THE AUTHORS

Harry C. Minor is an Associate Professor of Agronomy and State Extension Specialist, Carl G. Morris is a Senior Research Specialist, and Delbert R. Knerr, Eric Lawman, and Kurt Hohnstrater are Research Specialists.

ACKNOWLEDGEMENTS

The authors recognize and express their appreciation to the following individuals for their part in making the 1985 soybean trials possible: Seymour Brothers, Fairfax; Dennis Onks, Superintendent, North Missouri Center, Spickard; Randall Smoot, Foreman, Greenley Memorial Center, Novelty; Frank Swisher, Marshall; John Poehlmann, Superintendent, Agronomy Research Center, Columbia; Richard Schipper, O'Fallon; Wally Norton, Lamar; Norman Justus, Superintendent, Southwest Center, Mt. Vernon; Kenneth Heath Farms, Bertrand; Claude Keasler Farms, Inc., Parma; and Joe Scott, Superintendent, Delta Center, Portageville.

Special recognition is given to Richard Mattas of the Southwest Center for his assistance in all phases of the program, and to Calvin Jones for his assistance at Lamar. Appreciation is also extended to Steve Burns for his computer programming of this Special Report.

MISSOURI CROP PERFORMANCE

1985

SOYBEAN

This report is a contribution of the Department of Agronomy, University of Missouri Agricultural Experiment Station, which reports on Research Project 363. This work was supported in part by funds from the Missouri Seed Improvement Association and fees from the companies submitting varieties for evaluation. Soybeans were first included in the University of Missouri's variety performance testing program in 1973. The number of entries in the program has grown from 51 in 1973 to 316 today.

The large number of varieties available makes selection of a superior variety difficult. To select intelligently, a reliable unbiased up-to-date source of information that will permit valid comparisons among available varieties is needed. The objective of the University of Missouri's performance testing program is to provide this information. The tests are conducted under as uniform conditions as possible. Small plots are used to reduce the chance of soil and climatic variations occurring between one variety plot and another. Results obtained should aid the individual grower to judge the relative merits of many of the commercial soybean varieties available in Missouri today.

COMPARING VARIETIES

The performance of a variety cannot be measured with absolute precision. Uncontrollable variability is involved in the determination of each yield average. This variability is often the result of soil disuniformity, but many other conditions may contribute to it. Because variability exists in all field experimentation, statistics are used as a tool to assist with making decisions. The statistical tool used in the analysis of trials reported here is the test of least significant difference (L.S.D.). The L.S.D. is quite simple to apply. When two entries are compared and the difference between them is greater than the L.S.D., the entries are judged to be significantly different. Differences smaller than the L.S.D. may have occurred by chance and are judged to be non-significant.

Variety performance may seem inconsistent from location to location and from year to year because of differences in rainfall, temperature, soil fertility, diseases, insects, and other factors. To obtain an improved estimate of relative variety performance, results from more than one location or year should be considered. In this publication, an effort has been made to facilitate comparisons across years or locations.

In each trial, the "top yielding" varieties in each maturity group have been identified. These varieties are those which did not yield significantly less than the highest yielding variety in the same group. They are denoted in the tables by an asterisk (*) next to their yield. Thus, by going down a column, the highest yielding varieties can be readily identified. By going across, the relative performance of a variety during several years or at several locations can be evaluated. From the standpoint of yield, the most desirable varieties will be those among the "top yielding" varieties (that is, have an asterisk) the greatest number of times.

Although yield usually receives first consideration, other agronomic characteristics may be equally important when selecting a soybean variety. Standability, maturity, and disease resistance are among the characteristics which deserve careful consideration. Several diseases prevalent in Missouri can be devastating to susceptible varieties. Lodging may reduce yields and slow harvest. Poor seed quality is often associated with varieties which mature while temperatures are still high, and late maturing varieties are occasionally killed by frost. Selection of varieties from several maturity groups can be helpful in spreading harvest dates. Therefore, information presented on disease reaction, lodging, and maturity group should be considered when selecting a variety.

EXPERIMENTAL PROCEDURES

On the basis of geographic characteristics, the state was divided into regions. Soybean variety evaluations were located in the northern, central, southwestern, and southeastern regions of the state. Locations of individual sites are shown in Figure 1, Page 6.

Entries. Two types of tests were conducted. 'Standard' tests evaluated varieties, brands, or blends currently marketed in Missouri. 'Experimental entry' tests evaluated experimental lines, and released varieties, brands, or blends not currently marketed in Missouri. All producers of soybean seed were eligible to enter varieties or blends in the 1985 evaluation plots. Participation was voluntary, and no control was exercised by the program over which, or how many, varieties were entered. However, to help finance the evaluation program, a fee of \$60 per location was charged for each entry entered by the seed producer.

Field Plot Design. In all tests, a randomized complete block design with three or four replications was used. Individual plots were four rows wide and 25 feet long. The center two rows of these plots were harvested to determine yield.

Plot Management. The tests were planted with commercial equipment modified for small plot work. Fertilizer applied at each site was equal to, or above, that recommended by the University of Missouri's Soil Testing Laboratory. Herbicides were used for weed control, and additional hand weeding was done as required. Management details varied from location to location and are summarized in Table 1, Page 5.

Data Recorded. Maturity group classification was indicated by the entry sponsor. Maturity data was recorded when approximately 75% of pods had turned color. Lodging and height were determined immediately before harvest. A scale of 1 to 5 was used to score lodging. Interpretation of the scale is as follows:

- 1 = all plants erect;
- 2 = all plants leaning slightly or a few plants down;
- 3 = all plants leaning moderately or 20 to 50% down
- 4 = all plants leaning considerably or 50 to 80% down;
- 5 = all plants down.

Yield was measured in bushels (60 pounds) per acre at a moisture content of 13.0%. An electronic moisture tester was used for all moisture readings.

MISSOURI

FIGURE 1. TEST SITE LOCATIONS.

- STANDARD TEST
- ✖ STANDARD AND EXPERIMENTAL TESTS

SUMMARY OF RESULTS

Results are presented by regions of the state. For each entry and location, data on maturity, plant height, lodging, and yield adjusted to 13.0% moisture are given. As emphasized previously, because of the influence of environmental conditions on soybean productivity, the reader is encouraged to give more weight to results from several locations or years than to those from a single test.

Soybean varieties and blends were evaluated in eleven standard, and eight experimental studies in 1985 (Figure 1, Page 6). An overview of management is given in Table 1, Page 5.

Average yields and ranges observed at each location are summarized below in Table 2. The ranges shown give the value for the lowest and highest yielding varieties in each test. This value provides an indication of the variation in yield potential among soybean varieties available on the market in Missouri. Use of data presented in the individual location tables of this Special Report should increase the probability of selecting varieties which combine high yield potential with other agronomic characteristics appropriate to specific farming situations.

All tests showed a wide range in yields, partly caused by soybean diseases, weather, soil type, plot management, previous cropping system, and other problems inherent to their regions. A test established at O'Fallon was eliminated due to partial flooding.

The experimental studies were composed of experimental lines and varieties, brands or blends which were not currently released to the public, or marketed in Missouri. Well adapted varieties are indicated as checks.
