disappearance experiments with $L \sim 1$ km, $\langle E \rangle \sim 3$ MeV are sensitive to $E/L \sim 3 \times 10^{-3}$ eV$^2 \sim |\Delta m^2_{31(32)}|$. At this baseline distance, the reactor $\bar{\nu}_e$ oscillations driven by Δm^2_{21} are negligible. Therefore, as can be seen from Eq. (14.44) and Eq. (14.46), θ_{13} can be directly measured. An experiment at the Chooz Nuclear Power Station in France [51] was the first experiment of this kind. The detector was located in an underground laboratory with 300 mwe (meter water equivalent) rock overburden, at about 1 km from the neutrino source. It consisted of a central 5-ton target filled with 0.09% Gd-loaded liquid scintillator, surrounded by an intermediate 17-ton and outer 90-ton regions filled with Gd-free liquid scintillator. Another experiment at the Palo Verde Nuclear Generating Station in Arizona, United States, also searched for $\bar{\nu}_e$ disappearance using 11.34 tons of Gd-loaded liquid scintillator located at a shallow (32 mwe) underground site, about 800 m from the neutrino source [231].

Although these two experiments in the late 1990s had found no evidence for $\bar{\nu}_e$ disappearance, after establishment of atmospheric and solar neutrino oscillations the importance of the reactor neutrino oscillation experiment to measure θ_{13} was widely recognized, and this led to the realization of the three new reactor experiments, Double Chooz in France, RENO in Korea, and Daya Bay in China. The Double Chooz experiment [30,33] measures electron antineutrinos from two 4.25 GW$_{\rm th}$ reactors with a far detector at an average distance of 1050 m from the two reactor cores. The Daya Bay experiment [31,35] measures $\bar{\nu}_e$s from the Daya Bay nuclear power complex (six 2.9 GW$_{\rm th}$ reactors), initially with six functionally identical detectors deployed in two near (470 m and 576 m of flux-weighted baselines) and one far (1648 m) underground halls. The first Daya Bay result [31] was obtained with this detector configuration. Later, two detectors were further installed, one in one of the near detector hall and the other in the far detetor hall. The RENO experiment [32] measures electron antineutrinos from four 2.8 GW$_{\rm th}$ and two 2.66 GW$_{\rm th}$ reactors at Yonggwang Nuclear Power Plant with two identical detectors located at 294 m and 1383 m from the reactor array center (or flux-weighted baseline distance of 408.56 m and 1443.99 m, respectively). Antineutrino detectors of these experiments have similar structures. They consist of three layers and an optically independent outer veto detector. The innermost layer of the antineutrino detector is filled with Gd-loaded liquid scintillator, which is surrounded by a "γ-catcher" layer filled with Gd-free liquid scintillator, and outside the γ-catcher is a buffer layer filled with mineral oil. An outer veto detector is filled with purified water (Daya Bay and RENO) or liquid scintillator (Double Chooz). In addition, the Double Chooz near detector tank is shielded by a 1 m thick water buffer. RENO and Daya Bay started measurements with both the near and far detectors from the beginning. However, the Double Chooz near detector has been completed at the end of 2014. All these experiments published their first results on reactor $\bar{\nu}_e$ disappearance in 2012.

For longer baseline distance of $L \sim$ a few hundred km, a reactor neutrino oscillation experiment is sensitive to Δm^2 down to $\sim 10^{-5}$ eV^2. Therefore, such an experiment can test the LMA (Large Mixing Angle) solution of the solar neutrino problem, assuming CPT invariance. However, a higher $\bar{\nu}_e$ flux and a larger target mass are needed compared to short-baseline reactor experiments to obtain statistically significant event rate. So far, KamLAND is the only experiment of this kind. It is located at the old Kamiokande's site in Japan. Its neutrino target is 1-kton ultra-pure liquid scintillator contained in a transparent balloon, which is hold inside a spherical tank with buffer oil filled between the baloon and the tank. The tank is surrounded by an outer water Cherenkov detector. Before the Great East Japan Earthquake in March 2011, many nuclear reactors were operating in Japan, and more than 79% of the $\bar{\nu}_e$ flux at KamLAND was coming from 26 reactors between 138 - 214 km away, with a flux-weighted average distance of ~ 180 km.

In future, medium baseline (~ 50 km) reactor neutrino oscillation experiments with neutrino target mass of ~ 20 kton and with a very good energy resolution of $3\%/\sqrt{E_\nu(\mathrm{MeV})}$, not reached in any previous experiment with liquid scintillator, are aiming, in particular, to determine the type of spectrum the neutrino masses obey, *i.e.*, the neutrino mass ordering (see Section 14.2). These experiments have additional rich physics program. The Jiangmen Underground Neutrino Observatory (JUNO) [232] at Kaiping, Jiangmen in Southern China will be located at 53 km from both of the planned Yangjiang and Taishan nuclear power plants. The neutrino target of this experiment will be 20 kton liquid scintillator. JUNO is a funded project, and its construction started in January, 2015. A similar experiment, RENO50 [127], is also proposed in Korea.

14.10. Results of solar neutrino experiments and KamLAND

In 1967, analyzing the possible effects of neutrino oscillations on the solar neutrino flux measurements, B. Pontecorvo predicted the solar neutrino "deficit" in experiments detecting solar neutrinos via a CC reaction [1] before the first solar neutrino data were available. The solar-neutrino problem, *i.e.*, the problem of understanding the origin of the observed deficit of solar neutrinos, remained unsolved for more than 30 years since the late 1960s, but solar neutrino experiments have achieved remarkable progress since the beginning of the new century, and the solar-neutrino problem has been understood as due to neutrino flavour conversion.

14.10.1. *Measurements of Δm^2_{21} and θ_{12}* :

From the very beginning of the solar-neutrino observation by the Homestake chlorine experiment [233] in the late 1960s, it was recognized that the observed flux was significantly smaller than the SSM prediction. The subsequent radiochemical solar neutrino experiments using ^{71}Ga, SAGE [234] and GALLEX [9] also reported smaller solar neutrino fluxes than the SSM predictions in the early 1990s. final results of these experiments [235] are compared with the SSM predictions in Table 14.5. Experiments with water Cherenkov detectors, Kamiokande and Super-Kamiokande, observed almost pure ^{8}B solar neutrinos through νe elastic scattering, and they also reported a clear deficit of ^{8}B solar neutrino flux.

Table 14.5: Results from radiochemical solar-neutrino experiments. The predictions of the standard solar model BPS08(GS) are also shown. The first and the second errors in the experimental results are the statistical and systematic errors, respectively. SNU (Solar Neutrino Unit) is defined as 10^{-36} neutrino captures per atom per second.

	^{37}Cl→^{37}Ar (SNU)	^{71}Ga→^{71}Ge (SNU)
Homestake [6]	$2.56 \pm 0.16 \pm 0.16$	–
GALLEX [10]	–	$77.5 \pm 6.2^{+4.3}_{-4.7}$
GNO [11]	–	$62.9^{+5.5}_{-5.3} \pm 2.5$
GNO+GALLEX [11]	–	$69.3 \pm 4.1 \pm 3.6$
SAGE [8]	–	$65.4^{+3.1+2.6}_{-3.0-2.8}$
SSM [BPS08(GS)] [100]	$8.46^{+0.87}_{-0.88}$	$127.9^{+8.1}_{-8.2}$

In 2001, the initial SNO CC result combined with the Super-Kamiokande's high-statistics νe elastic scattering result [236] provided direct evidence for flavour conversion of solar neutrinos [13]. Later, SNO's NC measurements further strengthened this conclusion [14,192,193]. From the salt-phase measurement [192], the fluxes

measured with CC, ES, and NC events were obtained as

$$\phi_{\rm SNO}^{\rm CC} = (1.68 \pm 0.06^{+0.08}_{-0.09}) \times 10^6 {\rm cm}^{-2}{\rm s}^{-1} \ , \quad (14.97)$$

$$\phi_{\rm SNO}^{\rm ES} = (2.35 \pm 0.22 \pm 0.15) \times 10^6 {\rm cm}^{-2}{\rm s}^{-1} \ , \quad (14.98)$$

$$\phi_{\rm SNO}^{\rm NC} = (4.94 \pm 0.21^{+0.38}_{-0.34}) \times 10^6 {\rm cm}^{-2}{\rm s}^{-1} \ , \quad (14.99)$$

where the first errors are statistical and the second errors are systematic. In the case of $\nu_e \to \nu_{\mu,\tau}$ transitions, Eq. (14.99) is a mixing-independent result and therefore tests solar models. It shows good agreement with the ^{8}B solar-neutrino flux predicted by the solar model [98]. Fig. 14.8 shows the salt phase result on the $\nu_\mu + \nu_\tau$ flux $\phi(\nu_{\mu,\tau})$ versus the flux of electron neutrinos $\phi(\nu_e)$ with the 68%, 95%, and 99% joint probability contours. The flux of non-ν_e active neutrinos, $\phi(\nu_{\mu,\tau})$, can be deduced from these results. It is

$$\phi(\nu_{\mu,\tau}) = \left(3.26 \pm 0.25^{+0.40}_{-0.35}\right) \times 10^6 {\rm cm}^{-2}{\rm s}^{-1}. \quad (14.100)$$

The non-zero $\phi(\nu_{\mu,\tau})$ is strong evidence for neutrino flavor conversion. These results are consistent with those expected from the LMA (large mixing angle) solution of solar neutrino oscillation in matter [26,27] with $\Delta m^2_{21} \sim 7.5 \times 10^{-5}$ eV^2 and $\tan^2\theta_{12} \sim 0.45$. However, with the SNO data alone, the possibility of other solutions of solar neutrino oscillation in matter cannot be excluded with sufficient statistical significance.

The KamLAND experiment solved this problem and finally identified the LMA solution as the true solution of the solar neutrino problem. With the reactor $\bar{\nu}_e$'s energy spectrum (< 8 MeV) and a prompt-energy analysis threshold of 2.6 MeV, this experiment has a sensitive Δm^2 range down to $\sim 10^{-5}$ eV^2. Therefore, if the LMA solution is the real solution of the solar neutrino problem, KamLAND should observe reactor $\bar{\nu}_e$ disappearance, assuming CPT invariance.

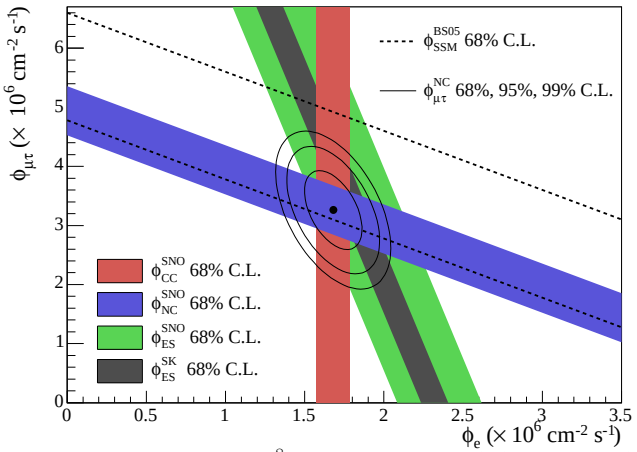

Figure 14.8: Fluxes of ^{8}B solar neutrinos, $\phi(\nu_e)$, and $\phi(\nu_{\mu,\tau})$, deduced from the SNO's CC, ES, and NC results of the salt phase measurement [192]. The Super-Kamiokande ES flux is from Ref. 237. The BS05(OP) standard solar model prediction [98] is also shown. The bands represent the 1σ error. The contours show the 68%, 95%, and 99% joint probability for $\phi(\nu_e)$ and $\phi(\nu_{\mu,\tau})$. The figure is from Ref. 192.

The first KamLAND results [15] with 162 ton·yr exposure were reported in December 2002. The ratio of observed to expected (assuming no $\bar{\nu}_e$ oscillations) number of events was

$$\frac{N_{\rm obs} - N_{\rm BG}}{N_{\rm NoOsc}} = 0.611 \pm 0.085 \pm 0.041 \quad (14.101)$$

with obvious notation. This result showed clear evidence of an event deficit expected from neutrino oscillations. The 95% CL allowed regions are obtained from the oscillation analysis with the observed event rates and positron spectrum shape. A combined global solar + KamLAND analysis showed that the LMA is a unique solution to the solar neutrino problem with $> 5\sigma$ CL [238]. With increased statistics [16,239,240], KamLAND observed not only the distortion of the $\bar{\nu}_e$ spectrum, but also for the first time the periodic dependence on the neutrino energy of the $\bar{\nu}_e$ survival probability expected from neutrino oscillations (see Fig. 14.9).

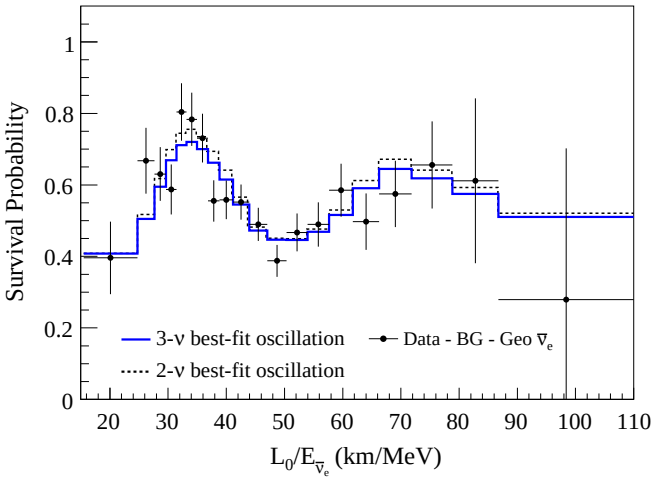

Figure 14.9: The ratio of the background and geoneutrino-subtracted $\bar{\nu}_e$ spectrum, observed in the KamLAND experiment, to the predicted one without oscillations (survival probability) as a function of L_0/E, where L_0=180 km. The histograms show the expected distributions based on the best-fit parameter values from the two- and three-flavor neutrino oscillation analyses. The figure is from Ref. 240.

It should be noted that with accumulation of precise solar neutrino data, analyses using only solar neutrino data [241,242,198] have attained sufficiently high statistical significance ($> 99.73\%$ or $> 3\sigma$ CL) to show the LMA solution to be the real solution to the solar neutrino problem without resorting to the KamLAND data, namely, without assuming CPT invariance, though the allowed Δm^2_{21} range is better determined by the KamLAND data.

The values of Δm^2_{21} and θ_{12} have been frequently updated by experimental groups or by phenomenological analysis groups, using the global solar neutrino data, or the KamLAND data alone, or the global solar + KamLAND data, or the global neutrino oscillation data. The latest global analysis results found in Ref. 60 are shown in Table 14.1.

Regarding the consistency between the KamLAND and solar neutrino experiments on the values of Δm^2_{21} and θ_{12}, it has been noted that there is a $\sim 2\sigma$ level tension between the best-fit value of Δm^2_{21} determined by the KamLAND collaboration and that obtained from analyses using global solar neutrino data [53]. The solar data prefer lower Δm^2_{21} value. The KamLAND and global solar best-fit values of θ_{12} are consistent.

14.10.2. *Solar neutrino flux measurements and indications of matter effects* :

So far, the pp, pep, ^{7}Be, ^{8}B solar neutrino fluxes have been measured, and upper limits have been set for the hep and CNO solar neutrino fluxes, with various techniques. Chlorine (Homestake) and gallium (SAGE, GALLEX, and GNO) radiochemical experiments measured capture rates of solar neutrinos above threshold (see Table 14.5). Light-water Cherenkov detectors, Kamiokande [7] and Super-Kamiokande [189,191], measured the ^{8}B neutrino flux and set an upper limit for the hep neutrino flux using νe elastic scattering [189]. A heavy-water Cherenkov detector, SNO [242], also measured the ^{8}B neutrino flux, but with three different reactions, NC, CC, and νe elastic scattering. Liquid scintillator detectors, Borexino and KamLAND, measured low-energy solar neutrinos using νe elastic

scattering. In particular, Borexino [198] successfully measured the pp [196], pep [195], and ^{7}Be [194] solar neutrino fluxes and set an upper limit for the CNO solar neutrino flux [195]. KamLAND also measured the ^{7}Be solar neutrino flux [199]. In addition, both Borexino [197] and KamLAND [200] measured the ^{8}B neutrino flux. The measured fluxes or upper limits from all these experiments are listed in the Particle Listings of this RPP edition.

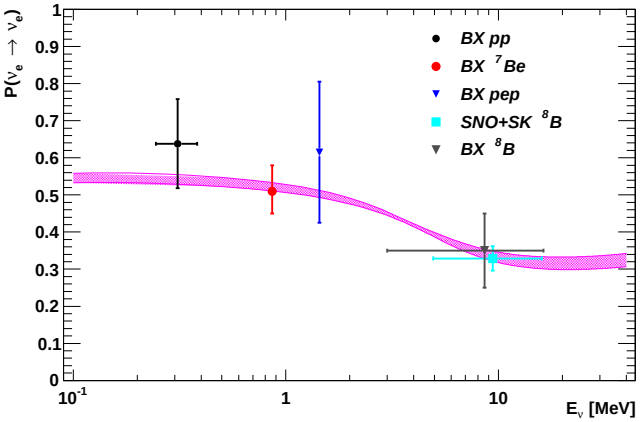

Figure 14.10: Electron neutrino survival probability as a function of neutrino energy according to the MSW-LMA model. The low-energy region (< 1 MeV) of the curve is calculated for pp and ^{7}Be neutrinos, and the high-energy region for ^{8}B neutrinos, using the parameter values given in Ref. 52. The width of the curve reflects $\pm 1\sigma$ uncertainties, determined by a Monte Carlo method sampling errors on parameters [52]. The points represent the Borexino pp, ^{7}Be, pep, and ^{8}B data and the SNO+SK ^{8}B data. This figure is provided by A. Ianni in the name of the BOREXINO Collaboration.

Fig. 14.10 plots the survival probability of solar ν_e as a function of neutrino energy. The data points are from the Borexino results except the SNO+SK ^{8}B data. As explained in Section 14.8.2.2, matter effects on solar neutrino oscillation is expected to be given by the average two-neutrino vacuum oscillation probability, $1 - \frac{1}{2}\sin^2 2\theta_{12}$ for survival of pp neutrinos. It is ~ 0.58 for $\sin^2\theta_{12} = 0.297$. For ^{8}B neutrinos, transitions are adiabatic and the survival probability is given by $\sin^4\theta_{13} + \cos^4\theta_{13}\sin^2\theta_{12} \sim 0.28$ for $\sin^2\theta_{13} = 0.0214$ (for normal mass ordering) and $\sin^2\theta_{12} = 0.297$. All the data shown in this plot are consistent with the theoretically calculated curve. This indicates that these solar neutrino results are consistent with the MSW-LMA solution of the solar neutrino problem.

In the nighttime, solar neutrino experiments observe neutrinos propagated through the Earth. Therefore, a non-zero day-night flux (or interaction rate) asymmetry implies the Earth matter effects on flavour oscillations of solar neutrinos. In particular, if the nighttime flux is higher than the daytime flux, it implies a ν_e regeneration by the Earth matter effects (see Section 14.8.2.3). Previously, SNO [242] and Borexino [243] searched for day-night flux asymmetries of ^{8}B and ^{7}Be neutrinos, respectively, but they observed no statistically significant asymmetries. Recently, the Super-Kamiokande experiment has reported [244] a 2.7 σ indication of non-zero day-night asymmetry of ^{8}B solar neutrinos, $A_{DN} = 2(R_D - R_N)/(R_D + R_N) = -0.032 \pm 0.011 \pm 0.005$, where R_D and R_N are the average day and average night νe elastic-scattering rates of ^{8}B solar neutrinos. This result is consistent with the Δm^2_{21} and θ_{12} values in the LMA region.

14.11. Measurements of $|\Delta m^2_{31(32)}|$ and θ_{23}, and related topics

The first compelling evidence for the neutrino oscillation was ν_μ disappearance observed by the Super-Kamiokande Collaboration in 1998 [17] in the measurement of atmospheric neutrinos produced by cosmic-ray interactions in the atmosphere. A striking feature of atmospheric neutrino oscillations was a surprisingly large mixing angle θ_{23}. Whether mixing is maximal, *i.e.*, $\theta_{23} = \pi/4$, or, if not, in which octant θ_{23} lies, is one of the questions drawing much interest in neutrino physics because the measurement of certain fundamental physical observables depends on the value of $\sin^2\theta_{23}$ (see, *e.g.*, Sections 14.2 and 14.8.1). The high precision measurement of $\sin^2\theta_{23}$ will provide also a test of a large class of theories of neutrino masses and mixing, based, in particular, on discrete symmetries (see, *e.g.*, the first two articles quoted in Ref. 87 and Ref. 245).

14.11.1. ν_μ *disappearance* :

Prior to the Super-Kamiokande's discovery of atmospheric neutrino oscillations, a deficit of atmospheric $\nu_\mu + \bar{\nu}_\mu$ flux was indicated by the Kamiokande experiment [204]. Actually, Kamiokande reported the double ratio $R(\nu_\mu/\nu_e) = (\text{Measured } \nu_\mu/\nu_e)/(\text{Expected } \nu_\mu/\nu_e) < 1$ to reduce systematic effects due to rather large flux uncertainties. The IMB [206] and Soudan 2 [208] experiments also observed $R < 1$, but the Frejus experiment [207] did not see such a tendency. Kamiokande further observed zenith-dependence of $\nu_\mu + \bar{\nu}_\mu$ flux deficit [205]. However, all these results from early experiments did not have conclusive statistical significance.

In 1998, the Super-Kamiokande Collaboration reported a significant zenith-angle (Θ) dependent deficit of μ-like events compared to the no-oscillation expectation [17]. For multi-GeV (visible energy > 1.33 GeV) FC+PC muons, the asymmetry A, defined as $A = (U - D)/(U + D)$, where U is the number of upward-going events ($-1 < \cos\Theta < -0.2$) and D is the number of downward-going events ($0.2 < \cos\Theta < 1$), was observed to be $A = -0.296 \pm 0.048 \pm 0.01$ which deviates from 0 by more than 6σ. This asymmetry is expected to be ~ 0 independent of the atmospheric neutrino flux model for neutrino energy > 1 GeV. On the other hand, the zenith-angle distribution of the e-like events was consistent with the expectation in the absence of oscillations. Fig. 14.11 shows the recent compilation of zenith-angle distributions of e-like and μ-like events from the Super-Kamiokande atmospheric observation. Events included in these plots are single-ring FC events subdivided into sub-GeV (visible energy < 1.33 GeV) events and multi-GeV events. The zenith-angle distribution of the multi-GeV μ-like events is shown combined with that of the PC events. The final-state leptons in these events have good directional correlation with the parent neutrinos. The dotted histograms show the Monte Carlo expectation for neutrino events. If the produced flux of atmospheric neutrinos of a given flavour remains unchanged at the detector, the data should have similar distributions to the expectation. However, the zenith-angle distribution of the μ-like events shows a strong deviation from the expectation. On the other hand, the zenith-angle distribution of the e-like events is consistent with the expectation. This characteristic feature is interpreted that muon neutrinos coming from the opposite side of the Earth's atmosphere, having travelled $\sim 10,000$ km, oscillate into other neutrinos and disappeared, while oscillations still do not take place for muon neutrinos coming from above the detector, having travelled from a few to a few tens km. These results are in good agreement with $\nu_\mu \leftrightarrow \nu_\tau$ two-flavour neutrino oscillations, because there is no indication of electron neutrino appearance. The atmospheric neutrinos corresponding to the events shown in Fig. 14.11 have $E = 1 \sim 10$ GeV. With $L = 10000$ km, neutrino oscillations suggests $\Delta m^2 \sim 10^{-3} - 10^{-4}$ eV^2. A significant deficit of μ-like events suggests a large mixing angle. Super-Kamiokande's initial results on the oscillation parameters for $\nu_\mu \leftrightarrow \nu_\tau$ were $5 \times 10^{-4} < \Delta m^2 < 6 \times 10^{-3}$ eV^2 and $\sin^2 2\theta > 0.82$ at 90% CL [17].

Although the Super-Kamiokande's atmospheric neutrino data are consistent with $\nu_\mu \leftrightarrow \nu_\tau$ oscillations, this interpretation will be strengthened if ν_τ appearance and characteristic sinusoidal behavior of the ν_μ survival probability as a function of L/E were observed. In fact, other exotic explanations such as neutrino decay [246] and quantum

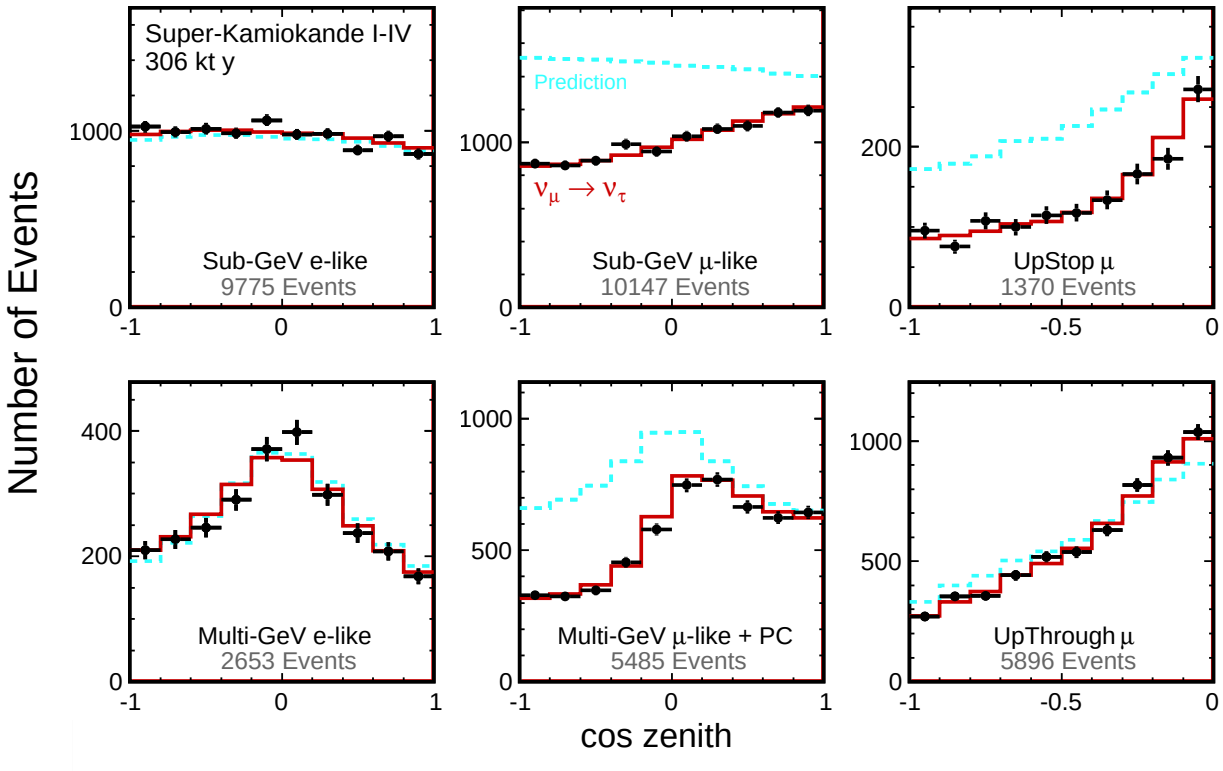

Fig. 14.11: The zenith angle distributions for fully contained 1-ring e-like and μ-like events with visible energy < 1.33 GeV (sub-GeV) and > 1.33 GeV (multi-GeV). For multi-GeV μ-like events, a combined distribution with partially contained (PC) events is shown. The dotted histograms show the non-oscillated Monte Carlo events, and the solid histograms show the best-fit expectations for $\nu_\mu \leftrightarrow \nu_\tau$ oscillations. (This figure is provided by the Super-Kamiokande Collab.)

decoherence [247] cannot be completely ruled out from the zenith-angle distributions alone. By selecting events with high L/E resolution, evidence for the dip in the L/E distribution was observed at the right place expected from the interpretation of the Super-Kamiokande's data in terms of $\nu_\mu \leftrightarrow \nu_\tau$ oscillations [18], see Fig. 14.12. This dip cannot be explained by alternative hypotheses of neutrino decay and neutrino decoherence, and they are excluded at more than 3σ in comparison with the neutrino oscillation interpretation. For ν_τ appearance, see Section 14.11.4.

The muon neutrino disappearance discovered by Super-Kamiokande has been confirmed subsequently by atmospheric neutrino experiments, MACRO [209] and Soudan 2 [248], long baseline accelerator experiments, K2K [19], MINOS [20,21], T2K [22,23], and NOνA [55], and neutrino telescope experiments, ANTARES [211] and IceCube-DeepCore [212]. Fig. 14.13 shows 90% CL allowed regions in the $\sin^2 2\theta_{23}$ - $\Delta m^2_{32(31)}$ plane, for the case of normal mass ordering, reported by the T2K [249], MINOS [250], Super-Kamiokande [251], and IceCube-DeepCore [212] experiments. All these regions are derived from three-neutrino oscillation analyses.

14.11.2. *Octant of θ_{23}* :

The two-flavour ν_μ survival probability in vacuum is degenerate with respect to the interchange $\theta_{23} \leftrightarrow \pi/2 - \theta_{23}$. In other words, the ν_μ disappearance is not sensitive to the octant of θ_{23} in the leading order. To determine the octant of θ_{23}, it is necessary to perform, *e.g.*, precise measurements of ν_μ disappearance and analyses in terms of three-neutrino oscillations, or combined analysis of ν_μ disappearance and $\nu_\mu \rightarrow \nu_e$ appearance.

MINOS [252] has made a combined analysis of the ν_μ disappearance [250] and $\nu_\mu \rightarrow \nu_e$ appearance [41] data using the complete set of accelerator and atmospheric neutrino data. The results obtained are $|\Delta m^2_{32}| = (2.28 - 2.46) \times 10^{-3}$ eV^2 (68% CL) and $\sin^2\theta_{23} = 0.35 - 0.65$ (90% CL) for normal mass ordering and $|\Delta m^2_{32}| = (2.32 - 2.53) \times 10^{-3}$ eV^2 (68% CL) and $\sin^2\theta_{23} = 0.34 - 0.67$ (90% CL) for inverted mass ordering. From this analysis, the best-fit value of $\sin^2\theta_{23} < 0.5$ ($\theta_{23} < \pi/4$) is obtained for inverted ordering.

T2K [249] has estimated these parameters in two methods. In an analysis of ν_μ disappearance alone [249], the 1D 68% CL intervals obtained are $\sin^2\theta_{23} = 0.514^{+0.055}_{-0.056}$ and $\Delta m^2_{32} = (2.51 \pm 0.10) \times 10^{-3}$ eV^2 for normal mass ordering and $\sin^2\theta_{23} = 0.511 \pm 0.055$ and $\Delta m^2_{13} = (2.48 \pm 0.10) \times 10^{-3}$ eV^2 for inverted mass ordering. These results are derived by fitting the reconstructed neutrino energy spectrum of 120 1-ring μ-like events. In an analysis of combined measurements of ν_μ disappearance and $\nu_\mu \rightarrow \nu_e$ appearance with inclusion of reactor data, normal mass ordering is weakly favored, and 1D 68% CL intervals obtained are $\sin^2\theta_{23} = 0.528^{+0.055}_{-0.038}$ and $\Delta m^2_{32} = (2.51 \pm 0.11) \times 10^{-3}$ eV^2. The T2K results for $\sin^2\theta_{23}$ are consistent with maximal mixing, $\theta_{23} = \pi/4$.

14.11.3. *$\bar{\nu}_\mu$ disappearance* :

The CPT symmetry requires neutrinos and antineutrinos to have the same masses and mixing parameters. In vacuum, this means the same survival probabilities for a neutrino and an antineutrino which have the same energy and which traveled the same distance. In matter, ν_μ and $\bar{\nu}_\mu$ survival probabilities are different, but with the experimental conditions of MINOS and T2K, the differences are small.

MINOS first observed muon antineutrino disappearance [253] with the NUMI beam line optimized for $\bar{\nu}_\mu$ production. Actually, MINOS produced a "ν_μ-dominated" or "$\bar{\nu}_\mu$-enhanced" beam by selectively focusing positive or negative pions and kaons. In Ref. 250, MINOS reported the results of the neutrino oscillation analysis based on the data obtained with 10.71×10^{20} POT of the ν_μ-dominated beam and 3.36×10^{20} POT of the $\bar{\nu}_\mu$-enhanced beam. In addition, they used the atmospheric neutrino data based on the MINOS far detector exposure

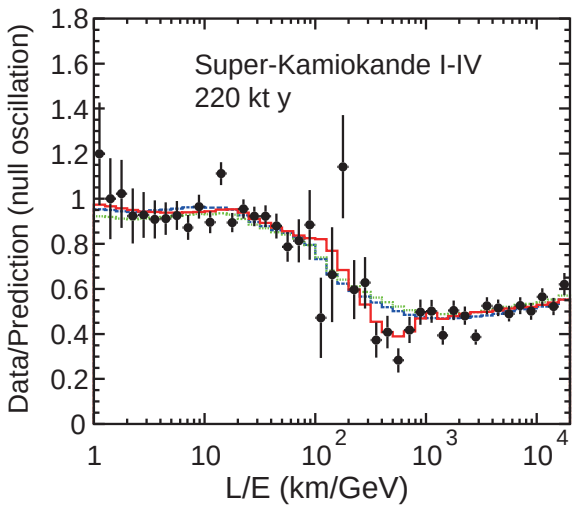

Figure 14.12: Results of the L/E analysis of SK1-SK4 atmospheric neutrino data. The points show the ratio of the data to the Monte Carlo prediction without oscillations, as a function of the reconstructed L/E. The error bars are statistical only. The solid line shows the best fit with 2-flavour $\nu_\mu \leftrightarrow \nu_\tau$ oscillations. The dashed and dotted lines show the best fit expectations for neutrino decay and neutrino decoherence hypotheses, respectively. (This figure is provided by the Super-Kamiokande Collab.)

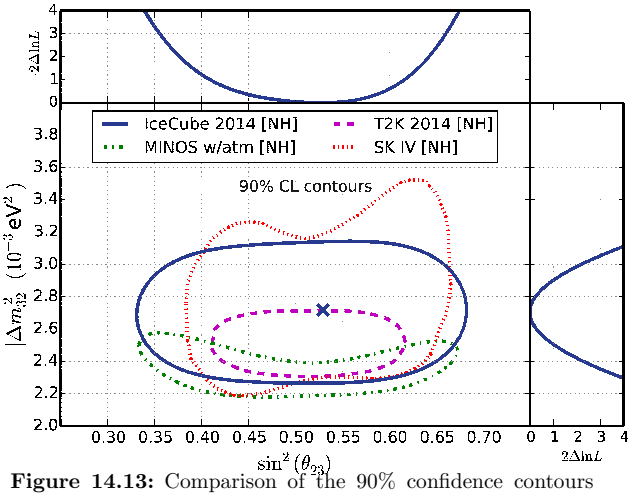

Figure 14.13: Comparison of the 90% confidence contours on the atmospheric oscillation parameters derived from the T2K [249], MINOS [250], Super-Kamiokande [251], and Icecube [214] experiments. The Icecube's log-likelihood profiles for individual oscillation parameters are also shown (right and top). A normal mass ordering is assumed. This figure is taken from arXiv:1410.7227v2.

of 37.88 kt·yr [210]. Because the MINOS detector has a capability to separate neutrinos and antineutrinos on an event-by-event basis, it can use both ν_μ and $\bar{\nu}_\mu$ contained events from the ν_μ-dominated beam. From the $\bar{\nu}_\mu$-enhanced beam, $\bar{\nu}_\mu$ contained events are used. For the complete data sets used, refer to Ref. 250. Assuming the identical oscillation parameters for neutrinos and antineutrinos, the results of the fit within the two-neutrino oscillation framework using the full MINOS data sample yielded $\Delta m^2 = (2.41^{+0.09}_{-0.10}) \times 10^{-3}$ eV^2 and $\sin^2 2\theta = 0.950^{+0.035}_{-0.036}$, or $\sin^2 2\theta > 0.890$ at 90% CL. Allowing independent oscillations for neutrinos and antineutrinos, characterised respectively by Δm^2, θ and $\Delta\bar{m}^2$, $\bar{\theta}$, the results of the fit are $\Delta\bar{m}^2 = (2.50^{+0.23}_{-0.25}) \times 10^{-3}$ eV^2 and $\sin^2 2\bar{\theta} = 0.97^{+0.03}_{-0.08}$, or $\sin^2 2\bar{\theta} > 0.83$ at 90% CL, and Δm^2 - $\Delta\bar{m}^2 = (0.12^{+0.24}_{-0.26}) \times 10^{-3}$ eV^2. This result shows that the neutrino and antineutrino mass splittings are in agreement, which is compatible with CPT invariance.

T2K also observed $\bar{\nu}_\mu$ disappearance [59] using an off-axis quasi-monochromatic $\bar{\nu}_\mu$ beam peaked at ~ 0.6 GeV with the polarity of the horn current set to focus negative pions. With 4.01×10^{20} POT, 34 fully contained μ-like events were observed at the Super-Kamiokande. Oscillation parameters $\sin^2\bar{\theta}_{23}$ and $\Delta\bar{m}^2_{32}$ are estimated in the three-neutrino oscillation framework assuming the normal mass ordering, and all other parameters fixed to the values taken from the previous T2K fits [57] and Review of Particle Properties [103]. The best-fit parameters obtained are $\Delta\bar{m}^2_{32} = 2.51 \times 10^{-3}$ eV^2 and $\sin^2\bar{\theta}_{23} = 0.45$, with 68% confidence intervals of $(2.26 - 2.80) \times 10^{-3}$ eV^2 for $\Delta\bar{m}^2_{32}$ and 0.38 - 0.64 for $\sin^2\bar{\theta}_{23}$. These results are consistent with the MINOS $\bar{\nu}_\mu$ disappearance results [253] as well as the ν_μ disappearance parameters measured by T2K [57].

14.11.4. ν_τ *appearance* :

Super-Kamiokande Collaboration searched for the appearance of τ leptons from the CC interactions of oscillation-generated ν_τ in the detector using the atmospheric neutrino data [254,24]. An excess of τ-like events is expected in the upward-going direction. Though the Super-Kamiokande detector cannot identify a CC ν_τ interaction on an event by event basis, the Super-Kamiokande Collaboration excluded the no-tau-appearance hypothesis at the 3.8σ level through a neural network analysis on the zenith-angle distribution of multi-GeV contained events [24].

For the purpose of demonstrating the appearance of tau neutrinos on an event-by-event basis, a promising method is an accelerator long-baseline experiment using emulsion technique to identify short-lived τ leptons produced in the ν_τ CC interactions. OPERA adopted this strategy and searched for the appearance of ν_τ in the CNGS muon neutrino beam during 2008 and 2012, corresponding to a live exposure of 17.97×10^{19} POT in total. In 2010, OPERA reported observation of the first ν_τ candidate [141]. As of July 2015, OPERA has reported observation of the fifth ν_τ candidate [255]. The observed candidate events are classified into the four decay channels, $\tau \to 1h$ (hadronic 1-prong), $\tau \to 1h$ (hadronic 3-prong), $\tau \to \mu$, and $\tau \to e$, and expected signal and background events are calculated for each decay channel. The expected total signal and background events are, respectively, 2.64 ± 0.53 and 0.25 ± 0.05. With 5 events observed, the OPERA Collaboration concludes the discovery of ν_τ appearance with a significance larger than 5σ.

14.12. Measurements of θ_{13}

In 2012, the last neutrino mixing angle θ_{13} was established to be non-zero by reactor experiments. The measured value of θ_{13} was sufficiently large to widen the opportunities to measure the unknown CP-violating phase δ in the PMNS matrix and the neutrino mass ordering.

14.12.1. *Overview* :

Reactor $\bar{\nu}_e$ disappearance experiments with $L \sim 1$ km, $\langle E \rangle \sim 3$ MeV are sensitive to $\sim E/L \sim 3 \times 10^{-3}$ eV$^2 \sim |\Delta m^2_{31(32)}|$. At this baseline distance, the reactor $\bar{\nu}_e$ oscillations driven by Δm^2_{21} are negligible. Therefore, as can be seen from Eq. (14.44) and Eq. (14.46), θ_{13} can be directly measured. The first reactor neutrino oscillation experiment of this kind, Chooz [51] found no evidence for $\bar{\nu}_e$ disappearance and set a 90% CL excluded region on the $\sin^2 2\theta$ - Δm^2 plane. Another reactor experiment Palo Verde reported somewhat less restrictive results [231].

In the accelerator neutrino oscillation experiments with conventional neutrino beams, θ_{13} can be measured using $\nu_\mu \to \nu_e$ appearance. In 2011, experimental indications of $\nu_\mu \to \nu_e$ oscillations and a non-zero θ_{13} was reported by the T2K experiment. T2K observed, with 1.43×10^{20} POT, six ν_e candidate events, while the expectation for $\theta_{13} = 0$ was 1.5 ± 0.3 events. This result implied a non-zero θ_{13} with statistical significance of 2.5σ [28]. The MINOS Collaboration also searched for the $\nu_\mu \to \nu_e$ appearance signal, and obtained the results that disfavored the $\theta_{13} = 0$ hypothesis at the 89% CL [29].

In 2012, the three reactor neutrino experiments Double Chooz [30], Daya Bay [31], and RENO [32], published their first results on $\bar{\nu}_e$

disappearance. With measurements by a far detector, Double Chooz ruled out the no-oscillation hypothesis at the 94.6% C.L. [30]. Then, Daya Bay reported 5.2σ evidence for non-zero θ_{13} from live-time exposure in 55 days [31]. Also, RENO reported non-zero θ_{13} with a significance of 4.9σ from 229 days of exposure [32]. Both Daya Bay and RENO results were obtained from rate-only analyses of the $\bar{\nu}_e$ disappearance measurements with near and far detectors. These three experiments have been accumulating statistics and improved results have been frequently reported. For their latest results, see Section 14.12.2.

In 2014, T2K announced [42] the observation of 28 ν_e appearance events with 4.92 ± 0.55 predicted background events. For $\sin^2 2\theta_{23} = 1$ and $\delta = 0$, this result means that $\theta_{13} = 0$ is excluded with a significance of 7.3σ. For more details of the T2K results [42] as well as the 2013 MINOS results [41], see Section 14.12.3.

14.12.2. *Latest reactor results* :

The latest Daya Bay results [38] are obtained from a total exposure of 6.9×10^5 $\mathrm{GW_{th}} \cdot \mathrm{ton} \cdot \mathrm{days}$ over 404 days from October 2012 to November 2013. The Daya Bay collaboration has adopted the three-flavour oscillation scheme and analyzed the relative antineutrino rates and energy spectra between detectors using a method to predict the signal in the far hall based on measurements obtained in the near halls. With this method, they have minimized the model dependence on reactor antineutrino emission. Also, improvements in energy calibration (0.2% between detectors) and background estimation helped reduce systematic errors. Their reported new result, $\sin^2 2\theta_{13} = 0.084 \pm 0.005$ is the most precise measurement of θ_{13} to date. To obtain this result, they used $\sin^2 2\theta_{12} = 0.857 \pm 0.024$ and $\Delta m^2_{21} = (7.50 \pm 0.20) \times 10^{-5}$ eV^2, but the dependence on these parameters is weak. They also found for the effective mass-squared difference $|\Delta m^2_{ee}| = (2.42 \pm 0.11) \times 10^{-3}$ eV^2, where Δm^2_{ee} is obtained by replacing $\cos^2\theta_{12} \sin^2 \Delta m^2_{31} L/(4E) + \sin^2\theta_{12} \sin^2 \Delta m^2_{32} L/(4E)$ with $\sin^2 \Delta m^2_{ee} L/(4E)$. From the measured value of $|\Delta m^2_{ee}|$, they deduce $\Delta m^2_{32} = (2.37 \pm 0.11) \times 10^{-3}$ eV^2 for the normal mass ordering and $\Delta m^2_{32} = -(2.47 \pm 0.11) \times 10^{-3}$ eV^2 for the inverted mass ordering. These results on Δm^2_{32} are consistent with the T2K and MINOS results.

The latest RENO results are reported in 2016 [39] based on 500 live days of data. From the measured far-to-near ratio of prompt spectra, $\sin^2 2\theta_{13} = 0.082 \pm 0.009 \pm 0.006$ and $|\Delta m^2_{ee}| = (2.62^{+0.21+0.12}_{-0.23-0.13}) \times 10^{-3}$ eV^2 have been obtained.

The latest results from Double Chooz using the data collected by the far detector in 467.90 live days have been published in Ref. 40. From a fit to the observed spectrum ("Rate + Shape analysis") in the two-flavour oscillation scheme, Double Chooz obtained $\sin^2 2\theta_{13} = 0.090^{+0.032}_{-0.029}$ for the normal mass ordering using $\Delta m^2_{31} = (2.44^{+0.09}_{-0.10}) \times 10^{-3}$ eV^2 from MINOS [252]. For the inverted mass ordering, they obtained $\sin^2 2\theta_{13} = 0.092^{+0.033}_{-0.029}$, using $|\Delta m^2_{31}| = (2.38^{+0.09}_{-0.10}) \times 10^{-3}$ eV^2 [252].

14.12.3. $\nu_\mu \to \nu_e$ *appearance and constraints on* δ :

By examining the expression for the probability of $\nu_\mu \to \nu_e$ oscillations in matter (given by Eq. (14.72)) it is understood that subleading terms could have rather large effects and the unknown CP-violating phase δ, in particular, causes uncertainties in determining the value of θ_{13}. Actually, from the measurement of $\nu_\mu \to \nu_e$ appearance, θ_{13} is given as a function of δ for a given sign and value of Δm^2_{31}, and values of θ_{23}, Δm^2_{21} and θ_{12}. Therefore, a single experiment with a neutrino beam cannot determine the value of θ_{13}, although it is possible to establish a non-zero θ_{13}. On the other hand, a combination of the $\nu_\mu \to \nu_e$ appearance results and the precise measurements of θ_{13} from the reactor experiments can yield constraints on the possible value of δ.

In Ref. 42, with the observation of 28 ν_e appearance events with 4.92 ± 0.55 predicted background events, for $\delta = 0$, $\sin^2\theta_{23} = 0.5$ and $|\Delta m^2_{31(32)}| = 2.4 \times 10^{-3}$eV^2, the T2K collaborations finds in the case of $\Delta m^2_{31(32)} > 0$ ($\Delta m^2_{31(32)} < 0$): $\sin^2 2\theta_{13} = 0.140^{+0.038}_{-0.032}$ ($0.170^{+0.045}_{-0.037}$). The significance of nonzero θ_{13} is 7.3σ for these fixed values of θ_{23} and δ. Changing the values of θ_{23} and δ within uncertainties, the significance remains above 7σ. The best fit value of $\sin^2 2\theta_{13}$ thus found in the T2K experiment is approximately by a factor of 1.6 (1.9) bigger than that found in the Daya Bay experiment [36]. This implies that the compatibility of the results of the two experiments on $\sin^2 2\theta_{13}$ requires, in particular, that $\delta \neq 0$ and/or $\sin^2\theta_{23} \neq 0.5$. As we have seen in Section 14.2, the indicated results lead to a certain indication about the possible value of δ in the global analyses of the neutrino oscillation data. T2K has also calculated the 68% and 90% CL allowed regions for $\sin^2 2\theta_{13}$, as a function of δ. The results are shown in Fig. 14.14 where the 1σ range of the $\sin^2 2\theta_{13}$ value from reactor experiments is also shown. T2K has further calculated

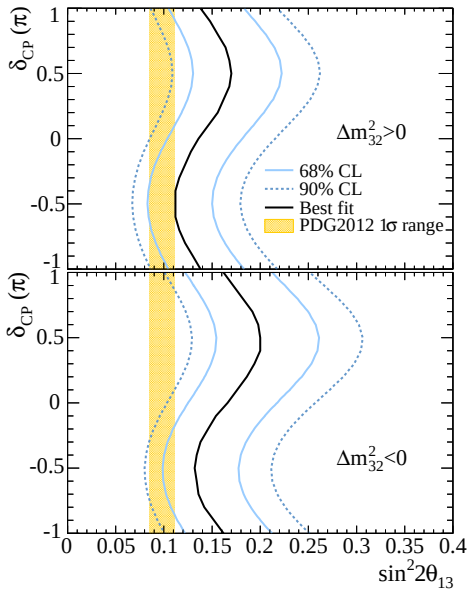

Figure 14.14: The T2K 68% and 90% CL allowed regions for $\sin^2 2\theta_{13}$, as a function of the CP violating phase δ assuming normal mass ordering (top) and inverted mass ordering (bottom). The solid line represents the best fit $\sin^2 2\theta_{13}$ value for given δ values. The values of $\sin^2\theta_{23}$ and Δm^2_{32} are varied in the fit with the constraint from Ref. 23. The shaded region shows the average θ_{13} value from Ref. 256. This figure is taken from arXiv:1311.4750.

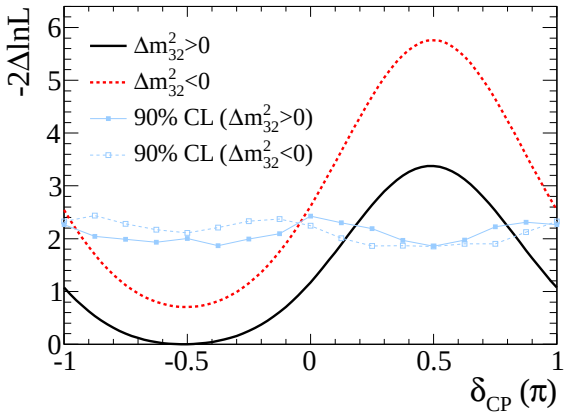

Figure 14.15: The T2K value of $-2\Delta \ln \mathcal{L}$ as a function of the CP violating phase δ for normal mass ordering (solid line) and inverted mass ordering (dotted line). The likelihood is marginalized over $\sin^2 2\theta_{13}$, $\sin^2\theta_{23}$ and Δm^2_{32}. The solid (dotted) line with markers corresponds to the 90% CL limits for normal (inverted) mass ordering, evaluated by using the Feldman-Cousins method. The δ regions with values above the lines are excluded at 90% CL. This figure is taken from arXiv:1311.4750.

constraints on δ by combining the $\nu_\mu \to \nu_e$ appearance results with the θ_{13} value from reactor experiments into a likelihood function $\mathcal{L}$. Fig. 14.15 shows the $-2\Delta \ln \mathcal{L}$ value as a function of δ. From this figure, it is seen that the combined T2K and reactor measurements prefer $\delta = -\pi/2$ or $3\pi/2$ for both the normal and inverted mass ordering, and some δ regions are excluded at 90% CL.

In Ref. 41, MINOS has extended the analysis using 10.6×10^{20} POT ν-beam mode and 3.3×10^{20} POT $\bar{\nu}$-beam mode appearance data. Assuming $\Delta m^2_{31(32)} > 0$ ($\Delta m^2_{31(32)} < 0$), $\delta = 0$, and $\theta_{23} < \pi/4$, the results of this analysis imply that $0.01\ (0.03) < 2\ \sin^2\theta_{23}\ \sin^2 2\theta_{13} < 0.12\ (0.18)$ at the 90% CL, with the best fit value $2\ \sin^2\theta_{23}\ \sin^2 2\theta_{13} = 0.051^{+0.038}_{-0.030}\ (0.093^{+0.054}_{-0.049})$. MINOS has also placed constraints on the value of δ by combining the full MINOS appearance data and the reactor measurements of θ_{13}.

In 2016, NOνA reported its first result of ν_e appearance measurement [56]. The data were taken between February 2014 and May 2015. During this period, the effective fiducial mass of the NOνA far detector varied from 2.3 kt for 4.0 kt of total mass to 10 kt for the full 14 kt. The exposure corresponding to these data is equivalent to 2.74×10^{20} POT collected in the full 14 kt far detector, and 6 ν_e-like events were observed compared to 0.99 ± 0.11 (syst.) expected background events: a 3.3σ excess over the background prediction. NOνA also quote the result of a secondary event selection method. With this analysis, 11 events were observed over the expected background of 1.07 ± 0.14 (syst.) events.

14.13. Search for Oscillations Involving Light Sterile Neutrinos

Although the mixing of the 3 flavour neutrino states has been experimentally well established, implying the existence of 3 light neutrinos ν_j having masses m_j not exceeding approximately 1 eV, there have been possible hints for the presence in the mixing of one or more additional neutrino states with masses at the eV scale. If these states exist, they must be related to the existence of one or more sterile neutrinos (sterile neutrino fields) which mix with the active flavour neutrinos (active flavour neutrino fields). The hints under discussion have been obtained: i) in the LSND $\bar{\nu}_\mu \to \bar{\nu}_e$ appearance experiment [225], in which a significant excess of events over the background is claimed to have been observed, ii) from the analysis of the $\bar{\nu}_\mu \to \bar{\nu}_e$ [228] and $\nu_\mu \to \nu_e$ [227] appearance data of the MiniBooNE experiment, iii) from the re-analyses of the short baseline (SBL) reactor neutrino oscillation data using newly calculated fluxes of reactor $\bar{\nu}_e$ [257,119], which show a possible "disappearance" of the reactor $\bar{\nu}_e$ ("reactor neutrino anomaly"), and iv) from the data of the radioactive source calibrations of the GALLEX [202] and SAGE [203] solar neutrino experiments.

The short baseline neutrino oscillation experiment MiniBooNE at Fermilab investigated ν_e [227] and $\bar{\nu}_e$ [228] appearance in ν_μ and $\bar{\nu}_\mu$ beams, respectively, with a detector containing 800 tons of mineral oil and located 541 m downstream of the production target. With the antineutrino running mode [228], a 2.8σ excess of events over the background was observed in the energy range of $200 < E_\nu < 1250$ MeV in the charged-current quasielastic data. Excess events were observed, in particular, in the interval of energies $200 < E_\nu < 475$ MeV, which corresponds to L/E range outside of that probed in the LSND experiment. The origin of this excess is not understood. Employing a simple 2-neutrino oscillation hypothesis and using the data from the entire neutrino energy interval $200 < E_\nu < 1250$ MeV used in the data analysis, this result, interpreted in terms of $\nu_\mu \to \nu_e$ oscillations, corresponds to an allowed region in the $\sin^2 2\theta - \Delta m^2$ plane, which overlaps with the allowed region obtained from the interpretation of the LSND data in terms of $\bar{\nu}_\mu \to \bar{\nu}_e$ oscillations. The overlap region at the 90% CL extends over $\Delta m^2 \sim$ a few $\times 10^{-2}$ eV^2 at $\sin^2 2\theta = 1$ to 1 eV^2 at $\sin^2 2\theta =$ a few $\times 10^{-3}$. The MiniBooNE Collaboration studied also the CP conjugate oscillation channel [227], $\nu_\mu \to \nu_e$, and observed a 3.4 σ excess of events in the same energy range. Most of the excess events lie in the interval $200 < E_\nu < 475$ MeV and are incompatible with the $\bar{\nu}_\mu \to \bar{\nu}_e$ oscillation interpretation of the LSND data. The energy spectra of the excess events observed in the ν_μ [227] and $\bar{\nu}_\mu$ [228] runs are only marginally compatible with each other and thus with the simple 2-neutrino oscillation hypothesis.

The reactor neutrino anomaly [257] is related to the results of a new and very detailed calculation of the reactor $\bar{\nu}_e$ fluxes [119] which were found to be by approximately 3.5% larger than the fluxes calculated in Ref. 122 and widely used in the past in the interpretation of the data of the SBL reactor $\bar{\nu}_e$ oscillation experiments. These data show indications for reactor $\bar{\nu}_e$ "disappearance" when analyzed using the fluxes from [119]. It should be added that there are a number of uncertainties in the calculation of the fluxes under discussion (associated, *e.g.*, with the weak magnetism term contribution to the corresponding β-decay rates [120], the contribution of a relatively large number of "forbidden" β-decays [258], etc.) which can be of the order of the difference between the "old" and "new" fluxes.

Radioactive source calibrations of the GALLEX [202] and SAGE [203] experiments also showed a deficit of the measured fluxes compared to the expected fluxes ("Gallium anomaly"), and therefore might be interpreted as hints for ν_e disappearance.

Significant constraints on the parameters characterizing the oscillations involving sterile neutrinos follow from the negative results of the searches for $\nu_\mu \to \nu_e$ and/or $\bar{\nu}_\mu \to \bar{\nu}_e$ oscillations in the Karmen [226], NOMAD [259], ICARUS [224], and OPERA [260] experiments, and from the nonobservation of effects of oscillations into sterile neutrinos in the solar neutrino experiments and in the studies of ν_μ and/or $\bar{\nu}_\mu$ disappearance in the CDHSW [261], MINOS and SuperKamiokande experiments.

Two possible "minimal" phenomenological models (or schemes) with light sterile neutrinos are widely used in order to explain the data discussed in this section in terms of neutrino oscillations: the so-called "3 + 1" and "3 + 2" models. They contain respectively one and two sterile neutrinos (right-handed sterile neutrino fields). Thus, the "3 + 1" and "3 + 2" models have altogether 4 and 5 light massive neutrinos ν_j, which in the minimal versions of these models are Majorana particles. The additional neutrinos ν_4 and ν_4, ν_5 should have masses m_4 and m_4, m_5 at the eV scale (see below). It follows from the data that if ν_4 or ν_4, ν_5 exist, they couple to the electron and muon in the weak charged lepton current with couplings U_{ek} and $U_{\mu k}$, $k = 4;\ 4, 5$, which are approximately $|U_{ek}| \sim 0.1$ and $|U_{\mu k}| \sim 0.1$.

Global analysis of all the data (positive evidences and negative results) relevant for the test of the sterile neutrino hypothesis were performed in Ref. 262 and in Ref. 263. Analyzing the data within the $3 + 1$ scheme, the authors of Ref. 262 find for the best fit values of the parameters $|U_{e4}|^2$, $|U_{\mu 4}|^2$ and $\Delta m^2_{\rm SBL} \equiv m^2_4 - m^2_{min}$, where $m_{min} = \min(m_j)$, $j = 1, 2, 3$, characterizing the active-sterile neutrino (antineutrino) oscillations:

$$|U_{e4}|^2 = 0.0225\,, \quad |U_{\mu 4}|^2 = 0.0289\,, \quad \Delta m^2_{\rm SBL} = 0.93\ \text{eV}^2\,. \quad (14.102)$$

In contrast to Ref. 262, the authors of Ref. 263 reported also results within the $3 + 1$ scheme without including in the data set used in their global analysis the MiniBooNE data at $E_\nu \leq 0.475$ GeV. As we have already mentioned, these data show an excess of events over the estimated background [227,228] whose nature is presently not well understood. For the best fit values of $|U_{e4}|^2$, $|U_{\mu 4}|^2$ and $\Delta m^2_{\rm SBL}$ in this case the authors of Ref. 263 find:

$$|U_{e4}|^2 = 0.03\,, \quad |U_{\mu 4}|^2 = 0.013\,, \quad \Delta m^2_{\rm SBL} = 1.60\ \text{eV}^2\,. \quad (14.103)$$

In the context of the "3+1" model, the Daya Bay Collaboration recently searched for relative spectral distortion in their reactor antineutrino data, due to possible mixing of a light sterile neutrino in the $|\Delta m^2_{41}| < 0.3$ eV^2 region [264]. The result is consistent with no sterile neutrino mixing, leading to the most stringent limits on $\sin^2\theta_{14}$ in the 10^{-3} eV$^2 < |\Delta m^2_{41}| < 0.1$ eV^2 region.

The existence of light sterile neutrinos has cosmological implications the discussion of which lies outside the scope of the present article (for a discussion of the cosmological constraints on light sterile neutrinos see, *e.g.*, [265,75]) .

The hypothesis of existence of light sterile neutrinos with eV scale masses and charged current couplings to the electron and muon quoted

above will be tested in a number of experiments with reactor and accelerator neutrinos, and neutrinos from artificial sources, some of which are under preparation and planned to start taking data already this year (see, *e.g.*, [266] for a detailed list and discussion of the planned experiments).

14.14. Outlook

The currently available data on neutrino oscillations are summarised in Fig. 14.16.

The program of experimental research in neutrino physics extends beyond 2030 (see, *e.g.*, Refs. [80,83,84,85,219]) . In the coming years we expect a wealth of new data that, it is hoped, will shed light on the fundamental aspects of neutrino mixing: the nature - Dirac or Majorana - of massive neutrinos, the type of spectrum the neutrino masses obey, the status of CP symmetry in the lepton sector, the absolute neutrino mass scale, the origin of the observed patterns of the neutrino masses and mixing, and, eventually, on the mechanism of neutrino mass generation. We are looking forward to these exciting developments in neutrino physics.

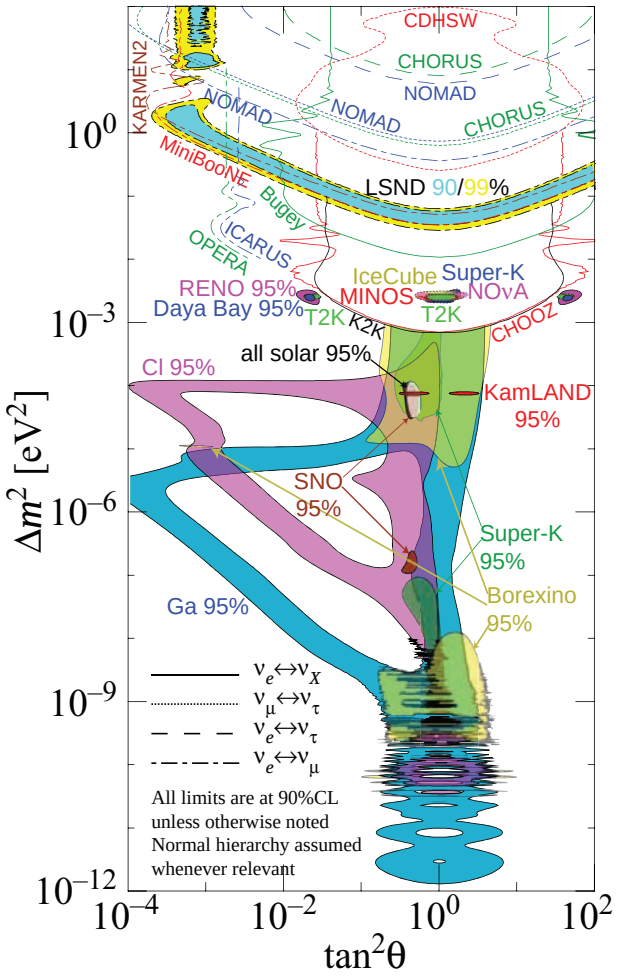

Figure 14.16: The regions of squared-mass splitting and mixing angle favored or excluded by various neutrino oscillation experiments. The figure was contributed by H. Murayama (University of California, Berkeley, and Kavli IPMU, University of Tokyo). References to the data used in the figure and the description of how the figure was obtained can be found at `http://hitoshi.berkeley.edu/neutrino`.

147. P. Langacker, J.P. Leveille, and J. Sheiman, Phys. Rev. **D27**, 1228 (1983).
148. The difference between the ν_μ and ν_τ indices of refraction arises at one-loop level and can be relevant for the $\nu_\mu - \nu_\tau$ oscillations in very dense media, like the core of supernovae, *etc.*; see F.J. Botella, C.S. Lim, and W.J. Marciano, Phys. Rev. **D35**, 896 (1987).
149. The relevant formulae for the oscillations between the ν_e and a sterile neutrino ν_s, $\nu_e \leftrightarrow \nu_s$, can be obtained from those derived for the case of $\nu_e \leftrightarrow \nu_{\mu(\tau)}$ oscillations by Refs. [65,147] replacing N_e with $(N_e - 1/2N_n)$, N_n being the neutron number density in matter.

179. An expression for the "jump" probability P' for N_e varying linearly along the neutrino path was derived in W.C. Haxton, Phys. Rev. Lett. **57**, 1271 (1986) and in Ref. 171 on the basis of the old Landau-Zener result: L.D. Landau, Phys. Z. USSR **1**, 426 (1932), C. Zener, Proc. R. Soc. A **137**, 696 (1932). An analytic description of the solar ν_e transitions based on the Landau-Zener jump probability was proposed in Ref. 171 and in W.C. Haxton, Phys. Rev. **D35**, 2352 (1987). The precision limitations of this description, which is less accurate than that based on the exponential density approximation, were discussed in S.T. Petcov, Phys. Lett. **B191**, 299 (1987) and in Ref. 173.

15. QUARK MODEL

Revised August 2015 by C. Amsler (University of Bern), T. DeGrand (University of Colorado, Boulder), and B. Krusche (University of Basel).

15.1. Quantum numbers of the quarks

Quantum chromodynamics (QCD) is the theory of the strong interactions. QCD is a quantum field theory and its constituents are a set of fermions, the quarks, and gauge bosons, the gluons. Strongly interacting particles, the hadrons, are bound states of quark and gluon fields. As gluons carry no intrinsic quantum numbers beyond color charge, and because color is believed to be permanently confined, most of the quantum numbers of strongly interacting particles are given by the quantum numbers of their constituent quarks and antiquarks. The description of hadronic properties which strongly emphasizes the role of the minimum-quark-content part of the wave function of a hadron is generically called the quark model. It exists on many levels: from the simple, almost dynamics-free picture of strongly interacting particles as bound states of quarks and antiquarks, to more detailed descriptions of dynamics, either through models or directly from QCD itself. The different sections of this review survey the many approaches to the spectroscopy of strongly interacting particles which fall under the umbrella of the quark model.

Table 15.1: Additive quantum numbers of the quarks.

	d	u	s	c	b	t
Q – electric charge	$-\frac{1}{3}$	$+\frac{2}{3}$	$-\frac{1}{3}$	$+\frac{2}{3}$	$-\frac{1}{3}$	$+\frac{2}{3}$
I – isospin	$\frac{1}{2}$	$\frac{1}{2}$	0	0	0	0
I_z – isospin z-component	$-\frac{1}{2}$	$+\frac{1}{2}$	0	0	0	0
S – strangeness	0	0	-1	0	0	0
C – charm	0	0	0	$+1$	0	0
B – bottomness	0	0	0	0	-1	0
T – topness	0	0	0	0	0	$+1$

Quarks are strongly interacting fermions with spin 1/2 and, by convention, positive parity. Antiquarks have negative parity. Quarks have the additive baryon number 1/3, antiquarks -1/3. Table 15.1 gives the other additive quantum numbers (flavors) for the three generations of quarks. They are related to the charge Q (in units of the elementary charge e) through the generalized Gell-Mann-Nishijima formula

$$\mathsf{Q} = \mathsf{I}_z + \frac{\mathcal{B} + \mathsf{S} + \mathsf{C} + \mathsf{B} + \mathsf{T}}{2} \ , \tag{15.1}$$

where $\mathcal{B}$ is the baryon number. The convention is that the *flavor* of a quark (I_z, S, C, B, or T) has the same sign as its *charge* Q. With this convention, any flavor carried by a charged meson has the same sign as its charge, *e.g.*, the strangeness of the K^+ is +1, the bottomness of the B^+ is +1, and the charm and strangeness of the D_s^- are each −1. Antiquarks have the opposite flavor signs. The hypercharge is defined as

$$\mathsf{Y} = \mathcal{B} + \mathsf{S} - \frac{\mathsf{C} - \mathsf{B} + \mathsf{T}}{3} \ .$$

Thus Y is equal to $\frac{1}{3}$ for the u and d quarks, $-\frac{2}{3}$ for the s quark, and 0 for all other quarks.

15.2. Mesons

Mesons have baryon number $\mathcal{B} = 0$. In the quark model, they are $q\overline{q}'$ bound states of quarks q and antiquarks $\overline{q}'$ (the flavors of q and q' may be different). If the orbital angular momentum of the $q\overline{q}'$ state is ℓ, then the parity P is $(-1)^{\ell+1}$. The meson spin J is given by the usual relation $|\ell - s| \leq J \leq |\ell + s|$, where s is 0 (antiparallel quark spins) or 1 (parallel quark spins). The charge conjugation, or C-parity $C = (-1)^{\ell+s}$, is defined only for the $q\bar{q}$ states made of quarks and their own antiquarks. The C-parity can be generalized to the G-parity $G = (-1)^{I+\ell+s}$ for mesons made of quarks and their own antiquarks (isospin $\mathsf{I}_z = 0$), and for the charged $u\bar{d}$ and $d\bar{u}$ states (isospin $\mathsf{I} = 1$).

The mesons are classified in J^{PC} multiplets. The $\ell = 0$ states are the pseudoscalars (0^{-+}) and the vectors (1^{--}). The orbital excitations $\ell = 1$ are the scalars (0^{++}), the axial vectors (1^{++}) and (1^{+-}), and the tensors (2^{++}). Assignments for many of the known mesons are given in Tables 15.2 and 15.3. Radial excitations are denoted by the principal quantum number n. The very short lifetime of the t quark makes it likely that bound-state hadrons containing t quarks and/or antiquarks do not exist.

States in the natural spin-parity series $P = (-1)^J$ must, according to the above, have $s = 1$ and hence, $CP = +1$. Thus, mesons with natural spin-parity and $CP = -1$ (0^{+-}, 1^{-+}, 2^{+-}, 3^{-+}, *etc.*) are forbidden in the $q\bar{q}'$ model. The $J^{PC} = 0^{--}$ state is forbidden as well. Mesons with such *exotic* quantum numbers may exist, but would lie outside the $q\bar{q}'$ model (see section below on exotic mesons).

Following SU(3), the nine possible $q\bar{q}'$ combinations containing the light u, d, and s quarks are grouped into an octet and a singlet of light quark mesons:

$$\mathbf{3} \otimes \overline{\mathbf{3}} = \mathbf{8} \oplus \mathbf{1} \ . \tag{15.2}$$

A fourth quark such as charm c can be included by extending SU(3) to SU(4). However, SU(4) is badly broken owing to the much heavier c quark. Nevertheless, in an SU(4) classification, the sixteen mesons are grouped into a 15-plet and a singlet:

$$\mathbf{4} \otimes \overline{\mathbf{4}} = \mathbf{15} \oplus \mathbf{1} \ . \tag{15.3}$$

The *weight diagrams* for the ground-state pseudoscalar (0^{-+}) and vector (1^{--}) mesons are depicted in Fig. 15.1. The light quark mesons are members of nonets building the middle plane in Fig. 15.1(a) and (b).

Isoscalar states with the same J^{PC} will mix, but mixing between the two light quark isoscalar mesons, and the much heavier charmonium or bottomonium states, are generally assumed to be negligible. In the following, we shall use the generic names a for the $\mathsf{I} = 1$, K for the $\mathsf{I} = 1/2$, and f and f' for the $\mathsf{I} = 0$ members of the light quark nonets. Thus, the physical isoscalars are mixtures of the SU(3) wave function ψ_8 and ψ_1:

$$f' = \psi_8 \cos\theta - \psi_1 \sin\theta \ , \tag{15.4}$$

$$f = \psi_8 \sin\theta + \psi_1 \cos\theta \ , \tag{15.5}$$

where θ is the nonet mixing angle and

$$\psi_8 = \frac{1}{\sqrt{6}}(u\bar{u} + d\bar{d} - 2s\bar{s}) \ , \tag{15.6}$$

$$\psi_1 = \frac{1}{\sqrt{3}}(u\bar{u} + d\bar{d} + s\bar{s}) \ . \tag{15.7}$$

These mixing relations are often rewritten to exhibit the $u\bar{u} + d\bar{d}$ and $s\bar{s}$ components which decouple for the "ideal" mixing angle θ_i, such that $\tan\theta_i = 1/\sqrt{2}$ (or $\theta_i = 35.3°$). Defining $\alpha = \theta + 54.7°$, one obtains the physical isoscalar in the flavor basis

$$f' = \frac{1}{\sqrt{2}}(u\bar{u} + d\bar{d})\cos\alpha - s\bar{s} \ \sin\alpha \ , \tag{15.8}$$

Table 15.2: Suggested $q\overline{q}$ quark-model assignments for some of the observed light mesons. Mesons in bold face are included in the Meson Summary Table. The wave functions f and f' are given in the text. The singlet-octet mixing angles from the quadratic and linear mass formulae are also given for the well established nonets. The classification of the 0^{++} mesons is tentative: the light scalars $a_0(980)$, $f_0(980)$, $f_0(500)$ and $K_0^*(800)$ are often considered to be meson-meson resonances or four-quark states, and are omitted from the table. The isoscalar 0^{++} mesons are expected to mix. In particular, the $f_0(1710)$ mixes with the $f_0(1500)$ and the $f_0(1370)$. The $a_0(1450)$ is not firmly established. See the "Note on Non-$q\bar{q}$ mesons" and the "Note on Scalar Mesons" in the Meson Listings for details and alternative schemes. In the 1^{++} nonet the isoscalar slot is disputed by the $f_1(1510)$. The isoscalar assignments in the 2^1S_0 (0^{++}) nonet are also tentative. See the "Note on The Pseudoscalar and Pseudovector Mesons in the 1400 MeV Region" in the Meson Listings.

† The masses of these states are considerably smaller than most theoretical predictions. They have also been considered as four-quark states.

‡ These states are mixtures of the $1\,^3D_1$ and $2\,^3S_1$ states.

The open flavor states in the 1^{+-} and 1^{++} rows are mixtures of the $1^{+\pm}$ states.

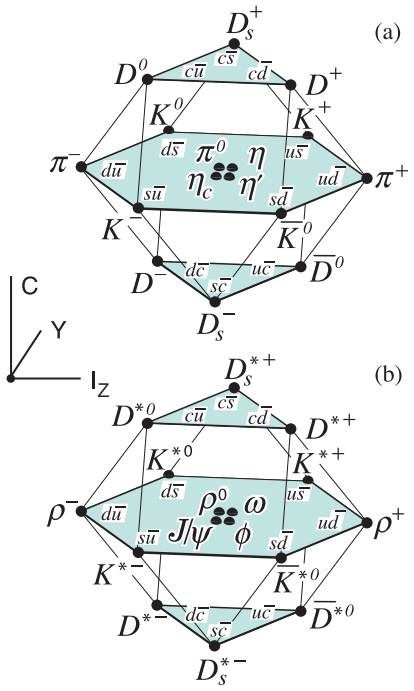

Figure 15.1: SU(4) weight diagram showing the 16-plets for the pseudoscalar (a) and vector mesons (b) made of the u, d, s, and c quarks as a function of isospin I_z, charm C, and hypercharge $\mathsf{Y} = \mathcal{B} + \mathsf{S} - \frac{\mathsf{C}}{3}$. The nonets of light mesons occupy the central planes to which the $c\bar{c}$ states have been added.

and its orthogonal partner f (replace α by α –90°). Thus for ideal mixing ($\alpha_i = 90°$), the f' becomes pure $s\bar{s}$ and the f pure $u\bar{u} + d\bar{d}$. The mixing angle θ can be derived by diagonalizing the mass matrix

$$\begin{pmatrix} m_8 & m_{81} \\ m_{18} & m_1 \end{pmatrix}$$

The mass eigenvalues are $m_{f'}$ and m_f. The mixing angle is given by

$$\tan\theta = \frac{m_8 - m_{f'}}{m_{81}} \ .$$

Calculating m_8 and m_{81} from the wave functions Eq. (15.6) and Eq. (15.7), and expressing the quark masses as a function of the $\mathsf{I} = 1/2$ and $\mathsf{I} = 1$ meson masses, one obtains

$$\tan\theta = \frac{4m_K - m_a - 3m_{f'}}{2\sqrt{2}(m_a - m_K)} \ , \tag{15.9}$$

which also determines the sign of θ. Alternatively, one can express the mixing angle as a function of all nonet masses. The octet mass is given by

$$m_8 = m_{f'}\cos^2\theta + m_f \sin^2\theta$$

whence

$$\tan^2\theta = \frac{4m_K - m_a - 3m_{f'}}{-4m_K + m_a + 3m_f} \ . \tag{15.10}$$

Eliminating θ from Eq. (15.9) and Eq. (15.10) leads to the sum rule [1]

$$(m_f + m_{f'})(4m_K - m_a) - 3m_f m_{f'} = 8m_K^2 - 8m_K m_a + 3m_a^2. \tag{15.11}$$

This relation is verified for the ground-state vector mesons. We identify the $\phi(1020)$ with the f' and the $\omega(783)$ with the f. Thus

$$\phi(1020) = \psi_8 \cos\theta_V - \psi_1 \sin\theta_V \ , \tag{15.12}$$

$$\omega(782) = \psi_8 \sin\theta_V + \psi_1 \cos\theta_V \ , \tag{15.13}$$

with the vector mixing angle $\theta_V = 36.4°$ from Eq. (15.10), very close to ideal mixing. Thus $\phi(1020)$ is nearly pure $s\bar{s}$. For ideal mixing, Eq. (15.9) and Eq. (15.10) lead to the relations

$$m_K = \frac{m_f + m_{f'}}{2} \ , \quad m_a = m_f \ , \tag{15.14}$$

which are satisfied for the vector mesons.

The situation for the pseudoscalar and scalar mesons is not so clear cut, either theoretically or experimentally. For the pseudoscalars, the mixing angle is small. This can be understood qualitatively via gluon-line counting of the mixing process. The size of the mixing process between the nonstrange and strange mass bases scales as α_s^2, not α_s^3, because of two rather than three gluon exchange as it does for the vector mesons. It may also be that the lightest isoscalar pseudoscalars mix more strongly with excited states or with states of substantial non-$\bar{q}q$ content, as will be discussed below.

A variety of analysis methods lead to similar results: First, for these states, Eq. (15.11) is satisfied only approximately. Then Eq. (15.9) and Eq. (15.10) lead to somewhat different values for the mixing angle. Identifying the η with the f' one gets

$$\eta = \psi_8 \cos\theta_P - \psi_1 \sin\theta_P \ , \tag{15.15}$$

$$\eta' = \psi_8 \sin\theta_P + \psi_1 \cos\theta_P \ . \tag{15.16}$$

Following chiral perturbation theory, the meson masses in the mass formulae (Eq. (15.9) and Eq. (15.10)) might be replaced by their squares. Table 15.2 lists the mixing angle $\theta_{\rm lin}$ from Eq. (15.10) (using the neutral members of the nonets) and the corresponding $\theta_{\rm quad}$ obtained by replacing the meson masses by their squares throughout.

The pseudoscalar mixing angle θ_P can also be measured by comparing the partial widths for radiative J/ψ decay into a vector and a pseudoscalar [2], radiative $\phi(1020)$ decay into η and η' [3], or $\bar{p}p$ annihilation at rest into a pair of vector and pseudoscalar or into two pseudoscalars [4,5]. One obtains a mixing angle between –10° and –20°. More recently, a lattice QCD simulation, Ref. 6, has successfully reproduced the masses of the η and η', and as a byproduct find a mixing angle $\theta_{lin} = -14.1(2.8)°$. We return to this point in Sec. 15.6.

The nonet mixing angles can be measured in $\gamma\gamma$ collisions, *e.g.*, for the 0^{-+}, 0^{++}, and 2^{++} nonets. In the quark model, the amplitude for the coupling of neutral mesons to two photons is proportional to $\sum_i Q_i^2$, where Q_i is the charge of the i-th quark. The 2γ partial width of an isoscalar meson with mass m is then given in terms of the mixing angle α by

$$\Gamma_{2\gamma} = C(5\cos\alpha - \sqrt{2}\sin\alpha)^2 m^3 \ , \tag{15.17}$$

for f' and f ($\alpha \to \alpha$ – 90°). The coupling C may depend on the meson mass. It is often assumed to be a constant in the nonet. For the isovector a, one then finds $\Gamma_{2\gamma} = 9\ C\ m^3$. Thus the members of an ideally mixed nonet couple to 2γ with partial widths in the ratios $f : f' : a = 25 : 2 : 9$. For tensor mesons, one finds from the ratios of the measured 2γ partial widths for the $f_2(1270)$ and $f_2'(1525)$ mesons a mixing angle α_T of $(81\pm 1)°$, or $\theta_T = (27 \pm 1)°$, in accord with the linear mass formula. For the pseudoscalars, one finds from the ratios of partial widths $\Gamma(\eta' \to 2\gamma)/\Gamma(\eta \to 2\gamma)$ a mixing angle $\theta_P = (-18 \pm 2)°$, while the ratio $\Gamma(\eta' \to 2\gamma)/\Gamma(\pi^0 \to 2\gamma)$ leads to $\sim$ –24 °. SU(3) breaking effects for pseudoscalars are discussed in Ref. 7.

The partial width for the decay of a scalar or a tensor meson into a pair of pseudoscalar mesons is model-dependent. Following Ref. 8,

$$\Gamma = C \times \gamma^2 \times |F(q)|^2 \times q \ . \tag{15.18}$$

C is a nonet constant, q the momentum of the decay products, $F(q)$ a form factor, and γ^2 the SU(3) coupling. The model-dependent form factor may be written as

$$|F(q)|^2 = q^{2\ell} \times \exp(-\frac{q^2}{8\beta^2}), \tag{15.19}$$

where ℓ is the relative angular momentum between the decay products. The decay of a $q\bar{q}$ meson into a pair of mesons involves the creation of a $q\bar{q}$ pair from the vacuum, and SU(3) symmetry assumes that the matrix elements for the creation of $s\bar{s}$, $u\bar{u}$, and $d\bar{d}$ pairs are equal. The couplings γ^2 are given in Table 15.4, and their dependence upon the mixing angle α is shown in Fig. 15.2 for isoscalar decays. The generalization to unequal $s\bar{s}$, $u\bar{u}$, and $d\bar{d}$ couplings is given in Ref. 8. An excellent fit to the tensor meson decay widths is obtained assuming SU(3) symmetry, with $\beta \simeq 0.5$ GeV/c, $\theta_V \simeq 26$ ° and $\theta_P \simeq -17$ ° [8].

Table 15.4: SU(3) couplings γ^2 for quarkonium decays as a function of nonet mixing angle α, up to a common multiplicative factor C ($\phi \equiv 54.7^\circ + \theta_P$).

Isospin	Decay channel	γ^2
0	$\pi\pi$	$3\cos^2\alpha$
	$K\overline{K}$	$(\cos\alpha - \sqrt{2}\sin\alpha)^2$
	$\eta\eta$	$(\cos\alpha\cos^2\phi - \sqrt{2}\sin\alpha\sin^2\phi)^2$
	$\eta\eta'$	$\frac{1}{2}\sin^2 2\phi\ (\cos\alpha + \sqrt{2}\sin\alpha)^2$
1	$\eta\pi$	$2\cos^2\phi$
	$\eta'\pi$	$2\sin^2\phi$
	$K\overline{K}$	1
$\frac{1}{2}$	$K\pi$	$\frac{3}{2}$
	$K\eta$	$(\sin\phi - \frac{\cos\phi}{\sqrt{2}})^2$
	$K\eta'$	$(\cos\phi + \frac{\sin\phi}{\sqrt{2}})^2$

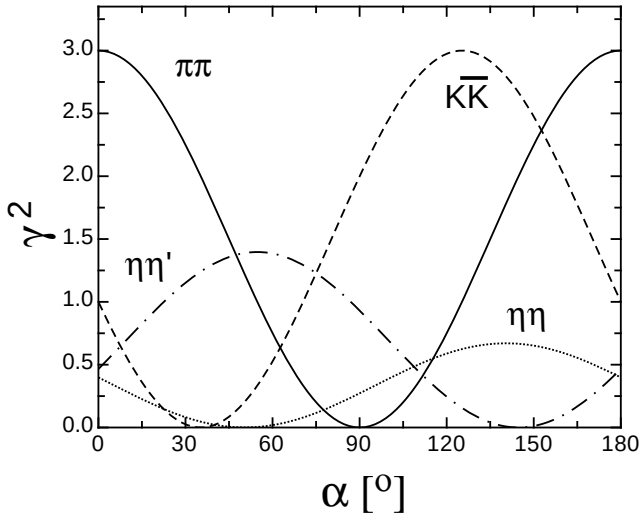

Figure 15.2: SU(3) couplings as a function of mixing angle α for isoscalar decays, up to a common multiplicative factor C and for $\theta_P = -17.3^\circ$.

15.3. Exotic mesons

The existence of a light nonet composed of four quarks with masses below 1 GeV was suggested a long time ago [9]. Coupling two triplets of light quarks u, d, and s, one obtains nine states, of which the six symmetric (uu, dd, ss, $ud+du$, $us+su$, $ds+sd$) form the six dimensional representation **6**, while the three antisymmetric ($ud-du$, $us-su$, $ds-sd$) form the three dimensional representation $\overline{\mathbf{3}}$ of SU(3):

$$\mathbf{3} \otimes \mathbf{3} = \mathbf{6} \oplus \overline{\mathbf{3}}\ . \qquad (15.20)$$

Combining with spin and color and requiring antisymmetry, one finds that the most deeply bound diquark (and hence the lightest) is the one in the $\overline{\mathbf{3}}$ and spin singlet state. The combination of the diquark with an antidiquark in the **3** representation then gives a light nonet of four-quark scalar states. Letting the number of strange quarks determine the mass splitting, one obtains a mass inverted spectrum with a light isosinglet ($ud\bar{u}\bar{d}$), a medium heavy isodoublet (*e.g.*, $ud\bar{s}\bar{d}$) and a heavy isotriplet (*e.g.*, $ds\bar{u}\bar{s}$) + isosinglet (*e.g.*, $us\bar{u}\bar{s}$). It is then tempting to identify the lightest state with the $f_0(500)$, and the heaviest states with the $a_0(980)$, and $f_0(980)$. Then the meson with strangeness $K_0^*(800)$ would lie in-between.

QCD predicts the existence of extra isoscalar mesons. In the pure gauge theory they contain only gluons, and are called the glueballs. The ground state glueball is predicted by lattice gauge theories to be 0^{++}, the first excited state 2^{++}. Errors on the mass predictions are large. From Ref. 10 one obtains 1750 (50) (80) MeV for the mass of the lightest 0^{++} glueball from quenched QCD. As an example for the glueball mass spectrum, we show in Fig. 15.3 a calculation from Ref. 11. A mass of 1710 MeV is predicted for the ground state, also with an error of about 100 MeV. Earlier work by other groups produced masses at 1650 MeV [12] and 1550 MeV [13] (see also [14]). The first excited state has a mass of about 2.4 GeV, and the lightest glueball with exotic quantum numbers (2^{+-}) has a mass of about 4 GeV.

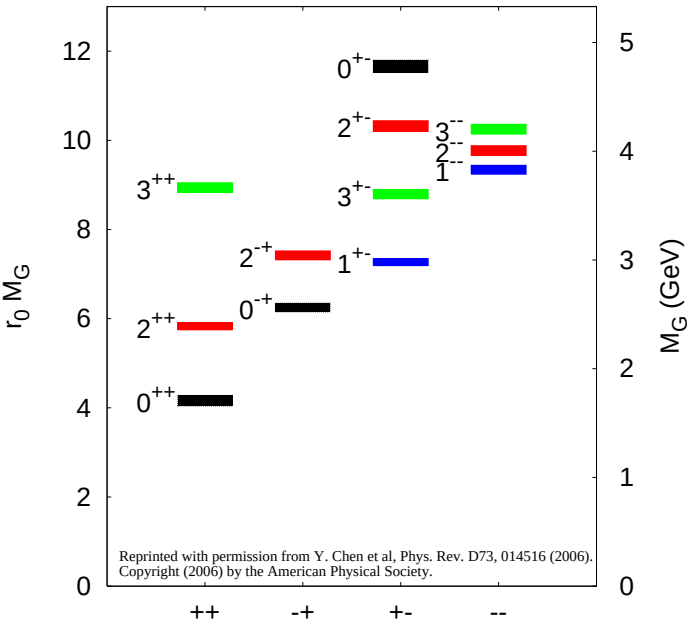

Figure 15.3: Predicted glueball mass spectrum from the lattice in quenched approximation (from Ref. 11)

These calculations are made in the so-called "quenched approximation" which neglects $q\bar{q}$ loops. However, both glue and $q\bar{q}$ states will couple to singlet scalar mesons. Therefore glueballs will mix with nearby $q\bar{q}$ states of the same quantum numbers. For example, the two isoscalar 0^{++} mesons around 1500 MeV will mix with the pure ground state glueball to generate the observed physical states $f_0(1370)$, $f_0(1500)$, and $f_0(1710)$ [8,15]. The first results from lattice calculations, which include these effects, indicate that the mass shifts are small. We return to a discussion of this point in Sec. 15.6.

The existence of three singlet scalar mesons around 1.5 GeV suggests additional degrees of freedom such as glue, since only two mesons are predicted in this mass range. The $f_0(1500)$ [8,15] or, alternatively, the $f_0(1710)$ [12], have been proposed as candidates for the scalar glueball, both states having considerable mixing also with the $f_0(1370)$. Other mixing schemes, in particular with the $f_0(500)$ and the $f_0(980)$, have also been proposed [16]. Details can be found in the "Note on Non-$q\bar{q}$ Mesons" in the Meson Listings and in Ref. 17 See also the "Note on Scalar Mesons below 2 GeV".

Mesons made of $q\bar{q}$ pairs bound by excited gluons g, the hybrid states $q\bar{q}g$, are also predicted. They should lie in the 1.9 GeV mass region, according to gluon flux tube models [18]. Lattice QCD also predicts the lightest hybrid, an exotic 1^{-+}, at a mass of 1.8 to 1.9 GeV [19]. However, the bag model predicts four nonets, among them an exotic 1^{-+} around or above 1.4 GeV [20,21]. There are so far two candidates for exotic states with quantum numbers 1^{-+}, the $\pi_1(1400)$ and $\pi_1(1600)$, which could be hybrids or four-quark states (see the "Note on Non-$q\bar{q}$ Mesons" in the Meson Listings and in Ref. 17)

15.4. Baryons: *qqq* states

Baryons are fermions with baryon number $\mathcal{B} = 1$, *i.e.*, in the most general case, they are composed of three quarks plus any number of quark - antiquark pairs. So far all established baryons are 3-quark (qqq) configurations (the LHCb collaboration has very recently announced observation of two charmed 'pentaquark' states of minimal quark content $c\bar{c}uud$ at invariant masses close to 4.4 GeV [23]). The color part of their state functions is an SU(3) singlet, a completely antisymmetric state of the three colors. Since the quarks are fermions, the state function must be antisymmetric under interchange of any two equal-mass quarks (up and down quarks in the limit of isospin symmetry). Thus it can be written as

$$|\,qqq\,\rangle_A = |\,\text{color}\,\rangle_A \times |\,\text{space, spin, flavor}\,\rangle_S\ , \tag{15.21}$$

where the subscripts S and A indicate symmetry or antisymmetry under interchange of any two equal-mass quarks. Note the contrast with the state function for the three nucleons in ^{3}H or ^{3}He:

$$|\,NNN\,\rangle_A = |\,\text{space, spin, isospin}\,\rangle_A\ . \tag{15.22}$$

This difference has major implications for internal structure, magnetic moments, *etc.* (For a nice discussion, see Ref. 24)

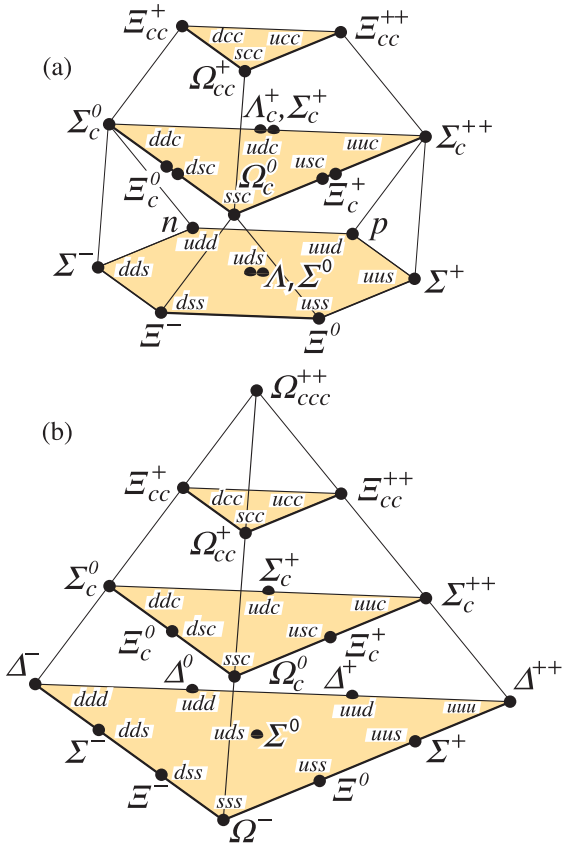

Figure 15.4: SU(4) multiplets of baryons made of u, d, s, and c quarks. (a) The 20-plet with an SU(3) octet. (b) The 20-plet with an SU(3) decuplet.

The "ordinary" baryons are made up of u, d, and s quarks. The three flavors imply an approximate flavor SU(3), which requires that baryons made of these quarks belong to the multiplets on the right side of

$$\mathbf{3} \otimes \mathbf{3} \otimes \mathbf{3} = \mathbf{10}_S \oplus \mathbf{8}_M \oplus \mathbf{8}_M \oplus \mathbf{1}_A \tag{15.23}$$

(see Sec. 46, on "SU(n) Multiplets and Young Diagrams"). Here the subscripts indicate symmetric, mixed-symmetry, or antisymmetric states under interchange of any two quarks. The $\mathbf{1}$ is a uds state (Λ_1), and the octet contains a similar state (Λ_8). If these have the same spin and parity, they can mix. The mechanism is the same as for the mesons (see above). In the ground state multiplet, the SU(3) flavor singlet Λ_1 is forbidden by Fermi statistics. Section 45, on "SU(3) Isoscalar Factors and Representation Matrices," shows how relative decay rates in, say, $\mathbf{10} \to \mathbf{8} \otimes \mathbf{8}$ decays may be calculated.

The addition of the c quark to the light quarks extends the flavor symmetry to SU(4). However, due to the large mass of the c quark, this symmetry is much more strongly broken than the SU(3) of the three light quarks. Figures 15.4(a) and 15.4(b) show the SU(4) baryon multiplets that have as their bottom levels an SU(3) octet, such as the octet that includes the nucleon, or an SU(3) decuplet, such as the decuplet that includes the $\Delta(1232)$. All particles in a given SU(4) multiplet have the same spin and parity. The charmed baryons are discussed in more detail in the "Note on Charmed Baryons" in the Particle Listings. The same multiplets as shown in 15.4 can be constructed when the c quark is replaced by the b quark, or they can be embedded in a larger SU(5) group that accounts for all baryons that can be constructed from the five quark flavors. The existence of baryons with t-quarks is very unlikely due to the short lifetime of the t-quark. The heavy quark baryons have recently gained a lot of interest. Their relatively narrow widths allow to isolate the states much easier than the light quark baryon resonances which require intricate partial wave analyses. The only problem on the experimental side are the small production cross sections, but the recent measurements at the e^+e^- colliding B factories, at the $p\bar{p}$ Tevatron collider, and at LHCb at CERN have boosted this field. A recent summary is given in Ref. 25. A possible candidate for a doubly charmed baryon had been reported by the SELEX experiment [26,27] but could so far not be confirmed by other experiments, and quark model predictions for baryons with two heavy quarks are given in Ref. 28.

For the "ordinary" baryons (no c or b quark), flavor and spin may be combined in an approximate flavor-spin SU(6), in which the six basic states are $d\uparrow$, $d\downarrow$, $\cdots$, $s\downarrow$ ($\uparrow, \downarrow$ = spin up, down). Then the baryons belong to the multiplets on the right side of

$$\mathbf{6} \otimes \mathbf{6} \otimes \mathbf{6} = \mathbf{56}_S \oplus \mathbf{70}_M \oplus \mathbf{70}_M \oplus \mathbf{20}_A\ . \tag{15.24}$$

These SU(6) multiplets decompose into flavor SU(3) multiplets as follows:

$$\mathbf{56} = {}^4\mathbf{10} \oplus {}^2\mathbf{8} \tag{15.25a}$$

$$\mathbf{70} = {}^2\mathbf{10} \oplus {}^4\mathbf{8} \oplus {}^2\mathbf{8} \oplus {}^2\mathbf{1} \tag{15.25b}$$

$$\mathbf{20} = {}^2\mathbf{8} \oplus {}^4\mathbf{1}\ , \tag{15.25c}$$

where the superscript $(2S+1)$ gives the net spin S of the quarks for each particle in the SU(3) multiplet. The $J^P = 1/2^+$ octet containing the nucleon and the $J^P = 3/2^+$ decuplet containing the $\Delta(1232)$ together make up the "ground-state" 56-plet, in which the orbital angular momenta between the quark pairs are zero (so that the spatial part of the state function is trivially symmetric). The **70** and **20** require some excitation of the spatial part of the state function in order to make the overall state function symmetric. States with nonzero orbital angular momenta are classified in SU(6)⊗O(3) supermultiplets.

It is useful to classify the baryons into bands that have the same number N of quanta of excitation. Each band consists of a number of supermultiplets, specified by (D, L_N^P), where D is the dimensionality of the SU(6) representation, L is the total quark orbital angular momentum, and P is the total parity. Supermultiplets contained in bands up to N = 12 are given in Ref. 29. The N = 0 band, which contains the nucleon and $\Delta(1232)$, consists only of the $(56,0_0^+)$ supermultiplet. The N = 1 band consists only of the $(70,1_1^-)$ multiplet and contains the negative-parity baryons with masses below about 1.9 GeV. The N = 2 band contains five supermultiplets: $(56,0_2^+)$, $(70,0_2^+)$, $(56,2_2^+)$, $(70,2_2^+)$, and $(20,1_2^+)$.

The wave functions of the non-strange baryons in the harmonic oscillator basis are often labeled by $|X^{2S+1}L_\pi J^P\rangle$, where S, L, J, P are as above, $X = N$ or Δ, and $\pi = S, M$ or A denotes the symmetry of the spatial wave function. The possible model states for the bands with N=0,1,2 are given in Table 15.5. The assignment of experimentally observed states is only complete and well established

Table 15.5: N and Δ states in the N=0,1,2 harmonic oscillator bands. L^P denotes angular momentum and parity, S the three-quark spin and 'sym'=A,S,M the symmetry of the spatial wave function. Only dominant components indicated. Assignments in the N=2 band are partly tentative.

N	sym	L^P	S	$N(I=1/2)$				$\Delta(I=3/2)$			
2	A	1^+	1/2	$1/2^+$	$3/2^+$						
2	M	2^+	3/2	$1/2^+$	$3/2^+$	$5/2^+$	$7/2^+$				
2	M	2^+	1/2		$3/2^+$	$5/2^+$		$3/2^+$	$5/2^+$		
2	M	0^+	3/2		$3/2^+$						
2	M	0^+	1/2	$1/2^+$				$1/2^+$			
				$N(1710)$				$\Delta(1750)$			
2	S	2^+	3/2					$1/2^+$	$3/2^+$	$5/2^+$	$7/2^+$
								$\Delta(1910)$	$\Delta(1920)$	$\Delta(1905)$	$\Delta(1950)$
2	S	2^+	1/2		$3/2^+$	$5/2^+$					
					$N(1720)$	$N(1680)$					
2	S	0^+	3/2						$3/2^+$		
									$\Delta(1600)$		
2	S	0^+	1/2	$1/2^+$							
				$N(1440)$							
1	M	1^-	3/2	$1/2^-$	$3/2^-$	$5/2^-$					
				$N(1650)$	$N(1700)$	$N(1675)$					
1	M	1^-	1/2	$1/2^-$	$3/2^-$			$1/2^-$	$3/2^-$		
				$N(1535)$	$N(1520)$			$\Delta(1620)$	$\Delta(1700)$		
0	S	0^+	3/2						$3/2^+$		
									$\Delta(1232)$		
0	S	0^+	1/2	$1/2^+$							
				$N(938)$							

up to the N=1 band. Some more tentative assignments for higher multiplets are suggested in Ref. 30.

In Table 15.6, quark-model assignments are given for many of the established baryons whose SU(6)⊗O(3) compositions are relatively unmixed. One must, however, keep in mind that apart from the mixing of the Λ singlet and octet states, states with same J^P but different L, S combinations can also mix. In the quark model with one-gluon exchange motivated interactions, the size of the mixing is determined by the relative strength of the tensor term with respect to the contact term (see below). The mixing is more important for the decay patterns of the states than for their positions. An example are the lowest lying $(70, 1^-_1)$ states with J^P=1/2$^-$ and 3/2$^-$. The physical states are:

$$|\,N(1535)1/2^-\rangle = \cos(\Theta_S)|N^2P_M1/2^-\rangle - \sin(\Theta_S)|N^4P_M1/2^-\rangle \quad (15.26)$$

$$|\,N(1520)3/2^-\rangle = \cos(\Theta_D)|N^2P_M3/2^-\rangle - \sin(\Theta)_D|N^4P_M3/2^-\rangle \quad (15.27)$$

and the orthogonal combinations for $N(1650)1/2^-$ and $N(1700)3/2^-$. The mixing is large for the J^P=1/2$^-$ states ($\Theta_S \approx$ -32^o), but small for the J^P=3/2$^-$ states ($\Theta_D \approx +6^o$) [31,32].

All baryons of the ground state multiplets are known. Many of their properties, in particular their masses, are in good agreement even with the most basic versions of the quark model, including harmonic (or linear) confinement and a spin-spin interaction, which is responsible for the octet - decuplet mass shifts. A consistent description of the ground-state electroweak properties, however, requires refined relativistic constituent quark models.

The situation for the excited states is much less clear. The assignment of some experimentally observed states with strange quarks to model configurations is only tentative and in many cases candidates are completely missing. Recently, Melde, Plessas and Sengl [33] have calculated baryon properties in relativistic constituent quark models, using one-gluon exchange and Goldstone-boson exchange for the modeling of the hyperfine interactions (see Sec. 15.5 on Dynamics). Both types of models give qualitatively comparable results, and underestimate in general experimentally observed decay widths. Nevertheless, in particular on the basis of the observed decay patterns, the authors have assigned some additional states with strangeness to the SU(3) multiplets and suggest re-assignments for a few others. Among the new assignments are states with weak experimental evidence (two or three star ratings) and partly without firm spin/parity assignments, so that further experimental efforts are necessary before final conclusions can be drawn. We have added their suggestions in Table 15.6.

In the non-strange sector there are two main problems which are illustrated in Fig. 15.5, where the experimentally observed excitation spectrum of the nucleon (N and Δ resonances) is compared to the results of a typical quark model calculation [34]. The lowest states from the N=2 band, the $N(1440)1/2^+$, and the $\Delta(1600)3/2^+$, appear lower than the negative parity states from the N=1 band (see Table 15.5) and much lower than predicted by most models. Also negative parity Δ states from the N=3 band ($\Delta(1900)1/2^-$, $\Delta(1940)3/2^-$, and $\Delta(1930)5/2-$) are too low in energy. Part of the problem could be experimental. Among the negative parity Δ states, only the $\Delta(1930)5/2^-$ has three stars and the uncertainty in the position of the $\Delta(1600)3/2^+$ is large (1550 - 1700 MeV).

Furthermore, many more states are predicted than observed. This has been known for a long time as the 'missing resonance' problem [31]. Up to an excitation energy of 2.4 GeV, about 45 N states are predicted, but only 14 are established (four- or three-star; see Note on N and Δ Resonances for the rating of the status of resonances) and 10 are tentative (two- or one-star). Even for the N=2 band, up to now only half of the predicted states have been observed. The most recent partial wave analysis of elastic pion scattering and charge exchange data by Arndt and collaborators [35] has made the situation even worse. They found no evidence for almost half of the states listed in this review (and included in Fig. 15.5).

Such analyses are of course biased against resonances which couple only weakly to the $N\pi$ channel. Quark model predictions for the couplings to other hadronic channels and to photons are given in Ref. 34. A large experimental effort is ongoing at several electron accelerators to study the baryon resonance spectrum with real and virtual photon-induced meson production reactions. This includes the search for as-yet-unobserved states, as well as detailed studies of the properties of the low lying states (decay patterns, electromagnetic couplings, magnetic moments, *etc.*) (see Ref. 36 for recent reviews). This experimental effort has currently entered its final phase with the measurement of single and double polarization observables for many different meson production channels, so that a much better understanding of the experimental spectrum can be expected for the near future.

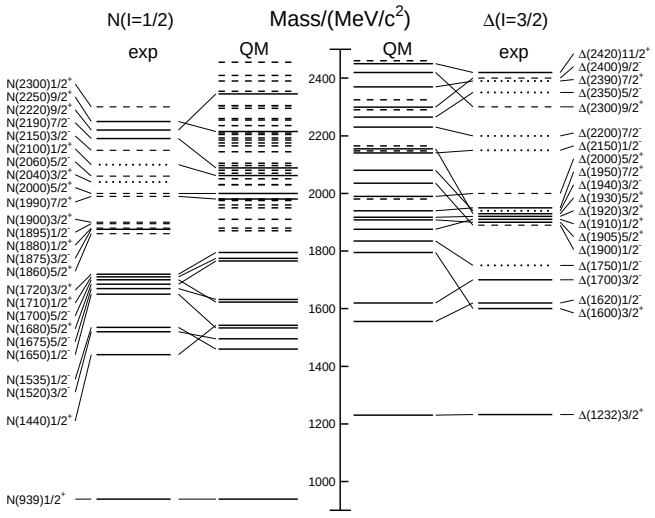

Figure 15.5: Excitation spectrum of the nucleon. Compared are the positions of the excited states identified in experiment, to those predicted by a relativized quark model calculation. Left hand side: isospin $I = 1/2$ N-states, right hand side: isospin $I = 3/2$ Δ-states. Experimental: (columns labeled 'exp'), three- and four-star states are indicated by full lines (two-star dashed lines, one-star dotted lines). At the very left and right of the figure, the spectroscopic notation of these states is given. Quark model [34]: (columns labeled 'QM'), all states for the N=1,2 bands, low-lying states for the N=3,4,5 bands. Full lines: at least tentative assignment to observed states, dashed lines: so far no observed counterparts. Many of the assignments between predicted and observed states are highly tentative.

In quark models, the number of excited states is determined by the effective degrees of freedom, while their ordering and decay properties are related to the residual quark - quark interaction. An overview of quark models for baryons is given in Ref. 32, recent discussions of baryon spectroscopy are given in Refs. 30 and 25. The effective degrees of freedom in the standard nonrelativistic quark model are three equivalent valence quarks with one-gluon exchange-motivated, flavor-independent color-magnetic interactions. The QCD aspect of gluon-gluon interactions is emphasized by the hypercentral quark model [37], [38], which includes in a natural way three-body forces between the quarks. A different class of models uses interactions which give rise to a quark - diquark clustering of the baryons: for a review see Ref. 39. If there is a tightly bound diquark, only two degrees of freedom are available at low energies, and thus *fewer* states are predicted. Furthermore, selection rules in the decay pattern may arise from the quantum numbers of the diquark. *More* states are predicted by collective models of the baryon like the algebraic approach in Ref. 40. In this approach, the quantum numbers of the valence quarks are distributed over a Y-shaped string-like configuration, and additional states arise *e.g.*, from vibrations of the strings. *More* states are also predicted in the framework of flux-tube models, see Ref. 41, which are motivated by lattice QCD. In addition to the quark degrees of freedom, flux-tubes responsible for the confinement of the quarks are considered as degrees of freedom. These models include hybrid baryons containing explicit excitations of the gluon fields. However, since all half integral J^P quantum numbers are possible for ordinary baryons, such 'exotics' will be very hard to identify, and probably always mix with ordinary states. So far, the experimentally observed number of states is still far lower even than predicted by the quark–diquark models.

Table 15.6: Quark-model assignments for some of the known baryons in terms of a flavor-spin SU(6) basis. Only the dominant representation is listed. Assignments for several states, especially for the $\Lambda(1810)$, $\Lambda(2350)$, $\Xi(1820)$, and $\Xi(2030)$, are merely educated guesses. † recent suggestions for assignments and re-assignments from Ref. 33. For assignments of the charmed baryons, see the "Note on Charmed Baryons" in the Particle Listings.

Recently, the influence of chiral symmetry on the excitation spectrum of the nucleon has been hotly debated from a somewhat new perspective. Chiral symmetry, the fundamental symmetry of QCD, is strongly broken for the low lying states, resulting in large mass differences of parity partners like the J^P=$1/2^+$ $N(938)1/2^+$ ground state and the J^P=$1/2^-$ $N(1535)1/2^-$ excitation. However, at higher excitation energies there is some evidence for parity doublets and even some very tentative suggestions for full chiral multiplets of N^* and Δ resonances. An effective restoration of chiral symmetry at high excitation energies due to a decoupling from the quark condensate of the vacuum has been discussed (see Ref. 42 for recent reviews) as a possible cause. In this case, the mass generating mechanisms for low and high lying states would be essentially different. As a further consequence, the parity doublets would decouple from pions, so that experimental bias would be worse. However, parity doublets might also arise from the spin-orbital dynamics of the 3-quark system. Presently, the status of data does not allow final conclusions.

The most recent developments on the theory side are the first unquenched lattice calculations for the excitation spectrum discussed in Sec. 15.6. The results are basically consistent with the level counting of SU(6)⊗O(3) in the standard non-relativistic quark model and show no indication for quark-diquark structures or parity

doubling. Consequently, there is as yet no indication from lattice that the mis-match between the excitation spectrum predicted by the standard quark model and experimental observations is due to inappropriate degrees of freedom in the quark model.

15.5. Dynamics

Quantum chromodynamics (QCD) is well-established as the theory for the strong interactions. As such, one of the goals of QCD is to predict the spectrum of strongly-interacting particles. To date, the only first-principles calculations of spectroscopy from QCD use lattice methods. These are the subject of Sec. 15.6. These calculations are difficult and unwieldy, and many interesting questions do not have a good lattice-based method of solution. Therefore, it is natural to build models, whose ingredients are abstracted from QCD, or from the low-energy limit of QCD (such as chiral Lagrangians) or from the data itself. The words "quark model" are a shorthand for such phenomenological models. Many specific quark models exist, but most contain a similar basic set of dynamical ingredients. These include:

i) A confining interaction, which is generally spin-independent (*e.g.*, harmonic oscillator or linear confinement);

ii) Different types of spin-dependent interactions:

a) commonly used is a color-magnetic flavor-independent interaction modeled after the effects of gluon exchange in QCD (see *e.g.*, Ref. 43) For example, in the S-wave states, there is a spin-spin hyperfine interaction of the form

$$H_{HF} = -\alpha_S M \sum_{i>j} (\overrightarrow{\sigma}\lambda_a)_i (\overrightarrow{\sigma}\lambda_a)_j \ , \tag{15.28}$$

where M is a constant with units of energy, λ_a $(a = 1, \cdots, 8,)$ is the set of SU(3) unitary spin matrices, defined in Sec. 45, on "SU(3) Isoscalar Factors and Representation Matrices," and the sum runs over constituent quarks or antiquarks. Spin-orbit interactions, although allowed, seem to be small in general, but a tensor term is responsible for the mixing of states with the same J^P but different L, S combinations.

b) other approaches include flavor-dependent short-range quark forces from instanton effects (see *e.g.*, Ref. 44) This interaction acts only on scalar, isoscalar pairs of quarks in a relative S-wave state:

$$\langle q^2; S, L, T|W|q^2; S, L, T\rangle = -4g\delta_{S,0}\delta_{L,0}\delta_{I,0}\mathcal{W} \tag{15.29}$$

where $\mathcal{W}$ is the radial matrix element of the contact interaction.

c) a rather different and controversially discussed approach is based on flavor-dependent spin-spin forces arising from one-boson exchange. The interaction term is of the form:

$$H_{HF} \propto \sum_{i<j} V(\overrightarrow{r}_{ij})\lambda_i^F \cdot \lambda_j^F \overrightarrow{\sigma}_i \cdot \overrightarrow{\sigma}_j \tag{15.30}$$

where the λ_i^F are in flavor space (see *e.g.*, Ref. 45).

iii) A strange quark mass somewhat larger than the up and down quark masses, in order to split the SU(3) multiplets;

iv) In the case of spin-spin interactions (iia,c), a flavor-symmetric interaction for mixing $q\overline{q}$ configurations of different flavors (*e.g.*, $u\overline{u} \leftrightarrow d\overline{d} \leftrightarrow s\overline{s}$), in isoscalar channels, so as to reproduce *e.g.*, the η - η' and ω - ϕ mesons.

These ingredients provide the basic mechanisms that determine the hadron spectrum in the standard quark model.

15.6. Lattice Calculations of Hadronic Spectroscopy

Lattice calculations are a major source of information about QCD masses and matrix elements. The necessary theoretical background is given in Sec. 18 of this *Review*. Here we confine ourselves to some general comments and illustrations of lattice calculations for spectroscopy.

In general, the cleanest lattice results come from computations of processes in which there is only one particle in the simulation volume. These quantities include masses of hadrons, simple decay constants, like pseudoscalar meson decay constants, and semileptonic form factors (such as the ones appropriate to $B \to Dl\nu$, $Kl\nu$, $\pi l\nu$). The cleanest predictions for masses are for states which have narrow decay widths and are far below any thresholds to open channels, since the effects of final state interactions are not yet under complete control on the lattice. As a simple corollary, the lightest state in a channel is easier to study than the heavier ones. "Difficult" states for the quark model (such as exotics) are also difficult for the lattice because of the lack of simple operators which couple well to them.

Good-quality modern lattice calculations will present multi-part error budgets with their predictions. A small part of the uncertainty is statistical, from sample size. Typically, the quoted statistical uncertainty includes uncertainty from a fit: it is rare that a simulation computes one global quantity which is the desired observable. Simulations which include virtual quark-antiquark pairs (also known as "dynamical quarks" or "sea quarks") are often done at up and down quark mass values heavier than the experimental ones, and it is then necessary to extrapolate in these quark masses. Simulations can work at the physical values of the heavier quarks' masses. They are always done at nonzero lattice spacing, and so it is necessary to extrapolate to zero lattice spacing. Some theoretical input is needed to do this. Much of the uncertainty in these extrapolations is systematic, from the choice of fitting function. Other systematics include the effect of finite simulation volume, the number of flavors of dynamical quarks actually simulated, and technical issues with how these dynamical quarks are included. The particular choice of a fiducial mass (to normalize other predictions) is not standardized; there are many possible choices, each with its own set of strengths and weaknesses, and determining it usually requires a second lattice simulation from that used to calculate the quantity under consideration.

A systematic error of major historical interest is the "quenched approximation," in which dynamical quarks are simply left out of the simulation. This was done because the addition of these virtual pairs presented an expensive computational problem. No generally-accepted methodology has ever allowed one to correct for quenching effects, short of redoing all calculations with dynamical quarks. Recent advances in algorithms and computer hardware have rendered it obsolete.

With these brief remarks, we turn to examples. The field of lattice QCD simulations is vast, and so it is not possible to give a comprehensive review of them in a small space. The history of lattice QCD simulations is a story of thirty years of incremental improvements in physical understanding, algorithm development, and ever faster computers, which have combined to bring the field to a present state where it is possible to carry out very high quality calculations. We present a few representative illustrations, to show the current state of the art.

By far, the major part of all lattice spectroscopy is concerned with that of the light hadrons, and so we illustrate results in Fig. 15.6, a comprehensive summary provided by A. Kronfeld [46].

Flavor singlet mesons are at the frontier of lattice QCD calculations, because one must include the effects of "annihilation graphs," for the valence q and $\bar{q}$. Recently, several groups, Refs. 6, 53–56, have reported calculations of the η and η' mesons. The numbers of Ref. 6 are typical, finding masses of 573(6) and 947(142) MeV for the η and η'. The singlet-octet mixing angle (in the conventions of Table 15.2) is $\theta_{lin} = -14.1(2.8)^\circ$.

The spectroscopy of mesons containing heavy quarks has become a truly high-precision endeavor. These simulations use Non-Relativistic QCD (NRQCD) or Heavy Quark Effective Theory (HQET), systematic expansions of the QCD Lagrangian in powers of the heavy quark velocity, or the heavy quark mass. Terms in the Lagrangian have obvious quark model analogs, but are derived directly from QCD. For example, the heavy quark potential is a derived quantity, extracted from simulations. Fig. 15.7 shows the mass spectrum for mesons containing at least one heavy (b or c) quark from Ref. 59 It also contains results from Refs. 61 and 62 The calculations uses a discretization of nonrelativistic QCD for bottom quarks with charm and lighter quarks being handled with an improved relativistic action. Four flavors (u, d, s, c) of dynamical quarks are included.

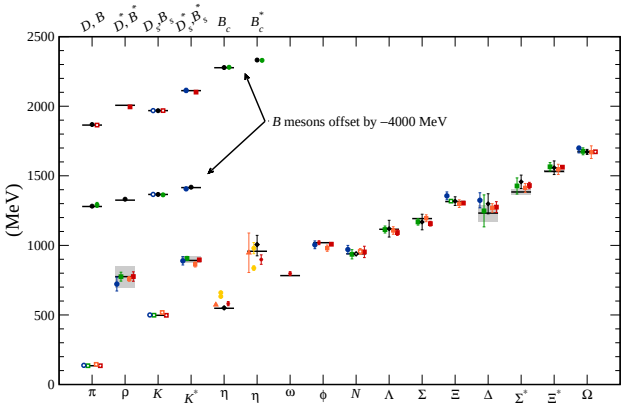

Figure 15.6: Hadron spectrum from lattice QCD. Comprehensive results for mesons and baryons are from MILC [47,48], PACS-CS [49], BMW [50], QCDSF [51], and ETM [68]. Results for η and η' are from RBC & UKQCD [6], Hadron Spectrum [54](also the only ω mass), UKQCD [53], and Michael, Ottnad, and Urbach [55]. Results for heavy-light hadrons from Fermilab-MILC [57], HPQCD [58,59], and Mohler and Woloshyn [60]. Circles, squares, diamonds, and triangles stand for staggered, Wilson, twisted-mass Wilson, and chiral sea quarks, respectively. Asterisks represent anisotropic lattices. Open symbols denote the masses used to fix parameters. Filled symbols (and asterisks) denote results. Red, orange, yellow, green, and blue stand for increasing numbers of ensembles (i.e., lattice spacing and sea quark mass). Black symbols stand for results with 2+1+1 flavors of sea quarks. Horizontal bars (gray boxes) denote experimentally measured masses (widths). b-flavored meson masses are offset by −4000 MeV.

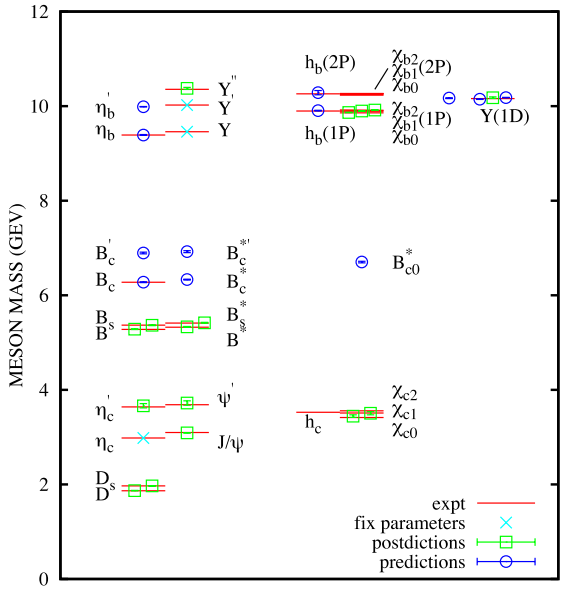

Figure 15.7: Spectroscopy for mesonic systems containing one or more heavy quarks (adapted from Ref. 59) Particles whose masses are used to fix lattice parameters are shown with crosses; the authors distinguish between "predictions" and "postdictions" of their calculation. Lines represent experiment.

Fig. 15.8 shows a compilation of recent lattice results for doubly and triply charmed baryons, from Ref. 63.

There are a number of reported states near the charmonium-$D-\bar{D}$ threshold, including the X(3872), $D^*_{s0}(2317)$, $Z_c^{\pm}(3900)$ and X(4140), whose quark composition is obscure (see the "Note on Non-$q\bar{q}$ mesons in the Meson Listings." The current status of lattice studies of these

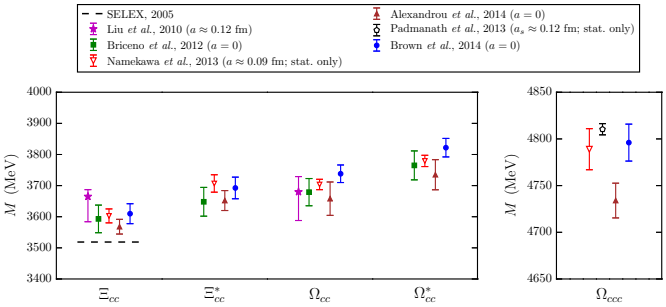

Figure 15.8: Comparison of lattice QCD results for the doubly and triply charmed baryon masses. Labels are Liu, *et al.*, [64]; Briceno, *et al.*, [65]; Namekawa, *et al.*, [66]; Padmanath, *et al.*, [67]; Alexandrou, *et al.*, [68]; and Brown, *et al.*, citequarkmod:Brown:2014ena. Only calculations with dynamical light quarks are included; for the doubly charmed baryons, only calculations were performed at or extrapolated to the physical pion mass are shown. Results without estimates of systematic uncertainties are labeled "stat. only". The lattice spacing values used in the calculations are also given; $a = 0$ indicates that the results have been extrapolated to the continuum limit. In the plot of the doubly charmed baryons, the unconfirmed experimental result for the Ξ_{cc}^+ mass from SELEX [26,27] is shown with a dashed line.

states is reviewed in Ref. 69.

Recall that lattice calculations take operators which are interpolating fields with quantum numbers appropriate to the desired states, compute correlation functions of these operators, and fit the correlation functions to functional forms parametrized by a set of masses and matrix elements. As we move away from hadrons which can be created by the simplest quark model operators (appropriate to the lightest meson and baryon multiplets) we encounter a host of new problems: either no good interpolating fields, or too many possible interpolating fields, and many states with the same quantum numbers. Techniques for dealing with these interrelated problems vary from collaboration to collaboration, but all share common features: typically, correlation functions from many different interpolating fields are used, and the signal is extracted in what amounts to a variational calculation using the chosen operator basis. In addition to mass spectra, wave function information can be garnered from the form of the best variational wave function. Of course, the same problems which are present in the spectroscopy of the lightest hadrons (the need to extrapolate to infinite volume, physical values of the light quark masses, and zero lattice spacing) are also present. We briefly touch on three different kinds of hadrons: excited states of mesons (including hybrids), excited states of baryons, and glueballs. The quality of the data is not as good as for the ground states, and so the results continue to evolve.

Modern calculations use a large bases of trial states, which allow them to probe many quantum number channels simultaneously. This is vital for studying "difficult sectors" of QCD, such as the isoscalar mesons. A recent example of meson spectroscopy where this is done, by Ref. 56, is shown in Fig. 15.9. The quark masses are still heavier than their physical values, so the pion is at 391 MeV. The authors can assign a relative composition of nonstrange and strange quark content to their states, observing, for example, a nonstrange ω and a strange ϕ. Some states also have a substantial component of gluonic excitation. Note especially the three exotic channels $J^{PC} = 1^{-+}$, 0^{+-}, and 2^{+-}, with states around 2 GeV. These calculations will continue to improve as the quark masses are carried lower.

The interesting physics questions of excited baryon spectroscopy to be addressed are precisely those enumerated in the last section. An example of a recent calculation, due to Ref. 70 is shown in Fig. 15.10. Notice that the pion is not yet at its physical value. The lightest positive parity state is the nucleon, and the Roper resonance has not yet appeared as a light state.

In Fig. 15.3 we showed a figure from Ref. 11 presenting a lattice prediction for the glueball mass spectrum in quenched approximation. A true QCD prediction of the glueball spectrum requires dynamical

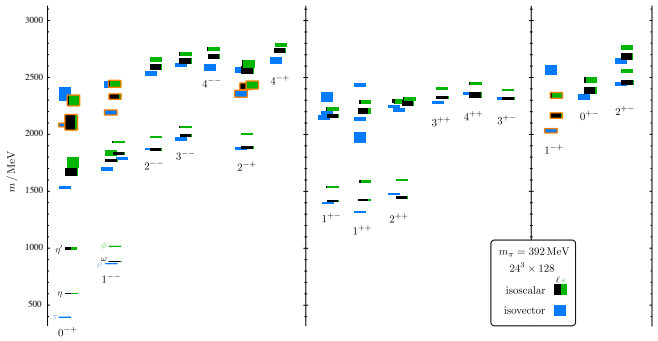

Figure 15.9: Isoscalar (green and black) and isovector (blue) spectrum from Ref. 56. States are labeled J^{PC}. The quark mass is heavier than its physical value; $m_\pi = 391$ MeV. The vertical height of each box indicates the statistical uncertainty in the mass. Black and green indicate relative nonstrange and strange composition. Orange outlines show states with a large chromomagnetic component to their wave function, which the authors of Ref. 56 argue are hybrid states. Note the exotic states in the three rightmost columns.

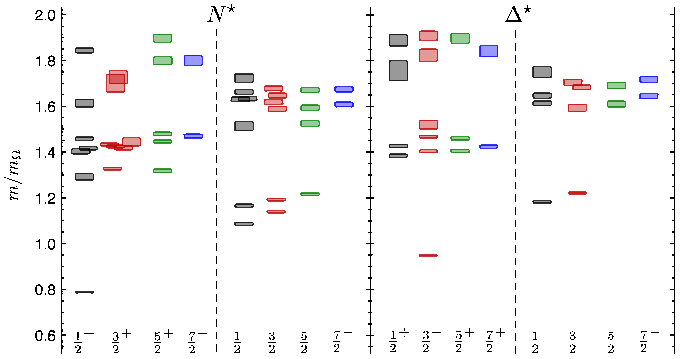

Figure 15.10: Spin-identified spectrum of nucleons and deltas, from lattices where $m_\pi = 396$ MeV, in units of the calculated Ω mass, from Ref. 70. The colors just correspond to the different J assignments: grey for $J = 1/2$, red for $J = 3/2$, green for 5/2, blue for $J = 7/2$.

light quarks and (because glueball operators are intrinsically noisy) high statistics. Only recently have the first useful such calculations appeared. Fig. 15.11 shows results from Ref. 71, done with dynamical u, d and s quarks at two lattice spacings, 0.123 and 0.092 fm, along with comparisons to the quenched lattice calculation of Ref. 10 and to experimental isosinglet mesons. The dynamical simulation is, of course, not the last word on this subject, but it shows that the effects of quenching seem to be small.

Several other features of hadronic spectroscopy are also being studied on the lattice.

Electromagnetic mass splittings (such as the neutron - proton mass difference) are interesting but difficult. These calculations are important for determining the values of the quark masses (for a discussion see the review in the PDG). Knowing that the neutron is heavier than the proton tells us that these splittings have a complicated origin. One part of the shift is because the up and down quarks have slightly different masses. The second is that the quarks have (different) charges. In pre-lattice days, phenomenologists would combine Coulomb forces and spin-dependent electromagnetic hyperfine interactions to model their charge effects. These days, in order to compute hadronic mass differences on the lattice, electromagnetic interactions must be included in the simulations. This creates a host of technical issues. An important one is that electromagnetic interactions are long range, but lattice simulations are done in finite volumes. A recent calculation, Ref. 72, has presented the first results for electromagnetic mass splittings in the baryon octet. The situation is summarized in the review Ref. 73.

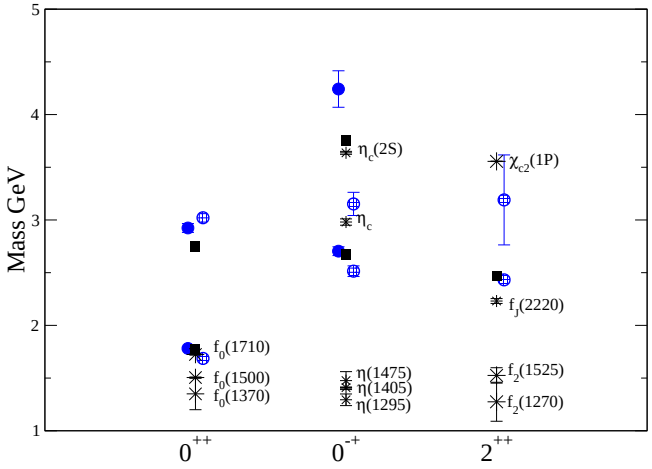

Figure 15.11: Lattice QCD predictions for glueball masses. The open and closed circles are the larger and smaller lattice spacing data of the full QCD calculation of glueball masses of Ref. 71. Squares are the quenched data for glueball masses of Ref. 10. The bursts labeled by particle names are experimental states with the appropriate quantum numbers.

Most hadrons are resonances, and their widths are the last target of lattice simulations we will mention. The actual calculation is of the combined mass of two (or more) hadrons in a box of finite size. The combined mass is shifted from being the sum of the individual masses because the finite box forces the hadrons to interact with each other. The volume-dependent mass shift yields the phase shift for the continuum scattering amplitude, which in turn can be used to extract the resonance mass and width, with some degree of modeling. So far only two-body resonances, the rho meson and a few others, have been well studied. This is an active research topic. A recent review, Ref. 74, summarizes the situation, and an example of a calculation of the rho meson's decay width is Ref. 75.

16. GRAND UNIFIED THEORIES

Revised January 2016 by A. Hebecker (U. Heidelberg) and J. Hisano (Nagoya U.)

16.1. The Standard Model

The Standard Model (SM) may be defined as the renormalizable field theory with gauge group $G_{SM} = SU(3)_C \times SU(2)_L \times U(1)_Y$, with 3 generations of fermions in the representation

$$(\mathbf{3},\mathbf{2})_{1/3} + (\bar{\mathbf{3}},\mathbf{1})_{-4/3} + (\bar{\mathbf{3}},\mathbf{1})_{2/3} + (\mathbf{1},\mathbf{2})_{-1} + (\mathbf{1},\mathbf{1})_{2}\ , \qquad (16.1)$$

and a scalar Higgs doublet H transforming as $(\mathbf{1},\mathbf{2})_1$. Here and below we use boldface numbers to specify the dimension of representations of non-Abelian groups (in this case fundamental and antifundamental) and lower indices for $U(1)$ ffichargs. The fields of Eq. (16.1) should also be familiar as $[Q, u^c, d^c, L, e^c]$, with $Q = (u, d)$ and $L = (\nu, e)$ being the quark and lepton $SU(2)$-doublets and u^c, d^c, e^c charge conjugate $SU(2)$-singlets.† Especially after the recent discovery of the Higgs, this model is remarkably complete and consistent with almost all experimental data.

A notable exception are neutrino masses, which are known to be non-zero but are absent in the SM even after the Higgs acquires its vacuum expectation value (VEV). The minimalist attitude is to allow for the dimension-five operator $(HL)^2$, which induces (Majorana) neutrino masses. In the seesaw mechanism [1,2,3] this operator is generated by integrating out heavy singlet fermions (r.h. neutrinos). Alternatively, neutrinos can have Dirac masses if light singlet neutrinos are added to the SM spectrum.

Conceptual problems of the SM include the absence of a Dark Matter candidate, of a mechanism for generating the baryon asymmetry of the universe, and of any reason for the observed smallness of the θ parameter of QCD (θ_{QCD}). In addition, the apparently rather complex group-theoretic data of Eq. (16.1) remains unexplained. Together with the abundance of seemingly arbitrary coupling constants, this disfavors the SM as a candidate fundamental theory, even before quantum gravity problems arise at energies near M_P.

To be precise, there are 19 SM parameters which have to be fitted to data: Three gauge couplings* g_3, g_2 and g_1, 13 parameters associated with the Yukawa couplings (9 charged fermion masses, three mixing angles and one CP phase in the CKM matrix.), the Higgs mass and quartic coupling, and θ_{QCD}. In addition, Majorana neutrinos introduce 3 more masses and 6 mixing angles and phases.

As we will see, the paradigm of grand unification addresses mainly the group theoretic data of Eq. (16.1) and the values of the three gauge couplings. In many concrete realizations, it then impacts also the other mentioned issues of the SM, such as e.g. the family structure and fermion mass hierarchy.

More specifically, after precision measurements of the Weinberg angle θ_W in the LEP experiments, supersymmetric GUTs (SUSY GUTs) have become the leading candidates in the search for 'Physics beyond the SM'. Supersymmetry (SUSY) is a symmetry between bosons and fermions which requires the addition of superpartners to the SM spectrum, thereby leading to the noted prediction of θ_W [4]. The measured Higgs mass (~ 125 GeV) is in principle consistent with this picture, assuming superpartners in the region of roughly 10 TeV. Such heavy superpartners then induce radiative corrections raising the Higgs mass above the Z boson mass m_Z [5,6]. However, if SUSY is motivated as a solution to the gauge hierarchy problem (i.e. to the naturalness problem of the Higgs mass) [7], its minimal incarnation in terms of the MSSM is becoming questionable. Indeed, compared to expectations based on the **minimal** SUSY SM (MSSM) with superpartner masses below about 1 TeV, the Higgs mass is somewhat too high [8]. Independently, the LHC has disfavored light colored superpartners. These facts represent new hints for future work on SUSY GUTs or on GUTs without TeV-scale supersymmetry.

† In our convention the electric charge is $Q = T_3 + Y/2$ and all our spinor fields are left-handed.

* Equivalently, the $SU(2)_L$ and $U(1)_Y$ couplings are denoted as $g = g_2$ and $g' = \sqrt{3/5}\ g_1$. One also uses $\alpha_s = \alpha_3 = (g_3^2/4\pi)$, $\alpha_{EM} = (e^2/4\pi)$ with $e = g\ \sin\theta_W$ and $\sin^2\theta_W = (g')^2/(g^2 + (g')^2)$.

16.2. Basic Group Theory and Charge Quantization

Historically, the first attempt at unification was the Pati-Salam model with gauge group $G_{PS} = SU(4)_C \times SU(2)_L \times SU(2)_R$ [9]. It unifies SM fermions in the sense that one generation (plus an extra SM singlet) now comes from the $(\mathbf{4},\mathbf{2},\mathbf{1}) + (\bar{\mathbf{4}},\mathbf{1},\mathbf{2})$ of G_{PS}. This is easy to verify from the breaking pattern $SU(4)_C \to SU(3)_C \times U(1)_{B-L}$ together with the identification of SM hypercharge as a linear combination between $B - L$ (baryon minus lepton number) with the T_3 generator of $SU(2)_R$. This model explains charge quantization, that is, why all electric charges are integer multiples of some smallest charge in the SM. However, G_{PS} is not simple (containing three simple factors), and thus it does not predict gauge coupling unification.

Since G_{SM} has rank four (two for $SU(3)_C$ and one for $SU(2)_L$ and $U(1)_Y$, respectively), the rank-four group $SU(5)$ is the minimal choice for unification in a simple group [10]. The three SM gauge coupling constants derive from a universal coupling α_G at the GUT scale M_G. Explicitly embedding G_{SM} in $SU(5)$ is straightforward, with $SU(3)_C$ and $SU(2)_L$ corresponding e.g. to the upper-left 3×3 and lower-right 2×2 blocks, respectively, in traceless 5×5 matrices for $SU(5)$ generators of the fundamental representation. The $U(1)_Y$ corresponds to matrices generated by $\mathrm{diag}(-2/3,-2/3,-2/3,1,1)$, which hence commute with $SU(3)_C \times SU(2)_L \subset SU(5)$. It is then easy to derive how one SM generation precisely comes from the $\mathbf{10}+\bar{\mathbf{5}}$ of $SU(5)$ (where $\mathbf{10}$ is the antisymmetric rank-2 tensor):

$$\mathbf{10}: \begin{pmatrix} 0 & u_b^c & -u_g^c & u_r & d_r \\ -u_b^c & 0 & u_1^c & u_g & d_g \\ u_g^c & -u_r^c & 0 & u_b & d_b \\ -u_r & -u_g & -u_b & 0 & e^c \\ -d_r & -d_g & -d_b & -e^c & 0 \end{pmatrix} \quad \text{and} \quad \bar{\mathbf{5}}: \begin{pmatrix} d_r^c \\ d_g^c \\ d_b^c \\ e \\ -\nu_e \end{pmatrix} \qquad (16.2)$$

Since $SU(5)$ has 24 generators, $SU(5)$ GUTs have 12 new gauge bosons known as X bosons (or X/Y bosons) in addition to the SM. X bosons form an $SU(3)_C$-triplet and $SU(2)_L$-doublet. Their interaction connects quarks and leptons such that baryon and lepton numbers are not conserved and nucleon decay is predicted. Furthermore, $U(1)_Y$ hypercharge is automatically quantized since it is embedded in $SU(5)$.

In order to break the electroweak symmetry at the weak scale and give mass to quarks and leptons, Higgs doublets are needed. In the minimal $SU(5)$ model, they can sit in either a $\mathbf{5_H}$ or $\bar{\mathbf{5}}_\mathbf{H}$. The three additional states are referred to as color-triplet Higgs scalars. Their couplings also violate baryon and lepton numbers, inducing nucleon decay. In order not to violently disagree with the non-observation of nucleon decay, the triplet mass must be greater than $\sim 10^{11}$ GeV [11]. Moreover, in SUSY GUTs [12], in order to cancel anomalies as well as give mass to both up and down quarks, both Higgs multiplets $\mathbf{5_H}$, and $\bar{\mathbf{5}}_\mathbf{H}$ are required. As we shall discuss later, nucleon decay now constrains the Higgs triplets to have mass significantly greater than M_G in the minimal SUSY $SU(5)$ GUT since integrating out the Higgs triplets generates dimension-five baryon-number-violating operators [13]. The mass splitting between doublet and triplet in the $\mathbf{5_H}$ (and $\bar{\mathbf{5}}_\mathbf{H}$) comes from their interaction with the $SU(5)$ breaking sector.

While $SU(5)$ allows for the minimal GUT models, unification is not complete: Two independent representations, $\mathbf{10}$ and $\bar{\mathbf{5}}$, are required for one SM generation.

A further representation, an SU(5) singlet, has to be added to serve as r.h. neutrino in the seesaw mechanism. In this case, the r.h. neutrino masses are not necessarily related to the GUT scale.

By contrast, a single **16**-dimensional spinor representation of $SO(10)$ accommodates a full SM generation together with an extra singlet, potentially providing a r.h. neutrino [14]. This is most easily understood from the breaking pattern $SO(10) \to SU(5) \times U(1)_X$ and the associated branching rule* $\mathbf{16} = \mathbf{10}_{-5} + \bar{\mathbf{5}}_3 + \mathbf{1}_{-1}$. Here the indices refer to charges under the $U(1)_X$ subgroup, which is orthogonal to $SU(5)$ and reflects the fact that $SO(10)$ has rank five. From the above, it is easy to see that $U(1)_X$ charges can be given as $2Y - 5(B - L)$.

* Useful references on group theory in the present context include [15] and refs. therein.

Intriguingly, all representations of $SO(10)$ are anomaly free in four dimensions (4d). Thus, the absence of anomalies in an $SU(5)$-GUT or a SM generation can be viewed as deriving from this feature.

Table 16.1 presents the states of one family of quarks and leptons, as they appear in the **16**. To understand this, recall that the Γ-matrices of the 10d Clifford algebra give rise to five independent, anticommuting 'creation-annihilation' operators $\Gamma^{a\pm} = (\Gamma^{2a-1} \pm i\Gamma^{2a})/2$ with $a = 1, ..., 5$. These correspond to five fermionic harmonic oscillators or "spin" 1/2 systems. The 32-dimensional tensor product of those is reducible since the 10d rotation generators $M_{mn} = -i[\Gamma^m, \Gamma^n]/4$ $(m, n = 1, ..., 10)$ always flip an even number of "spins". This gives rise to the **16** as displayed in Table 16.1.

Next, one also recalls that the natural embedding of $SU(5)$ in $SO(10)$ relies on 'pairing up' real dimensions, $R^{10} \equiv C^5$, similarly to the paring up of Γ^ms used above. This makes it clear how to associate one $|\pm>$ system to each complex dimension of $SU(5)$, which explains the labeling of the "spin" columns in Table 16.1: The first three and last two "spins" correspond to $SU(3)_C$ and $SU(2)_L$ respectively. In fact, an $SU(3)_C$ rotation just raises one color index and lowers another, changing colors $\{r,\ b,\ y\}$, or changes relative phases between the three spin states. Similarly, an $SU(2)_L$ rotation raises one weak index and lowers another, thereby flipping the weak isospin from up to down or vice versa, or changes the relative phase between the two spin states. In this representation $U(1)_Y$ hypercharge is simply given by $Y = -2/3(\sum \text{ color spins}) + (\sum \text{ weak spins})$. $SU(5)$ rotations corresponding to X bosons then raise (or lower) a color index, while at the same time lowering (or raising) a weak index. It is easy to see that such rotations can mix the states $\{Q,\ u^c,\ e^c\}$ and $\{d^c, L\}$ among themselves and ν^c is a singlet. Since $SO(10)$ has 45 generators, additional 21 gauge bosons are introduced including the $U(1)_X$ above. The 20 new $SO(10)$ rotations not in $SU(5)$ are then given by either raising any two spins or lowering them. With these rotations, **1** and **5** are connected with **10**. The last $SO(10)$ rotation changes phases of states with weight $2(\sum \text{ color spins}) + 2(\sum \text{ weak spins})$, which corresponds to $U(1)_X$.

Table 16.1: Quantum numbers of **16**-dimensional representation of $SO(10)$.

state	Y	Color	Weak	$SU(5)$	$SO(10)$
ν^c	0	− − −	−−	**1**	
e^c	2	− − −	++		
u_r	1/3	+ − −	−+		
d_r	1/3	+ − −	+−		
u_b	1/3	− + −	−+		
d_b	1/3	− + −	+−	**10**	
u_y	1/3	− − +	−+		
u_y	1/3	− − +	+−		**16**
u_r^c	−4/3	− + +	−−		
u_b^c	−4/3	+ − +	−−		
u_y^c	−4/3	+ + −	−−		
d_r^c	2/3	− + +	++		
d_b^c	2/3	+ − +	++		
d_y^c	2/3	+ + −	++	$\bar{\mathbf{5}}$	
ν	−1	+ + +	−+		
e	−1	+ + +	+−		

$SO(10)$ has two inequivalent maximal subgroups and hence breaking patterns, $SO(10) \to SU(5) \times U(1)_X$ and $SO(10) \to SU(4)_C \times SU(2)_L \times SU(2)_R$. In the first case, one can carry on breaking to $G_{SM} \subset SU(5)$ precisely as in the minimal $SU(5)$ case above. Alternatively, one can identify $U(1)_Y$ as an appropriate linear combination of $U(1)_X$ and the $U(1)$ factor from $SU(5)$, leading to the so-called flipped $SU(5)$ [16] as an intermediate step in breaking $SO(10)$ to G_{SM}. In the second case, we have an intermediate Pati-Salam model thanks to the branching rule $\mathbf{16} = (\mathbf{4}, \mathbf{2}, \mathbf{1}) + (\overline{\mathbf{4}}, \mathbf{1}, \mathbf{2})$. Finally, $SO(10)$ can break directly to the SM at M_G. Gauge coupling unification remains intact in the case of this 'direct' breaking and for the breaking pattern $SO(10) \to SU(5) \to G_{SM}$ (with $SU(5)$ broken at M_G). In the case of intermediate-scale Pati-Salam or flipped $SU(5)$ models, gauge coupling predictions are modified. The Higgs multiplets in minimal $SO(10)$ come from the fundamental representation, $\mathbf{10_H} = \mathbf{5_H} + \bar{\mathbf{5}}_\mathbf{H}$. Note, only in $SO(10)$ does the representation type distinguish SM matter from Higgs fields.

Finally, larger symmetry groups can be considered. For example, the exceptional group E_6 has maximal subgroup $SO(10) \times U(1)$ [17]. Its fundamental representation branches as $\mathbf{27} = \mathbf{16}_1 + \mathbf{10}_{-2} + \mathbf{1}_4$. Another maximal subgroup is $SU(3)_C \times SU(3)_L \times SU(3)_R \subset E_6$ with branching rule $\mathbf{27} = (\mathbf{3}, \mathbf{3}, \mathbf{1}) + (\bar{\mathbf{3}}, \mathbf{1}, \bar{\mathbf{3}}) + (\mathbf{1}, \bar{\mathbf{3}}, \mathbf{3})$. Independently of any underlying E_6, the group $[SU(3)]^3$ with additional permutation symmetry Z_3 interchanging the three factors can be considered. This is known as "trinification" [18]. The $E_6 \to [SU(3)]^3$ breaking pattern has been used in phenomenological analyses of the heterotic string [19]. However, in larger symmetry groups, such as E_6, $SU(6)$, etc., there are now many more states which have not been observed and must be removed from the effective low-energy theory.

Intriguingly, the logic by which G_{SM} is a maximal subgroup of $SU(5)$, which together with $U(1)_X$ is a maximal subgroup of $SO(10)$, continues in a very elegant and systematic way up to the largest exceptional group. The resulting famous breaking chain $E_8 \to E_7 \to E_6 \to SO(10) \to SU(5) \to G_{SM}$ together with the special role played by E_8 in group and in string theory is a tantalizing hint at deeper structures. However, since all representations of E_8 and E_7 are real and can not lead to 4d chiral fermions, this is necessarily outside the 4d GUT framework.

16.3. GUT breaking and doublet-triplet splitting

In the standard, 4d field-theoretic approach to GUTs, the unified gauge group is broken spontaneously by an appropriate GUT Higgs sector. Scalar potentials (or superpotentials in SUSY GUTs) exist whose vacua spontaneously break $SU(5)$ or $SO(10)$. While these potentials are ad hoc (just like the Higgs potential in the SM), the most naive expectation is that all their dimensionful parameters are $O(M_G)$. In the simplest case of $SU(5)$, the **24** (adjoint) GUT Higgs develops a VEV along the G_{SM}-singlet direction as $\langle\Phi\rangle \propto diag(-2/3, -2/3, -2/3, 1, 1)$. In order for $SO(10)$ to break to $SU(5)$, the **16** or **126**, which have a G_{SM}-singlet with non-zero $U(1)_X$ charge, get a VEV.

The masses of doublet and triplet in the $\mathbf{5_H}$ (and $\bar{\mathbf{5}}_\mathbf{H}$) generically split due to their coupling to the GUT Higgs. In addition, both the doublet and the triplet mass also get an equal contribution from an $SU(5)$-invariant GUT-scale mass term. Without any further structure, an extreme fine-tuning between two large effects is then necessary to keep the doublet mass at the electroweak scale. Supersymmetry plays an important role in forbidding large radiative correction to the doublet mass due to the non-renormalization theorem [7]. However, even in this case we have to fine tune parameters at tree level. This is the doublet-triplet splitting problem which, in the SUSY context, is clearly related the μ-term problem of the MSSM (the smallness of the coefficient of $\mu H_u\ H_d$).

Several mechanisms for natural doublet-triplet splitting have been suggested under the assumption of supersymmetry, such as the sliding singlet [20], missing partner [21] or missing VEV [22], and pseudo-Nambu-Goldstone boson mechanisms [23]. Particular examples of the missing partner mechanism for $SU(5)$ [24], the missing VEV mechanism for $SO(10)$ [25,26] and the pseudo-Nambu-Goldstone boson mechanism for $SU(6)$ [23,27] have been shown to be consistent with gauge coupling unification and nucleon decay. From the GUT-scale perspective, one is satisfied if the triplets are naturally heavy and the doublets are massless ($\mu \simeq 0$). There are also several mechanisms for resolving the subsequent issue of why μ is of order

the SUSY breaking scale [28]. * For a review of the μ problem and some suggested solutions in SUSY GUTs and string theory, see [29,30,31,32] and references therein.

In general, GUT-breaking sectors successfully resolving the doublet-triplet splitting problem, dynamically stabilizing all GUT-scale VEVs and allowing for realistic neutrino masses and Yukawa couplings (including the GUT-symmetry violation in the latter) require a number ingredients. However, for validity of the effective theory, introduction of higher or many representations is limited, otherwise a Landau pole may appear below the Planck scale. In addition, GUTs are only effective theories below the Planck scale in the 4d field-theoretic approach. Since M_G is close to this scale, the effects of higher-dimension operators are not obviously negligible. In particular, operators including the GUT-breaking Higgs may affect low-energy predictions, such as quark and lepton masses.

Thus, especially in the context of GUT breaking and doublet-triplet splitting, models beyond 4d field theory appear attractive. While this is mainly the subject of the next section, some advantages can already be noted: In models with extra dimensions, in particular string constructions, GUT breaking may occur due to boundary conditions in the compactified dimensions [33,34,35,36]. No complicated GUT breaking sector is then required. Moreover, boundary conditions can give mass only to the triplet, leaving the doublet massless. This is similar to the 'missing partner mechanism' since the effective mass term does not 'pair up' the triplets from $\mathbf{5_H}$ and $\overline{\mathbf{5}}_\mathbf{H}$ but rather each of them with further fields which are automatically present in the higher-dimensional theory. This can eliminate dimension-five nucleon decay (cf. Sec. 16.6).

16.4. String-theoretic and Higher-dimensional Unified Models

As noted earlier, the GUT scale is dangerously close to the scale of quantum gravity. It may hence be necessary to discuss unified models of particle physics in the latter, more ambitious context. Among the models of quantum gravity, superstring or M-theory stands out as the best-studied and technically most developed proposal, possessing in particular a high level internal, mathematical consistency. For our purposes, it is sufficient to know that five 10d and one 11d low-energy effective supergravity theories arise in this setting (cf. [37] and refs. therein).

Grand unification is realized most naturally in the context of the two 'heterotic' theories with gauge groups $\mathrm{E}_8\times\mathrm{E}_8$ and $SO(32)$ respectively [35](see [38] for some of the more recent results). Justified in part by the intriguing breaking path $\mathrm{E}_8 \to \cdots \to G_{SM}$ mentioned above, the focus has historically largely been on $\mathrm{E}_8\times\mathrm{E}_8$. To describe particle physics, solutions of the 10d theory with geometry $R^{1,3}\times M_6$ are considered, where M_6 is a Calabi-Yau (CY) 3-fold (with 6 real dimensions). The background solution involves expectation values of higher-dimensional components of the $\mathrm{E}_8\times\mathrm{E}_8$ gauge fields. This includes both Wilson lines [33] and non-vanishing field-strength and leads, in general, to a reduced gauge symmetry and to chirality in the resulting 4d effective theory. The 4d fermions arise from 10d gauginos.

Given an appropriate embedding of G_{SM} in $\mathrm{E}_8\times\mathrm{E}_8$, gauge coupling unification is automatic at leading order. Corrections arise mainly through (string)-loop effects and are similar to the familiar field-theory thresholds of 4d GUTs [39]. Thus, one may say that coupling unification is a generic prediction in spite of the complete absence* of a 4d GUT at any energy scale. This absence is both an advantage and a weakness. On the up side, GUT breaking and doublet-triplet splitting [41] are more naturally realized and dimension-five nucleon decay is relatively easy to avoid. On the down side, there is no reason to expect full GUT representations in the matter sector and flavor model building is much less tied to the GUT structure than in 4d.

One technical problem of heterotic constructions is the dependence on the numerous size and shape parameters of M_6 (the so-called moduli), the stabilization of which is poorly understood (see [42] for recent developments). Another is the sheer mathematical complexity of the analysis, involving in particular the study of (non-Abelian) gauge-bundles on CY spaces [43](see however [44]) .

An interesting sub-chapter of heterotic string constructions is represented by orbifold models [34]. Here the internal space is given by a six-torus, modded out by a discrete symmetry group (e.g. T^6/Z_n). More recent progress is reported in [45], including in particular the systematic exploration of the phenomenological advantages of so-called 'non-prime' (referring to n) orbifolds. The symmetry breaking to G_{SM} as well as the survival of Higgs doublets without triplet partners is ensured by the appropriate embedding of the discrete orbifold group in $\mathrm{E}_8\times\mathrm{E}_8$.

String theory on such spaces, which are locally flat but include singularities, is much more calculable than in the CY case. The orbifold geometries can be viewed as singular limits of CYs.

An even simpler approach to unified models, which includes many of the advantages of full-fledged string constructions, is provided by Orbifold GUTs [36]. These are (mostly) 5d or 6d SUSY field theories with unified gauge group (e.g. $SU(5)$ or $SO(10)$), broken in the process of compactifying to 4d. To give a particularly simple example, consider $SU(5)$ on $R^{1,3}\times S^1/(Z_2\times Z_2')$. Here the compact space is an interval and the embedding of Z_2' in the hypercharge direction of $SU(5)$ realizes the breaking to G_{SM}. Concretely, 5d X bosons are given Neumann BCs at one endpoint of the interval and thus have no Kaluza-Klein (KK) zero mode. Their lightest modes have mass $\sim 1/R$, making the KK-scale the effective GUT scale. As an implication, the boundary theory has no $SU(5)$ invariance. Nevertheless, since the $SU(5)$-symmetric 5d bulk dominates 4d gauge couplings, unification remains a prediction. Many other features but also problems of 4d GUTs can be circumvented, especially doublet-triplet splitting is easily realized.

With the advent of the string-theory 'flux landscape' [46], which is best understood in 10d type-IIB supergravity, the focus in string model building has shifted to this framework. While type II string theories have no gauge group in 10d, brane-stacks support gauge dynamics. A particularly appealing setting (see e.g. [47]) is provided by type IIB models with D7 branes (defining 8d submanifolds). However, in the $SO(10)$ context the **16** is not available and, for $SU(5)$, the top-Yukawa coupling vanishes at leading order [48]. As a crucial insight, this can be overcome on the non-perturbative branch of type IIB, also known as F-theory [49,50]. This setting allows for more general branes, thus avoiding constraints of the Dp-brane framework. GUT breaking can be realized using hypercharge flux (the VEV of the $\mathrm{U}(1)_Y$ field strength), an option not available in heterotic models. The whole framework combines the advantages of the heterotic or higher-dimensional unification approach with the more recent progress in understanding moduli stabilization. It thus represents at this moment the most active and promising branch of theory-driven GUT model building (see e.g. [51] and refs. therein).

As a result of the flux-breaking, a characteristic 'type IIB' or 'F-theoretic' tree-level correction to gauge unification arises [52]. The fact that this correction can be rather significant numerically is occasionally held against the framework of F-theory GUTs. However, at a parametric level, this correction nevertheless behaves like a 4d threshold, i.e., it provides $\mathcal{O}(1)$ additive contributions to the inverse 4d gauge coupling $\alpha_i^{-1}(M_{\mathrm{GUT}})$.

A final important issue in string GUTs is the so-called string-scale/GUT-scale problem [53]. It arises since, in heterotic compactifications, the Planck scale and the high-scale value of the gauge coupling unambiguously fix the string-scale to about 10^{18} GeV. As the compactification radius R is raised above the string length, the GUT scale (identified with $1/R$) goes down and the string coupling goes up. Within the domain of perturbative string theory, a gap of about a factor ~ 20 remains between the lowest GUT scale achievable in this way and the phenomenological goal of 2×10^{16} GeV. The situation

* The solution of [28] relies on the absence of the fundamental superpotential term $\mu H_u\, H_d$ (or $\mu\, \mathbf{5}_H\overline{\mathbf{5}}_H$). This is ensured by a $U(1)_R$. The latter clashes with typical superpotentials for the GUT breaking sector. However, higher-dimensional or stringy GUTs, where the triplet Higgs is simply projected out, can be consistent with the $U(1)_R$ symmetry.

* See however [40].

can be improved by venturing into the non-perturbative regime [53] or by considering 'anisotropic' geometries with hierarchically different radii R [53,54].

In F-theory GUTs, the situation is dramatically improved since the gauge theory lives only in four out of the six compact dimensions. This allows for models with a 'decoupling limit', where the GUT scale is parametrically below the Planck scale [50]. However, moduli stabilization may not be without problems in such constructions, in part due to a tension between the required large volume and the desirable low SUSY breaking scale.

16.5. Gauge Coupling Unification

The quantitative unification of the three SM gauge couplings at the energy scale M_G is one of the cornerstones of the GUT paradigm. It is obviously of direct phenomenological relevance. Gauge coupling unification is best understood in the framework of effective field theory (EFT) [55]. In the simplest case, the relevant EFT at energies $\mu \gg M_G$ has a unified gauge symmetry (say $SU(5)$ for definiteness) and a single running gauge coupling $\alpha_G(\mu)$. At energies $\mu \ll M_G$, states with mass $\sim M_G$ (such as X bosons, GUT Higgs, color-triplet Higgs) have to be integrated out. The EFT now has three independent couplings and SM (or MSSM) matter content. One-loop renormalization group equations readily allow for an extrapolation to the weak scale,

$$\alpha_i^{-1}(m_Z) = \alpha_G^{-1}(M_G) + \frac{b_i}{2\pi}\log\left(\frac{M_G}{m_Z}\right) + \delta_i\,. \qquad (16.3)$$

Here we defined δ_i to absorb all sub-leading effects, including threshold corrections at or near the weak scale (e.g. from superpartners and the additional Higgs bosons in the case of SUSY). We will discuss them momentarily.

It is apparent from Eq. (16.3) that the three low-scale couplings can be very different. This is due to the large energy range $m_Z \ll \mu \ll M_G$ and the non-universal β-function coefficients ($b_i^{\rm SM} = \{41/10, -19/6, -7\}$ or $b_i^{\rm MSSM} = \{33/5, 1, -3\}$). Incomplete GUT multiplets, such as gauge and Higgs bosons in the SM and also their superpartners and the additional Higgs bosons in the MSSM, contribute to the differences between the β functions. Inverting the argument, one expects that extrapolating the measured couplings to the high scale, we find quantitative unification at $\mu \sim M_G$. While this fails in the SM, it works intriguingly well in the MSSM (cf. Fig. 1).

The three equations contained in (Eq. (16.3)) can be used to determine the three 'unknowns' $\alpha_3(m_Z)$, $\alpha_G(M_G)$ and M_G, assuming that all other parameters entering the equations are given. Focusing on the SUSY case and using the $\overline{\rm MS}$ coupling constants $\alpha_{\rm EM}^{-1}(m_Z)$ and $\sin^2\theta_W(m_Z)$ from [56],

$$\alpha_{\rm EM}^{-1}(m_Z) = 127.940 \pm 0.014\,, \qquad (16.4)$$

$$\sin^2\theta_W(m_Z) = 0.23126 \pm 0.00005\,, \qquad (16.5)$$

as input, one determines $\alpha_{1,2}^{-1}(m_Z)$, which then gives

$$\alpha_G^{-1}(M_G) \simeq 24.3 \qquad \text{and} \qquad M_G \simeq 2\times 10^{16}\ \text{GeV}\,. \qquad (16.6)$$

Here we have set $\delta_i = 0$ for simplicity. Crucially, one in addition obtains a prediction for the low-energy observable α_3,

$$\alpha_3^{-1}(m_Z) = -\frac{5}{7}\alpha_1^{-1}(m_Z) + \frac{12}{7}\alpha_2^{-1}(m_Z) + \Delta_3\,, \qquad (16.7)$$

where

$$\Delta_3 = \frac{5}{7}\delta_1 - \frac{12}{7}\delta_2 + \delta_3\,. \qquad (16.8)$$

Here we followed the elegant formulation in Ref. [57] of the classical analyses of [4]. Of course, it is a matter of convention which of the three low-energy gauge coupling parameters one 'predicts' and indeed, early work on the subject discusses the prediction of $\sin^2\theta_W$ in terms of α_{EM} and α_3 [58,59].

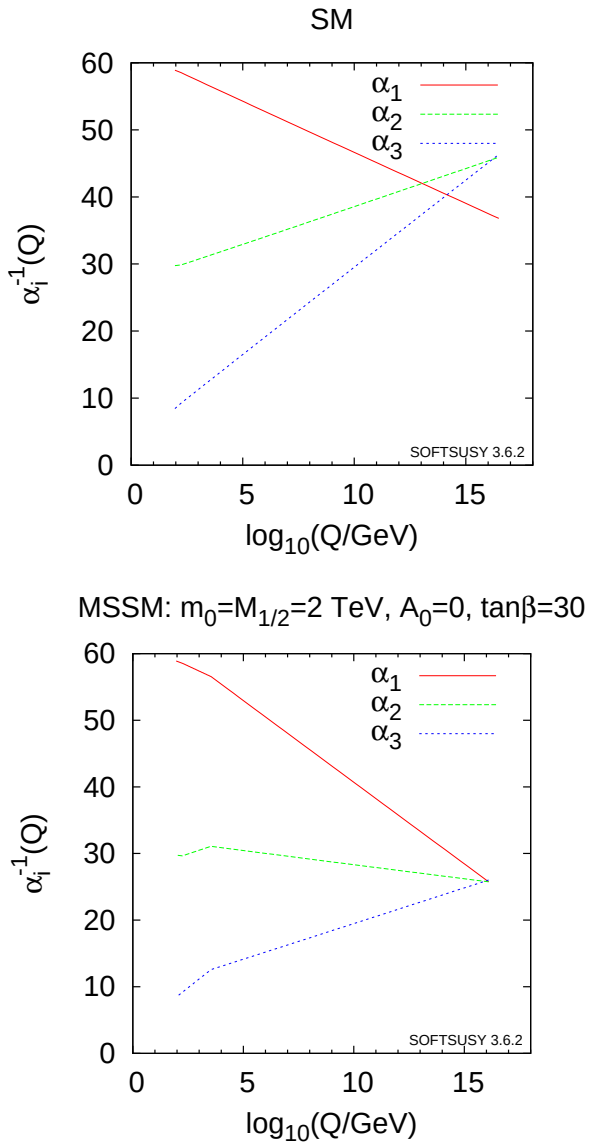

Figure 16.1: Running couplings in SM and MSSM using two-loop RG evolution. The SUSY threshold at 2 TeV is clearly visible on the r.h. side. (We thank Ben Allanach for providing the plots created using SOFTSUSY [61].)

Remarkably, the leading order result (i.e. Eq. (16.7) with $\delta_i = 0$) is in excellent agreement with experiments [56]:

$$\alpha_3^{\rm LO}(m_Z) = 0.117 \qquad \text{vs.} \qquad \alpha_3^{\rm EXP}(m_Z) = 0.1185 \pm 0.0006\,. \qquad (16.9)$$

However, this near perfection is to some extent accidental. To see this, we now discuss the various contributions to the δ_i (and hence to Δ_3).

The two-loop running correction from the gauge sector $\Delta_3^{(2)}$ and the low-scale threshold correction $\Delta_3^{(l)}$ from superpartners can be summarized as [57]

$$\Delta_3^{(2)} \simeq -0.82 \qquad \text{and} \qquad \Delta_3^{(l)} \simeq \frac{19}{28\pi}\log\left(\frac{m_{\rm SUSY}}{m_Z}\right)\,. \qquad (16.10)$$

The relevant scale $m_{\rm SUSY}$ can be estimated as [60]

$$m_{\rm SUSY} \;\to\; m_H^{3/19} m_{\widetilde{H}}^{12/19} m_{\widetilde{W}}^{4/19} \times \left(\frac{m_{\widetilde{W}}}{m_{\widetilde{g}}}\right)^{28/19} \left(\frac{m_{\widetilde{l}}}{m_{\widetilde{q}}}\right)^{3/19}\,, \qquad (16.11)$$

where m_H stands for the masses of non-SM Higgs states and superpartner masses are given in self-evident notation. Detailed

analyses including the above effects are best done using appropriate software packages, such as SOFTSUSY [61](or alternatively SuSpect or SPheno [62]) . See also [61] for references to the underlying theoretical two-loop analyses.

To get a very rough feeling for these effects, let us assume that all superpartners are degenerate at $m_{\rm SUSY} = 1$ TeV, except for heavier gluinos: $m_{\widetilde{W}}/m_{\widetilde{g}} \simeq 1/3$. This gives $\Delta_3^{(l)} \simeq -0.35 + 0.22\ln(m_{\rm SUSY}/m_Z) \simeq 0.18$. The resulting prediction of $\alpha_3(m_Z) \simeq 0.126$ significantly upsets the perfect one-loop agreement found earlier. Before discussing this issue further, it is useful to introduce yet another important type of correction, the high- or GUT-scale thresholds.

To discuss high-scale thresholds, let us set all other corrections to zero for the moment and write down a version of Eq. (16.3) that captures the running near and above the GUT scale more correctly. The threshold correction at one-loop level can be evaluated accurately by the simple step-function approximation for the β functions in the $\overline{\rm DR}$ scheme* [66],

$$\alpha_i^{-1}(m_Z) = \alpha_G^{-1}(\mu) + \frac{1}{2\pi}\left[b_i \ln\frac{\mu}{m_Z} + b_i^C \ln\frac{\mu}{M_C} + b_i^X \ln\frac{\mu}{M_X} + b_i^\Phi \ln\frac{\mu}{M_\Phi}\right] . \quad (16.12)$$

Here we started the running at some scale $\mu \gg M_G$, including the contribution of the minimal set of states relevant for the transition from the high-scale $SU(5)$ model to the MSSM. These are the color-triplet Higgs multiplets with mass M_C, massive vector multiplets of X-bosons with mass M_X (including GUT Higgs degrees of freedom), and the remaining GUT-Higgs fields and superpartners with mass M_Φ. The coefficients $b_i^{C,X,\Phi}$ can be found in Ref. [67]. Crucially, the b_i in Eq. (16.12) conspire to make the running GUT-universal at high scales, such that the resulting prediction for α_3 does not depend on the value of μ.

To relate this to our previous discussion, we can, for example, define $M_G \equiv M_X$ and then choose $\mu = M_G$ in Eq. (16.12). This gives the high-scale threshold corrections

$$\delta_i^{(h)} = \frac{1}{2\pi}\left[b_i^C \ln\frac{M_G}{M_C} + b_i^\Phi \ln\frac{M_G}{M_\Phi}\right] , \quad (16.13)$$

and a corresponding correction $\Delta_3^{(h)}$. To get some intuition for the magnitude, one can furthermore assume $m_\Phi = M_G$, finding (with $b_i^C = \{2/5, 0, 1\}$)

$$\Delta_3^{(h)} = \frac{9}{14\pi}\ln\left(\frac{M_G}{M_C}\right) . \quad (16.14)$$

To obtain the desired effect of +0.64, the triplet Higgs would have to be by about a factor 20 lighter than the GUT scale. While this is ruled out by nucleon decay in the minimal model [68] as will be discussed Sec. 16.6, it is also clear that threshold corrections of this order of magnitude can, in general, be realized with a certain amount of GUT-scale model building, e.g. in specific $SU(5)$ [24] or $SO(10)$ [25,26] constructions. It is, however, a significant constraint on the 4d GUT sector of the theory.

The above analysis implicitly assumes universal soft SUSY breaking masses at the GUT scale, which directly affect the spectrum of SUSY particles at the weak scale. In the simplest case we have a universal gaugino mass $M_{1/2}$, a universal mass for squarks and sleptons m_{16} and a universal Higgs mass m_{10}, as motivated by $SO(10)$. In some cases, threshold corrections to gauge coupling unification can be exchanged for threshold corrections to soft SUSY parameters (see [69] and refs. therein). For example, if gaugino masses were not unified at M_G and, in particular, gluinos were lighter than winos at the weak scale (cf. Eq. (16.11))), then it is possible that, due to weak scale threshold corrections, a much smaller or even slightly positive threshold correction at the GUT scale would be consistent with gauge coupling unification [70].

It is also noteworthy that perfect unification can be realized without significant GUT-scale corrections, simply by slightly raising the (universal) SUSY breaking scale. In this case the dark matter abundance produced by thermal processes in the early universe (if the lightest neutralino is the dark matter particle) is too high. However, even if the gaugino mass in the MSSM is about 1 TeV, if the Higgsino and the non-SM Higgs boson masses are about 10-100 TeV, the effective SUSY scale can be raised [71]. This setup is realized in split SUSY [72] or the pure gravity mediation model [73] based on anomaly mediation [74]. Since the squarks and sleptons are much heavier than the gaugino masses in those setups, a gauge hierarchy problem is reintroduced. The facts that no superpartners have so far been seen at the LHC and that the observed Higgs mass favors heavier stop masses than about 1 TeV force one to accept a certain amount of fine-tuning anyway.

For non-SUSY GUTs or GUTs with a very high SUSY breaking scale to fit the data, new light states in incomplete GUT multiplets or multiple GUT breaking scales are required. For example, non-SUSY models $SO(10) \to SU(4)_C \times SU(2)_L \times SU(2)_R \to$SM, with the second breaking scale of order an intermediate scale, determined by light neutrino masses using the see-saw mechanism, can fit the low-energy data for gauge couplings [75] and at the same time survive nucleon decay bounds [76]. Alternatively, one can appeal to string-theoretic corrections discussed in Sec. 16.4 to compensate for a high SUSY breaking scale. This has, for example, been concretely analyzed in the context of F-theory GUTs in [77].

In 5d or 6d orbifold GUTs, certain "GUT scale" threshold corrections come from the Kaluza-Klein modes between the compactification scale, M_c, and the effective cutoff scale M_*. In string theory, this cutoff scale is the string scale. Gauge coupling unification at two loops then constrains the values of M_c and M_*.* Typically, one finds M_c to be lower than the 4d GUT scale. Since the X-bosons, responsible for nucleon decay, get mass at the compactification scale, this has significant consequences for nucleon decay.

Finally, it has been shown that non-supersymmetric GUTs in warped 5d orbifolds can be consistent with gauge coupling unification. This assumes (in 4d language) that the r.h. top quark and the Higgs doublets are composite-like objects with a compositeness scale in the TeV range [79].

16.6. Nucleon Decay

Quarks and leptons are indistinguishable in any 4d GUT, and both the baryon (B) and lepton number (L) are not conserved. This leads to baryon-number-violating nucleon decay. In addition to baryon-number violation, lepton-number violation is also required for nucleon decay since, in the SM, leptons are the only free fermions which are lighter than nucleons. The lowest-dimension operators relevant for nucleon decay are (B+L) violating dimension-six four-fermion-terms since all baryon-violating operators with dimension less than seven preserve (B–L) [80]. In $SU(5)$ GUTs, they are induced by X boson exchange. These operators are suppressed by $(1/M_G^2)$, and the nucleon lifetime is given by $\tau_N \propto M_G^4/(\alpha_G^2\, m_p^5)$ (m_p is proton mass). The dominant decay mode of the proton (and the baryon-violating decay mode of the neutron), via X boson exchange, is $p \to e^+\,\pi^0$ ($n \to e^+\,\pi^-$). In any simple gauge symmetry, with one universal GUT coupling α_G and scale M_G, the nucleon lifetime from gauge boson exchange is calculable. Hence, the GUT scale may be directly observed via the extremely rare decay of the nucleon. Experimental searches for nucleon decay began with the Kolar Gold Mine, Homestake, Soudan, NUSEX, Frejus, HPW, and IMB detectors [58]. The present experimental bounds come from Super-Kamiokande and Soudan II. We discuss these results shortly. While non-SUSY GUTs are constrained by the non-observation of nucleon decay, a precise and general statement is hard to make. The reason is that gauge couplings do not unify with

* The $\overline{\rm DR}$ scheme is frequently used in a supersymmetric regularization [63]. The renormalization transformation of the gauge coupling constants from $\overline{\rm MS}$ to $\overline{\rm DR}$ scheme is given in Ref. [64]. For an alternative treatment using holomorphic gauge couplings and NSVZ β-functions see e.g. [65].

* It is interesting to note that a ratio $M_*/M_c \sim 100$, needed for gauge coupling unification to work in orbifold GUTs, is typically the maximum value for this ratio consistent with perturbativity [78].

just the SM particle content. Once extra states or large thresholds are included to ensure precision unification, a certain range of unification scales is allowed. By contrast, in SUSY GUTs one generically has $M_G \sim 2 \times 10^{16}$ GeV. Hence dimension-six baryon-number-violating operators are predicted to induce a lifetime of about $\tau_p \sim 10^{36}$ years.

However, in SUSY GUTs there are additional sources for baryon and/or lepton-number violation – dimension-four and five operators [13]. These arise since, in the SUSY SM, quarks and leptons have scalar partners (squarks and sleptons). Although our notation does not change, when discussing SUSY models our fields are chiral superfields and both fermionic and bosonic matter is implicitly represented by those. In this language, baryon- and/or lepton-number-violating dimension-four and five operators are given as so-called F terms of products of chiral superfields, which contain two fermionic components and the rest scalars or products of scalars. Within the context of $SU(5)$ the dimension-four and five operators have the form

$$(\mathbf{10}\ \bar{\mathbf{5}}\ \bar{\mathbf{5}}) \supset (u^c\ d^c\ d^c) + (Q\ L\ d^c) + (e^c\ L\ L),$$

$$(\mathbf{10}\ \mathbf{10}\ \mathbf{10}\ \bar{\mathbf{5}}) \supset (Q\ Q\ Q\ L) + (u^c\ u^c\ d^c\ e^c)$$

$$+B\text{- and } L\text{-conserving terms},$$

respectively. The dimension-four operators are renormalizable, with dimensionless couplings similar to Yukawa couplings. By contrast, the dimension-five operators have a dimensionful coupling of order $(1/M_G)$. They are generated by integrating out the color-triplet Higgs with GUT-scale mass. Note that both triplet Higgsinos (due to their fermionic nature) and Higgs scalars (due to their mass-enhanced trilinear coupling with matter) contribute to the operators.

The dimension-four operators violate either baryon number or lepton number. The nucleon lifetime is extremely short if both types of dimension-four operators are present in the SUSY SM since squark or slepton exchange induces the dangerous dimension-six SM operators. Even in the case that they violate baryon number or lepton number only but not both, they are constrained by various phenomena [81]. For example, the primordial baryon number in the universe is washed out unless the dimensionless coupling constants are less than 10^{-7}. Both types of operators can be eliminated by requiring R parity, which distinguishes Higgs from ordinary matter multiplets. R parity [82] or its cousin, matter parity [12,83], act as $F \to -F$, $H \to H$ with $F = \{\mathbf{10}, \bar{\mathbf{5}}\}$, $H = \{\bar{\mathbf{5}}_\mathbf{H}, \mathbf{5}_\mathbf{H}\}$ in $SU(5)$. This forbids the dimension-four operator $(\mathbf{10}\ \bar{\mathbf{5}}\ \bar{\mathbf{5}})$, but allows the Yukawa couplings for quark and lepton masses of the form $(\mathbf{10}\ \bar{\mathbf{5}}\ \bar{\mathbf{5}}_\mathbf{H})$ and $(\mathbf{10}\ \mathbf{10}\ \mathbf{5}_\mathbf{H})$. It also forbids the dimension-three, lepton-number-violating operator $(\bar{\mathbf{5}}\ \mathbf{5}_\mathbf{H}) \supset (L\ H_u)$ as well as the dimension-five, baryon-number-violating operator $(\mathbf{10}\ \mathbf{10}\ \mathbf{10}\ \bar{\mathbf{5}}_\mathbf{H}) \supset (Q\ Q\ Q\ H_d) + \cdots$. In $SU(5)$, the Higgs multiplet $\bar{\mathbf{5}}_\mathbf{H}$ and the matter multiplets $\bar{\mathbf{5}}$ have identical gauge quantum numbers. In E_6, Higgs and matter multiplets could be unified within the fundamental **27** representation. Only in $SO(10)$ are Higgs and matter multiplets distinguished by their gauge quantum numbers. Moreover the Z_4 center of $SO(10)$ distinguishes **10**s from **16**s and can be associated with R parity [84].

The dimension-five baryon-number-violating operators may also be forbidden at tree level by certain symmetries consistent with $SU(5)$ [13]. However, these symmetries are typically broken by the VEVs responsible for the color-triplet Higgs masses. Consequently the dimension-five operators are generically generated via the triplet Higgs exchange in SUSY $SU(5)$ GUTs, as mentioned above. Hence, the triplet partners of Higgs doublets must necessarily obtain mass of order the GUT scale. In addition, it is also important to note that Planck or string scale physics may independently generate the dimension-five operators, even without a GUT. These contributions must be suppressed by some underlying symmetry; for example, the same flavor symmetry which may be responsible for hierarchical fermion Yukawa matrices.

As a general remark, appealing to global symmetries to suppress specific interactions may not always be as straightforward as it naively seems. Indeed, there are two possibilities: On the one hand, the relevant symmetry might be gauged at a higher scale. Effects of the VEVs responsible for the spontaneous breaking are then in principle dangerous and need to be quantified.

On the other hand, the symmetry might be truly only global. This must e.g. be the case for anomalous symmetries, which are then also violated by field-theoretic non-perturbative effects. The latter can in principle be exponentially small. It is, however, widely believed that global symmetries are always broken in quantum gravity (see e.g. [85]) . One then needs to understand which power or functional form the Planck scale suppression of the relevant interaction has. For example, dimension-five baryon number violating operators suppressed by just one unit of the Planck or string scale are completely excluded.

In view of the above, it is also useful to recall that in string models 4d global symmetries generally originate in higher-dimensional gauge symmetries. Here 'global' implies that the gauge boson has acquired a Stückelberg-mass. This is a necessity in the anomalous case (Green-Schwarz mechanism) but can also happen to non-anomalous symmetries. One expects no symmetry violation beyond the well-understood non-perturbative effects. Discrete symmetries arise as subgroups of continuous gauge symmetries, such as $Z_N \subset U(1)$. In particular, non-anomalous subgroups of Stückelberg-massive $U(1)$s represent unbroken discrete gauge symmetries and as such are non-perturbatively exact (see e.g. [86]) . Of course, such discrete gauge symmetries may also arise as remnants of continuous gauge symmetries after conventional 4d spontaneous breaking.

Dimension-five operators include squarks and/or sleptons. To allow for nucleon decay, these must be converted to light quarks or leptons by exchange of a gaugino or Higgsino in the SUSY SM. The nucleon lifetime is proportional to $M_G^2\ m_{\rm SUSY}^2/m_p^5$, where $m_{\rm SUSY}$ is the SUSY breaking scale. Thus, dimension-five operators may predict a shorter nucleon lifetime than dimension-six operators. Unless accidental cancellations are present, the dominant decay modes from dimension-five operators include a K meson, such as $p \to K^+\ \bar{\nu}$ ($n \to K^0\ \bar{\nu}$). This is due to a simple symmetry argument: The operators are given as $(Q_i\ Q_j\ Q_k\ L_l)$ and $(u_i^c\ u_j^c\ d_k^c\ e_l^c)$, where i, j, k, l (= 1–3) are family indices and color and weak indices are implicit. They must be invariant under $SU(3)_C$ and $SU(2)_L$ so that their color and weak doublet indices must be anti-symmetrized. Since these operators are given by bosonic superfields, they must be totally symmetric under interchange of all indices. Thus the first operator vanishes for $i = j = k$ and the second vanishes for $i = j$. Hence a second or third generation member exists in the dominant modes of nucleon decay unless these modes are accidentally suppressed [83].

Recent Super-Kamiokande bounds on the proton lifetime severely constrain the dimension-six and five operators. With 306 kton-years of data they find $\tau_p/{\rm Br}(p \to e^+\pi^0) > 1.67 \times 10^{34}$ years and $\tau_p/{\rm Br}(p \to K^+\bar{\nu}) > 6.6 \times 10^{33}$ years at 90% CL [87]. The hadronic matrix elements for baryon-number-violating operators are evaluated with lattice QCD simulations [88]. The lower bound on the X boson mass from null results in nucleon decay searches is approaching 10^{16} GeV in SUSY $SU(5)$ GUTs [89]. In the minimal SUSY $SU(5)$, $\tau_p/{\rm Br}(p \to K^+\bar{\nu})$ is smaller than about 10^{31} years if the triplet Higgs mass is 10^{16} GeV and $m_{\rm SUSY} = 1$ TeV [90]. The triplet Higgs mass bound from nucleon decay is then in conflict with gauge coupling unification so that this model is considered to be ruled out [68].

Since nucleon decay induced by the triplet Higgs is a severe problem in SUSY GUTs, various proposals for its suppression have been made. First, some accidental symmetry or accidental structure in non-minimal Higgs sectors in $SU(5)$ or $SO(10)$ theories may suppress the dimension-five operators [25,26,21,91]. As mentioned above, the triplet Higgs mass term violates symmetries which forbid the dimension-five operators. In other words, the nucleon decay is suppressed if the Higgs triplets in $\bar{\mathbf{5}}_\mathbf{H}$ and $\mathbf{5}_\mathbf{H}$ do not have a common mass term but, instead, their mass terms involve partners from other $SU(5)$ multiplets. Second, the SUSY breaking scale may be around O(10–100) TeV in order to explain the observed Higgs boson mass at the LHC. In this case, nucleon decay is automatically suppressed [72,92,93]. Third, accidental cancellations among diagrams due to a fine-tuned structure of squark and slepton flavor mixing might suppress nucleon decay [94]. Last, we have also implicitly assumed a hierarchical structure for Yukawa matrices in the analysis. It is however possible to fine-tune a hierarchical structure for quarks and leptons which baffles the family structure so that the nucleon decay is suppressed [95]. The upper bound on the proton lifetime from some

of these theories is approximately a factor of 10 above the experimental bounds. Future experiments with larger neutrino detectors, such as JUNO [96], Hyper-Kamiokande [97] and DUNE [98], are planned and will have higher sensitivities to nucleon decay.

Are there ways to avoid the stringent predictions for proton decay discussed above? Orbifold GUTs and string theories, see Sec. 16.4, contain grand unified symmetries realized in higher dimensions. In the process of compactification and GUT symmetry breaking, the triplet Higgs states may be removed (projected out of the massless sector of the theory). In such models, the nucleon decay due to dimension-five operators can be severely suppressed or eliminated completely. However, nucleon decay due to dimension-six operators may be enhanced, since the gauge-bosons mediating proton decay obtain mass at the compactification scale, M_c, which is typically less than the 4d GUT scale (cf. Sec. 16.5). Alternatively, the same projections which eliminate the triplet Higgs may rearrange the quark and lepton states such that the massless states of one family come from different higher-dimensional GUT multiplets. This can suppress or completely eliminate even dimension-six proton decay. Thus, enhancement or suppression of dimension-six proton decay is model-dependent. In some complete 5-d orbifold GUT models [99,57] the lifetime for the decay $\tau_p/\mathrm{Br}(p \to e^+\pi^0)$ can be near the bound of 1×10^{34} years with, however, large model-dependence and/or theoretical uncertainties. In other cases, the modes $p \to K^+\bar{\nu}$ and $p \to K^0\mu^+$ may be dominant [57]. Thus, interestingly, the observation of nucleon decay may distinguish string or higher-dimensional GUTs from 4d ones.

In orbifold GUTs or string theory, new discrete symmetries consistent with SUSY GUTs can forbid all dimension-three and four baryon- and lepton-number-violating operators. Even the μ term and dimension-five baryon- and lepton-number-violating operators can be forbidden to all orders in perturbation theory [32]. The μ term and dimension-five baryon- and lepton-number-violating operators may then be generated, albeit sufficiently suppressed, via non-perturbative effects. The simplest example of this is a Z_4^R symmetry which is the unique discrete R symmetry consistent with $SO(10)$ [32]. In this case, nucleon decay is completely dominated by dimension-six operators.

16.7. Yukawa Coupling Unification

In the SM, masses and mixings for quarks and leptons come from the Yukawa couplings with the Higgs doublet, but the values of these couplings remain a mystery. GUTs provide at least a partial understanding since each generation is embedded in unified multiplet(s). Specifically, since quarks and leptons are two sides of the same coin, the GUT symmetry relates the Yukawa couplings (and hence the masses) of quarks and leptons.

In $SU(5)$, there are two types of independent renormalizable Yukawa interactions given by λ_{ij} $(\mathbf{10}_i\ \mathbf{10}_j\ \mathbf{5_H}) + \lambda'_{ij}$ $(\mathbf{10}_i\ \bar{\mathbf{5}}_j\ \bar{\mathbf{5}}_{\mathbf{H}})$. These contain the SM interactions λ_{ij} $(Q_i\ u^c_j\ H_u) + \lambda'_{ij}$ $(Q_i\ d^c_j\ H_d\ +\ e^c_i\ L_j\ H_d)$. Here $i, j\,(=1\text{–}3)$ are, as before, family indices. Hence, at the GUT scale we have tree-level relations between Yukawa coupling constants for charged lepton and down quark masses, such as $\lambda_b = \lambda_\tau$ in which $\lambda_{b/\tau}$ are the bottom quark /τ lepton Yukawa coupling constants [100,101]. In $SO(10)$, there is only one type of independent renormalizable Yukawa interaction given by λ_{ij} $(\mathbf{16}_i\ \mathbf{16}_j\ \mathbf{10_H})$, leading to relations among all Yukawa coupling constants and quark and lepton masses within one generation [102,103](such as $\lambda_t = \lambda_b = \lambda_\tau$, with λ_t the top quark Yukawa coupling constant).

16.7.1. *The third generation, b–τ or t–b–τ unification* :

Third generation Yukawa couplings are larger than those of the first two generations. Hence, the fermion mass relations predicted from renormalizable GUT interactions which we introduced above are expected to be more reliable. In order to compare them with data, we have to include the radiative correction to these relations from the RG evolution between GUT and fermion mass scale, from integrating out heavy particles at the GUT scale, and from weak scale thresholds.

Since testing Yukawa coupling unification is only possible in models with successful gauge coupling unification, we here focus on SUSY GUTs. In the MSSM, top and bottom quark and τ lepton masses are related to the Yukawa coupling constants at the scale m_Z as

$$m_t(m_Z) = \lambda_t(m_Z)\ v_u(1 + \delta m_t/m_t),$$

$$m_{b/\tau}(m_Z) = \lambda_{b/\tau}(m_Z)\ v_d(1 + \delta m_{b/\tau}/m_{b/\tau}),$$

where $\langle H^0_u\rangle \equiv v_u = \sin\beta\ v/\sqrt{2}$, $\langle H^0_d\rangle \equiv v_d = \cos\beta\ v/\sqrt{2}$, $v_u/v_d \equiv \tan\beta$ and $v \sim 246$ GeV is fixed by the Fermi constant, G_μ. Here, $\delta m_f/m_f$ $(f = t, b, \tau)$ represents the threshold correction due to integrating out SUSY partners. For the bottom quark mass, it is found [104] that the dominant corrections come from the gluino-sbottom and from the Higgsino-stop loops,

$$\left(\frac{\delta m_b}{m_b}\right)_{g_3} \sim \frac{g_3^2}{6\pi^2}\frac{m_{\tilde{g}}\mu}{m^2_{\mathrm{SUSY}}}\tan\beta$$

and

$$\left(\frac{\delta m_b}{m_b}\right)_{\lambda_t} \sim \frac{\lambda_t^2}{16\pi^2}\frac{A_t\mu}{m^2_{\mathrm{SUSY}}}\tan\beta\,, \qquad (16.15)$$

where $m_{\tilde{g}}$, μ, and A_t stand for gluino and Higgsino masses and trilinear stop coupling, respectively. Note that Eq. (16.15) only illustrates the structure of the corrections – non-trivial functional dependences on several soft parameters $\sim m_{\mathrm{SUSY}}$ have been suppressed. For the full one-loop correction to the bottom quark mass see, for example, Ref. [105].

Note also that the corrections do not go to zero as SUSY particles become much heavier than m_Z. They may change the bottom quark mass at the 10% level for $\tan\beta = O(10)$. The total effect is sensitive to the relative phase between gluino and Higgsino masses since $A_t \sim -m_{\tilde{g}}$ due to the infrared fixed point nature of the RG equation for A_t [106] in settings where SUSY breaking terms come from Planck scale dynamics, such as gravity mediation. The τ lepton mass also receives a similar correction, though only at the few % level. The top quark mass correction, not being proportional to $\tan\beta$, is at most 10% [107].

Including one loop threshold corrections at m_Z and additional RG running, one finds the top, bottom and τ pole masses. In SUSY GUTs, b–τ unification has two possible solutions with $\tan\beta \sim 1$ or $O(10)$. The small $\tan\beta$ solution may be realized in the MSSM if superpartner masses are $O(10)$ TeV, as suggested by the observed Higgs mass [92]. The large $\tan\beta$ limit such as $\tan\beta \sim$ 40–50 overlaps the $SO(10)$ symmetry relation. When $\tan\beta$ is large, there are significant threshold correction to down quark mass as mentioned above, and Yukawa unification is only consistent with low-energy data in a restricted region of SUSY parameter space, with important consequences for SUSY searches [107,108]. More recent analyses of Yukawa unification after LHC Run-I are found in Ref. [109].

Gauge coupling unification is also successful in the scenario of split supersymmetry [72], in which squarks and sleptons have mass at a scale $\tilde{m} \gg m_Z$, while gauginos and Higgsinos have masses of order the weak scale. Unification of b–τ Yukawa couplings requires $\tan\beta$ to be fine-tuned close to 1 [92]. If by contrast, $\tan\beta \gtrsim 1.5$, b–τ Yukawa unification only works for $\tilde{m} \lesssim 10^4$ GeV. This is because the effective theory between the gaugino mass scale and $\tilde{m}$ includes only one Higgs doublet, as in the standard model. As a result, the large top quark Yukawa coupling tends to increase the ratio λ_b/λ_τ due to the vertex correction, which is absent in supersymmetric theories, as one runs down in energy below $\tilde{m}$. This is opposite to what happens in the MSSM where the large top quark Yukawa coupling lowers the ratio λ_b/λ_τ [101].

16.7.2. *Beyond leading order: three-family models* :

Simple Yukawa unification is not possible for the first two generations. Indeed, $SU(5)$ implies $\lambda_s = \lambda_\mu$, $\lambda_d = \lambda_e$ and hence $\lambda_s/\lambda_d = \lambda_\mu/\lambda_e$. This is an RG-invariant relation which extrapolates to $m_s/m_d = m_\mu/m_e$ at the weak scale, in serious disagreement with data ($m_s/m_d \sim 20$ and $m_\mu/m_e \sim 200$). An elegant solution to this problem was given by Georgi and Jarlskog [110](for a recent analysis in the SUSY context see [111]) .

More generally, we have to recall that in all of the previous discussion of Yukawa couplings, we assumed renormalizable interactions as well

as the minimal matter and Higgs content. Since the GUT scale is close to the Planck scale, higher-dimension operators involving the GUT-breaking Higgs may modify the predictions, especially for lower generations. An example is provided by the operators $\mathbf{10}\ \bar{\mathbf{5}}\ \bar{\mathbf{5}}_{\mathbf{H}}\ \mathbf{24}_{\mathbf{H}}$ with $\mathbf{24}_{\mathbf{H}}$ the GUT-breaking Higgs of $SU(5)$. We can fit parameters to the observed fermion masses with these operators, though some fine-tuning is introduced in doing so. The SM Higgs doublet may come in part from higher representations of the GUT group. For example, the **45** of $SU(5)$ includes an $SU(2)_L$ doublet with appropriate $U(1)_Y$ charge [110]. This **45** can, in turn, come from the **120** or **126** of $SO(10)$ after its breaking to $SU(5)$ [112]. These fields may also have renormalizable couplings with quarks and leptons. The relations among the Yukawa coupling constants in the SM are modified if the SM Higgs doublet is a linear combination of several such doublets from different $SU(5)$ multiplets. Finally, the SM fermions may not be embedded in GUT multiplets in the minimal way. Indeed, if all quarks and leptons are embedded in **16**s of $SO(10)$, the renormalizable interactions with $\mathbf{10}_{\mathbf{H}}$ cannot explain the observed CKM mixing angles. This situation improves when extra matter multiplets, such as **10**, are introduced: After $U(1)_X$, which distinguishes the $\bar{\mathbf{5}}$s coming from the **16** and the **10** of $SO(10)$, is broken (e.g. by a VEV of $\mathbf{16}_{\mathbf{H}}$ or $\mathbf{126}_{\mathbf{H}}$), the r.h. down quarks and l.h. leptons in the SM can be linear combinations of components in **16**s and **10**s. As a result, $\lambda \neq \lambda'$ in $SU(5)$ [113].

To construct realistic three-family models, some or all of the above effects can be used. Even so, to achieve significant predictions for fermion masses and mixing angles grand unification alone is not sufficient. Other ingredients, for example additional global family symmetries are needed (in particular, non-abelian symmetries can strongly reduce the number of free parameters). These family symmetries constrain the set of effective higher-dimensional fermion mass operators discussed above. In addition, sequential breaking of the family symmetry can be correlated with the hierarchy of fermion masses. One simple, widely known idea in this context is to ensure that each $\mathbf{10}_i$ enters Yukawa interactions together with a suppression factor ϵ^{3-i} (ϵ being a small parameter). This way one automatically generates a stronger hierarchy in up-type quark Yukawas as compared to down-type quark and lepton Yukawas and no hierarchy for neutrinos, which agrees with observations at the $\mathcal{O}(1)$-level. Three-family models exist which fit all the data, including neutrino masses and mixing [26,114].

Finally, a particularly ambitious variant of unification is to require that the fermions of all three generations come from a single representation of a large gauge group. A somewhat weaker assumption is that the flavor group (e.g. $SU(3)$) unifies with the SM gauge group in a simple gauge group at some energy scale $M \geq M_G$. Early work on such 'flavor-unified GUTs', see e.g. [115], has been reviewed in [116,117]. For a selection of more recent papers see [118]. In such settings, Yukawa couplings are generally determined by gauge couplings together with symmetry breaking VEVs. This is reminiscent of heterotic string GUTs, where all couplings come from the 10d gauge coupling. However, while the $\mathrm{E}_8 \to SU(3)\times\mathrm{E}_6$ branching rule $\mathbf{248} = (\mathbf{8},\mathbf{1}) + (\mathbf{1},\mathbf{78}) + (\mathbf{3},\mathbf{27}) + (\overline{\mathbf{3}},\overline{\mathbf{27}})$ looks very suggestive in this context, the way in which most modern heterotic models arrive at three generations is actually more complicated.

16.7.3. ***Flavor violation*** : Yukawa interactions of GUT-scale particles with quarks and leptons may leave imprints on the flavor violation induced by SUSY breaking parameters [119]. To understand this, focus first on the MSSM with universal Planck-scale boundary conditions (as e.g. in gravity mediation). Working in a basis where up-quark and lepton Yukawas are diagonal, one finds that the large top-quark Yukawa coupling reduces the l.h. squark mass squareds in the third generation radiatively. It turns out that only the l.h. down-type squark mass matrix has sizable off-diagonal terms in the flavor basis after CKM-rotation. However, in GUTs the color-triplet Higgs has flavor violating interactions from the Yukawa coupling λ_{ij} $(\mathbf{10}_i\ \mathbf{10}_j\ \mathbf{5}_{\mathbf{H}})$, such that flavor-violating r.h. slepton mass terms are radiatively generated in addition [120]. If r.h. neutrinos are introduced as $SU(5)$ singlets with interactions λ''_{ij} $(\mathbf{1}_i\ \bar{\mathbf{5}}_j\ \mathbf{5}_{\mathbf{H}})$, the doublet and color-triplet Higgses acquire another type of Yukawa coupling, respectively. They then radiatively generate flavor-violating l.h. slepton [121] and r.h. down squark masses [122]. These flavor-violating SUSY breaking terms induce new contributions to FCNC processes in quark and lepton sectors, such as $\mu \to e\gamma$ and K^0–$\bar{K}^0$ and B^0–$\bar{B}^0$ mixing. EDMs are also induced when both l.h. and r.h. squarks/sleptons have flavor-violating mass terms with relative phases, as discussed for $SO(10)$ in [123] or for $SU(5)$ with r.h. neutrinos in [124]. Thus, such low-energy observables constrain GUT-scale interactions.

16.8. Neutrino Masses

We see from atmospheric and solar neutrino oscillation observations, along with long baseline accelerator and reactor experiments, that neutrinos have finite masses. By adding three "sterile" neutrinos ν_i^c with Yukawa couplings $\lambda_{\nu,ij}$ $(\nu_i^c\ L_j\ H_u)$ $(i,j = 1\text{–}3)$, one easily obtains three massive Dirac neutrinos with mass $m_\nu = \lambda_\nu\ v_u$, analogously to quark and charged lepton masses. However, in order to obtain a τ neutrino with mass of order 0.1 eV, one requires the exceedingly small coupling ratio $\lambda_{\nu_\tau}/\lambda_\tau \lesssim 10^{-10}$. By contrast, the seesaw mechanism *naturally* explains such tiny neutrino masses as follows [1,2,3]: The sterile neutrinos have no SM gauge quantum numbers so that there is no symmetry other than global lepton number which forbids the Majorana mass term $\frac{1}{2}M_{ij}\ \nu_i^c\ \nu_j^c$. Note also that sterile neutrinos can be identified with the r.h. neutrinos necessarily contained in complete families of $SO(10)$ or Pati-Salam models. Since the Majorana mass term violates $U(1)_X$ in $SO(10)$, one might expect $M_{ij} \sim M_G$. The heavy sterile neutrinos can be integrated out, defining an effective low-energy theory with only three light active Majorana neutrinos with the effective dimension-five operator

$$-\mathcal{L}_{eff} = \frac{1}{2}c_{ij}\ (L_i\ H_u)\ (L_j\ H_u)\,, \tag{16.16}$$

where $c = \lambda_\nu^T\ M^{-1}\ \lambda_\nu$. This then leads to a 3×3 Majorana neutrino mass matrix $m = m_\nu^T\ M^{-1}\ m_\nu$.

Atmospheric neutrino oscillations require neutrino masses with $\Delta m_\nu^2 \sim 2.5\times 10^{-3}$ eV^2 with maximal mixing, in the simplest two neutrino scenario. With hierarchical neutrino masses this implies $m_{\nu_\tau} = \sqrt{\Delta m_\nu^2} \sim 0.05$ eV. Next, we can try to relate the neutrino Yukawa coupling to the top quark Yukawa coupling, $\lambda_{\nu_\tau} = \lambda_t$ at the GUT scale, as in $SO(10)$ or $SU(4)\times SU(2)_L \times SU(2)_R$ models. This gives $M \sim 10^{14}$ GeV, which is remarkably close to the GUT scale.

Neutrinos pose a special problem for SUSY GUTs. The question is why are the quark mixing angles in the CKM matrix small, while there are two large lepton mixing angles in the PMNS matrix (cf. however the comment at the end of Sec. 16.7). Discussions of neutrino masses and mixing angles can, for example, be found in Refs. [125] and [126]. For SUSY GUT models which fit quark and lepton masses, see Ref. [25]. Finally, for a compilation of the range of SUSY GUT predictions for neutrino mixing, see [127].

The seesaw mechanism implemented by r.h. neutrinos is sometimes called the type-I seesaw model. There are variant models in which the dimension-five operator for neutrino masses is induced in different ways: In the type-II model, an $SU(2)_L$ triplet Higgs boson Σ is introduced to have couplings ΣL^2 and also ΣH_u^2 [128]. In the type-III model, an $SU(2)_L$ triplet of fermions $\tilde{\Sigma}$ with a Yukawa coupling $\tilde{\Sigma}LH_u$ is introduced [129]. In these models, the dimension-five operator is induced by integrating out the triplet Higgs boson or fermions. Such models can also be implemented in GUTs by introducing Higgs bosons in the **15** or fermions in the **24** in $SU(5)$ GUTs or the **126** in $SO(10)$ GUTs. Notice that the gauge non-singlet fields in the type-II and III models have masses at the intermediate scale. Thus, gauge coupling unification is not automatic if they are implemented in SUSY GUTs.

16.9. Selected Topics

16.9.1. *Magnetic Monopoles* :

In the broken phase of a GUT there are typically localized classical solutions carrying magnetic charge under an unbroken $U(1)$ symmetry [130]. These magnetic monopoles with mass of order M_G/α_G can be produced during a possible GUT phase transition in the early universe. The flux of magnetic monopoles is experimentally found to be less than $\sim 10^{-16}$ cm^{-2} s^{-1} sr^{-1} [131]. Many more are however predicted, hence the GUT monopole problem. In fact, one of the original motivations for inflation was to solve the monopole problem by exponential expansion after the GUT phase transition [132] and hence dilution of the monopole density. Other possible solutions to the monopole problem include: sweeping them away by domain walls [133], $U(1)$ electromagnetic symmetry breaking at high temperature [134] or GUT symmetry non-restoration [135]. Parenthetically, it was also shown that GUT monopoles can catalyze nucleon decay [136]. A significantly lower bound on the monopole flux can then be obtained by considering X-ray emission from radio pulsars due to monopole capture and the subsequent nucleon decay catalysis [137].

Note that the present upper bound on the inflationary vacuum energy density is very close to the GUT scale, $V_{inf}^{1/4} \lesssim M_G$ [138]. This almost guarantees that reheating does not lead to temperatures above M_G and hence the monopole problem is solved by inflation.

16.9.2. *Anomaly constraints vs. GUT paradigm* :

As emphasized at the very beginning, the fact that the SM fermions of one generation fill out the $\mathbf{10}+\overline{\mathbf{5}}$ of $SU(5)$ appears to provide overwhelming evidence for some form of GUT embedding. However, one should be aware that a counterargument can be made which is related to the issue of 'charge quantization by anomaly cancellation' (see [139,140] for some early papers and [141] for a more detailed reference list): Imagine we only knew that the low-energy gauge group were G_{SM} and the matter content included the $(\mathbf{3},\mathbf{2})_Y$, i.e. a 'quark doublet' with $U(1)$-charge Y. One can then ask which possibilities exist of adding further matter to ensure the cancellation of all triangle anomalies. It turns out that this problem has only three different, minimal* solutions [140]. One of those is precisely a single SM generation, with the apparent '$SU(5)$-ness' emerging accidentally. Thus, if one randomly picks models from the set of consistent gauge theories, preconditioning on G_{SM} and $(\mathbf{3},\mathbf{2})_Y$, one may easily end up with '$\mathbf{10}+\overline{\mathbf{5}}$' of an $SU(5)$ that is in no way dynamically present. This is precisely what happens in the context of non-GUT string model building [142].

16.9.3. *GUT Baryogenesis and Leptogenesis* :

Baryon-number-violating operators in $SU(5)$ or $SO(10)$ preserve the global symmetry $(B-L)$. Hence the value of the cosmological $(B-L)$ density is an initial condition of the theory and is typically assumed to be zero. On the other hand, anomalies of the electroweak symmetry violate $(B+L)$ while also preserving $(B-L)$. Hence thermal fluctuations in the early universe, via so-called sphaleron processes, can drive $(B+L)$ to zero, washing out any net baryon number generated in the early universe at GUT temperatures. In particular, this affects the old idea of GUT baryogenesis [143,144], where a $(B+L)$ asymmetry is generated by the out-of-equilibrium decay of the color-triplet Higgs. A possible way out [145] uses lepton-number violating interaction of neutrinos to create a $(B-L)$ asymmetry from the $(B+L)$ symmetry, before sphaleron processes become sufficiently fast at $T < 10^{12}$ GeV. This $(B-L)$ asymmetry can then survive the subsequent sphaleron dominated phase. Note that this does not work in the minimal SUSY GUT setting, with the triplet Higgs above the GUT scale. The reason is that a correspondingly high reheating temperature would be required, leading to monopole overproduction.

However, the most widely accepted simple way out of the dilemma is to directly generate a net $(B-L)$ asymmetry dynamically in the early universe, also using r.h. neutrinos. Indeed, we have seen that neutrino oscillations suggest a new scale of physics of order 10^{14} GeV. This scale is associated with heavy Majorana neutrinos in the seesaw mechanism. If in the early universe, the decay of the heavy neutrinos is out of equilibrium and violates both lepton number and CP, then a net lepton number may be generated. This lepton number will then be partially converted into baryon number via electroweak processes [146]. This mechanism is called leptogenesis.

If the three heavy Majorana neutrino masses are hierarchical, the net lepton number is produced by decay of the lightest one, and it is proportional to the CP asymmetry in the decay, ϵ_1. The CP asymmetry is bounded from above, and the lightest neutrino mass is required to be larger than 10^9 GeV in order to explain the observed baryon asymmetry [147]. This implies that the reheating temperature after inflation should be larger than 10^9 GeV so that the heavy neutrinos are thermally produced. In supersymmetric models, there is a tension between leptogenesis and Big Bang Nucleosynthesis (BBN) if gravitinos decay in the BBN era. The gravitino problem gives a constraint on the reheating temperature $\lesssim 10^{6-10}$ GeV though the precise value depends on the SUSY breaking parameters [148]. Recent reviews of leptogenesis can be found in Ref. [149].

16.10. Conclusion

Most conservatively, grand unification means that (some of) the SM gauge interactions of $U(1)_Y$, $SU(2)_L$ and $SU(3)_C$ become part of a larger, unifying gauge symmetry at a high energy scale. In most models, especially in the simplest and most appealing variants of $SU(5)$ and $SO(10)$ unification, the statement is much stronger: One expects the three gauge couplings to unify (up to small threshold corrections) at a unique scale, M_G, and the proton to be unstable due to exchange of gauge bosons of the larger symmetry group. Supersymmetric grand unified theories provide, by far, the most predictive and economical framework allowing for perturbative unification. For a selection of reviews, with many more details than could be discussed in the present article, see [116,150].

Thus, the three classical pillars of GUTs are gauge coupling unification at $M_G \sim 2\times 10^{16}$ GeV, low-energy supersymmetry (with a large SUSY desert), and nucleon decay. The first of these may be viewed as predicting the value of the strong coupling – a prediction which has already been verified (see Fig. 16.1). While this remains true even if SUSY partner masses are somewhat above the weak scale, the possible complete absence of SUSY in the LHC energy range is nevertheless problematic for the GUT paradigm: If the independent, gauge-hierarchy-based motivation for SUSY is completely abandoned, the SUSY scale and hence α_3 become simply free parameters and the first two pillars crumble. It is the more important to keep pushing bounds on proton decay which, although again not completely universal in all GUT constructions, is arguably a more generic part of the GUT paradigm than low-energy SUSY.

Whether or not Yukawa couplings unify is more model dependent. However, irrespective of possible (partial) Yukawa unification, there certainly exists a very interesting and potentially fruitful interplay between flavor model building and grand unification. Especially in the neutrino sector this is strongly influenced by the developing experimental situation.

It is probably fair to say that, due to limitations of the 4d approach, including especially remaining ambiguities (free parameters or ad hoc assumptions) in models of flavor and GUT breaking, the string theoretic approach has become more important in GUT model building. In this framework, challenges include learning how to deal with the many vacua of the 'landscape' as well as, for each vacuum, developing the tools for reliably calculating detailed, phenomenological observables. Finally, due to limitations of space, the present article has barely touched on the interesting cosmological implications of GUTs. They may become more important in the future, especially in the case that a high inflationary energy scale is established observationally.

* Adding extra vector-like sets of fields, e.g. two fermions which only transform under $U(1)$ and have charges Y and $-Y$, is considered to violate minimality.
