

White Maize

1983 National Crop Performance

Special Report 307

January, 1984

Darrah and Zuber

**University of Missouri-Columbia Agricultural Experiment Station
Agricultural Research Service, U.S. Dept. of Agriculture**

ACKNOWLEDGEMENTS

This Bulletin is a contribution of the Department of Agronomy, University of Missouri and the Agricultural Research Service, U. S. Department of Agriculture in cooperation with the Department of Agronomy, Purdue University; Department of Agronomy, Kansas State University; Department of Agronomy, University of Kentucky; Departments of Entomology and Plant Pathology, University of Missouri; Department of Plant and Soil Science, University of Tennessee; Department of Soil and Crop Science, Texas A & M University; Illinois Foundation Seeds, Inc., Champaign, IL; Funk Seeds International, Union City, TN; and The Quaker Oats Company research laboratory at Barrington, IL. We thank Laurie Deane for assistance in data processing.

COLLABORATORS

Dr. L. F. Bauman, Purdue University

Dr. C. E. Wassom, Kansas State University

Dr. C. G. Poneleit, University of Kentucky

Dr. B. D. Barry and Dr. J. R. Wallin, ARS, USDA and University of Missouri

Dr. D. R. West and Mr. H. C. Kincer, University of Tennessee

Dr. A. J. Bockholt, Texas A & M University

Dr. M. Rode and Mr. R. Lundquist, Illinois Foundation Seeds, Inc.

Dr. T. R. Colbert, Funk Seeds International

Mr. M. K. Lenz and Mr. L. R. Young, The Quaker Oats Company

THE AUTHORS

L. L. Darrah is a research geneticist, ARS, USDA and associate professor of agronomy, University of Missouri; and M. S. Zuber is an emeritus professor of agronomy, University of Missouri, Columbia, MO 65211.

Kernel quality data for the 1982 National White Maize Variety Trial.....	Table 18

The 1983 National White Maize Variety Trial involved 97 hybrids plus three yellow checks submitted by 20 commercial seed producers or public institutions (Table 1). Fourteen locations were included in the agronomic evaluation. Acceptable data were received from sites in Indiana, Kansas, Tennessee, and Texas. Virus data were obtained from Waverly, Tennessee, and House Springs, Missouri; and European corn borer data were taken at Columbia and Portageville, Missouri. Grain samples were evaluated for quality aspects at The Quaker Oats Company research laboratory at Barrington, Illinois.

ENTRIES AND SEED SOURCES

Contributors of seed for the 1983 evaluation are listed in Table 1. Those entries that have an EXP as part of the hybrid name, such as Jacques EXP 83110, have not been released. The last three named hybrids in each table are yellow kernel hybrid checks.

For averages over years, entry names have been changed to present designations so an experimental hybrid would be identified as the released hybrid. Pioneer Brand EXP X5386 was released as Pioneer Brand 519. Sturdy Grow EXP 9649 was released as Sturdy Grow SG910W, and Sturdy Grow EXP 0614 was released as Sturdy Grow SG912W. The ACCO brand name was changed to Paymaster for all numbered hybrids. Meacham's MV48, MV58, MV68, and MV88 are now listed as White Seeds with the same numbers.

Seed of the yellow check entry B73 x Mo17 was provided by Dr. J. Thomas, formerly of the Missouri Farmers Association, Columbia, Missouri; Pioneer Brand 3320 was contributed by Dr. J. Wright, Pioneer Hi-Bred International, Union City, Tennessee; and US13 was provided by the University of Missouri.

SITE LOCATIONS AND AGRONOMIC PRACTICES

Table 2 lists the sites returning acceptable data, together with a record of the agronomic practices. Dots indicate that treatment was not applied or the information was not available.

DATA COLLECTED

Yield

Yields were measured on a plot basis, converted to bushels per acre, and adjusted to 15.5 percent moisture.

Stand

Stand is expressed as a percentage of the optimum plot stand or planted stand.

Root and stalk lodging

Lodging is expressed as a percentage of the total plants for each hybrid. Generally, a plant was rated as root lodged if it leaned more than 30 degrees from vertical, and as stalk lodged if it was broken over or off below the ear. Breakage above the ear was not counted.

Ear height

Ear height was measured from the soil level to the top ear leaf collar. Heights are expressed in inches.

Days to flowering

The number of days from planting to mid-tassel or mid-silk is shown.

Grain moisture

Grain moisture was measured at harvest or when the grain was weighed.

European corn borer

Feeding by the second generation of the European corn borer was determined by splitting stalks of 10 randomly infested plants per plot, counting the number of tunnels, and visually estimating the length of tunneling in inches. The minimum tunnel length associated with one hole was 1 inch. Three egg masses and 20 larvae were applied at flowering, and stalks were split six or more weeks later.

Virus ratings

Virus infection percentage is the percentage of plants in the plot

showing symptoms. Virus severity is a rating of diseased plants, using a scale on which 2 represents a mildly diseased plant and 9 represents a severely damaged plant. Non-affected plants (scored 1) are not included. Average virus rating is the mean severity of all plants in the plot. Viruses included in the rating were maize dwarf mosaic virus and maize chlorotic dwarf virus which occur together under field conditions.

Environmental yield response (b_I) and standard deviation of fit

These statistics are shown only in Table 10 for the entry means combined over all sites. The yield response (b_I) is expressed as bu/a/unit increase in the environmental index, where the index for a site is the average performance of all hybrids at the site. The deviation of fit is given in bu/a. The origin and use of these statistics are fully described below.

Percent horneous endosperm

The percent horneous endosperm was visually estimated using a candling light. Ten to 15 kernels were observed for each entry.

Kernel weight

The 100-kernel weight in grams was obtained from 100 randomly selected whole kernels.

Kernel density

Kernel density was calculated from kernel weight and volume using water displacement. Values are in grams per cubic centimeter.

STATISTICAL ANALYSIS AND INTERPRETATION

The data were analyzed as a three-replication, triple lattice at each site. Means adjusted for blocks were used only for yield; other character means are those from a randomized complete block analysis. If an observation was missing in one replication, the average of those observations in the remaining replications was used to approximate the missing observation. The least significant differences at probability level 0.05 (LSD 0.05) and coefficients of variation percentages (CV%) were calculated from the site analyses

of variance (AOV). Where differences among hybrids were not significant for a character, no LSD or CV% is shown. Occasionally, data were observed in only one or two replications; a footnote is used to identify those situations.

The LSD 0.05 is used to compare the performance of two specific hybrids at a time. It should not be used, however, to compare all pairs of hybrids. If the mean of hybrid "X" exceeds the mean for hybrid "Y" by the LSD 0.05 or more, then the difference observed will be a true difference 19 out of 20 times the two hybrids are grown under conditions similar to those of the test.

The CV% relates error of measurement and the mean of the observed character. Values for lodging are sometimes much higher and are generally associated with nonsignificant differences among hybrids.

Agronomic data combined from seven locations with an appropriate LSD 0.05 for each character are shown in Table 10. The combined LSD 0.05 is based on the entry x site interaction versus the pooled error from the combined AOV. When a character was not observed at a site, dots show in the site analysis; the combined mean and LSD 0.05 have been adjusted accordingly.

Stability analysis gives information on the responsiveness of hybrids to changes in environment and the reliability with which these responses may be predicted. Mean performance of all hybrids at a site was the measure used to rate the environment. This environmental index (I) was then used as the independent variable in a regression analysis with the individual hybrid's performance at each site. A hybrid that is stable will have a regression coefficient (b_I) equal to 1.0, meaning that an increase in the environmental index would result in an equal increase in the hybrid's yield. Regression coefficients greater than 1.0 indicate relatively better performance in good environments. Hybrids with b_I values less than 1.0 would have a relative advantage in poor environments.

Deviation from fit reflects the accuracy with which the regression line given by b_I represents probable performance. Low deviation indicates that a hybrid has greater stability.

Overall, a desirable hybrid would have a high mean yield, $b_I = 1.0$, and low deviation from fit. If a grower knew that he was producing on the high side of the environments sampled, then a hybrid with b_I greater than 1.0 would be more responsive than one with $b_I = 1.0$, and would be likely to yield more if mean yield levels were equivalent.

NARRATIVE SUMMARY

Yields from individual sites ranged from 139.9 bu/a at Halfway, TX to 43.4 bu/a at Highland, KS. The overall average for seven sites was 96.1 bu/a; considerably less than in 1982 (126.7 bu/a). Sites in Kentucky, Illinois, Iowa, and Missouri failed altogether and one site in Texas was lost. Plot stands averaged 86.5%, ranging from 66.8% at Highland, KS, to 100% at Union City, TN. Covariance adjustment of yield for stand was done at three sites where the relative efficiency ($100 \times$ unadjusted error mean square/adjusted error mean square) exceeded 104%. Root lodging was low at all sites except Highland, KS (26.2%), and Manhattan, KS (32.8%). Stalk lodging was low at Lafayette, IN (1.3%), and Knoxville, TN (1.5%), and moderate elsewhere. Average days to flowering (four sites) was 80.8, ranging from 77.0 days at Rossville, KS, to 85.7 days at Halfway, TX. Low grain moisture percentages would have been observed where plots were harvested and dried before shelling and weighing, however, most sites were combine harvested. Details of site data are in Tables 3-9.

Combined agronomic data from seven sites (Table 10)

Five white hybrids and one yellow check yielded significantly more than the mean of all entries: DeKalb 24301 (116.4 bu/a), IFSI 83-1 (115.3 bu/a), Whisnand 93W (112.2 bu/a), Sturdy Grow EXP 17563 (111.3 bu/a), Ring Around RA2606W (111.2 bu/a), and the yellow check Pioneer Brand 3320 (118.0 bu/a). The site x entry interaction was highly significant indicating different entry responses in different environments.

Root lodging occurred more frequently than in 1982. Princeton SX910 (18.4%) and Whisnand 91W (18.4%) lodged significantly more than the mean of all entries (9.8%).

Stalk lodging percentages averaged 10.5 for all hybrids and sites. NC+ 6708W (3.3%) and Sturdy Grow EXP 17563 (2.3%) lodged significantly less than the mean of all hybrids. The yellow check US13, Meacham's MX50W, DeKalb 24126, IFSI 81-5, O's Gold SX2560W, and Whisnand 55W all stalk lodged significantly more than the mean.

Nine white hybrids were significantly shorter than the average of all hybrids. Among these, with an ear height less than 40 inches, were: Golden Harvest H-2664W (39.9 in), MO EXP 83-9 (38.6 in), and Whisnand 53W (36.7 in).

DeKalb 24126 and Paymaster 399W had ear heights exceeding 50 inches.

Twenty-two hybrids were significantly earlier than the mean of all hybrids with Whisnand 53W (74.5 days), Golden Harvest H-2664W (75.1 days), and Jacques W200 (76.0 days) being the earliest. DeKalb 24126 (86.8 days) and Funk G-4787W (85.2 days) were significantly later than most other entries.

Differences in grain moisture measured when combine harvesting at one location are reduced when averaged with moistures measured after uniform drying of hand-harvested plots. Seventeen white hybrids and the three yellow checks had significantly lower moisture percentages than the average of all entries (20.8%). Jacques W190 (17.3%) and Whisnand 57W (17.4%) were two LSD's less than the mean. The wide range of moistures observed suggests that seedsmen are offering a range of maturities in white hybrids. None of the four highest yielding white hybrids had moistures significantly less than the mean, and two were significantly above the mean moisture.

The environmental response coefficients (b_I) and standard deviations of fit are shown in the last two columns of Table 10. (A difference of ± 0.18 from 1.0 is necessary for significance. The LSD 0.05 should be used when comparing coefficients of two hybrids.) The b_I for 24 entries was significantly greater than 1.0, indicating greater than average response to better environmental conditions, but poor performance in adverse environments. Hybrids that had environmental responses two or more LSD's above 1.0 were Funk G-4779W (1.36), O's Gold EXP 25501W (1.45), Ring Around RA2602W (1.47), Ring Around RA3605W (1.47), and Sturdy Grow EXP 17563 (1.39). Of these, only Sturdy Grow EXP 17563 was among the five white hybrids yielding significantly more than the mean of all hybrids. Twelve hybrids' responses were significantly lower than 1.0. Usually, nonresponsiveness is associated with low mean yields.

The standard deviations of fit varied for similar environmental response coefficients. For instance, Paymaster 399W ($b_I = 1.21$) had a standard deviation of 4.8 bu/a while White Seeds MV58 ($b_I = 1.20$) had a standard deviation of 15.7 bu/a. The latter's response to environment would be less predictable than the former's, though they both should respond far more than average ($b_I = 1.0$).

In choosing a hybrid, all agronomic factors must be considered in relation to the anticipated environment. Data from several sites are usually more reliable than data from a single site evaluated for two or three years.

Virus susceptibility data (Table 11)

Virus ratings were made at House Springs, MO, and Waverly, TN, under conditions expected to result in high levels of incidence. Differences among entries were not significant for percent infected plants, mean virus severity, or average virus rating at House Springs, MO. Only the data from Waverly, TN, have been included in this report. Eighty-eight percent of the plants were infected and showed virus symptoms with an average virus rating of 3.8 on a 1-to-9 scale in which 9 represented a severely infected plant. Four hybrids had virus infection percentages significantly lower than the mean: IFSI 80-6 (71.2%), IFSI 82-4 (71.1%), O's Gold EXP 25501W (72.6%), and Paymaster 386036W (67.5%). Three entries, IFSI 80-4, MO EXP 83-10, and P-A-G SX 70W had 100% infected plants.

European corn borer susceptibility data (Table 12)

Feeding of the first generation larvae was insufficient for ratings to be made. Corn borer tunnel length observations were made at Columbia and Portageville, MO. Differences among entries for numbers of tunnels and tunnel length were not significant at Portageville and those data are not shown. Tunneling due to the second and later generations of the corn borer averaged 5.6 inches per stalk at Columbia. Two white hybrids, P-A-G EXP 106184W (3.9 in) and Whisnand EXP 1W (3.9 in), and the yellow check Pioneer Brand 3320 (2.9 in) had significantly less tunneling than the average of all entries. Significantly more tunneling was found for IFSI 83-2 (7.3 in), Sturdy Grow SG910W (7.3 in), and Sturdy Grow SG935W (7.6 in) than in most other entries.

Two-, three-, four-, and five-year mean yields and agronomic performance (Tables 13-16)

Data were summarized for common entries in the last two, three, four, and five years of the National White Maize Variety Trial. Individual year means were averaged without weighting for the varying numbers of sites over the years. However, recently, the number of acceptable sites has ranged from 7 in 1983, to 15 in 1979. This procedure does not permit an LSD to be directly calculated. Since the yearly combined yield LSD has been running about 10% of the mean, approximate values of 8 bu/a for the two-year means, 7 bu/a for the three-year means, 5-6 bu/a for the four-year means, and 5 bu/a for the five-year means could be used to compare yields of individual entries in the

respective tables.

Among the common entries from 1979 to 1983, Pioneer Brand 519 (121.6 bu/a) and Sturdy Grow SG935W (118.3 bu/a) might be judged better than the average white entry. A relatively poorer performer was Golden Harvest H-2644W (92.3 bu/a).

Comparison of white and yellow kernel entries (Table 17)

Grain yield, stalk lodging, ear height, and days to flowering for the 97 white entries and two yellow checks, B73 x Mo17 and Pioneer Brand 3320, are compared in Table 17. At all sites, the average yield of the yellow checks was better than the white hybrids, having a 15.5 bu/a advantage overall. The yellow check, US13, was omitted since it is not currently grown, but can be used as a benchmark for performance in past years. The white entries generally lodged more, had slightly greater ear height, and were 3.3 days later to flowering than the two yellow checks.

Milling quality evaluation of entries in the 1982 Trial

Milling quality of entries in the 1982 National White Maize Variety Trial was evaluated by The Quaker Oats Company's research laboratories. Because of the time necessary for evaluation, results are not obtained until the following year. Target values used by The Quaker Oats Company are 90% or more horneous endosperm, a weight of 37 g or more per 100 kernels, and a density equal to or exceeding 1.20 g/cc.

According to their criteria, the following hybrids grown in 1982 would be most desirable: Asgrow RX813W, IFSI 74-3, Jacques W200, White Seeds MV78, Paymaster U398W, O's Gold SX2680W, and Sturdy Grow SG935W.
