ACKNOWLEDGMENTS

This bulletin is a contribution of the Plant Genetics Research Unit, Agricultural Research Service, U.S. Department of Agriculture and the Plant Science Unit, University of Missouri, Columbia, in cooperation with Illinois Foundation Seeds, Champaign, IL; Department of Agronomy, University of Kentucky; Department of Plant and Soil Science; Northrup King Company, Henderson, KY; University of Tennessee; Department of Agronomy, Purdue University; Department of Soil and Crop Science, Texas A & M University; Illinois Crop Improvement Association, Champaign, IL; Pioneer Hi-Bred International, Marion, IA; Department of Agronomy, Kansas State University; Department of Agronomy, Iowa State University; ICI Seeds, Marshall, MO; and Department of Agronomy, University of Nebraska. We thank Dr. D. P. Deutscher, Illinois Foundation Seeds, Inc., and Dr. S. H. Weaver, The Quaker Oats Company, for review of the manuscript, and Julie Barry and Charles Thiel for assembly and distribution of the seed. Supported, in part, by gifts from the American Corn Millers Federation and The Quaker Oats Company, which stimulated this work on evaluation of corn for use in food.

INTRODUCTION

The 1994 White Food Corn Performance Test (WFCPT) included 52 white hybrids, one white and three yellow hybrid checks submitted by 21 commercial seed producers (Table 1). Twelve locations were planted in the agronomic evaluation. Data were received from locations in Illinois, Indiana, Kansas, Kentucky, Missouri, Tennessee, and Texas. First and second generation European corn borer (*Ostrinia nubilalis* Hübner) data were observed at Columbia and Novelty, MO. Grain samples were evaluated for quality by L. W. Rooney at Texas A & M University and under contract by the Illinois Crop Improvement Association, Inc.

The 1994 Early White Food Corn Performance Test (EWFCPT) included 50 white hybrids and one yellow hybrid check. Entries were submitted by 17 commercial seed producers (Table 1). Ten locations were planted in Illinois, Indiana, Iowa, Nebraska, Tennessee, and Texas. Results from the test planted at North Platte, NE, were not included because five entries were removed from the test before planting since they were known to be too late maturity for the test location and data from the two replications grown showed no significant differences for any variable except stand percentage.

ENTRIES AND SEED SOURCES

Contributors of seed for the 1994 evaluations are listed in Table 1. Those entries that have an EXP as part of the hybrid name, such as Cargill EXP 29003¹, have not been released. The last hybrids in each table are yellow or white kernel hybrid checks.

For averages over years, entry names have been changed to current designations, so that an experimental hybrid from an earlier year is now identified as the released hybrid. Changes affecting the 1994 tests follow: AgriGold R4004-W (1991) was redesignated AgriGold XA4004W (1992) and subsequently released as AgriGold A6565W. All DeKalb Plant Genetics hybrids have been redesignated as DeKalb Genetics hybrids. Jacques 7860W and 8360W have been renamed Mycogen 7860W and 8360W, respectively. Ohlde EX198W has been released as Ohlde 198W and Ohlde 181W was renamed Ohlde 1219W. Vineyard Vx4532W was released as Vineyard V453W and Vineyard Vx4383W was released as Vineyard V438W. Wilson E11930 and Wilson E11934 have been released as Wilson 1780W and 1790W, respectively.

Seed of the white hybrid check (K55 × CI66)FR802W came from Mr. R. L. Lundquist, Illinois Foundation Seeds, Inc., Champaign, IL. B73 × Mo17 was contributed by Ciba Seeds, Bloomington, IL. The yellow hybrid checks Pioneer Brand 3245 and 3320 were contributed by Dr. C. T. Cunningham, Pioneer Hi-Bred International, Windfall, IN.

¹ Mention of a trademark or proprietary product does not constitute a guarantee, warranty, or recommendation of the product by the U.S. Department of Agriculture or the University of Missouri and does not imply its approval to the exclusion of other products that may also be suitable.

LOCATIONS AND AGRONOMIC PRACTICES

Table 2 lists the locations of the WFCPT and EWFCPT from which acceptable data were returned, together with a record of the agronomic practices. Note that tests at Rossville, KS; Clay Center, NE; and College Station and Springlake, TX, were irrigated. Partial irrigation may have been used elsewhere.

Figure 1 graphically depicts on a map where tests were planted.

DATA COLLECTED

Yield

Yields were measured on a plot basis, converted to bushels per acre (54 lb bu/a), and adjusted to 15.5% moisture. Yields were adjusted to the mean stand for a location, if the efficiency of adjustment exceeded 104% (ratio of unadjusted error sum of squares to adjusted error sum of squares).

Stand

Stand is expressed as a percentage of the optimum plot stand or planted stand.

Root and stalk lodging

Lodging is expressed as a percentage of the total plants for each hybrid. Generally, a plant was rated as root lodged if it leaned more than 30° from vertical, and as stalk lodged, if it was broken at or below the ear node. Breakage above the ear was not counted. In 1994, tests grown in Kansas and Nebraska suffered from stalk breakage during intense thunderstorms in late June and early July, and this is reflected in the stalk lodging data.

Ear height

Ear height was measured from the soil level to the top ear leaf collar. Heights are expressed in inches.

Days to flowering

The number of days from planting to mid-tassel or mid-silk is shown. Depending on weather conditions, the total number of days from planting to physiological maturity might be taken as 1.6 to 1.8 times the number of days to flowering.

Grain moisture

Grain moisture was measured at harvest or when the grain was weighed.

European corn borer

Leaf feeding by the first generation of the European corn borer was rated in nine classes. A score of 1 represented no feeding and 9 represented extensive damage. Plants in each plot were infested with about 120 larvae during the whorl stage of plant development. Ratings for leaf feeding were

made three weeks later.

Feeding by the second generation of the European corn borer was determined by splitting stalks of five randomly infested plants per plot, counting the number of tunnels, and visually estimating the length of tunneling in inches. The minimum tunnel length associated with one hole was 1 inch. About 120 larvae were applied at flowering, and stalks were split six or more weeks later.

Environmental yield response (b_I) and standard deviation of fit

These statistics are shown in Table 15 for the entry means combined over all locations for the 1994 WFCPT and in Table 32 for the EWFCPT. The yield response (b_I) is expressed as bu/a/unit increase in the environmental index (I), where the index for a location is the average performance of all hybrids at the location. The deviation of fit is given in bu/a. The origin and use of these statistics are fully described later.

Test weight

Bulk density was determined by measuring the weight of a pint of grain and converting that weight to pounds per bushel (Illinois Crop Improvement Association).

100-kernel weight

Weight of 100 whole, cleaned kernels was measured in grams (Illinois Crop Improvement Association).

Kernel size

Kernel size was determined using alcohol displacement and expressed in cc (Illinois Crop Improvement Association).

Thins

Thins were obtained by determining the percent of a 250-kernel sample that passed through a 20/64" round-hole sieve using 30 back-and-forth cycles on a Gamet shaker (Illinois Crop Improvement Association).

Density

Density was determined using a helium gas pycnometer and expressed in g/cc (Illinois Crop Improvement Association).

Percentage horny endosperm

The percentage horny endosperm was visually estimated using a candling light. Fifteen kernels per entry per location were evaluated (Illinois Crop Improvement Association).

Pericarp removal

Pericarp removal values relate to alkaline cooking quality where relatively easy removal of the pericarp is highly desirable. Corn pericarps that are easily removed require less time to cook and product quality is improved. The pericarp of all corn kernels can be eventually removed by extensive lime cooking, but the dry matter losses are much higher.

The pericarp removal test was conducted by cooking 10 g of corn in nylon bags in a steam kettle containing 167 g of lime in 50 L of water. Samples were cooked for 20 min at the boiling point. The samples were then washed and stained with eosine and methyl blue solution. The pericarp stains a blue-green color while the endosperm stains a light green color. Each sample was then rated on a scale in which 1 represented complete removal and 5 represented no removal (Texas A & M University).

STATISTICAL ANALYSES AND INTERPRETATIONS

Data from the WFCPT and EWFCPT were analyzed as a three-replication, randomized-complete-block-design experiment at each location. If an observation was missing in one replication, the average of those observations in the remaining replications was used to approximate the missing observation. The least significant differences at probability level 0.05 (LSD 0.05) and coefficients of variation percentages (CV%) were calculated from the location analyses of variance (AOV). Where differences among hybrids were not significant for a character, no LSD or CV% is shown. Where data were missing or observed in only one or two replications; a footnote is used to identify those situations.

The LSD 0.05 is used to compare the performance of two specific hybrids at a time. It should not be used, however, to compare all pairs of hybrids. If the mean of hybrid "X" exceeds the mean for hybrid "Y" by the LSD 0.05 or more, the difference observed is a true difference in 19 out of 20 instances when the two hybrids are grown under conditions like those of the test.

The CV% relates error of measurement and the mean of the observed character. Values of the CV% for root and stalk lodging are sometimes much higher than for other characters and are generally associated with nonsignificant differences among hybrids.

Agronomic data combined from 12 locations of the 1994 WFCPT with an appropriate LSD 0.05 for each character are shown in Table 15. Table 32 gives combined results for the 1994 EWFCPT. The combined LSD 0.05 and CV% are based on the entries \times locations interaction versus the pooled error from the combined AOV. When a character was not observed at a location, dots show in the location analysis; the combined mean and LSD 0.05 have been adjusted accordingly.

Stability analysis gives information on the responsiveness of hybrids to changes in environment and the reliability with which these responses may be predicted. Mean performance of all hybrids at a location was the measure used to rate the environment. This environmental index (I) was then used as the independent variable in a regression analysis with the individual hybrid's performance at each location. A hybrid that is stable will have a regression coefficient (b_I) equal to 1.0, which means that an increase in the environmental index would result in an equal increase in the hybrid's yield. Regression coefficients greater than 1.0 indicate relatively better performance in good environments.

Hybrids with b_I values less than 1.0 would have a relative advantage in poor environments.

Deviation from fit reflects the accuracy with which the regression line given by b_I represents probable performance. Low deviation indicates that a hybrid has greater stability.

Overall, a desirable hybrid would have a high mean yield, b_I near 1.0, and low deviation from fit. If a grower knew he or she was producing on the high side of the environments sampled, then a hybrid with b_I greater than 1.0 would be more responsive than one with $b_I = 1.0$, and would be likely to yield more if mean yield levels were equivalent. Conversely, if a grower knew he or she was producing on the low side of the environments sampled, then a hybrid with b_I less than 1.0 would be less influenced by environment than one with $b_I = 1.0$, and would be likely to yield more if mean yield levels were equivalent.

NARRATIVE SUMMARY

1994 White Food Corn Performance Test

Yields from individual locations ranged from 92.6 bu/a at Columbia, MO, to 224.0 bu/a at Paris, IL. The overall average for 12 locations was 178.2 bu/a compared to 140.3 bu/a in 1993 and 173.5 bu/a obtained in 1992. The 1994 mean yield is the highest obtained since the WFCPT began in 1977.

Plot stands averaged 92.7%, ranging from 75.8% at College Station, TX, to 100.0% at Henderson, KY. Covariance adjustment of yield for stand was done for yield data from West Lafayette, IN; Rossville, KS; Columbia, MO; Novelty, MO; Knoxville, TN; and College Station and Springlake, TX.

Root lodging was near zero (0.3% average) with the highest amount occurring at Champaign, IL (1.0%). Stalk lodging averaged 1.2% with Rossville, KS, having significantly more than other locations (6.3%). Much of the Rossville stalk lodging was due to stalk breakage in severe thunderstorms in late June and early July. Both root and stalk lodging averages were among the lowest to date in this test.

The number of days to flowering was recorded at six locations. An 18.9-day spread was observed, ranging from 65.5 days at Columbia, MO, to 84.4 days at College Station, TX. Low grain moisture percentages can be observed where plots were harvested and dried before shelling and weighing, but most locations were combine harvested. Details of individual location data are in Tables 3 to 14 with the combined data in Table 15. Yield data from all 12 locations are given in Table 16.

Combined agronomic data from 12 locations (Table 15)

One white hybrid and one yellow check yielded significantly more than the mean for all entries (178.2 bu/a): Pioneer Brand X1183WB (199.2 bu/a) and the yellow check Pioneer Brand 3245 (190.1 bu/a). Pioneer Brand X1183WB yielded significantly more than any other entry except the yellow check Pioneer Brand 3245.

Nine entries yielded significantly less than the mean of all entries: the white check (K55 × CI66)FR802W (158.5 bu/a), DeKalb Genetics 742W (160.7 bu/a), DeKalb Genetics 739W (162.0 bu/a), Vineyard V449W (162.5 bu/a), Triumph 1910W (163.8 bu/a), Pioneer Brand 3287W (164.0 bu/a), Sturdy Grow SG930W (165.5 bu/a), Hoegemeyer 1142W (166.3 bu/a), and Tennessee EXP 94-1 (166.5 bu/a). The entries × locations interaction was significant, indicating different entry responses in different environments.

vironments.

Plot stands were excellent and averaged almost 93%. Only stands for Genetic Resources PR26101 (86.3%), Sturdy Grow SG777W (87.6%), DeKalb Genetics DK703W (87.9%), and DeKalb Genetics EXP368W (88.5%) were significantly lower than the average of all entries.

Root lodging was low, averaging 0.2%, and there were no significant differences between entries in the test. Stalk lodging averaged 1.2% for all entries and differences between entries were not significant.

Eleven hybrids had ear heights significantly below the mean for all entries (43.8 inches): DeKalb Genetics 739W (36.2 inches), DeKalb Genetics 742W (36.3 inches), Golden Harvest H-2633W (39.6 inches), the yellow check Pioneer Brand 3245 (39.7 inches), Pioneer Brand 3287W (41.4 inches), Triumph 1910W (41.9 inches), Vineyard V449W (42.1 inches), Vineyard V453W (43.1 inches), IFSI 90-4 (43.5 inches), Wilson 1780W (43.5 inches), and Golden Harvest H-2651W (43.8 inches). Sixteen hybrids' ear heights were more than one LSD above the mean for all entries. The white check (K55 × CI66)FR802W (53.2 inches) and Zimmerman Z63W (51.0 inches) had ear heights that were two LSDs above the mean for all entries.

Five white hybrids had a significantly lower number of days to flower (earlier) than the 74.1-day mean for all entries: Pioneer Brand 3287W (70.3 days), Golden Harvest H-2633W (72.3 days), Vineyard Vx4483W (72.3 days), Wilson 1790W (72.5 days), DeKalb Genetics 742W (72.5 days), and Cargill EXP 29003 (72.9 days). Relatively later flowering hybrids included the white check (K55 × CI66)FR802W (78.0 days), Zimmerman Z63W (76.7 days), Genetic Resources PR26101 (76.3 days), Genetic Resources PR26113 (76.2 days), Zimmerman Z64W (76.1 days), Tennessee EXP 94-1 (75.7 days), Whisnand 74W (75.4 days), and Zimmerman Z62W (75.3 days). Because the WFCPT is grown primarily in the southern Corn Belt, some earlier maturity hybrids may be somewhat at a yield disadvantage in not using the full growing season.

Differences in grain moisture measured during early-season combine harvesting may be reduced when averaged with moistures after prolonged field or uniform drying. Grain moistures ranged from 18.7% for the yellow check Pioneer Brand 3245 to 24.3% for IFSI 94-3 with an overall average of 21.1%. Twelve white hybrids and the three yellow hybrid checks had grain moistures that were significantly less than the mean for all entries: the yellow check Pioneer Brand 3245 (18.7%), Sturdy Grow EXP 765W (19.2%), the yellow check B73 × Mo17 (19.5%), Pioneer Brand 3287W (19.6%), Ohlde 1219W (19.7%), DeKalb Genetics EXP368W (19.8%), Zimmerman Z62W (19.8%), Cargill EXP 29003 (19.9%), the yellow check Pioneer Brand 3320 (19.9%), Ohlde 198W (19.9%), Pioneer Brand 3281W (19.9%), DeKalb Genetics 739W (20.0%), Sturdy Grow SG777W (20.0%), Cargill 8097W (20.0%), and Whisnand 51AW (20.0%). Only two white hybrids (Cargill EXP 29003 and Pioneer Brand 3287W) and had both number of days to flower and grain moisture that were significantly below the means for all entries. The range of days to flower and grain moistures observed indicate that seed producers are offering a range of maturities in white hybrids.

The environmental response coefficients (b_1) and standard deviations of fit are shown in the last two columns of Table 15. (A difference of ± 0.06 from 1.00 is necessary for significance. The LSD

should be used when comparing coefficients of two hybrids.) Twenty-two white hybrids had b_I s that were significantly greater than 1.00, indicating greater than average response to better environmental conditions, but poor performance in adverse environments. Nineteen white hybrids, the white check ($K55 \times CI66$)FR802W, and the yellow check B73 \times Mo17 had environmental responses that were significantly less than 1.00. Pioneer Brand X1183WB (199.2 bu/a, $b_I = 1.27$ bu/a/I) had a significantly higher yield than the average entry and a b_I that was significantly greater than 1.0. Other hybrids that yielded above 185 bu/a and that had a b_I significantly greater than 1.0 included IFSI 94-3 (187.3 bu/a, $b_I = 1.06$ bu/a/I), Ohlde 198W (187.0 bu/a, $b_I = 1.13$ bu/a/I), Sturdy Grow SG797W (187.0 bu/a, $b_I = 1.08$ bu/a/I), Cargill 8097W (186.9 bu/a, $b_I = 1.10$ bu/a/I), Whisnand 51AW (186.7 bu/a, $b_I = 1.07$ bu/a/I), Zimmerman Z62W (186.6 bu/a, $b_I = 1.18$ bu/a/I), Ohlde 1219W (186.1 bu/a, $b_I = 1.16$ bu/a/I), Ohlde 197W (186.0 bu/a, $b_I = 1.19$ bu/a/I), Bo-Jac 523W (185.6 bu/a, $b_I = 1.13$ bu/a/I), Mycogen 7860W (185.3 bu/a, $b_I = 1.21$ bu/a/I), and Zimmerman Z64W (185.2 bu/a, $b_I = 1.29$ bu/a/I). These would be good selections when a favorable environment was anticipated.

Usually, low responsiveness is associated with low mean yields. Exceptions are occasionally found that are high yielding and have a low b_I , but no examples were found in this year's test. This type of response would be desirable where adverse conditions were frequently encountered,

The standard deviations of fit varied for similar environmental response coefficients. For example, Pioneer Brand 3287W (164.0 bu/a, $b_I = 0.85$ bu/a/I) and the white check hybrid ($K55 \times CI66$)FR802W (158.5 bu/a, $b_I = 0.85$ bu/a/I) had standard deviations of 9.9 and 26.0 bu/a, respectively. Pioneer Brand 3287W would be expected to be a more predictable performer in response to varied environments than the white check hybrid ($K55 \times CI66$)FR802W.

In choosing a hybrid, all agronomic factors must be considered in relation to the anticipated environment. Data from several locations are usually more reliable than data from a single location evaluated for two or three years.

European corn borer susceptibility data for the 1994 WFCPT (Table 17)

First generation leaf-feeding ratings were obtained at Columbia and Novelty, MO. Significant differences were found among entries. Zimmerman Z62W (2.2 rating), ICI Seeds 8122W (2.7 rating), and Zimmerman Z63W (2.7 rating) were significantly better than the mean of all entries (3.9 rating). Wilson 1780W (5.8 rating), Wilson 1790W (5.8 rating), DeKalb Genetics EXP368W (5.5 rating), DeKalb Genetics DK703W (5.2 rating) and the two susceptible checks for European corn borer, Ki3 (5.5 rating) and Wf9 \times W182E (5.5 rating), were more susceptible to leaf feeding damage than the average entry.

Significant differences among entries were also found for second generation stalk-feeding data that were obtained at Columbia and Novelty, MO. No entry was significantly better than the mean for either number of tunnels or tunnel length. Two entries had significantly more tunnels and tunnel length than the average entry and had numerically more than either of the two susceptible checks: DeKalb Genetics 742W (3.1 tunnels, 3.5 inches of tunneling) and Genetic Resources PR26113 (2.8 tunnels, 3.0 inches of tunneling).

Two-, three-, four-, and five-year mean yields and agronomic performance (Tables 18 to 21)

Data were summarized for common entries in the last two, three, four, and five years of the WFCPT. Individual year means were averaged without weighting for the varying numbers of locations over the years when they differed. For the past five years, the number of locations with acceptable data has been 12. Approximate values of 7 bu/a for the two-year means, 6 bu/a for the three-year means, 6 bu/a for the four-year means, and 5 bu/a for the five-year means could be used to compare yields of individual entries in the respective tables.

Among the hybrids included in the 1990 to 1994 tests (five-year means), Zimmerman Z63W (160.0 bu/a) and the yellow check Pioneer Brand 3320 (157.1 bu/a) could be judged to yield significantly more than the average of other entries (151.4 bu/a). Not distinguishable from Zimmerman Z63W were the yellow check Pioneer Brand 3320 (157.1 bu/a) and DeKalb Genetics DK703W (155.5 bu/a). Relatively poorer performing over this period was the white check hybrid (K55 × CI66)FR802W (134.9 bu/a).

For the four-year means, the yellow check Pioneer Brand 3245 (173.2 bu/a) and Northrup King N7580W (162.8 bu/a) would be judged above average. The yellow check Pioneer Brand 3245 yielded significantly more than any other entry in the four-year means. Among the remaining white hybrids, Northrup King N7580W (162.8 bu/a), Zimmerman Z63W (161.7 bu/a), Sturdy Grow SG798W (160.9 bu/a), Pioneer Brand 3281W (160.6 bu/a), and DeKalb Genetics DK703W (159.1 bu/a) could not be statistically differentiated.

Kernel quality evaluation of entries in the 1994 White Food Corn Performance Test (Table 22)

Milling quality of entries in the 1994 WFCPT was evaluated by the Illinois Crop Improvement Association, Inc. and Texas A & M University. Target values are a kernel weight of 37 g or more per 100 kernels, density equal to or exceeding 1.20 g/cc, and 90% or more horny endosperm. Significant differences among entries were found for all seven quality traits measured. Hybrids exceeding the target value of 37 g/100 kernels were Genetic Resources PR26101 (41.0 g), DeKalb Genetics EXP368W (40.5 g), DeKalb Genetics DK703W (39.9 g), Genetic Resources PR26113 (38.4 g), the white check (K55 × CI66)FR803W (38.4 g), IFSI 94-2 (38.3 g), Pioneer Brand X1183WB (38.2 g), the yellow check Pioneer Brand 3245 (38.1 g), Tennessee EXP 94-1 (38.1 g), and Sturdy Grow SG777W (37.7 g). All hybrids and checks in the test had grain densities greater than or equal to 1.3 g/cc. Only Whisnand 92AW (91%) and the yellow check Pioneer Brand 3245 (90%) met the desired 90% horny endosperm. Five hybrids had 89% horny endosperm, two had 88%, five had 87%, and nine had 86%. It is possible that the Illinois Crop Improvement Association laboratory differs from The Quaker Oats Company, Barrington, IL, laboratory (original source of the 90% horny endosperm criterion) in judging this trait and that a lower target value reflecting current data might be acceptable to most processors.

1994 Early White Food Corn Performance Test

Yields in the EWFCPT ranged from 121.0 bu/a at Clay Center, NE, to 207.3 bu/a at Galesburg, IL, with an overall average for six northern locations with yield data of 180.0 bu/a, and this was a record high. Stands averaged 94.1% overall, ranging from 81.1% at Ogden, IA, to 99.9% at St. Joseph, MO. Covariance adjustment of yield for stand was done for data from Champaign and Galesburg, IL; Ogden, IA; and Springlake, TX (the latter location was not included in the combined analysis).

Root lodging averaged 10.5% at seven northern locations, ranging from 0.0% at Galesburg, IL, to 46.7% at St. Joseph, MO. Most locations were under 9% and three locations had less than 1%. Stalk lodging ranged from 0.0% at Champaign, IL, and St. Joseph, MO, to 37.8% at Marion, IA, averaging 8.3% for the seven northern locations.

Days to flowering were recorded only at Marion, IA, where the mean was 82.5 days. Harvest grain moistures averaged 22.8%. The Clay Center, NE, location had 16.8% moisture at harvest, while Galesburg, IL, had 27.6% grain moisture at harvest.

Twenty-eight white hybrids and the yellow check B73 × Mo17 were grown in both the WFCPT and EWFCPT. Further testing will determine the appropriate environments for testing each hybrid. There will be hybrids, however, that are intermediate to the maturity zones of the two tests and will continue to be entered in both tests.

The test was also grown at Knoxville, TN (Table 30), and Halfway, TX (Table 31), but data were not included in the combined analysis of the northern locations. Individual location data are shown in Tables 23 to 31 with the combined data in Table 32. Yield data from six of the seven northern locations are given in Table 33. A problem with grain hopper closure when harvesting the Marion, IA, location caused unknown losses for 46 plots and no yield data are reported for that test.

Combined agronomic data from seven northern locations (Table 32)

The average yield from six northern locations was 180.0 bu/a compared to 126.5 bu/a in 1993 and 168.5 bu/a in 1992. Only one white hybrid yielded significantly more than the mean of all entries: Cargill 8097W (197.3 bu/a). Twenty-five white hybrids could not be statistically differentiated (yielded 180.4 bu/a or more) from Cargill 8097W. Included among entries that yielded significantly less than the average of all entries were DeKalb Genetics 555W (160.0 bu/a) and DeKalb Genetics 563W (160.5 bu/a).

Differences among hybrids for stand percentage were relatively small. No entry was significantly better than the mean of all entries as that required an average stand of 100%. Sturdy Grow SG777W (87.2%), DeKalb Genetics 563W (87.6%), Vineyard V449W (88.6%), DeKalb Genetics EXP368W (88.7%), IFSI 93-4 (89.4%), and NobleBear NB742W (90.3%) had significantly lower stand percentages than the mean for all entries, but these levels for stand were not of concern.

Differences among entries for root and stalk lodging were not significant even though there was an overall average of 10.5% for root lodging and 8.3% for stalk lodging. Only one location for each of these traits had significant amounts of lodging.

Ear heights ranged from 38.8 inches for DeKalb Genetics 739W to 54.5 inches for Ohlde 198W and

Sturdy Grow SG745W. Nine white hybrids were more than one LSD below the average of all entries: DeKalb Genetics 739W (38.8 inches), NobleBear NB742W (40.2 inches), DeKalb Genetics 742W (40.3 inches), NobleBear NB739W (40.9 inches), DeKalb Genetics 555W (42.2 inches), Sturdy Grow EXP 731W (43.1 inches), DeKalb Genetics 563W (43.3 inches), NobleBear NB571W (43.8 inches), and Pioneer Brand 3287W (44.0 inches). Six white hybrids were significantly taller than the average entry: Sturdy Grow SG745W (54.5 inches), Ohlde 198W (54.5 inches), NC+ 6555W (53.8 inches), IFSI 90-1 (53.7 inches), Whisnand 51AW (53.6 inches), NC+ RE672W (53.5 inches), and Triumph 1429W (53.5 inches).

The number of days to flowering was recorded only at Marion, IA. These data, however, together with grain moisture, give an indication of entries that are relatively late or early maturing in this test. Entries that were significantly earlier flowering and had significantly lower grain moisture than the average entry were Pioneer Brand 3463W (79.3 days, 19.5%), NobleBear NB710W (80.0 days, 20.3%), Pioneer Brand X1083WA (80.3 days, 19.5%), and NobleBear NB571W (80.3 days, 19.3%). Six white hybrids had moistures significantly exceeding the mean of 22.8% at harvest: Hoegemeyer 1142W (27.7%), Whisnand 92AW (26.9%), Whisnand 74W (25.8%), Asgrow X8983W (24.8%), NC+ RE672W (24.3%), and Hoegemeyer 1125W (24.3%).

The environmental response coefficients (b_I) and standard deviations of fit for the EWFCPT are shown in the last two columns of Table 32. (A difference of ± 0.16 from 1.00 is necessary for significance. The LSD should be used when comparing coefficients of two hybrids.) Twelve white hybrids had b_I s that were significantly greater than 1.00, indicating greater than average response to better environmental conditions, but poor performance in adverse environments. Of these, NobleBear NB710W (178.4 bu/a, $b_I = 1.93$ bu/a/I), DeKalb Plant Genetics 563W (160.5 bu/a, $b_I = 1.72$ bu/a/I), and NobleBear NB571W (164.4 bu/a, $b_I = 1.54$ bu/a/I) all had b_I s greater than 1.5 with mean yields less than average, especially the latter two hybrids. These hybrids would be very responsive in good environments, but likely not yield as much as a hybrid with a mean yield above 190 bu/a and a $b_I = 1.15$ to 1.25 (Sturdy Grow SG745W [194.0 bu/a, $b_I = 1.17$ bu/a/I] or Pioneer Brand X1183WB [193.0 bu/a, $b_I = 1.16$]), depending on just how good the environment was.

Fourteen white hybrids had environmental responses that were significantly less than 1.00. Usually, low response is associated with low mean yields. Hybrids can usually be found, however, that have high mean yield and that are less responsive to improved environments: Sturdy Grow EXP 765W (187.9 bu/a, $b_I = 0.76$ bu/a/I), NC+ RE672W (184.7 bu/a, $b_I = 0.65$ bu/a/I), and Wilson 1790W (184.5 bu/a, $b_I = 0.67$ bu/a/I). Response of such hybrids would be desirable where adverse conditions were frequently encountered.

The standard deviations of fit varied for similar environmental response coefficients. For example, AgriGold A6565W (189.7 bu/a, $b_I = 0.98$ bu/a/I) and Sturdy Grow EXP 731W (179.6 bu/a, $b_I = 0.98$ bu/a/I) had standard deviations of 3.8 and 10.0 bu/a, respectively. AgriGold A6565W would be expected to be a more predictable performer in response to varied environments than Sturdy Grow EXP 731W.

European corn borer susceptibility data for the 1994 EWFCPT (Table 34)

First generation leaf-feeding ratings were obtained at Columbia and Novelty, MO. Significant differences were found among entries. Three entries were significantly better than the mean of all entries (3.9 rating): Zimmerman Z62W (2.2 rating), Vineyard V449W (2.5 rating), and Pioneer Brand X1083WA (2.7 rating). Wilson 1780W (6.2 rating), DeKalb Genetics EXP368W (5.3 rating), and Wilson 1790W (5.3 rating) and the susceptible checks Ki3 (5.5 rating) and Wf9 × W182E (5.5 rating) were more susceptible to leaf feeding damage than the average entry.

Second generation stalk-feeding data were also obtained at Columbia and Novelty, MO. No entry was significantly better than the mean for tunnel number or tunnel length. Whisnand 92AW (0.9 tunnels, 1.0 inches of tunneling) was nearly the same as the resistant European corn borer check hybrid Pioneer Brand 3184 (0.8 tunnels, 1.0 inches of tunneling). Several other hybrids with less than 1.7 tunnels and less than 2.1 inches of tunneling also fall into the resistant category. Two hybrids had significantly more tunnels and tunnel length as compared to the average entry: NC+ RE672W (3.1 tunnels, 3.4 inches of tunneling) and Pioneer Brand X1183WB (2.6 tunnels, 3.2 inches of tunneling).

Two-, three-, four-, and five-year mean yields and agronomic performance (Tables 35 to 38)

Data were summarized for the last two, three, four, and five years of the EWFCPT. Year means were averaged without weighting for the varying numbers of locations over the years. For the past five years, the number of locations with acceptable data has ranged from four in 1992 to six (for yield) in 1993 and 1994. Although an LSD cannot be directly calculated, approximate values of 11 bu/a for the two-year means, 9 bu/a for the three-year means, 7.5 bu/a for the four-year means, and 6 bu/a for the five-year means can be used to compare yields of individual entries.

For the five-year means, NobleBear NB710W (163.3 bu/a) and IFSI 90-1 (163.1 bu/a) would be judged higher yielding than the average entry. Pioneer Brand 3463W (143.0 bu/a) was lower yielding than any other entry. Results from calculating four-year means showed that Cargill 8097W (164.6 bu/a), NC+ 6555W (163.8 bu/a), and IFSI 90-1 (163.3 bu/a) yielded more than the mean for all entries. NobleBear NB710W (161.3 bu/a), Whisnand 51AW (159.0 bu/a), and Vineyard V424W (157.9 bu/a) of the highest yielders were not statistically differentiable from the top yielder. Relatively lower yielding than other entries was Pioneer Brand 3463W (142.9 bu/a).

Kernel quality evaluation of entries in the 1994 Early White Food Corn Performance Test (Table 39)

Milling quality of entries in the 1994 EWFCPT was evaluated by the Illinois Crop Improvement Association, Inc. and Texas A & M University. Target values are a kernel weight of 37 g or more per 100 kernels, density equal to or exceeding 1.20 g/cc, and 90% or more horny endosperm. Meeting all of these criteria were two white hybrids: Vineyard Vx4143W (37.6 g/100 kernels, 1.35 g/cc, 95% horny endosperm) and Hoegemeyer 1142W (37.9 g/100 kernels, 1.35 g/cc, 90% horny endosperm). Twenty white hybrids had kernel weights at or above 37 g. All entries had kernel densities exceeding 1.29 g/cc. Three hybrids had 90% or more horny endosperm: two are mentioned as meeting all three

quality characteristics listed, and the third is Vineyard V442W (92% horny endosperm). As for the WFCPT, it is possible that the Illinois Crop Improvement Association laboratory differs from The Quaker Oats Company, Barrington, IL, laboratory (original source of the 90% horny endosperm criterion) in judging this trait and that a lower target value reflecting current data might be acceptable to most processors. Eleven additional hybrids had horny endosperm percentages between 85 and 88%, which would probably be judged acceptable.

Table 1. Sources of commercial white endosperm food corn hybrids entered in the 1994 White Food Corn Performance Test and the 1994 Early White Food Corn Performance Test.

[†] Data from Columbia, MO, were not included for testweight measurement because of inadequate sample size for 13 entries.

[‡] Percent of a 250-kernel sample passing through a 20/64" round-hole sieve.

[§] Rated on a scale in which 1 represents complete removal and 5 represents no removal.

[¶] Data missing from one location.
