ACKNOWLEDGMENTS

This bulletin is a contribution of the Plant Genetics Research Unit, Agricultural Research Service, U.S. Department of Agriculture and the Plant Science Unit, University of Missouri, Columbia, in cooperation with Illinois Foundation Seeds, Champaign, IL; Department of Plant and Soil Science, University of Tennessee; Department of Agronomy, University of Kentucky; Northrup King Company, Henderson, KY; Department of Agronomy, Purdue University; Department of Agronomy, Kansas State University; Pioneer Hi-Bred International, Marion, IA, and Union City, TN; Department of Agronomy, Iowa State University; ICI Seeds, Marshall, MO; Department of Agronomy, University of Nebraska; Department of Soil and Crop Science, Texas A & M University; Illinois Crop Improvement Association, Champaign, IL; and Limagrain Genetics, Lebanon, IN. We thank Dr. S. H. Weaver, The Quaker Oats Company, for review of the manuscript, and Julie Barry and Charles Thiel for assembly and distribution of the seed. Supported, in part, by gifts from the American Corn Millers Federation and The Quaker Oats Company, which stimulated this work on evaluation of corn for use in food.

INTRODUCTION

The 1995 White Food Corn Performance Test (WFCPT) included 54 white hybrids, one white and three yellow hybrid checks submitted by 20 commercial seed producers and the University of Tennessee (Table 1). Twenty-two white hybrids were new to the test in 1995. Thirteen locations were planted in the agronomic evaluation. Data were received from locations in Illinois, Indiana, Kansas, Kentucky, Missouri, Tennessee, and Texas. Data from Novelty, MO; Union City, TN; and Springlake, TX (grain quality samples from Springlake were used), were not included in the final analysis. First and second generation European corn borer (*Ostrinia nubilalis* Hübner) data were observed at Grand Pass, MO. European corn borer evaluation plots at Novelty, MO, were discarded. Grain samples were evaluated for quality by L. W. Rooney at Texas A & M University and under contract by the Illinois Crop Improvement Association, Inc.

The 1995 Early White Food Corn Performance Test (EWFCPT) included 66 white hybrids and two yellow hybrid checks. Entries were submitted by 23 commercial seed producers and Purdue University (Table 1). Twenty-eight white hybrids were new to the test in 1995. Ten locations were planted in Illinois, Indiana, Iowa, Nebraska, and Tennessee. The test planted at Lebanon, IN, was abandoned. First and second generation European corn borer (*Ostrinia nubilalis* Hübner) data were observed at Grand Pass, MO. European corn borer plots at Novelty, MO were discarded. Grain samples were evaluated for quality by L. W. Rooney at Texas A & M University and under contract by the Illinois Crop Improvement Association, Inc.

ENTRIES AND SEED SOURCES

Contributors of seed for the 1995 evaluations are listed in Table 1. Those entries that have an EXP as part of the hybrid name, such as DeKalb Genetics EXP566W¹, have not been released. The last hybrids in each table are yellow or white kernel hybrid checks.

For averages over years, entry names have been changed to current designations, so that an experimental hybrid from an earlier year is now identified as the released hybrid. Where a previously entered hybrid was entered by a new company in 1995, changes have been made to prior naming so the hybrid appears in the summaries over years (if continuously entered). Changes affecting the 1995 tests follow: Pioneer Brand 3203W was released from Pioneer Brand X1183WB and Pioneer Brand 3443W was released from Pioneer Brand X1083WA. Sturdy Grow SG731W was released from the experimental Sturdy Grow EXP 731W and Sturdy Grow SG765W was released from Sturdy Grow EXP 765W. Vineyard V414W was released from Vineyard Vx4143W and Vineyard V448W was the commercial release of Vineyard Vx4483W.

Seed of the white hybrid check (K55 × CI66)FR802W came from Mr. R. L. Lundquist, Illinois Foundation Seeds, Inc., Champaign, IL. The yellow hybrid checks Pioneer Brand 3245 and 3394 were

contributed by Dr. C. T. Cunningham, Pioneer Hi-Bred International, Windfall, IN.

LOCATIONS AND AGRONOMIC PRACTICES

Table 2 lists the locations of the WFCPT and EWFCPT from which acceptable data were returned, together with a record of the agronomic practices. Note that tests at Topeka, KS; Clay Center and Gothenburg, NE; and College Station, TX, were irrigated. Partial irrigation may have been used elsewhere.

Figure 1 shows map locations where tests were planted.

DATA COLLECTED

Yield

Yields were measured on a plot basis, converted to bushels per acre (54 lb bu/a), and adjusted to 15.5% moisture. No adjustment for plot stand was done.

Stand

Stand is expressed as a percentage of the optimum plot stand or planted stand.

Root and stalk lodging

Lodging is expressed as a percentage of the total plants for each hybrid. Generally, a plant was rated as root lodged if it leaned more than 30° from vertical, and as stalk lodged, if it was broken at or below the ear node. Breakage above the ear was not counted.

Ear height

Ear height was measured from the soil level to the top ear leaf collar. Heights are expressed in inches.

Days to flowering

The number of days from planting to mid-tassel or mid-silk is shown. Depending on weather conditions, the total number of days from planting to physiological maturity might be taken as 1.6 to 1.8 times the number of days to flowering.

Grain moisture

Grain moisture was measured at harvest or when the grain was weighed.

European corn borer

Leaf feeding by the first generation of the European corn borer was rated in nine classes. A score of 1 represented no feeding and 9 represented extensive damage. Plants in each plot were infested with about 120 larvae during the whorl stage of plant development. Ratings for leaf feeding were made three weeks later.

Feeding by the second generation of the European corn borer was determined by splitting stalks of five randomly infested plants per plot, counting the number of tunnels, and visually estimating the length of tunneling in inches. The minimum tunnel length associated with one hole was 1 inch. About 120 larvae were applied at flowering, and stalks were split six or more weeks later.

Environmental yield response (b_I) and standard deviation of fit

These statistics are shown in Table 13 for the entry means combined over all locations for the 1995 WFCPT and in Table 30 for the EWFCPT. The yield response (b_I) is expressed as bu/a/unit increase in the environmental index (I), where the index for a location is the average performance of all hybrids at the location. The deviation of fit is given in bu/a. The origin and use of these statistics are fully described later.

Test weight

Bulk density was determined by measuring the weight of a pint of grain and converting that weight to pounds per bushel (Illinois Crop Improvement Association).

100-kernel weight

Weight of 100 whole, cleaned kernels was measured in grams (Illinois Crop Improvement Association).

Kernel size

Kernel size was determined using alcohol displacement and expressed in cc (Illinois Crop Improvement Association).

Thins

Thins were obtained by determining the percent of a 250-kernel sample that passed through a 20/64" round-hole sieve using 30 back-and-forth cycles on a Gamet shaker (Illinois Crop Improvement Association).

Density

Density was determined using a helium gas pycnometer and expressed in g/cc (Illinois Crop Improvement Association).

Percentage horny endosperm

The percentage horny endosperm was visually estimated using a candling light. Fifteen kernels per entry per location were evaluated (Illinois Crop Improvement Association).

Pericarp removal

Pericarp removal values relate to alkaline cooking quality where relatively easy removal of the

pericarp is highly desirable. Corn pericarps that are easily removed require less time to cook and product quality is improved. The pericarp of all corn kernels can be eventually removed by extensive lime cooking, but the dry matter losses are much higher.

The pericarp removal test was conducted by cooking 10 g of corn in nylon bags in a steam kettle containing 167 g of lime in 50 L of water. Samples were cooked for 20 min at the boiling point. The samples were then washed and stained with eosine and methyl blue solution. The pericarp stains a blue-green color while the endosperm stains a light green color. Each sample was then rated on a scale in which 1 represented complete removal and 5 represented no removal (Texas A & M University).

STATISTICAL ANALYSES AND INTERPRETATIONS

Data from the WFCPT and EWFCPT were analyzed as a three-replication, randomized-complete-block-design experiment at each location. If an observation was missing in one replication, the average of those observations in the remaining replications was used to approximate the missing observation. The least significant differences at probability level 0.05 (LSD 0.05) and coefficients of variation percentages (CV%) were calculated from the location analyses of variance (AOV). Where differences among hybrids were not significant for a character, no LSD or CV% is shown. Where data were missing or observed in only one or two replications; a footnote is used to identify those situations.

The LSD 0.05 is used to compare the performance of two specific hybrids at a time. It should not be used, however, to compare all pairs of hybrids. If the mean of hybrid "X" exceeds the mean for hybrid "Y" by the LSD 0.05 or more, the difference observed is a true difference in 19 out of 20 instances when the two hybrids are grown under conditions like those of the test.

The CV% relates error of measurement and the mean of the observed character. Values of the CV% for root and stalk lodging are sometimes much higher than for other characters and are generally associated with nonsignificant differences among hybrids.

Agronomic data combined from 10 locations of the 1995 WFCPT with an appropriate LSD 0.05 for each character are shown in Table 13. Table 30 gives combined results for the 1995 EWFCPT. The combined LSD 0.05 is based on the entries \times locations interaction versus the pooled error from the combined AOV. When a character was not observed at a location, dots show in the location analysis; the combined mean and LSD 0.05 have been adjusted accordingly.

Stability analysis gives information on the responsiveness of hybrids to changes in environment and the reliability with which these responses may be predicted. Mean performance of all hybrids at a location was the measure used to rate the environment. This environmental index (I) was then used as the independent variable in a regression analysis with the individual hybrid's performance at each location. A hybrid that is stable will have a regression coefficient (b_I) equal to 1.0, which means that an increase in the environmental index would result in an equal increase in the hybrid's yield. Regression coefficients greater than 1.0 indicate relatively better performance in good environments. Hybrids with b_I values less than 1.0 would have a relative advantage in poor environments.

Deviation from fit reflects the accuracy with which the regression line given by b_I represents

probable performance. Low deviation indicates that a hybrid has greater stability.

Overall, a desirable hybrid would have a high mean yield, b_I near 1.0, and low deviation from fit. If a grower knew he or she was producing on the high side of the environments sampled, then a hybrid with b_I greater than 1.0 would be more responsive than one with $b_I = 1.0$, and would be likely to yield more if mean yield levels were equivalent. Conversely, if a grower knew he or she was producing on the low side of the environments sampled, then a hybrid with b_I less than 1.0 would be less influenced by environment than one with $b_I = 1.0$, and would be likely to yield more if mean yield levels were equivalent.

NARRATIVE SUMMARY

1995 White Food Corn Performance Test

Yields from individual locations ranged from 92.4 bu/a at Knoxville, TN, to 194.7 bu/a at College Station, TX. The overall average for 10 locations was 137.9 bu/a compared to 178.2 bu/a in 1994. The 1994 mean yield was the highest obtained since the WFCPT began in 1977. Late plantings (West Lafayette, IN, and Columbia, MO, were both planted in June, Table 2) and a cool, wet spring limited yield potentials.

Plot stands averaged 97.1% and all locations exceeded 93%, which is excellent. No adjustment of yield for plot stands was done.

Root lodging was near zero (0.5% average) with the highest amount occurring at Champaign, IL (1.5%). Stalk lodging averaged 2.1% with Columbia, MO (9.0%), having significantly more than other locations. Both root and stalk lodging averages were among the lowest observed in this test.

The number of days to flowering was recorded at five locations. A 17.8-day spread was observed, ranging from 69.2 days at Columbia, MO, to 87.0 days at Topeka, KS. Low grain moisture percentages can be observed where plots were harvested and dried before shelling and weighing, but most locations were combine harvested. Details of individual location data are in Tables 3 to 12 with the combined data in Table 13. Yield data from all 10 locations are given in Table 14.

Combined agronomic data from 10 locations (Table 13)

Five white hybrids and one yellow check yielded significantly more than the mean for all entries (137.9 bu/a): Cargill X7510W (160.3 bu/a), the yellow check Pioneer Brand 3245 (160.0 bu/a), Cargill X7511W (156.5 bu/a), IFSI 94-3 (151.0 bu/a), Zimmerman Z64W (149.6 bu/a), and Sturdy Grow SG797W (149.3 bu/a). The widely grown yellow check Pioneer Brand 3394 yielded 148.6 bu/a.

Five entries yielded significantly less than the mean of all entries: Wilson E954003 (114.8 bu/a), Wilson E954004 (116.4 bu/a), Pioneer Brand 3287W (125.6 bu/a), Genetic Resources GRI94181 (111.4 bu/a), and the white check (K55 × CI66)FR802W (82.9 bu/a). The entries × locations interaction was significant, indicating different entry responses in different environments.

Plot stands were excellent and averaged almost 97.1%. Only the stand for the white check (K55 × CI66)FR802W (83.4%) was significantly lower than the average of all entries.

Root lodging was low, averaging 0.5%. Entries having significantly more root lodging than the

average entry included the white check (*K55 × CI66*)FR802W (2.7%), Zimmerman Z64W (2.2%), and Genetic Resources GRI94181 (1.7%). Values this low over the seven locations with data, however, are completely acceptable. Stalk lodging averaged 2.1% for all entries. No entry had significantly less stalk lodging than the mean, but DeKalb Genetics 739W and Pioneer Brand 3287W both were less than 1%. Four entries had stalk lodging means exceeding that of the average entry: ICI Seeds 8320W (4.6%), Genetic Resources GRI94181 (4.5%), Whisnand 95W (4.3%), and the white check (*K55 × CI66*)FR802W (4.1%). Even these values, though statistically significantly different, are acceptable.

Nine white hybrids and two yellow check hybrids had ear heights significantly below the mean for all entries (43.7 inches): DeKalb Genetics 739W (34.5 inches), Asgrow X940481W (34.7 inches), DeKalb Genetics 742W (35.0 inches), DeKalb Genetics EXP566W (36.9 inches), Triumph 1910W (39.8 inches), Golden Harvest H-2633W (39.9 inches), the yellow check Pioneer Brand 3245 (40.0 inches), Vineyard V442W (40.3 inches), Pioneer Brand 3287W (40.9 inches), the yellow check Pioneer Brand 3394 (41.0 inches), and IFSI 94-3 (41.2 inches). Ten hybrids' ear heights were more than one LSD above the mean for all entries. The white check (*K55 × CI66*)FR802W (48.6 inches) and Genetic Resources GRI94181 (48.7 inches) had ear heights that were two LSDs above the mean for all entries.

Nine white hybrids and two yellow check hybrids had a significantly lower number of days to flower (earlier) than the 77.0-day mean for all entries: Pioneer Brand 3287W (74.5 days), DeKalb Genetics 739W (75.2 days), the yellow check Pioneer Brand 3394 (75.2 days), Asgrow X940481W (75.3 days), Cargill X7510W (75.3 days), Golden Harvest H-2633W (75.5 days), DeKalb Genetics EXP566W (75.5 days), DeKalb Genetics 742W (75.5 days), the yellow check B73 × Mo17 (75.8 days), Vineyard V442W (75.9 days), and IFSI 90-4 (75.9 days). Relatively later flowering hybrids included the white check (*K55 × CI66*)FR802W (81.3 days), Wilson E954003 (80.3 days), Genetic Resources GRI94181 (80.1 days), Genetic Resources GRI94185 (79.3 days), Wilson E954004 (79.1 days), Zimmerman Z64W (78.9 days), Whisnand 95W (78.3 days), Zimmerman Z70W (78.3 days), Zimmerman Z62W (78.1 days), and Pioneer Brand 3203W (78.1 days). Because the WFCPT is grown primarily in the southern Corn Belt, some earlier maturity hybrids may be at a yield disadvantage in not using the full growing season.

Differences in grain moisture measured during early-season combine harvesting may be reduced when averaged with moistures after prolonged field or uniform drying. Grain moistures ranged from 16.1% for the yellow check Pioneer Brand 3394 to 23.0% for Asgrow X940481W with an overall average of 19.4%. Eleven white hybrids and three yellow hybrid checks had grain moistures that were significantly less than the mean for all entries: the yellow check Pioneer Brand 3394 (16.1%), the yellow check B73 × Mo17 (16.6%), the yellow check Pioneer Brand 3245 (16.9%), Cargill X7510W (17.2%), Zimmerman Z62W (17.4%), DeKalb Genetics EXP567W (17.6%), Cargill X7511W (17.7%), Trisler T-93W2 (17.8%), Sturdy Grow SG765W (17.8%), Hoegemeyer X581W (17.9%), DeKalb Genetics EXP566W (18.0%), Bo-Jac 523W (18.1%), Pioneer Brand 3287W (18.2%), and IFSI 90-1 (18.2%).

Three white hybrids (Cargill X7510W, DeKalb Genetics EXP566W, Pioneer Brand 3287W) and two yellow check hybrids (Pioneer Brand 3394 and B73 × Mo17) had both number of days to flower and grain moisture that were significantly below the means for all entries. The range of days to flower and

grain moistures observed indicate that seed producers are offering a range of maturities in white hybrids.

The environmental response coefficients (b_I) and standard deviations of fit are shown in the last two columns of Table 13. (A difference of ± 0.07 from 1.00 is necessary for significance. The LSD should be used when comparing coefficients of two hybrids.) Twenty-one white hybrids had b_I 's that were significantly greater than 1.00, indicating greater than average response to better environmental conditions, but poor performance in adverse environments. Seventeen white hybrids, the white check (K55 \times CI66)FR802W, and the yellow check hybrids B73 \times Mo17 and Pioneer Brand 3394 had environmental responses that were significantly less than 1.00.

IFSI 94-3 (151.0 bu/a, $b_I = 1.20$ bu/a/I) had a significantly higher yield than the average entry and a b_I that was significantly greater than 1.0. Other hybrids that yielded above 145 bu/a and that had a b_I significantly greater than 1.0 included Zimmerman Z64W (149.6 bu/a, $b_I=1.25$ bu/a/I), Pioneer Brand 3203W (148.4 bu/a, $b_I=1.16$ bu/a/I), Sturdy Grow SG777W (146.3 bu/a, $b_F=1.17$ bu/a/I), Trisler T-93W2 (146.0 bu/a, $b_I=1.12$ bu/a/I), and ICI Seeds 8317W (145.0 bu/a, $b_F=1.21$ bu/a/I). These would be good selections when a favorable environment was anticipated.

Usually, low responsiveness is associated with low mean yields. Exceptions are occasionally found that are high yielding and have a low b_I . Examples in this year's test include Cargill X7510W (160.3 bu/a, $b_I=0.88$ bu/a/I), the yellow check Pioneer Brand 3394 (148.6 bu/a, $b_F=0.80$ bu/a/I), and IFSI 90-4 (147.5 bu/a, $b_I=0.90$ bu/a/I). This type of response would be desirable where adverse conditions were frequently encountered.

The standard deviations of fit varied for similar environmental response coefficients. For example, the yellow check Pioneer Brand 3245 (160.0 bu/a, $b_I=1.00$ bu/a/I) and Wilson E954003 (114.8 bu/a, $b_I=1.00$ bu/a/I) had standard deviations of 6.1 and 27.5 bu/a, respectively. The yellow check Pioneer Brand 3245 would be expected to be a more predictable performer in response to varied environments than Wilson E954003.

In choosing a hybrid, all agronomic factors must be considered in relation to the anticipated environment. Data from several locations are usually more reliable than data from a single location evaluated for two or three years.

European corn borer susceptibility data for the 1995 WFCPT (Table 15)

First-generation leaf-feeding ratings were obtained at Grand Pass, MO. The planting at Novelty, MO, was infested, but subsequently discarded. Significant differences were found among entries. No entry was significantly better than the mean of all entries (3.2 rating). NC+ 7248W (5.0 rating) and one susceptible check for European corn borer, Ki3 (5.0 rating), were more susceptible to leaf-feeding damage than the average entry. Thirty entries had ratings for first-generation damage of 3.0 or less.

Significant differences among entries were also found for second-generation stalk-feeding data that were obtained at Grand Pass, MO. The yellow check Pioneer Brand 3394 (0.6 tunnels) had significantly fewer tunnels than the average entry, and Vineyard V442W, Pioneer Brand 3287W, and Vineyard V448W had 1.0 or fewer tunnels per plant. Vineyard V442W (0.8 inches) had significantly

less tunneling than the average for all entries. Two other entries had tunnel lengths of 1.0 inches or less: the yellow check Pioneer Brand 3394 (0.9 inches) and Pioneer Brand 3287W (1.0 inches). Three entries had significantly more tunnels than average, and of those, TN 95-1 had an average tunnel length greater than the average entry: TN 95-1 (3.4 tunnels, 4.3 inches), the yellow check B73 x Mo17 (3.3 tunnels, 3.8 inches), and Vineyard V58W (3.2 tunnels, 3.9 inches).

Two-, three-, four-, and five-year mean yields and agronomic performance (Tables 16 to 19)

Data were summarized for common entries in the last two, three, four, and five years of the WFCPT. Individual year means were averaged without weighting for the varying numbers of locations over the years when they differed. For the past five years, the number of locations with acceptable data ranged from 10 for 1995 to 12 for 1991-1994. Approximate values of 8 bu/a for the two-year means, 6 bu/a for the three-year means, 5.5 bu/a for the four-year means, and 5 bu/a for the five-year means could be used to compare yields of individual entries in the respective tables.

Among the hybrids included in the 1991 to 1995 tests (five-year means), the yellow check Pioneer Brand 3245 (170.6 bu/a), Northrup King N7580W (159.4 bu/a), Sturdy Grow SG798W (156.8 bu/a), and Pioneer Brand 3281W (156.5 bu/a) could be judged to yield significantly more than the average of other entries (151.5 bu/a). Relatively poorer performing over this period was DeKalb Genetics 739W (144.5 bu/a) and the white check (K55 x CI66)FR802W (126.0 bu/a).

For the four-year means, the yellow check Pioneer Brand 3245 (174.4 bu/a), ICI Seeds 8320W (164.6 bu/a), Northrup King N7580W (164.3 bu/a), Cargill 8097W (164.1 bu/a), Whisnand 51AW (163.1 bu/a), and Sturdy Grow SG798W (161.8 bu/a) would be judged above average. The yellow check Pioneer Brand 3245 yielded significantly more than any other entry in the five- and four-year means. Lower yielding than the average for all entries in the four-year means were Pioneer Brand 3287W (146.7 bu/a), DeKalb Genetics 739W (146.7 bu/a), DeKalb Genetics 742W (145.3 bu/a), and the white check (K55 x CI66)FR802W (129.6 bu/a).

Kernel quality evaluation of entries in the 1995 White Food Corn Performance Test (Table 20)

Milling quality of entries in the 1995 WFCPT was evaluated by the Illinois Crop Improvement Association, Inc. and Texas A & M University. Target values are a kernel weight of 37 g or more per 100 kernels, density equal to or exceeding 1.20 g/cc, and 90% or more horny endosperm. Significant differences among entries were found for all seven quality traits measured.

No hybrid exceeded the target value of 37 g/100 kernels and the mean for 1995 was only 30.6 g. Three hybrids had kernel weights significantly greater than the mean for all entries: DeKalb Genetics DK703W (34.2 g), Genetic Resources GRI94181 (33.7 g), and TN95-1 (33.6 g). Low 100-kernel weights are a reflection of lower yields experienced in 1995 and a trend towards smaller, more dense kernels. All hybrids and checks in the test had grain densities greater than or equal to 1.3 g/cc. DeKalb Genetics EXP566W (91%), IFSI 95-1 (90%), Pioneer Brand 3287W (90%), and Wilson E954004 (90%) met the desired 90% horny endosperm criterion. Seven hybrids had 89% horny endosperm, four had

88%, and three had 86%. It is possible that the Illinois Crop Improvement Association laboratory differs from The Quaker Oats Company, Barrington, IL, laboratory (original source of the 90% horny endosperm criterion) in judging this trait and that a lower target value reflecting current data would be acceptable to most processors.

1995 Early White Food Corn Performance Test

Yields in the EWFCPT ranged from 117.6 bu/a at Clay Center, NE, to 163.4 bu/a at Wanatah, IN, with an overall average for eight northern locations of 133.3 bu/a. This contrasts to the average yield of 180.0 bu/a in 1994, which was a record high for this test. Stands averaged 92.9% overall, ranging from 86.5% at Clay Center, NE, to 99.8% at St. Joseph, MO. Covariance adjustment of yield for stand was not done for 1995 data.

Root lodging averaged 1.8% at seven northern locations, ranging from 0.0% at Galesburg, IL, and Marion, IA, to 6.6% at Clay Center, NE. Five locations were under 1.4% and three locations had less than 0.4%. Stalk lodging ranged from 0.2% at Champaign, IL, to 16.1% at Clay Center, NE, averaging 6.5% for the seven northern locations with data.

Days to flowering were recorded only at Marion, IA, where the mean was 71.0 days. Harvest grain moistures averaged 19.3%. The Clay Center, NE, location had 15.0% moisture at harvest, while Gothenburg, NE, had 24.1% grain moisture at harvest.

Twenty-six white hybrids and the yellow checks B73 × Mo17 and Pioneer Brand 3394 were grown in both the WFCPT and EWFCPT. Further testing will determine the appropriate environments for testing each hybrid. There will be hybrids, however, that are intermediate to the maturity zones of the two tests and will continue to be entered in both tests.

The test was also grown at Knoxville, TN (Table 29), but data were not included in the combined analysis of the northern locations. Individual location data are shown in Tables 21 to 29 with the combined data in Table 30. Yield data from the eight northern locations are given in Table 31.

Combined agronomic data from eight northern locations (Table 30)

The average yield from eight northern locations was 133.3 bu/a compared to 180.0 bu/a in 1994 and 126.5 bu/a in 1993. Three white hybrids and one yellow check yielded significantly more than the mean of all entries (133.3 bu/a): Cargill X7513W (153.4 bu/a), Cargill X7512W (151.6 bu/a), the yellow check Pioneer Brand 3394 (147.7 bu/a), and Sturdy Grow SG765W (146.2 bu/a). Ten white hybrids and two yellow checks could not be statistically differentiated (yielded 140.5 bu/a or more) from Cargill X7513W. Included among entries that yielded significantly less than the average of all entries were Pioneer Brand X1134WG (114.1 bu/a), Purdue H126W/FR819W (116.2 bu/a), and LG Seeds NB739W (117.4 bu/a).

Differences among hybrids for stand percentage were relatively small. No entry was significantly better than the mean of all entries as that required an average stand of 97.5%. Only Pioneer Brand X1134WG (85.0%) had a significantly lower stand percentage than the mean for all entries.

Differences among entries for root and stalk lodging were significant. Forty-eight entries had less than 2% root lodging, but with an LSD of 3.1% and a mean of 1.8%, nothing could be significantly less than the mean for all entries. Significantly worse for root lodging than the average entry were LG Seeds NB710W (6.9%) and Cargill X7512W (5.5%). For stalk lodging, no entry was better than the mean for all entries (required 0.9% or less). Two entries had significantly greater amounts of stalk lodging than the average entry: Cargill X7512W (14.4%) and Cargill X7513W (13.0%).

Ear heights ranged from 35.5 inches for DeKalb Genetics 742W to 53.3 inches for Trisler T-95W1. Thirteen white hybrids and one yellow check were more than one LSD below the average of all entries: DeKalb Genetics 742W (35.5 inches), LG Seeds NB742W (36.3 inches), LG Seeds NB739W (36.5 inches), DeKalb Genetics 555W (37.1 inches), Sturdy Grow SG731W (38.4 inches), LG Seeds NB571W (38.6 inches), DeKalb Genetics EXP566W (38.6 inches), Hoegemeyer 1142W (41.9 inches), Vineyard V453W (42.0 inches), the yellow check Pioneer Brand 3394 (42.2 inches), Vineyard V438W (42.6 inches), Vineyard V449W (43.0 inches), Vineyard V414W (43.1 inches), and Pioneer Brand 3463W (43.4 inches). Seventeen white hybrids were significantly taller than the average entry.

The number of days to flowering was recorded only at Marion, IA. These data, however, together with grain moisture, give an indication of entries that are relatively late or early maturing in this test. Entries that were significantly earlier flowering and had significantly lower grain moisture than the average entry were Pioneer Brand 3463W (67.7 days, 16.5%), Pioneer Brand 3443W (67.7 days, 16.5%), DeKalb Genetics 555W (67.7 days, 16.7%), LG Seeds NB710W (68.7 days, 18.2%), LG Seeds NB571W (69.0 days, 16.7%), DeKalb Genetics EXP566W (69.3 days, 18.3%), and Purdue H126W/FR819W (69.3 days, 17.1%). Twenty-one white hybrids had moistures significantly exceeding the mean of 19.3% at harvest. Of these, Hoegemeyer 1142W (25.0%) was significantly wetter at harvest than any other entry.

The environmental response coefficients (b_I) and standard deviations of fit for the EWFCPT are shown in the last two columns of Table 30. (A difference of ± 0.21 from 1.00 is necessary for significance. The LSD should be used when comparing coefficients of two hybrids.) Twenty-one white hybrids had b_I s that were significantly greater than 1.00, indicating greater than average response to better environmental conditions, but poor performance in adverse environments. Of these, Cargill X7513W (153.4 bu/a, $b_I=1.24$ bu/a/I) and AgriGold XA3302W (145.7 bu/a, $b_I=1.28$ bu/a/I) had mean yields over 145 bu/a and a high b_I . These hybrids would be very responsive in good environments.

Nineteen white hybrids and one yellow check had environmental responses that were significantly less than 1.00. Usually, low response is associated with low mean yields. Hybrids can usually be found, however, that have high mean yield and that are less responsive to improved environments: yellow check Pioneer Brand 3394 (147.7 bu/a, $b_I=0.40$ bu/a/I) and Asgrow X757920W (140.3 bu/a, $b_I=0.52$ bu/a/I). Response of such hybrids as these, in particular, would be desirable where adverse conditions were frequently encountered.

The standard deviations of fit varied for similar environmental response coefficients. For example, Cargill X7513W (153.4 bu/a, $b_I=1.24$ bu/a/I) and Merschman M-3114W (134.4 bu/a, $b_I=1.24$ bu/a/I) had standard deviations of 8.3 and 18.9 bu/a, respectively. Cargill X7513W would be expected to be a more

predictable performer in response to varied environments than Merschman M-3114W.

European corn borer susceptibility data for the 1995 EWFCPT (Table 32)

First generation leaf-feeding ratings were obtained at Grand Pass, MO. The planting at Novelty, MO, was infested, but subsequently discarded. Significant differences were not found among entries, but 36 hybrids rated 3.0 or less, indicating resistance to first-generation damage.

Second generation stalk-feeding data were also obtained at Grand Pass, MO. No entry was significantly better than the mean for tunnel number or tunnel length. Thirty-four hybrids with less than 1.0 tunnels and less than 1.6 inches of tunneling would fall into the resistant category under conditions of this evaluation.

Two-, three-, four-, and five-year mean yields and agronomic performance (Tables 33 to 36)

Data were summarized for the last two, three, four, and five years of the EWFCPT. Year means were averaged without weighting for the varying numbers of locations over the years. For the past five years, the number of locations with acceptable data has ranged from four in 1992 to eight in 1995. Although an LSD cannot be directly calculated, approximate values of 11 bu/a for the two-year means, 8 bu/a for the three-year means, 7 bu/a for the four-year means, and 6.5 bu/a for the five-year means can be used to compare yields of individual entries.

For the five-year means, Cargill 8097W (159.6 bu/a), NC+ 6555W (159.4 bu/a), and IFSI 90-1 (158.0 bu/a) would be judged higher yielding than the average entry (151.5 bu/a). Pioneer Brand 3463W (140.1 bu/a), Hoegemeyer 1142W (143.8 bu/a), and DeKalb Genetics 742W (144.8 bu/a) were lower yielding than the average entry. Results from calculating four-year means showed that Sturdy Grow SG797W (162.0 bu/a), NC+ 6555W (161.8 bu/a), and Cargill 8097W (161.2 bu/a) yielded more than the mean for all entries. Relatively lower yielding than other entries were Pioneer Brand 3463W (140.9 bu/a), DeKalb Genetics 555W (143.5 bu/a), DeKalb Genetics 742W (144.4 bu/a), and LG Seeds NB742W (145.8 bu/a).

Kernel quality evaluation of entries in the 1995 Early White Food Corn Performance Test (Table 37)

Milling quality of entries in the 1995 EWFCPT was evaluated by the Illinois Crop Improvement Association, Inc. and Texas A & M University. Target values are a kernel weight of 37 g or more per 100 kernels, density equal to or exceeding 1.20 g/cc, and 90% or more horny endosperm. Significant differences were found among entries for all seven quality traits.

No hybrid met the 37 g/100 kernel target value, likely because of the lower yields experienced in 1995 and the trend towards a smaller, denser kernel type. Late planting and stress during grain filling also reduce kernel weight. Kernel weights significantly greater than that for the average entry were observed for DeKalb Genetics DK703W (33.5 g) and Hoegemeyer 1142W (32.5 g). All entries had kernel densities greater than 1.20 g/cc. Two hybrids had 90% or more horny endosperm: Vineyard 414W (93%) and Vineyard Vx4134W (91%). Two hybrids had horny endosperm percentages of 89, five

were observed at 88%, and one at 86%. As for the WFCPT, it is possible that the Illinois Crop Improvement Association laboratory differs from The Quaker Oats Company, Barrington, IL, laboratory (original source of the 90% horny endosperm criterion) in judging this trait and that a lower target value reflecting current data would be acceptable to most processors.
