Special Report 209

November 1977

University of Missouri-Columbia

Agricultural Experiment Station

ACKNOWLEDGMENTS

This bulletin is a contribution of the Department of Agronomy, University of Missouri Agricultural Experiment Station which reports on Research Project 363. The work was supported in part by funds from the Missouri Seed Improvement Association.

The following individuals assisted in making the 1977 crop performance trials possible: John Jones and Bob Vette, Tarkio; Larkin Langford, Superintendent, North Missouri Center, Spickard; Lynn Douglas, Edina; Holton Eschenbach, Norborne; D. C. Mathews, Mexico; Thomas Kinyon, Clinton; Dr. Norman Justus, Superintendent, Southwest Center, Mt. Vernon; Joe Hoffmeister, Cape Girardeau; Charles Cromwell, Superintendent, Delta Center, Portageville; and C. G. Scott, Matthews.

Assistance was also received from the following area agronomy specialists: Charles P. Bruffy, Northwest Missouri Area; Ed Meek, Northeast Missouri Area; Ron Alexander, Missouri Valley Area; David Lindell, Show-Me Area; and Gail King, Southeast Missouri Area.

Special recognition is given to Louis Meinke of the North Missouri Center, Randall Smoot of the Greenley Memorial Center, and Richard Mattas, Southwest Center, for their aid in all phases of the program at their respective research centers.

THE AUTHORS

R. D. Horrocks, Professor of Agronomy and State Extension Agronomy Specialist, Carl G. Morris and Bill V. Emerine, Research Specialists, and Howard L. Mason, Research Technician.

SYNOPSIS

The fall of 1976 was open and harvest proceeded at a record pace, with 7% of the corn crop harvested by 7 September and 93 % by 15 November. In fact, by this date over 91% of the corn, grain sorghum, and soybean crops had been harvested and 60% of the fall plowing for spring crops had been completed. Spring plowing (1977) also proceeded very well and by April 20 was over 90% complete.

Because of the open fall (1976) and the dry winter that followed, most farmers were anticipating a summer drought of greater severity than usual, thus planting was completed with dispatch. By the end of the first week in May, 81% of the corn acreage had been planted.

Temperatures during the early and middle part of the growing season ranged from 2 to 6 degrees above the long-term average throughout the state. Although precipitation was generally below normal, distribution was good and the anticipated severe drought did not materialize for much of the state. Nevertheless specific localized areas of the north part of the state were struck particularly hard -- notably portions of the area between, and including, Atchison and Grundy counties.

Yields were good in some areas of the state, particularly central Missouri, but the overall state average was probably near the long-term average.

SELECTING A HYBRID FOR YOUR FARM

Period-of-Years Performance Records

A number of hybrids have been tested for periods of two or three years either in a single district or in groups of districts. These performance records are presented in tabular form for the respective districts.

Emphasis is placed upon the fact that results for a period of greater than one year are of greater value in assessing the performance of a hybrid than the results from a single year. If one must rely on results from any one year, it is best to use the average performance from as many testing locations as possible in the general area where the hybrid is to be grown.

Statistical Interpretations

The performance of each hybrid cannot be measured with absolute precision. Uncontrollable variability is involved in the determination of each yield average. The statistic used here as a measure of variability is called the least significant difference. It can be expressed at any probability level. We have chosen to present it at the 5 and 20 percent levels. It is usually written as "L.S.D.". In each single year table the L.S.D.

is given at the bottom in bushels per acre. The reader will note that the L.S.D.'s vary in magnitude from table to table. This means that the trials differ in their uncontrolled variability. One having an L.S.D. of 11 bushels has less variability than one with an L.S.D. of 15 bushels per acre. A yield difference of 12 bushels between two hybrids would be more meaningful in the first set of data than in the second. Interpreted in terms of probability of an event occurring, the L.S.D. values mean; (1) at the 5% level, if hybrid A exceeds hybrid B in yield by more than the L.S.D. value, then you would expect that 19 out of 20 years it would do so; (2) at the 20% level, if hybrid A exceeds hybrid B in yield by more than the L.S.D. value, then you would expect it to do so in 16 out of 20 years.

Recommendations

The Missouri Agricultural Experiment Station does not make specific recommendations for hybrids. It is suggested that the farmers growing a new hybrid for the first time consider the information contained in this booklet and then grow a small acreage to determine adaptability. This should be the practice for all new hybrids regardless of origin.

Planting Rates

The rate of planting has a direct bearing on corn yields. In Missouri, experimental work indicates that optimum populations are between 16,000 and 20,000 harvested plants per acre depending on the area. Where moisture stress can be minimized with irrigation higher populations may be acceptable. Perfect stands are rarely realized. There is generally a 10 to 25 percent loss in stand between planting and harvest even under ideal conditions.

The following table is presented as an aid in estimating per-acre plant populations.

Table 1. Distance between plants within a row required for a given per-acre plant population.

Inches Between Each Plant in Row	Row Width in Inches				
	20	30	36	38	40
6	-----	34,850	29,040	27,540	26,130
7	-----	29,870	24,890	23,630	22,410
8	-----	26,140	21,780	20,640	19,600
9	-----	23,230	19,360	18,340	17,424
10	31,360	20,910	17,420	16,510	15,680
12	26,140	17,420	14,520	13,750	13,070
14	22,400	14,930	12,450	11,790	11,200
16	19,600	14,930	10,890	10,317	9,800
18	17,420	11,620	9,680	9,170	8,710
20	15,680	10,450	8,710	8,250	7,840

Date of Planting

Hybrids should be planted as soon as soil and climate permit. Research conducted at the North Missouri Research Center¹ indicates highest yield can be expected from plantings made between April 20 and May 10. A reduction of 0.4 of a bushel resulted for each day of delay in planting after May 10 until June 1. For each day of delay after June 1 a reduction of 2.4 bushels occurred.

At Columbia² a decrease of about 12 bushels per acre occurred when planting was delayed from April 20 to May 20. Only a small difference in yield was noted among the April 1, April 20, and May 10 plantings at the Delta Center.³ After May 10 a reduction of one bushel occurred for each day of delay in planting. In addition to higher yield, early planted corn generally had less lodging, lower ear height, less European corn borer and less earworm damage.

EXPERIMENTAL PROCEDURES

Testing Area

For statistical reporting purposes the state is divided into nine districts, each based on the geographical characteristics of the area. Tests were located in seven of the nine districts. Figure 1 shows the districts and the counties in which tests were conducted. Cultural practices applied at each site are given in Table 4.

Seed Sources

All producers of hybrid seed were eligible to enter hybrids in the 1977 evaluation plots. No limit was placed on the number of hybrids any one seed producer could enter in the trials on a fee basis. In addition to the fee entries, a broader-based program was continued in which certain widely-grown hybrids were included on a no-fee basis. Identification of these widely-grown hybrids was through an extensive mail survey of hybrids grown by farmers of Missouri. The number of subsidized entries from this option for each company was limited to three or less no-charge hybrids per location. Each company was also eligible to nominate two hybrids for inclusion in the irrigation trials. A minimum of 15 pounds of processed seed was supplied by the company or purchased from a seed dealer for each entry. Seed for the open-pedigree hybrids was furnished by the respective state agricultural experiment stations or by certified seed producers.

Field Design

Lattice field plot designs of appropriate size and random assignment of entry numbers were used in all tests to locate plots at random over the testing area. This was done to facilitate statistical analysis for computing the least significant differences (L.S.D.) and to minimize the effect of cultural and soil differences over the testing area. Three two-row plots of each hybrid were planted at all locations.

Stand

All plots were planted using conventional equipment modified for small plot work. Plots were over-planted for an expected 10 to 15 percent stand loss.

Lodging

A plant was classified as root-lodged if it leaned more than 30 degrees from the vertical through the first several internodes and stalk-lodged if it was broken below the ear. A plant that was both root and stalk-lodged was recorded in both categories. The percent lodged plants was calculated based on the total number of plants present at time of harvest.

Dropped Ears

The total number of ears dropped by each hybrid was recorded at harvest. Dividing this number by the total number of plants present and multiplying by 100 gave the percent of ears dropped. It was assumed that each plant produced one ear.

Ear-Height

The ear-height grade was determined from averages of the three plots of a hybrid at a location. The grade consisted of the approximate number of feet from the ground level to the point of attachment of the primary ear.

Yield

The corn from each plot was harvested with a two-row combine and then weighed. Yield was determined on the basis of shelled corn with a moisture content of 15.5 percent. Adjustments were not made for stand deviations. The reported yield at each location for each hybrid is the average yield of three two-row plots.

Moisture

The grain moisture of each entry was determined at harvest by obtaining a random sample from each plot during shelling. Grain from each plot was thoroughly mixed and the moisture content determined with a Burrows moisture tester. The moisture percentage reported in the tables for each hybrid is the average of three plots at all locations. The grain yields were adjusted to 15.5 percent moisture.

Table 1. Total rainfall, number of days with rain, and dry periods* from May 1 through August 31 at each testing location.

Location	Growing Season		May		June		July		August		Dry Periods*
	Total Rainfall	Days With Rain	Days With Rain								
Tarkio	16.48**	39**	5.62	14	1.49	4	Data Missing		9.37	21	
Spickard	16.39	43	4.49	12	1.78	6	1.33	5	8.79	20

Sikeston	17.45	46	2.28	6	5.02	15	4.54	13	5.61	12	(6-1 to 6-17) (5-7 to 5-22)
Portageville	15.77	42	5.62	14	3.59	11	3.00	8	3.56	9	

* A dry period is 15 or more days with less than 0.25 inch precipitation in any one day. All dates listed are inclusive.

The beginning date is the day after rainfall of 0.25 inch or more and the ending date is the day before a 0.25 inch rainfall.

** July data not included.

Table 2. Summary of temperature data for the period May 1 through August 31 at various Missouri locations.

Location	Month	Avg. Temp.	Degrees From Normal	Number of Days Above	
				90°	100°
Tarkio	May	69.9	6.5	0	0

*Applied at recommended rates. See MU Guide 4136 for 1977 Chemical Weed Control Recommendations and MU Guide 4150 for 1977 Soil Insect Control.

DISTRICT 1

Data for District 1 are presented in Tables 5 and 6. A summary of cultural practices applied may be found in Table 4.

This site was characterized by below normal rainfall; therefore, grain yields were considerably below normal (see Table 2).

The average yield from a harvest stand of 17,800 plants per acre was 62 bushels, down 69 bushels from the 1976 average. Hybrid yields ranged from 33 to 91 bushels per acre. The average stand loss for the hybrids was slightly more than the 15% allowance made at planting time. Stand loss for individual hybrids ranged from 3% to 45%, indicating that a considerable difference in seed quality and seedling vigor existed.

Root lodging, averaged over all hybrids, was 7.2% and the range was from a low of 0% to a high of 38.7%. Stalk lodging averaged 5.9% and ranged from 0 to 9.4%.

Weeds were not a problem during the growing season.

For the most reliable results, hybrids that have proven their potential over two or three growing seasons should be held with higher regard than those for which only one season's data are available. Such information is found in Tables 6, 7, 9, and 10.

DISTRICT 2

Data on agronomic performance of hybrids evaluated at this site were limited to the information presented in Table 7, which is the summary of all hybrids evaluated over a three-year period ending in 1976. Because of extreme drought at this site in 1977, which followed a drought in 1976 and a dry winter in which soil moisture was not replenished, the plots produced no grain in 1977; in fact all plants died during the period July 20 to August 1. See Table 3 for rainfall received.

For the most reliable results, hybrids that have proven their potential over a two- or three-year period should be considered before those having only one year of performance data available. Such information is presented in Tables 6, 7, 9, and 10.

DISTRICT 3

Data on the performance of hybrids evaluated at this location are presented in Tables 8 and 9.

The site was characterized by below normal rainfall during the 1977 growing season (see Table 3), but distribution was fairly good, thus providing respectable yields.

The average yield was 92 bushels per acre from a stand of 18,800 plants. The yield range for individual hybrids was from 58 to 118 bushels per acre. This is an increase of approximately 9 bushels over the 1976 average yield.

Root and stalk lodging were minimal at this site, ranging from 0% to 7.1% and 0% to 9.4%, respectively.

Weeds were not a factor in determining the final yield in 1977.

The most reliable results may be obtained from the use of hybrids that have proven their potential over a two- or three-year period. Such information is available in Tables 6, 7, 9, and 10.

SUMMARY OF NORTHERN LOCATIONS

The average performance of hybrids evaluated at the John Jones farm near Tarkio, Missouri (Atchison County) and the Lynn Douglas farm near Edina, Missouri (Knox County) is presented in Table 10. These data supply information from two locations, and therefore the inferences that may be drawn regarding the superiority or inferiority of a hybrid are more reliable than those drawn from the data in Tables 5 and 8. In reliability, these data (Table 10) are comparable to the 2-year averages presented in Tables 6, 7, and 9.

DISTRICT 4

Data for District 4 are presented in Tables 11 and 12. A summary of cultural practices is presented in Table 4.

This site was characterized by below normal precipitation during part of the 1977 growing season (see Table 2), however, the effect was alleviated to a large degree by some precipitation during critical periods of the corn growth cycle.

The average yield from a harvest stand of 17,000 plants was 110 bushels per acre, up 19 bushels from the 1976 average yield. Individual hybrid stands ranged from 10,900 to 20,100 plants per acre (49% to 6% losses, respectively, when compared to the population at planting time). This extensive loss by some hybrids indicates considerable differences existed in seed quality and seedling vigor among hybrids evaluated in 1977.

Stalk lodging ranged from 0.4 to 32.0% for individual hybrids. The average for all hybrids was 7.1%, indicating that many of the hybrids were influenced by significant amounts of lodging. Root lodging was important also, ranging from 0% to 58.4% and averaging 16.9% over all hybrids. These data emphasize the wide differences that exist among today's corn hybrids with respect to their response to insects and diseases that are harbingers of lodging problems.

Weeds were not a significant factor in determining 1977 grain yields.

For more reliable results, hybrids that have proven their potential over a two- or three-year period should be considered. Such information is found in Tables 12, 14, and 15.

DISTRICT 5

Data from District 5 are presented in Tables 13 and 14.

The average acre yield of the hybrids evaluated was 143 bushels, up 100 bushels from the 1976 yield. The range was from 115 to 176 bushels per acre. This was 7 bushels more than the record 1973 yield obtained from the evaluation plots at the Agronomy Research Center-Bradford Farm.

Total precipitation during the growing season in central Missouri was below normal, but good seasonal distribution allowed optimum production by early planted corn.

Stalk and root lodging were not important in these plots in 1977, likely because of the early harvest that was made (see Table 13 for harvest and planting dates) since European cornborer infestation was very heavy.

Weeds were not important in determining the 1977 yields. The most serious weed was yellow nutsedge, but it was controlled effectively with a combination of timely herbicide application and manual labor.

The most reliable results may be obtained from the use of hybrids that have proven their potential over a two- or three-year period. Such information is available in Tables 12, 14, and 15.

SUMMARY OF CENTRAL LOCATIONS

The average performance of hybrids evaluated at the Holton Eschenbach farm near Norborne, Missouri (Carroll County) and the Agronomy Research Center-Bradford Farm near Columbia, Missouri (Boone County) is presented in Table 15. This table supplies information from two locations, and therefore the inferences drawn from it are more reliable than those drawn from the one-year data in Tables 11 and 13.

DISTRICT 6

No evaluation plots were located in this district during 1977.

DISTRICT 7

An irrigation trial was located in this district at the Southwest Center near Mt. Vernon, Missouri (Lawrence County). The agronomic performance data for the period 1974, 1975, and 1977 are presented in Table 23. The 1977 yields are presented in Table 22.

DISTRICT 8

Since less than one percent of the land in this district is planted to corn, no hybrid evaluation trials were conducted within its boundaries.

DISTRICT 9

Data for this area are presented in Tables 16 through 19. Hybrids were evaluated at two locations in 1977 -- the Delta Center near Portageville (Pemiscot County) and the C. G. Scott farm near Matthews (New Madrid County). Forty-one of the 90 hybrids were lost because of cultural management problems after planting at the Delta Center, thus only 49 entries are presented in Table 16. The performance record for all 90 hybrids at the C. G. Scott farm is presented in Table 18.

Delta Center. Average yield from the 49 hybrids was 114 bushels, and the range was from 72 to 148 bushels per acre. Root lodging averaged less than 1% and ranged from 0% to 20.1%, while the stalk lodging averaged 8.0% and ranged from 0% to 33.2%.

Stand loss averaged 18%, or 3% more than allowed for at planting time. Individual hybrids ranged from 4% to 31% stand loss, indicating considerable variance in seed quality and/or seedling vigor.

Weeds were not important in determining the final grain yield at this site.

C. G. Scott Farm. Average yield from the 90 hybrids was 148 bushels per acre and the range was from 107 to 180 bushels. Root and stalk lodging respectively were: average -- 6.5% and 2.5%; range -- 0% to 38.6% and 0% to 20.5%, pointing out that there is a significant difference in the response of the hybrids being produced and marketed today to these characteristics.

Stand loss averaged 10%, well within the 15% allowance made at planting time by overplanting. Individual hybrids ranged from less than 0.5% to 35% loss, indicating considerable variance in seed quality and/or seedling vigor.

Weeds were not important in determining grain yields at this site.

Although these trials were not considered irrigation trials, both sites received supplemental irrigation during the season. Because of soil type and accessibility of water, irrigation is a common practice on corn in the Bootheel.

IRRIGATION EXPERIMENTS

Irrigation experiments were conducted at two locations to assess hybrid performance independent of stress caused by irregular precipitation patterns. These experiments were located at two of the Agricultural Experiment Station Research Centers -- the Claypan Research Center near McCredie in Callaway County and the Southwest Center near Mt. Vernon in Lawrence County. Cultural practices applied to the 1977 irrigation experiments are listed in Table 4.

Figures 2 and 3, respectively, present the inches of accumulated precipitation (includes rainfall and water applied in several irrigations) at McCredie and the Southwest Center. The cross-hatched area represents optimum soil moisture. Accumulated precipitation above this area represents excess moisture and runoff. The precipitation line, which is usually below the cross-hatched area, indicates possible soil moisture deficits and the need for supplemental irrigation.

At McCredie a 1.6" irrigation was made May 31 to bring the soil to near field capacity (in using this chart, one assumes that the soil is at field capacity June 1).

McCredie. The acre yield ranged from a high of 178 bushels to a low of 118 bushels per acre. The experiment average was 149 bushels. Root lodging and stalk lodging, respectively, ranged from 0% to 18.9% and 0.4% to 12.4%.

Performance data for this site are presented in Tables 20, 21, and 24.

Southwest Center. Acre yield ranged from a high of 181 to a low of 96 bushels per acre. The experiment average was 143 bushels. Root lodging was not significant for any of the hybrids. Stalk lodging averaged 7.8% for all hybrids and ranged from 1.9% to 20.4% for individual hybrids.

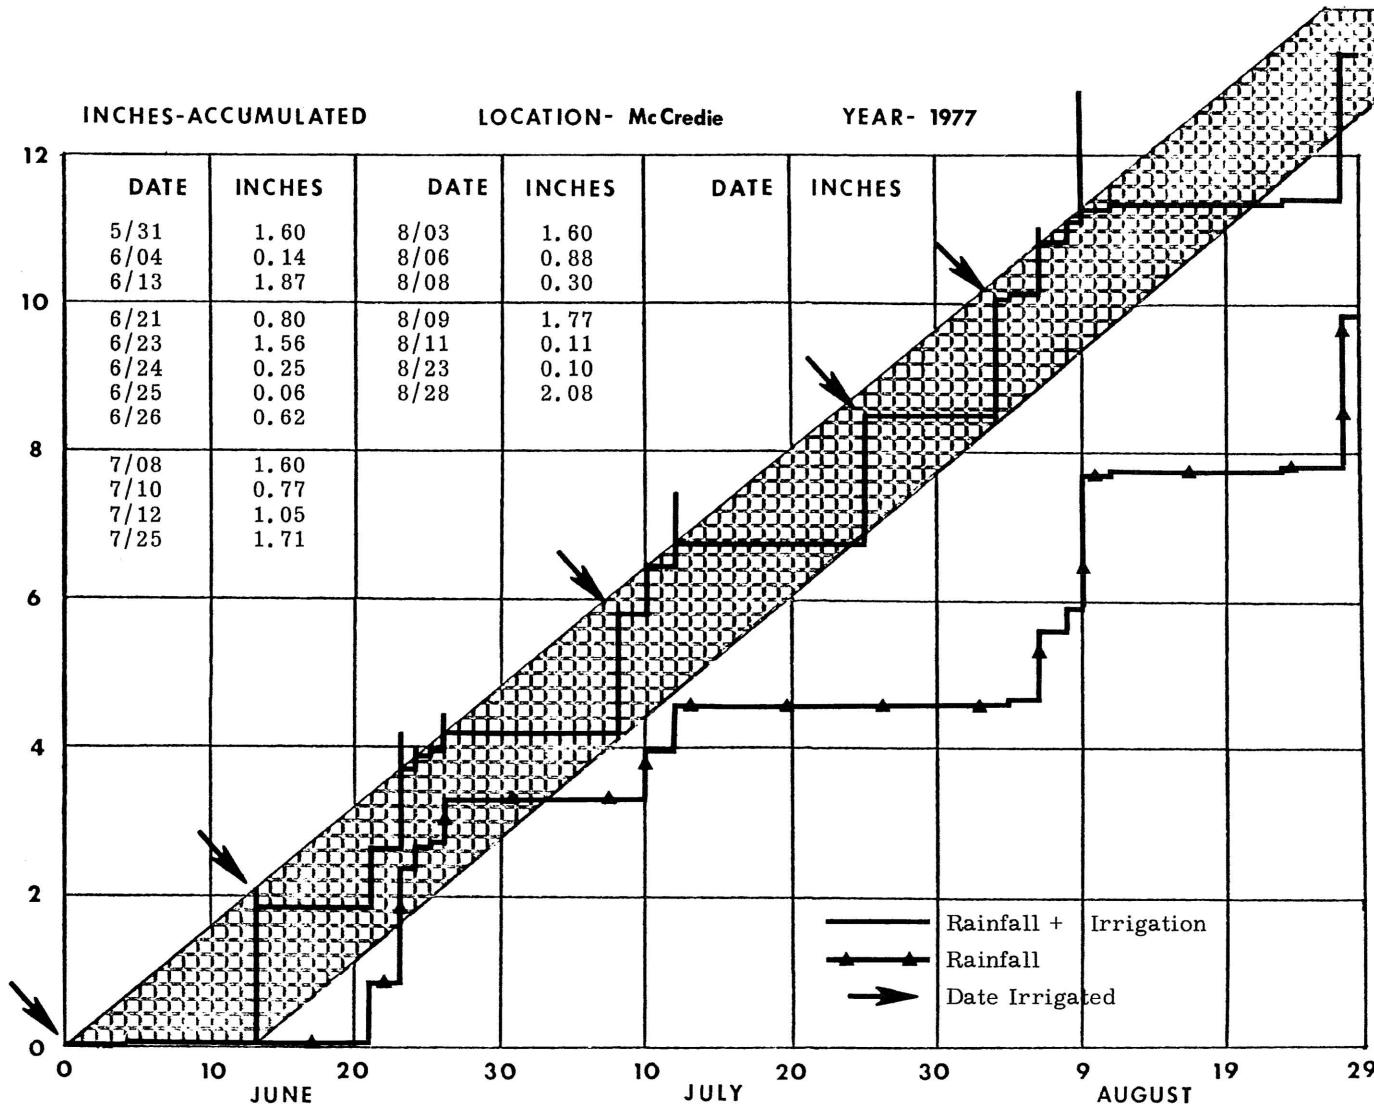

Figure 2. Precipitation pattern and irrigation schedule for 1977.

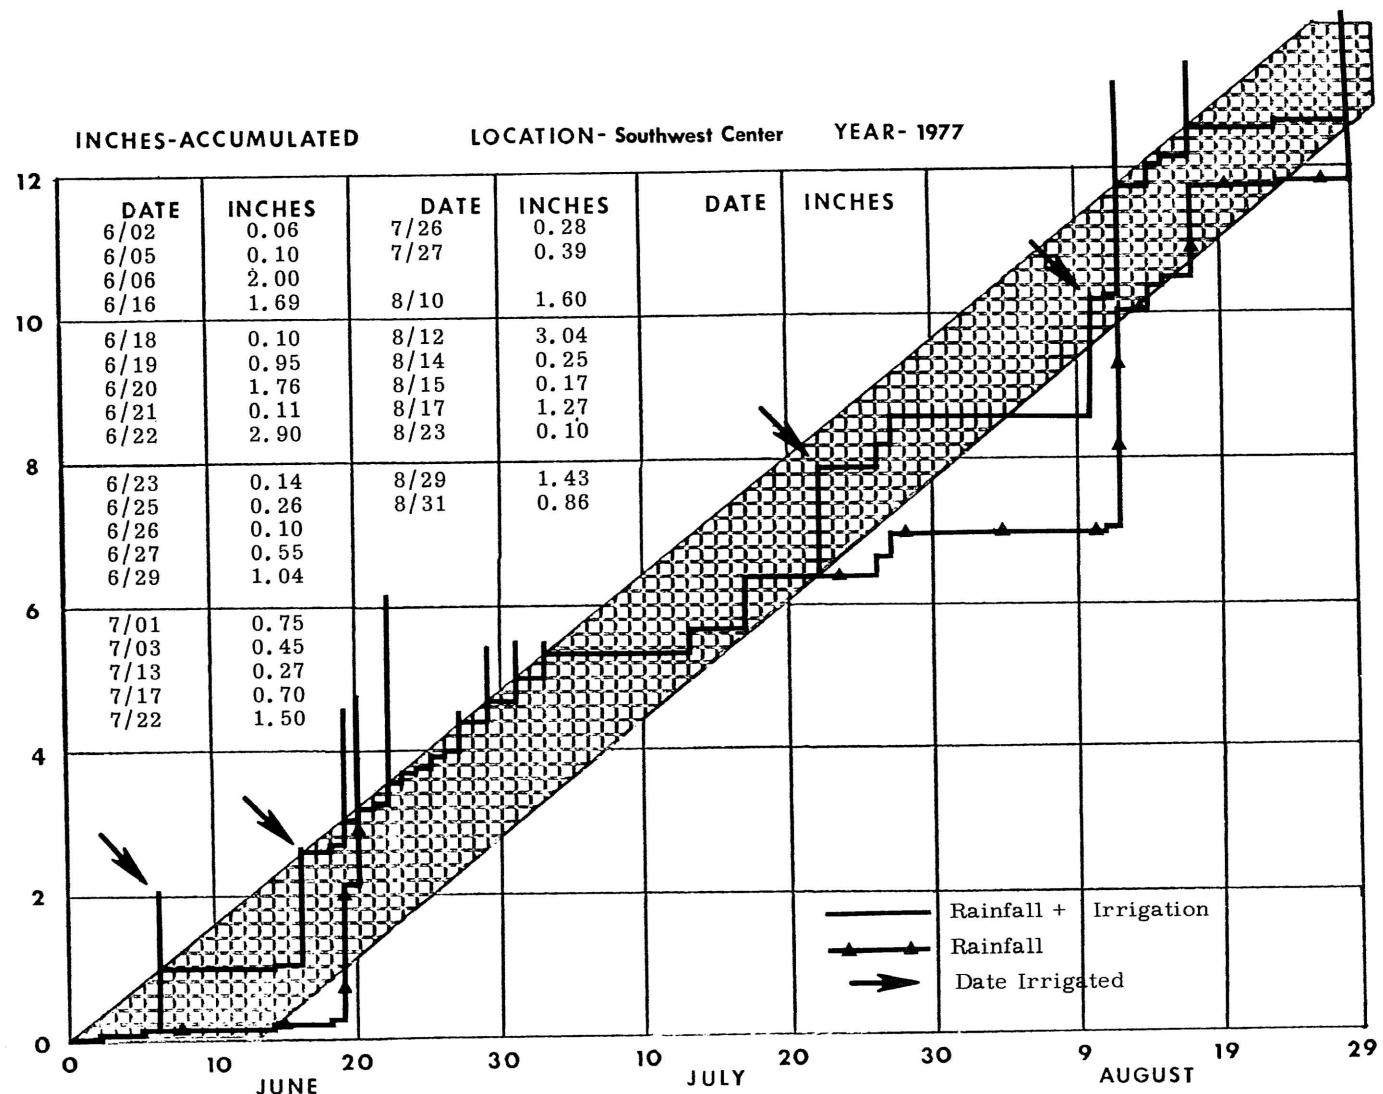

Figure 3. Precipitation pattern and irrigation schedule for 1977.

TABLE 5. PERFORMANCE OF CORN HYBRIDS EVALUATED ON THE JOHN JONES FARM (BOB VETTE OPERATOR) NEAR TARKIO, MISSOURI (ATCHISON COUNTY) DURING 1977.
PLANTED: 19 APRIL 1977. HARVESTED: 17 OCTOBER 1977.

BRAND-HYBRID	ACRE YIELD (BU)	MOISTURE IN GRAIN (%)	PLANTS PER ACRE (#)	LODGED ROOT (%)	PLANTS STALK (%)	DROPPED EARS (%)	EAR HEIGHT (FT)
