The Authors

Harry C. Minor is an Associate Professor of Agronomy and State Extension Specialist, Carl G. Morris is a Senior Research Specialist, and Delbert Knerr, Eric Lawman, and Kurt Hohnstrater are Research Specialists.

The authors recognize and express their appreciation to the following individuals for their part in making the 1985 corn performance trials possible: Seymour Brothers, Fairfax; Dennis Onks, Superintendent, North Missouri Center, Spickard; Randall Smoot, Foreman, Greenley Memorial Center, Novelty; Frank Swisher, Marshall; John Poehlmann, Superintendent, Agronomy Research Center, Columbia; Richard Lierheimer, Mexico; Richard Schipper, O'Fallon; Sherrell Bean, Lamar; and Johnny Hunter, Sikeston.

Appreciation is also extended to Steve Burns for his assistance in the computer programming necessary for this Special Report.

MISSOURI CROP PERFORMANCE

1985

CORN

This report is a contribution of the Department of Agronomy, University of Missouri Agricultural Experiment Station, which reports on Research Project 363. The work was supported in part by funds from the Missouri Seed Improvement Association and fees from the companies submitting hybrids for evaluation.

The University of Missouri's hybrid performance testing program was started in the mid-1930's, with the first publication of results in 1937. The number of commercial entries in the program has grown from fewer than 50 in the early years to over 200 today.

The large number of commercial hybrids available makes selection of a superior hybrid difficult. To select intelligently, a reliable, unbiased, up-to-date source of information which will permit valid comparisons among available hybrids is needed. The objective of the University of Missouri's performance testing program is to provide this information. The tests are conducted under as uniform conditions as possible. Small plots are used to reduce the chance of soil and climatic variations occurring between one hybrid plot and another. Results obtained should aid the individual grower in judging the relative merits of many of the commercial corn hybrids available in Missouri today.

COMPARING HYBRIDS

The performance of a hybrid cannot be measured with absolute precision. Uncontrollable variability is involved in the determination of each yield average. This variability is often the result of soil disuniformity, but many other conditions may contribute to it. Because variability exists in all field experimentation, statistics are used as a tool to assist in making decisions. The statistical tool used in the analysis of trials reported here is the test of least significant difference (L.S.D.). The L.S.D. is quite simple to apply; when two entries are compared and the difference between them is greater than the L.S.D., the entries are judged to be significantly different. Differences smaller than the L.S.D. may have occurred by chance and are judged to be nonsignificant.

Hybrid performance may seem inconsistent from location to location and from year to year because of differences in rainfall, temperature, soil fertility, diseases, insects, and other factors. To obtain an improved estimate of relative hybrid performance, results from more than one location or year should be considered. In this publication, an effort has been made to facilitate comparisons across years and locations.

In each trial, the "top yielding" hybrids have been identified. These hybrids are those which did not yield significantly less than the highest yielding hybrid in the test. They are denoted in the tables by an asterisk (*) next to their yields. Thus, by going down a column, the highest yielding hybrids in a trial can be readily identified. By going across, the relative performance of a hybrid during several years or at several locations can be evaluated. From the standpoint of yield, the most desirable hybrids will be those which are among the "top yielding" hybrids (that is, have an asterisk) the greatest number of times.

Although yield usually receives first consideration, other agronomic characteristics may be equally important when selecting a corn hybrid. Stalk strength, maturity, and resistance to insects and diseases are among the hybrid characteristics which deserve careful consideration. Later maturing hybrids may require more drying. The maturity classification listed for each hybrid in this bulletin is based solely on information supplied by the entry's sponsor. A hybrid with an abnormally high or low moisture content relative to other hybrids within the same maturity group may be misclassified as to maturity. Poor stalk strength and/or susceptibility to pests may decrease harvestable yield because of lodging or stand loss. Therefore, the data presented on final stand and lodging should also be considered when selecting a hybrid.

The Missouri Agricultural Experiment Station does not make specific recommendations for hybrids. It is suggested that the farmers growing a new hybrid for the first time consider the information contained in this report and then grow a small acreage to determine adaptability. This should be the practice for all new hybrids regardless of origin.

EXPERIMENTAL PROCEDURES

On the basis of geographical characteristics, the state is divided into sections. Corn hybrid evaluation trials are located in the northern, central, southwestern and southeastern sections of the state. These trial locations are shown in Figure 1, Page 5.

Entries. All producers of hybrid seed were eligible to enter hybrids in the 1985 evaluation trials. Participation was voluntary and no control was exercised by the program over which, or how many, hybrids were entered. However, to help finance the evaluation program, a fee of sixty dollars per location was charged for each hybrid entered by the seed producer. In addition to the fee entries, a broader-based program was continued in which certain widely-grown hybrids were included on a no-fee basis. Identification of these widely-grown hybrids was through a telephone survey of hybrids marketed by seed producers in Missouri. A total of 222 corn hybrids were tested in 1985.

Field Plot Design. All tests were arranged in lattice field plot designs with three replications. Plots were four rows wide but only the center two rows were harvested to determine yield. Spacing between the rows was 30 inches in all locations.

Plot Management. The tests were planted and harvested with commercial equipment modified for small plot work. Fertilizer applied at each site was equal to, or above, that recommended by the University of Missouri's Soil Testing Laboratory. Herbicides were used for weed control and additional hand weeding was done as required. Management details that varied from location to location are specified in Table 1, Page 6.

Data Recorded. Plant stand was counted near the time of tasseling. Lodging was determined immediately before harvest. Plants leaning more than 30 degrees from the vertical and those broken below the ear were counted as lodged. Yield was measured in bushels (56 pounds) per acre at a moisture content of 15.5 percent. An electronic moisture tester was used for all moisture readings.

2 IRRIGATED TRIAL

SUMMARY OF RESULTS

Results are presented by region of the state. For each location, data on final plant stand, total (root plus stalk) lodging, moisture content at harvest and yield adjusted to 15.5 percent moisture are given for each hybrid. As emphasized previously, because of the influence of environmental conditions on corn performance, the reader is encouraged to give more weight to results from several locations or years than to those from a single test.

Corn hybrids were evaluated in six non-irrigated and four irrigated studies in 1985 (Figure 1, Page 5). Management was as uniform as possible across locations. Details are presented in Table 1, Page 6.

Average yields and ranges observed at each location are summarized below. Rainfall during the growing season (May-September) was generally above normal, with the exception of a dry July. Yields achieved in the four irrigated trials were noticeably higher than those in the dryland trials. This indicates that even in a year of favorable rainfall, supplemental water thru irrigation can usually increase yields. Monthly rainfall and irrigation received at each irrigated location are shown in Table 3, Page 8.

Table 2. 1985 Hybrid Corn Yield Summary

Location	Number of Entries	Irrigated	Yield(Bushels/Acre)		Data Table
			Range	Average	
Fairfax	163	no	149- 60	123	4
Spickard	163	no	95- 21	57	5
Novelty	163	no	179- 98	149	6
Marshall	109	no	169- 92	139	8
Columbia	109	no	166-113	143	9
O'Fallon	109	no	138- 43	102	10
Columbia	100	yes	225-138	192	12
Mexico	100	yes	218-135	191	13
Lamar	81	yes	210-126	184	14
Sikeston	81	yes	211-118	174	14

The ranges shown give the values for the lowest and highest yielding corn hybrids in each test. This value gives an indication of the variation in yield potential among hybrids available on the market in Missouri today. Use of data presented in the individual location tables of this Special Report should increase the probability of selecting hybrids which combine high yield potential with other agronomic characteristics appropriate to specific farming situations.

Moisture percentage at the time of harvest is given for each entry. Because harvest was delayed until the latest hybrids in the test were mature, moisture differences among many of the early maturing entries may be small. Where large differences occur, it may indicate that entries with a high moisture content in a group are misclassified as to maturity. The listing of maturity groups found below were provided on the university entry form as a guide line for companies to use in classifying their hybrids.

- Group 1 - (90-110 days or <2600 GDD);
 Group 2 - (110-120 days or 2600-2699 GDD);
 Group 3 - (120-130 days or 2700-2799 GDD);
 Group 4 - (130-140 days or >2800 GDD).
¹
¹
¹
¹

1=Growing Degree Days.

Lodging data are provided for each location. Lodging was a problem in some of the irrigated tests. Most of the lodging was caused by corn borer, deer, and wind. Hybrids which consistently show above average lodging should be avoided.
