MISSOURI 1966 COOPERATIVE

CORN INVESTIGATIONS

by

M. S. Zuber, N. G. Weir and P. J. Loesch, Jr.*

The 1966 Cooperative Corn Investigations between the Missouri Agricultural Experiment Station and the U.S. Department of Agriculture included performance trials of experimental single crosses, double crosses, and three-way crosses. These trials were conducted at seven locations, two near Columbia, one each at Slater, Golden City, Higginsville, and Washington, Mo., and Cedar Rapids, Ia.

The 1966 growing season was less than ideal. Temperature during the flowering period was very high and moisture was limited over much of the state. The Golden City location was irrigated. The average corn yield for Missouri was 62 bushels per acre.

TESTING PROCEDURE

Plots consisted of 2 rows x 5 hills in a completely randomized block of two or four replications at one or more locations.

Stand:

All tests were planted at the rate of five seeds per hill. Plants were thinned to three per hill. The stand percentage was computed on the basis of the total plants present, divided by the number required for a perfect stand.

*The authors' titles are: Zuber, research agronomist, Crops Research Division, ARS, USDA, and professor, Department of Agronomy, University of Missouri; Weir, research technician, Department of Agronomy, University of Missouri; and Loesch, research geneticist, Crops Research Division, ARS, USDA, and assistant professor, Department of Agronomy and Genetics, University of Missouri.

Lodging:

A plant was classified as "root-lodged" if it leaned more than 30 degrees from the vertical and "stalk-lodged" if it was broken below the ear. A plant that was both root and stalk lodged was counted in both categories. The percentage was based on the total plants present.

Dropped Ears:

The total number of dropped ears for each hybrid was recorded at harvest. Dividing this number by the total number of plants present and multiplying by 100 gave the percent of dropped ears. It was assumed that each plant produced one ear.

Ear Height:

The ear-height grade was determined from averages of the two or four plots of a hybrid at a location. The grade consisted of the approximate number of feet from the base of the plant to the point of attachment of the upper ear.

Moisture:

The grain moisture of each entry was determined at harvest by removing two rows of kernels from each of 10 ears, randomly selected from the first replication. The grain was thoroughly mixed and the moisture content of a 100-gram sample was determined with a Steinlite moisture meter.

RESULTS

MIDSEASON MATURITY YELLOW SINGLE CROSSES

Performance records for 74 of the possible 78 single crosses among 13 inbred lines are given in Tables 1, 2, and 3 from experiments grown near Golden City, Columbia, and Slater, Mo., respectively. The mean performance record for the three locations is given in Table 4. The average performance for the parental inbreds as measured by the performance of their single-cross progenies is given in Table 5. The performance for a group of selected double crosses predicted from the single-cross data for each of the three locations is listed in Tables 6, 7, and 8. The predicted double crosses listed are those having high yield, lowest root and stalk lodging and with low ear placement.

MIDSEASON YELLOW DOUBLE CROSSES

(700—800 Maturity Series)

Performance records for 45 double-cross and three single-cross hybrids tested at four locations are presented in Tables 9, 10, 11, and 12. Pedigrees as given in Tables 9 through 12 are not intended to indicate the male and female parents. The experiments were conducted at Bradford Farm near Columbia, Golden City, Marshall, and Rollins Field near Columbia, respectively. The mean performance for all four locations is presented in Table 13. The results for midseason yellow doubles (800 maturity) grown at Rollins Field are presented in Table 14. The average performances for periods of years are presented in Tables 15 and 16.

Table 9. 1966 performance record for midseason yellow double crosses (700-800 Maturity Series).
 Tested at Bradford Farm near Columbia, Missouri. Planted May 17, 1966. Harvested
 November 14, 1966 (Exp. 22).

COOPERATIVE UNIFORM PERFORMANCE TRIALS

Midseason Yellow Single Crosses

(700-800 Maturity Series)

Performance records for 45 single crosses of 10 inbred lines grown near Columbia and Mt. Vernon, Mo., respectively, are presented in Tables 17 and 18. The mean performance for both locations is presented in Table 19. The average performance for the parental inbreds as measured by their single-cross progeny is given in Table 20.

<i>Inbred</i>	<i>Parentage</i>

Midseason White Single Crosses

(800 Maturity Series)

Performance records for 44 of the possible 45 single crosses among 10 inbred lines are given in Tables 22 and 23 from experiments grown near Columbia, Mo. The mean performance record for the two locations is given in Table 24. The average performance for the parental inbreds as measured by the performance of their single-cross progenies is given in Table 25. The performance for a group of selected double crosses predicted from the single-cross data for each of the locations is listed in Tables 26 and 27. The predicted double crosses listed are those having high yield, lowest root lodging and stalk lodging and with low ear placement.

Midseason and Late White Double and Single Crosses

(800—900 Maturity Series)

Performance of midseason white double- and single-cross hybrids (800 maturity series), tested at West Liberty, Ia., and Columbia, Mo., respectively, is presented in Tables 28 and 29. Late (900 maturity series) white single crosses tested at Bradford Farm near Columbia are presented in Table 30. Period-of-years performance records for midseason and late white doubles are presented in Table 31.

Table 28. 1966 performance record for midseason white hybrids tested near West Liberty, Iowa. Planted May 25, 1966. Harvested November 3, 1966 (Exp. 29). The test was conducted by the Iowa Agricultural Experiment Station, Ames, Iowa.

Midseason and Late Pipe Corn Double Crosses

(800—900 Maturity Series)

Performance records of 40 pipe corn double crosses are presented in Tables 32, 33, 34 and 35 for experiments grown near Golden City, Columbia, Higginsville, and Washington, Mo., respectively. The mean performance record for the four locations is given in Table 36.

Table 32. 1966 performance record for pipe corn double crosses (800-900 Maturity Series). Tested near Golden City, Missouri. Planted May 3, 1966. Harvested October 18, 1966 (Exp. 18).
