## ACKNOWLEDGEMENTS

This Bulletin is a contribution of the Department of Agronomy, University of Missouri Agricultural Experiment Station and Agricultural Research Service, Science and Education Administration, U.S. Department of Agriculture in cooperation with Department of Agronomy, Purdue University Agricultural Experiment Station; Department of Agronomy, Kansas State University Agricultural Experiment Station; Department of Agronomy, University of Kentucky Agricultural Experiment Station; Department of Plant and Soil Science, University of Tennessee Agricultural Experiment Station; Department of Soil and Crop Sciences, Texas Agricultural Experiment Station; Department of Agronomy, Virginia Agricultural Experiment Station; Corn Borer Research Laboratory, Agricultural Research Service, U.S. Department of Agriculture; Illinois Foundation Seeds, Inc., Champaign, IL; Funk Seeds International, Union City, TN; and The Quaker Oats Company research laboratory at Barrington, IL. We thank Linda Bode for typing of the manuscript, and Krystyna Lukaszewska and Robert Fincher for assistance in analyzing the results.

## COLLABORATORS

Dr. L. F. Bauman, Purdue University  
Dr. C. E. Wassom, Kansas State University  
Dr. C. G. Poneleit, University of Kentucky  
Dr. D. R. West and Mr. H. C. Kincer, University of Tennessee  
Dr. A. J. Bockholt, Texas A&M University  
Dr. H. S. Aycock, Virginia Polytechnic Institute and State University  
Dr. W. D. Guthrie, Corn Borer Research Laboratory, U.S. Department of Agriculture  
Dr. M. Rode and staff, Illinois Foundation Seeds, Inc.  
Mr. J. Bray, Missouri Farmers Association  
Dr. T. R. Colbert, Funk Seeds International  
Mr. L. R. Young, The Quaker Oats Company research laboratory, Barrington

## THE AUTHORS

L. L. Darrah is Research Geneticist, USDA, ARS and Associate Professor of Agronomy, University of Missouri; and M. S. Zuber is Professor of Agronomy, University of Missouri, Columbia, MO 65211.

Kernel quality data for 1980 White Maize Variety Trial. .	Table 20

The 1981 National White Maize Variety Trial involved 61 hybrids plus 4 yellow checks submitted by 17 commercial seed producers or public institutions (Table 1). Eighteen locations were included in the evaluation. Data were received from sites in Illinois, Iowa, Indiana, Kansas, Kentucky, Missouri, Tennessee, Texas, and Virginia. Virus data were obtained from Waverly, Tennessee and European corn borer ratings were taken at Ankeny, Iowa. Grain samples were evaluated for breakage susceptibility at Columbia, Missouri, and for quality aspects at The Quaker Oats Company at Barrington, Illinois.

#### ENTRIES AND SEED SOURCES

Contributors of seed for the 1981 evaluation are listed in Table 1. Those entries that have an EXP as part of the hybrid name, such as Funk EXP 29276, have not been released. The last four named hybrids in each table are yellow kernel hybrid checks.

Note that Whisnand 79W (Ga) contains the dominant gametic factor (Ga) for normal pollen sterility. This means that it could only be pollinated by itself or a genotype which was Ga. This may have resulted in limited pollen availability for this entry and caused reduced grain yields.

Seed of the yellow check entries B73 x Mo17 and Mo17 x N28 was provided by Dr. J. Thomas of the Missouri Farmers Association, Columbia, Missouri, Pioneer Brand 3320 was contributed through Dr. J. Wright, Pioneer Hi-Bred International, Union City, TN, and US13 was provided by the University of Missouri.

#### SITE LOCATIONS AND AGRONOMIC PRACTICES

Table 2 lists the sites returning acceptable data, together with a record of the agronomic practices. Dashed lines indicate that treatment was not applied or the information was not available.

#### DATA COLLECTED

##### Yield

Yields (YLD BU/A) were measured on a plot basis and converted to bushels per acre adjusted to 15.5 percent moisture.

##### Stand

Stand (STAND %) is expressed as a percentage of the optimum plot stand or planted stand.

##### Root stalk lodging

Lodging is expressed as a percentage of the counted stand for each

hybrid. Generally, a plant was rated as root lodged (ROOT L %) if it leaned more than 30 degrees from vertical; and as stalk lodged (STLK L %) if it was broken over or off below the ear. Breakage above the ear was not counted.

#### Ear height

Ear height (E HGT IN) was measured from the soil level to the top ear leaf collar. Heights are expressed in inches.

#### Days to flowering

The number of days (DAYS FLW) from planting to mid-tassel or mid-silk is shown.

#### Grain moisture

Grain moisture (MOIST %) was observed at harvest or when the grain was weighed.

#### European corn borer ratings

Leaf feeding by the first generation of the European corn borer (1ST ECB) was rated in nine classes in which a score of 1 represents no feeding, and 9 represents extensive feeding. Six plants in each plot were infested with two egg masses in each of four applications during the mid-whorl stage of plant development. Ratings for leaf feeding were made three weeks after egg hatch.

Sheath-collar feeding by the second generation of the European corn borer (2ND ECB) was rated on a 1 to 9 scale. Six plants per plot were infested with two egg masses in each of seven applications during pollen shedding. Rating of sheath-collar feeding was done about 60 days after egg hatch.

#### Virus ratings

Virus infection percentage (VIR INF %) is the percentage of plants in the plot showing symptoms. Virus severity (VIR SEVR) is a rating of diseased plants using a scale on which 2 represents a mildly diseased plant and 9 represents a severely damaged plant. Non-affected plants (scored 1) are not included in VIR SEVR. Average virus rating (AVG VIR) is the mean severity of all plants in the plot.

#### Kernel breakage

The percent broken kernels (BRKN K %) was obtained from grain of one replication from each of 11 sites subjected to the "Missouri corn cracker". Grain was hot air dried (40°C) to a uniform moisture percentage for the individual site (approx. 11.5%). It was then screened over a 6.4 mm screen and impacted by an impellor type device for evaluating resistance to breakage.

After impaction, grain was again screened, and the percent broken kernels passing through a 6.4 mm screen determined. A sample of 175 g was used for impaction.

#### Environmental yield response ( $b_I$ ) and standard deviation of fit (SD)

These statistics are shown only in Table 16 for the entry means combined over all sites. The yield response ( $b_I$ ) is expressed as bu/a/unit increase in the environmental index, where the index for a site is the average performance of all hybrids at the site. The deviation of fit is given in bu/a. The origin and use of these statistics are fully described below.

#### Percent horny endosperm

The percent horny endosperm (HORNY %) was visually estimated using a candling light. Ten to fifteen kernels were observed for each entry.

#### Kernel weight

The 100-kernel-weight (100 KW G) in grams was obtained from 100 randomly picked whole kernels.

#### Kernel density

Kernel density (KER DENS) was calculated from kernel weight and volume using water displacement. Values are in grams per cubic centimeter.

### STATISTICAL ANALYSIS AND INTERPRETATION

The evaluation was analysed as a three-replication, randomized complete block at each site. If an observation was missing in one replication, the average of those observations in the remaining replications was used to approximate the missing observation. The least significant differences at probability level 0.05 (LSD 0.05) and coefficients of variation percentages (CV%) were calculated from the site analyses of variance (AOV). Where differences among hybrids were not significant for a character, no LSD or CV% is shown. Occasionally, data were observed in only one or two replications; a footnote is used to identify those characters.

The LSD 0.05 is used to compare the performance of two specific hybrids at a time. It should not be used, however, to compare all pairs of hybrids. If the mean of hybrid "X" exceeds the mean for hybrid "Y" by the LSD 0.05 or more, then the difference observed will be a true difference 19 out of 20 times the two hybrids are grown under conditions similar to those of the test.

The CV% relates error of measurement and the mean of the observed charac-

ter. Values of 10 to 15 percent are common for yield, stand, and ear heights. Values for lodging are sometimes much higher and are generally associated with nonsignificant differences among hybrids.

Agronomic data combined from 13 locations with an appropriate LSD 0.05 for each character are shown in Table 16. The combined LSD 0.05 is based on the entry x site interaction versus the pooled error from the combined AOV. When a character was not observed at a site, zeros show in the site analysis; the combined mean and LSD 0.05 have been adjusted accordingly.

Stability analysis gives information on the responsiveness of hybrids to changes in environment and the reliability with which these responses may be predicted. Mean performance of all hybrids at a site was the measure used to rate the environment. This environmental index ( $I$ ) was then used as the independent variable in a regression analysis with the individual hybrid's performance at each site. A hybrid that is stable will have a regression coefficient ( $b_I$ ) equal to 1.0, meaning that an increase in the environmental index would result in an equal increase in the hybrid's yield. Regression coefficients greater than 1.0 indicate relatively better performance in good environments. Hybrids with  $b_I$  values less than 1.0 would be relatively advantageous in poor environments.

Deviation from fit reflects the accuracy with which the regression line given by  $b_I$  represents probable performance. Low deviation indicates that a hybrid has greater stability.

Overall, a desirable hybrid would have a high mean yield,  $b_I = 1.0$ , and low deviation from fit. If a grower knew that he was producing on the high side of the environments sampled, then a hybrid with  $b_I$  greater than 1.0 would be more responsive than one with  $b_I = 1.0$  and would be likely to yield more if mean yield levels were equivalent.

#### NARRATIVE SUMMARY

Individual site yields ranged from 100.3 bu/a at Troy, KS to 164.9 bu/a at Halfway, TX under irrigated conditions. The overall average was 129.2 bu/a. Plot stands averaged 93.7% ranging from 78.7% at Rossville, KS to 102.5% at Union City, TN. No stand data were recorded at Troy, KS. No covariance adjustment of yield for stand was done because of the relatively good stands and the poor stand for Funk EXP 29276 which averaged just 54.9% over all sites. Funk EXP 29276 had average stands significantly lower than the mean at nine sites. This may have been due to seed quality and germinability

under less than optimum conditions. The low stands significantly affected yield, resulting in Funk EXP 29276 being lowest yielding in the Trial.

Root lodging was generally low except at Lexington, KY where nearly 25% lodging occurred. Stalk lodging was very high (48.7%) at Halfway, TX under irrigated management, and relatively high at Lafayette, IN (23.9%). Average days to flowering ranged from 69.8 days at Knoxville, TN to 81.8 days at Troy, KS with an overall mean of 77.3 days. Harvest moistures were less than 22% at all but two sites. However, low moisture could also arise if ears were dried before shelling and weighing. Details of individual site data are in Tables 3-15.

Combined agronomic data from 13 sites (Table 16)

IFSI 81-3 (143.4 bu/a), IFSI 80-6 (146.9 bu/a), Lynks SC-WLA (142.9 bu/a), Meacham's MV58 (145.7 bu/a), Meacham's MV88 (146.9 bu/a), Pioneer Brand 519 (146.5 bu/a), and Sturdy Grow SG935W (142.5 bu/a) yielded significantly more than the mean of all entries (129.2 bu/a). The sites by entries interaction was highly significant indicating different entry responses in the environments sampled.

Root lodging percentages were generally low. MFA C4W (13.6%) lodged significantly more than the mean of all entries, but was not significantly different from half of the remaining entries. Five entries (IFSI 80-6, Meacham's MV68, O's Gold 26201W, Sturdy Grow EXP 0668 and 0695) had less than 1% root lodging.

Stalk lodging percentages were roughly twice as high as root lodging. Funk EXP 29276 lodged significantly less than the mean, but this was likely a result of the low stands already noted. Only Sturdy Grow EXP 0668 and the yellow check US13 stalk lodged more than the mean of all entries.

Six entries had significantly lower ear heights than the mean: Golden Harvest H-2644W (35.1"), IFSI 81-2 (36.3"), Meacham's MV68 (33.7"), O's Gold 26201W (34.2"), Sturdy Grow EXP 0641 (35.5") and 0695 (35.8"). In Meacham's MV68, O's Gold 26201W, Sturdy Grow EXP 0668 and 0695, lower ear height was associated with root lodging percentages of less than 1%. However, none of the stalk lodging percentages for these four hybrids was below the mean.

Little variation existed among entries for days to flowering with most entries falling between 76-79 days. Only Funk G4787W (79.9 days), Meacham's MV68 (75.3 days), and Sturdy Grow EXP 0668 differed significantly from the

mean. The yellow checks were uniformly earlier in flowering than most of the white hybrids.

The environmental response coefficients and standard deviations of fit are shown in the last two columns of Table 16. (A difference of  $\pm 0.17$  from 1.0 is necessary for significance. The LSD 0.05 should be used when comparing coefficients of two hybrids.) Twenty entries had  $b_I$ 's significantly greater than 1.0, indicating greater than average response to better environmental conditions, but poor performance in adverse environments.

Five hybrids had responses that were more than two LSD's greater than 1.0: IFSI 80-6 (1.37), IFSI 79-1 (1.39), Meacham's MV58 (1.38), Meacham's MV88 (1.35), and Sturdy Grow EXP 0641 (1.47). Three of these five hybrids were among the seven highest yielders. Pioneer Brand 519, however, was an exception. Its response of 0.73 was significantly lower than most entries, but it was among the four highest yielders (range 146.5 to 146.9 bu/a). Pioneer Brand 519 appears to be unaffected by what are stressful environments for most other hybrids, and it yields very well over the whole range of environments. Usually, this type of nonresponsiveness is associated with low rather than high mean yields.

In making a hybrid choice, all of the agronomic factors must be considered in relation to the anticipated environment. Data from several sites are usually more reliable than data from a single site evaluated for two or three years.

European corn borer, virus, and kernel breakage susceptibility ratings  
(Table 17)

The corn borer ratings were made at the USDA Corn Insects Research Laboratory at Ankeny, IA using hand infestation. For the first generation, ACCO UC1800W (4.0), O's Gold 26801W (4.3), and Pioneer Brand 519 (4.0) had significantly less damage than the mean of all entries (6.5). Three entries rated as completely susceptible (9.0) and eight more entries rated 8.0 or higher. Entries significantly better than the mean (7.0) for second generation European corn borer were Funk G-4768W (5.3), Funk G-4787W (5.3), Northrup King X233F6 (5.7), Tennessee T1108 (5.7), and Whisnand 91W (5.7). Seven white hybrids and one yellow check (B73 x Mo17) rated 8.0 or lower.

Virus ratings were made at Waverly, TN under conditions expected to result in high levels of incidence. Eighty-eight percent of the plants were noted as showing virus symptoms, with an average virus rating of 3.9 on a 1 to

9 scale in which 9 represented a severely affected plant. Only Meacham's MV58 (60.8%) was significantly better than the mean (88.0%). Six hybrids showed 100% infections: Funk G-4768W, Golden Harvest H-2644W, IFSI 81-2, IFSI 81-9, IFSI 80-13, and O's Gold 26301W. The average virus (AVG VIR) ratings of ACCO U398W (2.9), Funk G-4787W (2.6), Golden Harvest H-2660W (2.6), Lynks SC-WLA (2.8), Meacham's MV58 (2.7), Northrup King X233F6 (2.8), and Whisnand 91W (2.8) were better than the mean of all entries.

The "Missouri corn cracker" broke an average of 33% of the kernels impacted into pieces small enough to pass a 0.25" screen. Eight white hybrids broke less than the mean of all entries: ACCO UC1800W (27.5%), Golden Harvest H-2644W (28.7%), IFSI 81-2 (28.1%), IFSI 81-5 (26.5%), IFSI 81-9 (28.5%), IFSI 80-13 (24.6%), O's Gold 25610W (27.8%), and Sturdy Grow SG908W (27.3%). Funks G-4747W-1, Golden Harvest H-2660W, Lynks SC-WLA, and Meacham's MV88 showed more breakage susceptibility than the mean.

#### Performance of entries occurring in more than one year, 1977-81 (Table 18)

Fifty-nine entries have been entered in more than one year of the Trial. Seven entries have been entered in all five years. Comparisons among entries must be made with caution since entries could have been entered in different years. If an entry was entered in 1980 and perhaps 1978, its yield would appear relatively poor compared to its probable performance in 1979 and 1981 in which relatively high yields were obtained. This occurs with high yielding ACCO U398W (124.1 bu/a) which was entered each year except 1980, which was a very poor year. No LSD can be calculated due to the differing years and number of locations included in the means. However, since the yearly combined yield LSD has been approximatley 10% of the mean, a difference of more than 7% or 7.6 bu/a for two-year data would probably be significant. A slightly smaller value (5-6 bu/a) would apply when comparing hybrids in the trial for more than two years.

#### Comparison of white and yellow grain entries (Table 19)

Grain yield, stalk lodging, ear height, and days to flowering for the 61 white entries and the three yellow checks B73 x Mo17, Mo17 x N28, and Pioneer Brand 3320 are compared in Table 19. At five of 13 sites, the white entries outyielded the three yellow checks. Overall, however, the yellow checks had an 8 bu/a advantage. Note that the yellow check US13 was omitted since it is not currently grown. The white entries generally stalk lodged slightly more, were some 12" taller in ear height and less than a day later to flowering.

Milling quality evaluation (Table 20)

Milling quality of entries in the 1980 National White Maize Variety Trial was evaluated by The Quaker Oats Company's research laboratories. Due to the time necessary to make these evaluations, results are not obtained until the following year. Target values used by Quaker Oats are 90% or more horneous endosperm, kernel weight of 37 g or more, and density equal to or exceeding 1.22 g/cc. Grain samples from IFSI 74-3 and Ring Around RA3605W were the only ones wholly acceptable. All entries had acceptable kernel densities but only two had adequate kernel weights. This was due, in part, to extremely low yields experienced in 1980 where numbers and size of kernels were both reduced.
