ACKNOWLEDGEMENT

The authors wish to acknowledge the assistance of Mary Jackson and Sara Seidel in the typing and preparation of this report. The authors are indebted to Kristin Simpson, Aaron Wallman, Mary Jackson, Carol Ferguson, Edwin Lewis, Randall Smoot, Roger Wilkins and Johanne Wynne for their assistance in plot evaluations. They also express appreciation to Peter Schroeder for the cover drawing.

CORN SOIL INSECTS RESEARCH
1986 INSECTICIDE EVALUATIONS

Judy A. Grundler, Entomology Senior Research Specialist
Armon J. Keaster, Professor of Entomology
Department of Entomology, University of Missouri-Columbia

Soil insecticide evaluations are conducted to compare the relative efficacy of labeled and experimental compounds for control of corn soil insect pests. This report contains data on the efficacy of these compounds for control of western and northern corn rootworms (Diabrotica virgifera LeConte and D. longicornis (Say)), black cutworm (Agrotis ipsilon (Hufnagel)), and wireworms (Melanotus spp.).

This report and the data contained within are presented for purposes of information only to agribusiness industries and to University of Missouri extension and research personnel. The data do not reflect nor constitute a recommendation of specific compounds. The 10-year comparisons of performance for rootworm compounds do, however, provide a basis for comparison of efficacy for control over a period of time. The five-year comparison for cutworm control was discontinued because valid comparisons of insecticide efficacy cannot be made unless all compounds occur within the same test. Economic and labor constraints do not permit us to provide this service. For specific recommendations for control of corn soil insects, see UMC Agricultural Guides 4150 (Corn Cutworm Control), 4151 (Corn Rootworm Control), 4154 (Control of Wireworm and Other Corn Soil Insects) and 4906 (Soil Insect Control in Reduced Tillage Cropping Systems).

CORN SOIL INSECTS RESEARCH
1986

ROOTWORM INSECTICIDE EVALUATIONS

Rootworm insecticide evaluations were conducted at two locations: near Fairfax in Atchison County and at the University of Missouri Greenley Research Center in Novelty, Knox County. The plots near Fairfax were located in a corner of a 100-acre field planted to corn in 1984 and 1985. This field had an "organophosphate history" of Counter use on corn from 1981-84 and exhibited a decrease in insecticide efficacy in 1984. Plots at the Greenley Center were part of a 7 acre block that has been in continuous corn for seven years. This location is known to have a carbamate aggressive soil but has no actual history of repeated applications of carbamate class insecticides.

A two-row John Deere model 7100 max-emerge planter with a mounted V-belt seeder was used for the 7-inch band (7"B), in-furrow (IF) and behind the press wheel (BPW) treatments. Pre-weighed insecticide granules were placed uniformly along the V-belt seeder and directed through banders or tubes to obtain the desired placement. Banded sprays were applied at 30 pounds per square inch (psi) and 11 gallons per acre (gpa) with a tractor-mounted compressed-air sprayer. Insecticides were applied to two 35-foot rows and replicated four times. A randomized complete block design was used. A 15-foot alleyway separated each replication. Cultivation treatments (cult) were applied with an International cub tractor equipped with a one row cultivator and a compressed air sprayer. The sprays were applied at 30 psi in 14 gpa.

The efficacy of the treatments within each test was determined by digging 16 plants from each treatment (2 plants per row x 2 rows per plot x 4 replications). The root systems of the plants were washed free of dirt and evaluated as follows:

- A. General Root Rating - The entire root system was taken into consideration when assigned a rating according to the amount of visible rootworm damage. The ratings were assigned as follows: 1) no feeding damage, 2) light feeding damage with no pruning, 3) occasional pruning, 4) moderate to severe pruning (one node of roots destroyed), 5) severe pruning (two nodes of roots destroyed) and 6) three nodes of roots destroyed.
- B. Damaged Root Rating - The percentage of the roots showing rootworm damage in the second and third nodes below ground level was estimated and assigned to five categories as follows: 1) no injury, 2) 1-25%, 3) 26-50%, 4) 51-75% and 5) 76-100%.

- C. Pruned Root Rating - The same root systems evaluated under A and B were rated where only the percent of the roots pruned in the second and third nodes below ground level were estimated. Ratings were as follows:
 - 1) no pruning, 2) 1-25%, 3) 26-50%, 4) 51-75% and
 - 5) 76-100%.
- D. Combined Analysis Rating - The combined analysis rating is the average of the pruned root rating, damaged root rating and general root rating. Only the general root rating and the combined analysis ratings are reported herein as indicators of insecticide performance.

CUTWORM INSECTICIDE EVALUATIONS

Planting time evaluations were conducted in barrier plots on the University of Missouri-Columbia South Farms near Columbia, Boone County. Row-band treatments were applied with a V-belt seeder mounted on a two-row John Deere model 7100 max-emerge planter. Pre-weighed insecticide granules were placed uniformly along the V-belt seeder and directed through 7-inch banders to obtain the desired placement. Corn was planted in a conventional manner at the same time. Band and broadcast sprays were applied at the rate of 11 gallons of finished spray per acre at 30 psi through a tractor-mounted compressed-air sprayer. Pre-plant incorporated treatments were applied as a broadcast and incorporated with a motorized garden tiller prior to planting.

Individual plots were two 35-foot rows. Treatments were replicated three times according to a randomized complete block design. Following planting, metal barriers (8 inches in height) were driven approximately 3 inches into the soil to enclose portions of the 35-foot plots (15 feet x 2 rows). Twenty 3rd- to 5th-instar laboratory-reared black cutworm larvae were released in the barriers at seedling emergence. Efficacy of the treatments was evaluated by counting the number of plants cut on three different dates throughout the test period.

Rescue evaluations were also conducted on the South Farms. Rescue treatments were evaluated using metal barriers 8 inches in height and 6 feet in diameter placed over two rows of seedling corn. When the corn reached the two-leaf stage, each barrier was infested with 10 4th- to 5th-instar laboratory-reared black cutworms. Treatments were applied within two hours following infestation. Bait and granular treatments were hand broadcast in each individual barrier. Spray treatments were applied with a tractor-mounted compressed-air sprayer at 30 psi and 40 gallons per acre. All treatments were replicated three times in a randomized complete block design. Efficacy of treatments was measured by cut plant counts on three dates following treatments.

WIREWORM INSECTICIDE EVALUATIONS

Wireworm insecticide evaluations were conducted at two locations in 1986. The first location, near Schell City, Vernon County, was planted to sorghum in 1985 and a severe reduction in stand was observed by the farmer. The stand reduction was attributed to wireworm Melanotus species. The second location was near Shelbyville, Shelby County. According to the land owner, the field was noted to have a history of chronic wireworm problems. Severe damage to corn in 1983 occurred in an area approximately 20 acres in size with more than 50 percent stand loss. The remainder of the 90 acres suffered a loss of 5-10 percent. In 1984, evaluation plots were located in a portion of this field, with the remainder planted to soybeans. The same location was used for plots in 1985. The remainder of the field was planted to corn.

In 1986, a 5-acre area in each field was baited in early April to assess the potential for wireworm injury. An average of 4.0 and 6.34 wireworms per bait was found at Schell City and Shelbyville, respectively. Plots were placed in areas of heaviest wireworm concentration. Individual plots were two 35-foot rows and replicated four times according to a randomized complete block design. Performance of treatments was evaluated by counting the number of live and dead or injured plants in each row four weeks following planting.

The 7-inch band (7"B), in-furrow (IF) and behind the press wheel treatments (BPW) were made with a V-belt seeder mounted on a two-row John Deere model 7100 max-emerge planter. Pre-weighed insecticide granules were placed uniformly along the V-belt seeder and directed through banders or tubes to obtain the desired placement. Corn was planted in a conventional manner at the same time.
