MISSOURI
HYBRID
CORN
YIELD
TRIALS

O. V. SINGLETON
And
M. S. ZUBER

Special Report 30
February, 1964
University of Missouri

AGRICULTURAL EXPERIMENT STATION

ACKNOWLEDGMENTS

This is a joint contribution of the Department of Field Crops, University of Missouri Agricultural Experiment Station, and the Crops Research Division Agricultural Research Service, U.S. Department of Agriculture.

O. V. Singleton is an instructor, Department of Field Crops, University of Missouri, and M. S. Zuber is research agronomist, Crops Research Division, Agricultural Research Service, U. S. Department of Agriculture, and professor, Department of Field Crops, University of Missouri. The bulletin reports on Department of Field Crops Research Projects 85 and 310.

The statistics pertaining to corn production were furnished by A. C. Brittain of the U. S. Department of Agriculture, Agricultural Marketing Service, Columbia, Missouri. Climatological data were furnished by Wayne Decker, professor of climatology of the Missouri Agricultural Experiment Station.

The following individuals assisted in making the 1963 Corn Yield Trials possible: Norman Brown, Carl Hayward, Earl Barnes, Wm. H. Odom, Wm. A. Crane, Cecil Schull, Ernest Perkins, Ray Schmidt, D. L. Shrauner, Wilbert Fahrmeier, Ben F. Geisert and Sons, and Howard Wuertley. The following Agricultural Extension agents also aided in conducting the tests: Edward Meek, Gerald McPhee, Lloyd Redd, Ed Schwitzkey, and Doyle Jones.

1963

MISSOURI

HYBRID CORN YIELD TRIALS

O. V. Singleton and M. S. Zuber

The 1963 estimated average corn yield for Missouri is 61 bushels per acre which is the second highest yield on record. The average yield of all hybrids tested at the 9 testing locations was 117 bushels per acre which is the highest average yield during the 7-year period these tests have been conducted. The average yield of the hybrids tested exceeded 100 bushels per acre for all locations except at Columbia (District 5). A total of 102 closed-pedigree and 45 open-pedigree hybrids were tested at the 9 locations. The highest yielding hybrid, US 523WA, produced 155 bushels per acre at the Washington location (District 6).

The total rainfall from May 1 to September 15 ranged from nearly 12 inches to more than 21 inches while the number of days with temperatures exceeding 90° varied from 27 to 59 at the different testing locations. Dry periods of 15 to 49 days were reported. Stalk lodging was more severe at Higginsville (District 4), Sikeston (District 9), and Washington (District 6). The high amount of stalk lodging at these locations was attributed to European corn borer damage combined with high winds. Stalk lodging at the other locations was of a lesser extent. Root lodging was of little or no consequence at any of the 9 testing locations.

TESTING PROCEDURES

Testing Areas:

The state was divided into 9 districts with 1 test located in each. Figure 1 shows the districts and locations of testing fields. The 9 districts match those currently used for reporting the Missouri Farm Census.

Seed Source:

In 1963, all producers and distributors of hybrid seed corn were eligible to enter these tests. No limit was placed on the number of hybrids any one seed producer could enter and any hybrid could be entered in as many districts as desired. Fifteen pounds of seed for each district was supplied by firms for each entry. Seed for the open-pedigree hybrids was furnished by the state agricultural experiment stations and by certified seed producers.

Type of Field Design:

The number of hybrids tested in each district ranged from 44 in District 8 to 72 in District 9. Each hybrid was planted in 4 plots at each testing location. Plots consisted of 2 rows of 5 hills; they were located at random over the testing area to minimize cultural and soil differences.

Stand:

All test plots were planted at the rate of 5 seeds per hill. Plants were thinned to 3 or 4 per hill, at 8 locations, the number depending upon expected environmental conditions. There was no thinning at the Wayland location (District 3). The stand percentages were computed on the basis of the total plants present divided by the number required for a perfect stand.

Lodging:

A plant was classified as root-lodged if it leaned from the ground level more than 30 degrees from the vertical and stalk-lodged if it was broken below the ear. A plant that was both root and stalk lodged was counted in both categories. The percent was based on the total plants present.

Dropped Ears:

The total number of ears dropped by each hybrid was recorded at harvest. Dividing this number by the total number of plants present and multiplying by 100 gave the percent of ears dropped. It was assumed that each plant produced one ear.

Ear Height:

The ear-height grade was determined from averages of the 4 plots of a hybrid at a location. The grade consisted of the approximate number

of feet from the base of the plant to the point of attachment of the upper ear.

Moisture:

The grain moisture of each entry was determined at harvest by removing 2 rows of kernels from each of 10 ears, randomly selected from the first and fourth replications. The grain from each replication was thoroughly mixed and the moisture content of the 100-gram sample was determined with a Steinlite moisture meter. The moisture percentage reported is the average of the two replications.

Yield:

The corn from each plot was harvested and weighed. Yield was determined on the basis of shelled corn with a moisture content of 15.5 percent. Adjustments were made for missing hills, but not for other variations in stand. Therefore, the yields at each location constitute an average yield of the 4 plots after all adjustments were made.

1963 RESULTS

The 1963 results are reported on a relative maturity group basis. Group 1 - approximately 90 days; group 2 - 115 days; group 3 - 125 days; group 4 - 135 days.

Results reported for each district are for tests conducted in 1963. Summaries are for 1961, 1962, and 1963.

It has been the tendency for some farmers to select hybrids on a single year's yield test performance or results from a single location. Less risk is likely to be encountered if the choice of a hybrid is based on the average performance over a period of years.

THREE-YEAR PERFORMANCE RECORDS

A number of hybrids have been tested for a 3 or more years period, either in a single district or in groups of districts. Summaries of hybrids performance records for the 3-year period of 1961, 1962, and 1963 results are reported in tables for the respective districts.

It should be emphasized that the results of tests for a period of more than 1 year are of greater value in selecting hybrids than any single year's results. However, if one must rely on results from any

1 year, it is best to use the average performance from as many testing locations as possible in the area where the hybrid is to be grown.

The 3-year summaries of test results for hybrids grown in all of the 9 districts and in northern, central, and southern regions are found in Tables 10 to 13.

Pedigrees of all open-pedigree hybrids tested in 1963 are listed in Table 14.

Numerous new closed-pedigree hybrids were tested from 1957 through 1963 for the first time. The Missouri Agricultural Experiment Station does not make specific recommendations for these hybrids, but it is suggested that farmers growing a new hybrid for the first time try a small acreage to determine whether they like the hybrid before they plant a large acreage of it. This recommendation should be practiced for all new hybrids, whether of closed- or of open-pedigree origin.

Table 15 gives the districts in which different hybrids were entered by commercial companies in 1963. Table 16 gives the districts in which different open-pedigree hybrids were entered. Table 17 gives sources of seed of commercial hybrids.

DISTRICT 1

Data for District 1 are reported in Tables 1A to 1C. Temperatures averaged 1.7 degrees above normal. There were 51 days with temperatures above 90° and 4 days with temperatures above 100° F. Rainfall was slightly below the State average for the growing season, and there were 2 dry periods of 29, and 18 days, respectively. Leaf blight caused by *Helminthosporium turcicum*, was much less severe at this location than in 1962. This district had the highest average yield of 131.9 bushels per acre. The different hybrids in the test ranged from 107 to 150 bushels per acre.

Table 1A. Percent of Total Farmland Area Planted to Corn, Total Corn Acreage, Average Acre Yield and the Average Acre Yield for Hybrids Tested in the Missouri Corn Yield Trials for the 10-Year Period (1953-1962), 1961, 1962, and 1963 in District 1.

Period	Farmland Planted to Corn (%)			Avg. Acre Yield (Bu.)	Missouri Corn Yield Tests
	Total	Corn	Acreage

DISTRICT 2

Tables 2A to 2C give the 1963 results and 3-year summary for District 2. Environmental conditions were quite favorable for good yields at the Spickard location. The area received slightly above average rainfall and had the second lowest average temperature of all the testing locations in the State. There were only 27 days with temperatures above 90° F. This test had the second highest average yield of 131.5 bushels per acre with yield of the hybrids tested ranging from 115 to 148 bushels per acre.

Table 2A. Percent of Total Farmland Area Planted to Corn, Total Corn Acreage, Average Acre Yield and the Average Acre Yield for Hybrids Tested in the Missouri Corn Yield Trials for the 10-Year Period (1953-1962), 1961, 1962, and 1963 in District 2.

DISTRICT 3

Results for District 3 are reported in Tables 3A to 3C. Environmental conditions during the growing season were not favorable for corn at this location. Rainfall was the lowest of all locations in the State with only 34 days of rain during the growing season giving a total precipitation of less than 12 inches. There were two dry periods of 18 and 23 days. Temperatures were above normal having 40 days with temperatures of 90° or more. In spite of the unfavorable growing conditions the average yield of the test plot was 126.4 bushels, indicating the rainfall received was well distributed.

Table 3A. Percent of Total Farmland Area Planted to Corn, Total Corn Acreage, Average Acre Yield and the Average Acre Yield for Hybrids Tested in the Missouri Corn Yield Trials for the 10-Year Period (1953-1962), 1961, 1962, and 1963 in District 3.

Period		Farmland Planted to Corn (%)	Total Corn Acreage	Avg. Acre Yield (Bu.)	Missouri Corn Yield Tests
10-year average	1953-1962	12.8	403,100	49.3	
	1961	12.7	393,000	64.1	118.4
	1962	14.8	460,000	64.0	135.9
	1963	17.3*	540,000*	53.0*	126.4

* Estimated as of December 1, 1963.

DISTRICT 4

Results for District 4 are given in Tables 4A to 4C. Poor stands caused by wireworms at the Higginsville location necessitated the first planting (April 12) to be planted a second time on June 10. Two replications of the second planting were not harvested due to poor stands. The results from this location are the average of 2 replications. Rainfall was above the State average and there were 2 dry periods of 18 and 21 days, respectively, during the growing season. There were 58 days of temperatures of 90° or more with the second highest temperature among all testing locations. The highest stalk lodging occurred at this location as the results of heavy wind storms.

Table 4A. Percent of Total Farmland Area Planted to Corn, Total Corn Acreage, Average Acre Yield and the Average Acre Yield for Hybrids Tested in the Missouri Corn Yield Trials for the 10-Year Period (1953-1962), 1961, 1962, and 1963 in District 4.

DISTRICT 5

Tables 5A to 5C give results of the trials in District 5. Environmental conditions were unfavorable for corn production as evidenced by the lowest yield among the 9 districts. The total rainfall was below average for the growing season but not as low as experienced in some of the other locations. The reduced yields received at this location were attributed to the very low sub-soil moisture caused by the below average precipitation of the previous year. The accumulative effects of below average rainfall and low soil moisture apparently accounted for the lowest average yield of 64.1 bushels.

Table 5A. Percent of Total Farmland Area Planted to Corn, Total Corn Acreage, Average Acre Yield and the Average Acre Yield for Hybrids Tested in the Missouri Corn Yield Trials for the 10-Year Period (1953-1962), 1961, 1962, and 1963 in District 5.

Period		Farmland Planted to Corn (%)	Total Corn Acreage	Avg. Acre Yield (Bu.)	Missouri Corn Yield Tests
10-year average	1953-1962	8.9	553,600	43.6	
	1961	7.3	438,000	62.0	104.2
	1962	8.1	485,000	51.6	100.3
	1963	9.2*	575,000*	59.2*	64.1

* Estimated as of December 1, 1963

DISTRICT 6

Results for District 6 are found in Tables 6A to 6C. Rainfall was below average and was second lowest for the State. There was a dry period of 49 days from June 21 to August 9 which reduced yields considerably. European corn borer infestation and heavy winds resulted in considerable stalk lodging at this location, giving the third heaviest lodging record among the 9 testing locations.

Table 6A. Percent of Total Farmland Area Planted to Corn, Total Corn Acreage, Average Acre Yield and the Average Acre Yield for Hybrids Tested in the Missouri Corn Yield Trials for the 10-Year Period (1953-1962), 1961, 1962, and 1963 in District 6.

DISTRICT 7

Tables 7A to 7C report the results for District 7. Weather conditions were not favorable at Mt. Vernon for high yields. Temperatures averaged 2.5° F above normal and there were 49 days with temperatures above 90° F and 4 days of temperatures above 100° F. However, the stress conditions as indicated by the weather records were avoided to some extent by the early planting date of April 12, which resulted in an average yield of 122.3 bushels for the hybrids tested at this location.

Table 7A. Percent of Total Farmland Area Planted to Corn, Total Corn Acreage, Average Acre Yield and the Average Acre Yield for Hybrids Tested in the Missouri Corn Yield Trials for the 10-Year Period (1953-1962), 1961, 1962, and 1963 in District 7.

DISTRICT 8

Results of District 8 are given in Table 8A to 8C. The Summersville location had above average rainfall when compared with the State average, and environmental conditions were very favorable for high yields at this location. Hybrids tested at this location had the lowest average stalk lodging of all 9 locations.

Table 8A. Percent of Total Farmland Area Planted to Corn, Total Corn Acreage, Average Acre Yield and the Average Acre Yield for Hybrids Tested in the Missouri Corn Yield Trials for the 10-Year Period (1953-1962), 1961, 1962, and 1963 in District 8.

DISTRICT 9

Tables 9A to 9C give results of the test at Sikeston. Climatic conditions were not favorable at that location. There were 4 dry periods during the growing season, but irrigation helped the moisture situation. European corn borer and several heavy wind storms resulted in the second highest average stalk lodging record among the 9 testing locations. Undoubtedly these conditions also affected the resulting yields per acre.

Table 9A. Percent of Total Farmland Area Planted to Corn, Total Corn Acreage, Average Acre Yield and the Average Acre Yield for Hybrids Tested in the Missouri Corn Yield Trials for the 10-Year Period (1953-1962), 1961, 1962, and 1963 in District 9.
