Abstract

Cardiovascular disease (CVD) risk factors contribute to neuropathological changes within regions of the brain that are involved with both cognitive and motor control processes, and have been identified as potentially modifiable dementia and gait dysfunction risk factors. Exercise training is a corner-stone treatment for vascular risk factor control, and evidence suggests that physical and cognitive training can benefit cognition and gait; however, the exercise training modality that can provide the greatest cognitive benefit remains elusive. Therefore, the purpose of this thesis was three-fold: (i) to determine whether CVD risk factors and gait were associated with cognitive functioning, (ii) to determine whether blood pressure dipping status was associated with cognitive and gait impairments in community-dwelling older adults, and iii) to examine the impact of a dual-task gait training and aerobic exercise (DAE) on cognition, gait, and vascular health. Cumulative CVD risk was an independent predictor of executive functioning. Cross-sectional differences in cognition and usual and dual-task gait were observed between older adults with preserved blood pressure dipping and non-dippers. Last, 26-weeks of DAE training improved cognition and usual and dual-task gait, and the improvements in cognition were maintained for at least 6 months after the exercise program. The management of traditional and novel CVD risk factors should be a primary aim of prevention strategies aimed at mitigating cognitive decline. Although DAE training can benefit cognition and gait, further work is required to unequivocally determine the efficacy of DAE training as a method to improve brain health in older adults without dementia.

Keywords: cognition, dual-task exercise, vascular health, gait, QRISK2, blood pressure dipping

Co-Authorship Statement

Co-authors (Chapter 1): Dr. Gill and Petrella provided assistance with the design and format of the revisions to the document. Dr. Gill and Petrella also provided critical expertise and diligent reviews of the manuscripts prior to final submission for publication. Co-authors (Chapter 2): Dr. Gill, McGowan, and Petrella provided critical expertise and diligent reviews of the manuscript prior to final submission for publication. Dr. Gill was also consulted when designing the statistical analyses for this study. Dr. Liu-Ambrose, Hachinski, and Shoemaker contributed to the development of a research proposal that was funded as an Operating Grant by Canadian Institute of Health Research. Dr. Gill, McGowan, Shoemaker, Holmes, and Petrella also served as members of the thesis advisory committee, and helped to direct the design of the study and the analyses used therein.

Co-authors (Chapter 3): Dr. Gill, McGowan, and Petrella provided critical expertise and diligent reviews of the manuscript prior to final submission for publication. Dr. Gill was also consulted when designing the statistical analyses for this study. Dr. Liu-Ambrose, Hachinski, and Shoemaker contributed to the development of a research proposal that was funded as an Operating Grant by Canadian Institute of Health Research. Dr. Gill, McGowan, Shoemaker, Holmes, and Petrella also served as members of the thesis advisory committee, and helped to direct the design of the study and the analyses used therein.

Co-authors (Chapter 4): Dr. Gill, McGowan, and Petrella provided critical expertise and diligent reviews of the manuscript prior to final submission for publication. Dr. Gill was also consulted when designing the statistical analyses for this study.

Acknowledgements

First and foremost, I'd like to thank my supervisor Dr. Robert Petrella for providing me with support, direction, and copious academic opportunities throughout my time at Western. His guidance and insight into the world of academics has been irreplaceable, and I hope that our continued relationship will reinforce this bond as I continue with my future academic endeavors.

I would also like to thank Dr. Cheri McGowan and Dr. Dawn Gill. These two have always made themselves selflessly available and went above and beyond what could ever be reasonably expected from an individual in order to offer assistance whenever it was asked of them. I will always consider myself fortunate for having had the opportunity to work with these two amazing people, and hope to continue this in the future.

I must also acknowledge and thank the members of my thesis committee, Dr. Kevin Shoemaker and Dr. Jeff Holmes, as well as an additional member of my comprehensive examination committee, Dr. Andrew Johnson. The guidance and support that these individuals provided throughout the design and composition of these documents has been greatly appreciated.

I am also very grateful to our collaborators, Dr. Teresa Liu-Ambrose, Dr. Royosuke Shigematsu, Dr. Adrian Owen, Dr. Lindsay Nagamatsu, and Dr. Matt Heath. Their guidance and technical expertise has been a dependable and irreplaceable source of support throughout the past four years.

I must also take a moment to acknowledge all of my past and present lab mates, Noah Koblinsky, Heather Morton, Melanie Stuckey, Emily Knight, Sam Titheridge, John Bocti, Amada Deosaran, Erin Shellington, Claire Riley, Ashleigh DeCruz, Narlon Boa Sorte Silva, Steph Muise, Tina Felfeli, and all of the clinical trials and the administrative personnel that have work with Dr. Petrella. These individuals made the past four years as enjoyable of an experience as anyone could ever hope for, and for that I will be forever grateful.

I would like to thank my friends, Sarah Williams, Joel and Ryan Lodewegan, Mark Bachynski, Jay Hallatt, Craig Leightenberger, Brady, Dave, and Lynda Krzemein, and especially Corey Baker and Brianna Evans. Your homes were always open, the beers were (mostly) always cold, and your friendship, support, and constant belief in my ability to succeed have been irreplaceable sources of comfort and motivation while I have pursued my academic goals. And of course, I could not have accomplished anything without the unconditional support from my extended family. Your love has been a constant source of inspiration and motivation throughout my entire academic career, and I could never have done it without you all.

Finally, and most importantly, I would like to thank my family; my mother Jean, father Richard, sister Michelle, brother Sean, grandparents George and Jean Pollock and Jim and Joan Gregory, and my loving fiancée Damjana. Thank you all for your persistent encouragement, unconditional support, and love. Sean, you always have and continue to be a role model and a constant source of inspiration. Michelle, you have always been there to help whenever I've asked, I could never thank you enough. Mom and Dad, I could not have asked for more loving and selfless parents. Your values have molded me into the person that I am today, and for that I will be eternally grateful. And Damjana, you are one of the sweetest and toughest people I've ever known. I could never have done this without your selflessness and support throughout the final stages of the dissertation, and for that I will be forever grateful. Fortune has not only provided me with a loving fiancée, but also a devoted partner and a best friend, and even over a lifetime I will never be able to thank you for all that you've done. Volim te.

1   **The Burden of Cognitive Impairment and Dementia**

2   With the global population aging, there is a growing urgency to identify the most

3   effective strategies to prevent cognitive decline. In 2015, approximately 46 million older

4   adults worldwide were diagnosed with dementia, and by 2050 this number is expected to

5   reach 131.5 million (Prince et al., 2015). This projected increase in dementia cases

6   imposes an economic burden that is expected to reach a trillion dollars as early as 2018

7   (Prince et al., 2015). Moreover, the incidence of individuals exhibiting some form of

8   cognitive impairment, but not having met the diagnostic criteria for dementia (i.e., mild

9   cognitive impairment, MCI; or cognitive impairment – not dementia, CIND), is two-fold

10   greater than that for Alzheimer's disease (AD) and related dementias (Plassman et al.,

11   2011). Prior to the establishment of identifiable objective cognitive impairment, some

12   individuals are able to perceive recognizable changes/reductions in their cognitive

13   functioning and are able to identify and communicate these difficulties through the report

14   of subjective cognitive complaints. Due to the associated stigma and widespread under-

15   reporting of cognitive difficulties to general practitioners (Waldorff, Siersma, Vogel, &

16   Waldemar, 2012), the estimated prevalence of cognitive complaints in older adults ranges

17   between 11% and 56% (Jonker, Geerlings, & Schmand, 2000; Jorm, Christensen, Korten,

18   Jacomb, & Henderson, 2001; Waldorff et al., 2012). Cognitive complaints have been

19   associated with poorer scores on objective cognitive assessments (i.e., executive

20   functioning; EF; Amariglio, Townsend, Grodstein, Sperling, & Rentz, 2011; Benito-

21   Leon, Mitchell, Vega, & Bermejo-Pareja, 2010; Clarenette, Almeida, Forstl, Paton, &

22   Martins, 2001; Genziani et al., 2013), as well as cortical and hippocampal atrophy

23   (Saykin et al., 2006), and each identified cognitive complaint increases the likelihood of

24   developing cognitive impairment by approximately 20% (Amariglio et al., 2011). Hence,

25   it is of interest to examine older adults who demonstrate a wide range of cognitive

26   abilities (i.e., those with healthy cognition, and subjective or objective cognitive

27   difficulties) in order to understand the progression of the disease, and identify which

28   populations are best suited for intervention efforts (Jessen et al., 2010; Jessen et al.,

29   2014).

30   **Vascular Disease and the Establishment of Geriatric Conditions**

31   The term vascular cognitive disorders has been established to identify older adults

32   who exhibit cognitive impairments that primarily occur as a result of the accumulation of

33   vascular-related brain pathology (i.e., white matter hyperintensities, subcortical

34   microangiopathy, lacunar infarcts) in addition to other AD biomarkers (i.e., beta amyloid,

35   phosphorylated-tau, impaired glucose metabolism; Jellinger, 2013; Sachdev et al., 2014).

36   Individuals with vascular cognitive disorder are identified according to two core criterion:

37   i) the presence of a subjective cognitive complaint and objective cognitive deficits, and ii)

38   vascular disease is the dominant, if not exclusive cause of the cognitive impairment

39   (Sachdev et al., 2014). Vascular dementia is the second leading form of dementia in

40   Western nations, and the leading cause of dementia in the Orient (Fratiglioni, De Ronchi,

41   & Agüero-Torres, 1999). Indeed, vascular-related brain pathology is common; the

42   prevalence of unsuspected infarction of the cerebral deep small vessels ranges from 15%

43   (Bryan et al., 1999) to 28% (Price et al., 1997), and lesions within the deep subcortical

44   and periventricular white matter were present in 95% of the participants from the

45   neuroimaging extension of the Rotterdam study (de Leeuw et al., 2001). The

46   accumulation of vascular brain injury and the development of white matter lesions within

47   the frontal-subcortical regions of the brain impact the functional integrity of the

48   neurocircuitry within and between these regions (Pugh & Lipsitz, 2002). The frontal-

49   subcortical circuits that control both cognitive and motor processes are located in close

50   proximity; thus, small vascular lesions that accumulate within this region may

51   simultaneously cause dysfunction in both systems (Pugh & Lipsitz, 2002).

52   **Vascular Disease and Cognitive Impairments in Aging**

53   Cardiovascular disease (CVD) risk factors negatively influence brain health and

54   functioning in aging (Pugh & Lipsitz, 2002). Specifically, atherosclerosis and poor blood

55   pressure (BP) control are strongly associated with long-term risks of cognitive

56   impairment (Brickman et al., 2012; Launer, Masaki, Petrovich, Foley, & Havlik, 1995;

57   Moon et al., 2015). Elevations in BP and the associated arterial stiffening reduce

58   cerebrovascular reactivity and cerebral blood flow (Akinyemi, Mukaetova-Ladinska,

59   Attems, Ihara, & Kalaria, 2013; Brickman et al., 2010), predisposing older adults to

60   greater risk of cortical hypoperfusion (Akinyemi et al., 2013; Cohen, 2007; Dai et al.,

61   2008). These CVD risk factors also contribute to the establishment and presence of

62   cerebrovascular disease (Knopman et al., 2001), and have also been implicated as

63   potential risk factors for white matter lesions (Dufouil et al., 2001; Knopman et al., 2001).

64   Furthermore, sustained hypertension is the primary risk factor for stroke (O'Donnell et

65   al., 2010), and has been associated with hippocampal atrophy (Korf, White, Schelten, &

66   Launer, 2004; Brickman et al., 2015), the presence of neurotropic markers of AD

67   (Petrovitch et al., 2000; Langbaum et al., 2012; Rodrigue et al., 2013) and clinical

68   dementia (Launer et al., 2000; Xu et al., 2015). Arterial stiffness has also been

69   independently associated with presence of brain lesions (i.e., white matter

70   hyperintensities, lacunar infarcts, amyloid plaques, etc.; O'Rourke & Safar, 2005; Tsao et

71   al., 2013; Hughes et al., 2014; King, 2014; Nation et al., 2013; Singer, Trollor, Baune,

72   Sachdev, & Smith, 2014), and has been implicated as a risk factor for AD and dementia

73   (Vernooij et al., 2008; Tsao et al., 2013; Xu et al., 2015). Associations between CVD risk

74   factors and objective cognitive functioning have also been observed. Lower scores on the

75   Montreal Cognitive Assessment (MoCA) have been associated with increasing age, lower

76   levels of formal education, and the presence of a greater number of CVD risk factors. For

77   instance, the mean MoCA score among CVD populations has been reported as low as

78   22.8 +/- 2.3, with 72.1% of the population under investigation having scored below the

79   cut-off for cognitive impairment (< 26) (McLennan, Mathias, Brennan, & Stewart, 2011).

80   Aggregate CVD risk has also been associated with EF; a recently published study

81   observed a significant association between higher Framingham Cardiovascular Risk

82   scores and greater task-related activation within the left inferior parietal lobe and poorer

83   Flanker-task performance in community-dwelling older adults (Chuang et al., 2014).

84   These observations suggest that cardiovascular health and the presence of CVD risk

85   factors appear to be intimately linked with brain health in aging.

86   **Vascular Disease and Mobility Impairments in Aging**

87   Vascular brain injury (i.e., stroke) and vascular risk factors (i.e., hypertension)

88   have been associated with mobility and balance impairments in older adults. Gait

89   disorders are prevalent among those with pre-existing CVD (i.e., stroke) (Hajjar et al.,

90   2009) and CVD risk factors (i.e., hypertension) (Annweiler & Montero-Odasso, 2012),

91   and this relationship appears to be mediated by the presence of subclinical

92   cerebrovascular abnormalities (Rosano, Brach, Studenski, Longstreth, & Newman, 2007).

93   For instance, a recent review has revealed a persistent association between periventricular

94   white matter lesions and gait dysfunction in the elderly, where gait speed, stride length,

95   and stride time were consistently associated with white matter hyperintensity burden

96   (Annweiler & Montero-Odasso, 2012). Furthermore, a higher white matter lesion burden

97   has also been associated with increased gait variability (i.e., the stride-to-stride

98   fluctuations in spatiotemporal gait parameters) in community-dwelling older adults

99   (Rosano et al., 2007), a gait parameter that is considered a significant falls risk factor and

100 index of incident mobility (Brach, Berlin, VanSwearingen, Newman, & Studenski, 2005;

101 Hausdorff, Rios, & Edelberg, 2001).

102   Taken together, it appears that aging and the accumulation of cardiovascular

103 disease risk factors negatively impact brain health and function, and contribute to the

104 establishment of vascular-related brain injuries within regions of the brain that are

105 essential for healthy cognitive and motor control (Pugh & Lipsitz, 2002). However, as

106 CVD risk factors appear to contribute to the development of white matter lesions, frontal-

107 subcortical dysfunction, and the presence of cognitive and mobility impairments, these

108 significant geriatric conditions are potentially preventable. Although there is an

109 increasing consensus on the role of CVD risk factors in the development of vascular brain

110 injury and cognitive and mobility impairments, few studies have investigated the

111 cognitive and mobility benefits associated with interventions that hold the potential to

112 modify vascular risk in either healthy older adults, or those with cognitive impairments

113 (Naqvi, Liberman, Rosenberg, Alston, & Straus, 2013). Despite the paucity of available

114 research, interventions aimed at mitigating CVD risk factors burden and their impact on

115 the development of cerebrovascular disease may substantially contribute to the prevention

116 of cognitive and mobility impairments in aging (Pugh & Lipsitz, 2002). Indeed, this

117 theory has begun to gain traction; recent observations implicate the successful treatment

118   of CVD risk factors as a primary mechanism responsible for recent reductions in the

119   global incidence of dementia (Langa, 2015), while the pharmacological management of

120   hypertension has led to a reduced risk for MCI (Gelber et al., 2013; Yasar et al., 2013)

121   and AD (Yasar et al., 2013). Despite these promising initial observations, there is a

122   necessity to further investigate the effect of interventions that are aimed at concurrently

123   reducing CVD risk and improving cognition and mobility in older adults.

124   **The Prevention of Cognitive Impairment in Aging**

125   The trajectory of pathological cognitive decline in aging suggests that there are

126   many forms in which cognitive impairment can manifest, and there is a natural

127   progression from normal or "healthy" cognitive aging through to the development of

128   cognitive impairment and dementia (Sperling et al., 2011). Currently, there is no known

129   cure for AD or other dementias; thus, identifying tolerable, feasible, effective, and

130   scalable interventions that are aimed at mitigating the burden of age-related chronic

131   disease risk and cognitive decline is imperative. Developing interventions that could

132   produce modest delays in the onset of cognitive decline could significantly reduce this

133   economic and societal burden; specifically, a 5-year delay in the onset of cognitive

134   decline could translate to a 50% reduction in the incidence of dementia after several

135   decades (Brookmeyer, Johnson, Ziegler-Graham, & Arrighi, 2007; Camelli, Swan,

136   LaRue, & Eslinger, 1997). Thus, developing early prevention strategies for cognitive and

137   functional decline may provide the greatest impact on the incidence of cognitive

138   impairment in aging (Sperling et al., 2011; Jessen et al., 2010; National Institute of Aging

139   & National Institutes of Health, 2014; Stewart, 2012).

140   **Vascular Risk Factor Control to Prevent Cognitive Impairment in Aging**

141   A recent population-based study reported reductions in the incidence of dementia

142   among high-income nations (Langa, 2015), and these findings have been attributed to

143   advances in the treatment of vascular risk factors and an increased awareness of the

144   importance of preserving vascular health for the prevention of chronic conditions in

145   aging. Despite this promising trend, chronic CVD remains the leading cause of global

146   mortality (World Health Organization, 2012) and continues to contribute to cognitive

147   decline and the development of AD and related dementias. Cognitive and functional

148   impairments are common among individuals with established CVD risk; in fact, it is

149   estimated that 3% and 5% of worldwide AD cases are due to diabetes and hypertension,

150   respectively, while an additional 13% of AD cases can be attributed to physical inactivity

151   (Norton, Matthews, Barnes, Yaffe, & Brayne, 2014). Thus, developing interventions that

152   are specifically designed to mitigate CVD risk while providing a simultaneous benefit to

153   the health and functioning of the brain may provide an opportunity to halt the

154   development of significant vascular-related neuropathological changes to the brain.

155   Exercise training benefits cardiovascular fitness and can help to mitigate CVD risk factor

156   burden (Pescatello et al., 2004; Seals, Desouza, Donato, & Tanaka, 2008), and

157   surmounting evidence implicates exercise training as a method to benefit brain health and

158   functioning. These observations suggest that exercise-based interventions may be one of

159   the most effective strategies to reduce the risk of cognitive impairment by providing a

160   stimulus that can synchronously improve cardiovascular and cognitive health. However,

161   there is currently a paucity of data related to the impact of exercise-related changes

162   vascular health on brain structure and function (Tarumi & Zhang, 2014), and the

163   association between vascular health and functioning, cognition, and the risk for dementia

164   in aging remains equivocal (Barnes, 2015).

165   **Exercise Training and Cognition in Older Adults – the Current State of the**

166   **Evidence**

167   With the suggestion that lifestyle modifications may be the best method to prevent

168   cognitive decline (Daviglus et al., 2011; Lehert, Villaseca, Hogervorst, Maki, &

169   Henderson, 2015; Norton et al., 2014), the examination of the effect of exercise on brain

170   health and functioning has received considerable attention. Previously, our group

171   presented a review of the state of the evidence regarding the effect of exercise on brain

172   health and functioning among older adults with and without objective cognitive

173   impairment (Gregory, Gill, & Petrella, 2013). In the current review, the previous findings

174   will be expanded using recently published literature that has further described the effect

175   of exercise on brain health and functioning in older adults (Table 1.1). The relationship

176   between traditional exercise training programs (i.e., aerobic, resistance, and cognitive

177   training, combined and dual-task program) and cognition in community-dwelling older

178   adults is discussed. Lastly, the current state of the evidence is critically reviewed,

179   limitations within the current literature base are highlighted, and suggestions regarding

180   future directions for research are described (Table 1.2).

181   *Aerobic Exercise and Brain Health in Aging*

182   Leading a physically active lifestyle that involves the participation in aerobically-

183   based exercise training has been suggested as a method to prevent cognitive impairment

184   and dementia (Daviglus et al., 2011; Lehert et al., 2015; Naqvi et al., 2013). Although

185   these suggestions are promising, a recent Cochrane review concluded that there is a

186   paucity of evidence concerning the ability of aerobic exercise to benefit or improve

187   cognition in older adults, even in instances when the intervention lead to improvements in

188   cardiorespiratory fitness (Young, Angevaren, Rusted, & Tabet, 2015). This is despite an

189   exhaustive amount of literature that supports the notion that aerobic exercise (AE)

190   training can improve vascular function and reduce CVD risk, and also benefit the health

191   and functioning of the aging brain.

192   Observational studies have demonstrated that compared to sedentary age-matched

193   peers, individuals who are more physically active demonstrate greater cognitive

194   performance and are less likely to experience cognitive decline and dementia in later life

195   (Barnes, Yaffe, Satariano, & Tager, 2003; Johnson et al., 2016; Rovio et al., 2005;

196   Tierney, Moineddin, Morra, Manson, & Blake, 2010; Weuve et al., 2004; Wilbur et al.,

197   2012). Others have identified a link between higher cardiorespiratory fitness (i.e., VO2

198   max) and preserved brain structure (i.e., gray matter and hippocampal volume) and

199   function (i.e., white matter integrity) in aging (Colcombe et al., 2004; Teixeira et al.,

200   2016; Varma, Tang, & Carlson, 2016). Recent observations further this notion, as a

201   greater frequency, cumulative duration, and total amount of low-intensity daily walking

202   exercise have each been independently associated with increased total hippocampal

203   volume (Varma, Chuang, Harris, Tan, & Carlson, 2015), and navigation-based daily

204   walking exercise has been associated with increased volume within the subiculum of the

205   hippocampus (Varma et al., 2016) in cognitively healthy community-dwelling older

206   adults. The high accessibility and relatively low-cost and skill requirements of AE (e.g.,

207   walking, jogging, running, cycling, and swimming) are key components that have made

208   this exercise modality the primary focus of research and has thus, resulted in the

209   collection of the most robust evidence related to the effects of exercise on the aging brain.

210   Previous meta-analyses have concluded that AE training can indeed benefit

211   cognition, specifically EF (Colcombe & Kramer, 2003; Hindin & Zelinski, 2012),

212   information processing speed (Colcombe & Kramer, 2003; Smith et al., 2010), attention

213   and memory (Smith et al., 2010) in cognitively healthy older adults, and can benefit

214   verbal fluency (Gates, Fiatrone Singh, Sachdev, & Valenzuela, 2013) and general

215   cognitive functioning (Heyn, Abreu, & Ottenbacher, 2004) in older adults with objective

216   cognitive impairment. Several more recent reviews have led to some speculation around

217   the results and conclusions of these previous studies, as Kelly and colleagues (2014b) and

218   the above-noted recent Cochrane review (Young et al., 2015) failed to identify a

219   significant effect for AE training on any cognitive outcome. The inconsistencies in the

220   reported effect of AE on cognition can be attributed to an increase in the number and the

221   quality of the studies available for inclusion, the heterogeneity in the design of the studies

222   (i.e., the specific neuropsychological outcomes used, the intensity, frequency, and total

223   duration of the interventions, etc.) and the low statistical power of the interventions

224   included in these meta analyses. Although these studies span over a decade, the

225   recommendations that conclude each of these meta-analyses have followed a consistent

226   theme: i) the need for higher-quality interventions, ii) examine the cognitive effect of AE

227   interventions of various intensity and duration, iii) the identification and incorporation of

228   appropriate control groups, and iv) the examination of the maintenance of the effects (i.e.,

229   inclusion of follow-up periods). Thus, it appears that the effect of AE training on

230   cognitive functioning in older adults with and without objective cognitive impairment

231   will remain equivocal until a sufficient quantity of high quality interventions are

232   developed and evaluated.

233

Table 1.1

Key Features of the Reviewed Studies Examining the Effect of Exercise on Cognition In Older Adults.

Aerobic training and cognitive health					
Study	Design	Sample	Treatments	Outcome(s) & Measure Used	Main Findings
Colcombe *et al.,* (2004)	6 month RCT	29 high-functioning community-dwelling adults 65.6 ± 5.66 years 62% female	Intervention: Progressive walking 40-70% HRR Control: Stretching & toning 40-45 min/day, 3 days/week	Brain structure & activation: fMRI EF: Flanker Task	• Improved EF • Increased recruitment of parietal and frontal cortical regions necessary for successful task completion • Reduced activity in behavioural conflict and attentional control processing areas • The neurocognitive benefits of exercise can manifest in a relatively short time period (6 months) in aging humans
Colcombe *et al.,* (2006)	6 months RCT	59 Sedentary community-dwelling older adults 65.5 years 53% female	Intervention: Progressive walking 40-70% HRR Control: Stretching & toning 60 min/day, 3 days/week	Brain structure: MRI	• Elevated prefrontal and parietal cortical volume following aerobic training • The AE group had 27-42% less risk for brain volume loss compared to the control
Lautenschlager *et al.,* (2008)	6 month RCT	138 older adults with subjective memory complaints, or MCI 68.6 ± 8.7 years 50.5% female	Intervention: Individualized progressive walking & aerobics Control: Education & usual care 50 min/day, 3 days/week, accumulating 150 min/week	Dementia: ADAS-Cog	• Improved scores on ADAS-Cog scale occurred in older adults with subjective and objective MCI • The cognitive benefits present following 6 months of exercise can be maintained for ≥ 12 months in older adults with MCI
Williamson *et al.,* (2009)	12 month RCT	102 cognitively healthy sedentary older adults MMSE ≥ 21 76.8 ± 4.37 years 72% female	Intervention: Comprehensive fitness program that emphasised AE & walking Control: Health education	Global cognitive health: MMSE Cognitive flexibility, processing speed, & inhibition or disinhibition: Modified Stroop task Psychomotor speed & working	• Improvements in psychomotor speed and information processing were correlated with improved physical fitness

			2-3 days/week, achieving ≥150 min/week	memory: DSST Short- & long-term verbal memory: Rey's AVLT	
Baker *et al.*, (2010)	6 months RCT	33 older adults with aMCI 70.4 ± 8.33 years 52% female	Intervention: High-intensity AE using a treadmill, stationary bicycle, or elliptical trainer 85% HRR Control: Stretching 45-60 min/day, 4 days/week	EF: TMT B, Task Switching, Verbal Fluency, & Symbol-Digit modalities Memory: List learning Declarative memory: Story recall Visual memory: Delayed-Match-To-Sample Attention & response inhibition: Stroop CWT	• Women experienced significant improvements in multiple measures of EF • Males experienced improvements in EF, specific for TMT B • High-intensity AE-based exercise can improve EF in individuals with aMCI
Voelcker-Rehage *et al.*, (2011)	12 month RCT	44 cognitively healthy community-dwelling older adults MMSE ≥ 27 69.64 ± 3.84 years	Intervention: Progressive walking at spiroergometry exercise testing-based gas exchange threshold Control: Coordination training using exercise balls, twist boards, fitness balls, jump ropes, exercise bands, and stability boards 60 min/day, 3 days/week	Brain structure & activation: fMRI EF: Modified Flanker task Perceptual Speed: Visual Search Task	• Aerobic and coordination training differentially improve EF, performance accuracy, and speed in older adults • Reduced brain activation was associated with increased O_2 supply following 12 months of AE training • Improvements in brain activation were linear and did not plateau during the 12 month intervention
Erickson *et al.*, (2011)	12 month RCT	120 community-dwelling older adults 66.5 ± 5.63 years 67% female	Intervention: Progressive walking 60-75% HRR Control: Stretching & toning 40 min/day, 3 day/week	Brain structure: MRI Neural health: circulating BDNF Memory: Computerized spatial memory task	• 1 year of progressive walking can improve or reverse age-related reductions in anterior hippocampus volume • Increases in hippocampal volume are associated with elevated circulating BDNF and improved spatial memory in late adulthood

Uemura *et al.,* (2012)	12 month RCT	100 older adults with MCI 75.3 ± 6.8 years 51% female	Intervention: Moderate-intensity (60% HR_{max}) AE with strength and stretching 90 min/day, 2 days/week Control: Educational control, involving participation in 3 classes about health promotion over the course of the intervention	Blood markers and Blood Pressure: TC, HDL-C, TG, HbA1c, seated resting BP Physical fitness: 6MWT	• Improvements in physical fitness and reductions in TC and TC-HDL-C risk ratio were observed following the intervention • Exercise training can benefit vascular risk factor profiles in older adult with MCI
Nagamatsu *et al.,* (2013)	6 month RCT	86 older women with subjective memory complaints 74.9 ± 3.5 years	Interventions: Progressive AE involving walking 40% HRR at baseline, progressed to 70-80% HRR at 12 weeks Free weight and machine based RT of 7 muscle groups, progressed using the 7RM method 2 sets, 6-8 reps Control: Balance & toning 60 min/day, 2 days/week	Verbal learning & memory: Rey's AVLT total acquisition, recall after interference, loss after interference, and delayed recall Spatial memory: Customized, computer-based task, requiring participants to recall the spatial location of objects; reaction time and accuracy Physical performance: (SPPB Cardiovascular capacity: 6MWT	• There were no between group differences in total acquisition, recall after interference, delayed recall, or spatial memory task accuracy following the intervention • Loss after interference was reduced by 43.4% and 32.5% following AE and RT, respectively, but only the reduction following AE was significantly different than the BAT control • Reductions in loss after interference were not apparent at 3 months • Compared to BAT, improved reaction time to the spatial memory task were observed following AE and RT • Spatial memory task reaction times were positively associated with SBBP performance following AE
Ten Brinke *et al.,* (2014)	6 month RCT	86 older women with MCI MMSE > 24 MoCA < 26 74.9 ± 3.5 years	Interventions: Progressive AE involving walking 40% HRR at baseline, progressed to 70-80% HRR at 12 weeks	Hippocampal volume: MRI Verbal learning & memory: Rey's AVLT	• Compared to the balance and toning control, AE was associated with increased left, right and total hippocampal volume • Increased left hippocampal volume was correlated with

			Free weight and machine based RT of 7 muscle groups, progressed using the 7RM method 2 sets, 6-8 reps Control: Balance & toning 60 min/day, 2 days/week		- poorer performance on verbal learning and memory tasks - The influence of exercise-induced changes in hippocampal volume on memory performance in older adults with MCI remains equivocal
Maass *et al.,* (2015)	3 months non-randomized controlled trial	40 previously sedentary older adults 68.4 ± 4.3 years 55% female	Intervention: Progressive treadmill-based AE 65% target HR, increased by 5% every week for 4 weeks 30 min/day, 3 days/week Control: Relaxation & stretching 45 min/day, 2 days/week	Global cognitive health: MMSE Memory: VLMT, Complex Figure Test Brain structure & function: Perfusion imaging, MRI	3 months of progressive, treadmill-based AE increased hippocampal perfusion and volume - Structural and functional changes within the hippocampus are correlated with improvements in cardiorespiratory fitness and memory
Varma *et al.,* (2015) Varma *et al.,* (2016)	Cross-sectional	92 cognitively healthy community-dwelling older adults 67.3 ± 6.1 years 70% female 89% African American 90 cognitively healthy community-dwelling older adults 67.3 ± 6.0 years 70% female 89% African American (MMSE >26)	Assessed the association between objectively measured low-intensity daily walking activity and hippocampal volume	Daily walking activity: Total amount, duration, and frequency collected using Accelerometry for 3-7 days Hippocampal volume: MRI	- A higher frequency, duration, and total volume of low-intensity daily walking activity were each independently associated with increased total hippocampal volume and increased subiculum surface area among older women, but not men - Navigation-based low-intensity daily walking may provide specific benefits to sub-regions of the hippocampus - Low-intensity, non-exercise based lifestyle activities can benefit the structure of regions of the brain that are susceptible of Alzheimer's disease pathology

Resistance training and cognitive health					
Study	Design	Sample	Treatments	Outcome(s) & Measure Used	Main Findings
Perrig-Chiello *et al.,* (1997)	2 month RCT	46 older adults from the Interdisciplinary Aging Study 73.2 years 39% female	Intervention: 10 min warm-up 8 machine-based resistance exercises that focus on the major muscle groups Control: Unspecified 1 day/week	Memory: Immediate and delayed recall (8, two-syllable words) & recognition (original list + 8 distractor words) Cognitive speed: WAIS-revised digit-symbol subtest	• Improvements in delayed recall and immediate recognition following 2 months of RT • Improvements in free recall persisted up to 1 years post-intervention mechanisms influencing cognitive health following RT remain equivocal
Lachman *et al.,* (2006)	6 month RCT	210 community-dwelling older adults with ≥1 disability from the Short Form Health Survey physical-function scale 75.32 ± 7.37 years 77.6% female	Intervention: Home-based video-taped RT program consisting of 10 band exercises that focusing on movements used for functional activities Control: Wait-list control 35 min/day, 3 days/week	Memory: WAIS backwards digit span	• Changes in resistance level throughout the intervention was a significant predictor of memory change in the RT group • Strength training can benefit memory among older adults, especially when using higher resistance levels

Cassilhas *et al.,* (2007)	6 month RCT	63 cognitively healthy, sedentary older males (MMSE ≥ 24)
		
		68.71 ± 0.84 years
		sex undisclosed
			Interventions: *2 groups*
			ACSM guidelines for RT in seniors at *one of two* intensities:
			
			I) *Moderate intensity*
			  50% 1RM
			
			II) *High Intensity*
			  80% 1RM
			
			2 sets, 8 reps each set
			
			Control:
			Stretching & toning
			
			60 min/day, 3 days/week
				Central EF:
				WAIS-III similarities
				
				Short-term Memory:
				WAIS-III digit span forwards & backwards
				
				Visual modality of short-term memory:
				Corsi's block-tapping task forward and backward
				
				Long-term, episodic memory:
				Rey-Osterrieth complex figure test
				
				Attention:
				Toulouse-Pieron's concentration attention test
					• Both RT groups outperformed the controls on measures of short and long term memory
					• High intensity RT, but not moderate intensity RT, was also associated with better performance on measures of central EF and attention compared to the controls
					• Significant correlations were observed between elevations in circulating IGF-1 and improved cognitive performance following the intervention
					• Moderate- and high-intensity RT can impart beneficial effects on cognitive functioning in previously sedentary older adults
					• High intensity RT may be required to produce a greater IGF-1 response and stimulate

					changes in EF
Liu-Ambrose *et al.,* (2010)	12 month RCT	155 community-dwelling women 69.6 ± 2.9 years	Intervention: *2 RT groups* Machine-based and free weight RT (7 exercises focusing on major muscle groups) 2 sets, 8-10 reps each *I) 60 min/day, 1 day/week* *II) 60 min/day, 2 days/week* Control: Balance & toning 60 min/day, 2 days/week	Brain structure: MRI *Executive functions* Attention and conflict resolution: Stroop task Set-shifting: TMT A & B Working memory: WAIS-revised verbal digit span forwards & backwards	• 12 months of progressive RT once or twice-weekly can impart beneficial effects executive cognitive function, selective attention, and conflict resolution in comparison to a twice-weekly balance and toning group • However, reductions in brain volume were observed in both training groups • More research is needed to discern the effects of RT on cognitive health in older women
Anderson-Hanley *et al.,* (2010)	1 month Quasi-experimental design	16 community-dwelling older adults 72.1 ± 10 years 19% female	Intervention: Community-based exercise class focusing on chair and standing exercises using small free weights ("Strong Bones" Program, Tufts University) Control: Wait-list control 45 min/day 2-3 days/week	EF: WMS-III digit span backwards subtest, Stroop tasks C, & Colour Trails 2 Processing speed: WMS-III digit span forward, Stroop tasks A & B, colour trails 1, & letter-digit substitution test	• RT can benefit EF in community-dwelling older adults • Benefits of training were specific for measures of verbal fluency rather than global EF suggesting that specific aspects EF may be differentially affected by a specific exercise modality
Yerokhin *et al.,* (2012)	2.5 month Non-randomized clinical trial	13 older adults with early dementia (physician identified) 79.3 ± 11 years 9 cognitively healthy controls 62.8 ± 7.2 years	Intervention: Community-based exercise class focusing on chair and standing exercises using small free weights ("Strong Bones" Program, Tufts University 45 min/day, 3-5 days/week	Brain activity: EEG *Executive functions* Selective Attention & cognitive flexibility: Stroop task C, Colour Trails 2, WAIS-III digit span backwards *Memory* Immediate & delayed recall: Fuld Object Memory Evaluation Visuospatial skill & memory: Rey-Osterrieth and Taylor complex	• Improvements in verbal memory coincided with frontal beta and delta power asymmetries, and N200 amplitude asymmetry following RT • Improvements in cognitive efficiency were observed following 6 weeks of RT in older adults with early dementia • Changes in neurophysiology may occur more quickly than changes in neuropsychological performance following RT

				figure recall	
Xu *et al.,* (2014)	Cross-sectional	59 community-dwelling older adults MMSE ≥ 26 66.7 ± 9.6 years 57.6% female	Assessed the association between self-reported levels of RT and cerebral perfusion	Resting cortical blood flow: MRI Physical activity: Rapid Assessment of Physical Activity Questionnaire	• Compared to men, women demonstrated greater cerebral perfusion • Women who engaged in strength training ≥ 1 day/week had greater resting cerebral perfusion than those who did not • There was no relationship between physical activity and resting cerebral perfusion among men • There was no relationship between AE and resting cerebral perfusion
Iuliano *et al.,* (2015)	3 month RCT	80 community-dwelling older adults 67.0 ± 11.7 years 60% female	Interventions: I) Machine-based RT (exercises focused on 6 major muscle groups), progressed from 60-70% 1RM (weeks 1-4, 3 sets with 12 reps) to 80-85% 1RM (weeks 9-12, 3 sets with 6 reps) II) Treadmill- or ergometer-based AE, progressed from 50-60% HRR (weeks 1-2) to 70-80% HRR (weeks 11-12) III) Postural training, focused on flexibility, balance and relaxation 30 min/day, 3 days/week Control: Passive (maintained regular lifestyle routine throughout the intervention)	*Attention:* Attentive Matrices Test, Alternate version *Abstract reasoning:* Raven's Progressive Matrices Test *Inhibitory control:* Stroop Colour Word Test *Mental flexibility & set-shifting:* TMT A & B *Praxis:* Drawing Copy Test Strength: 1RM test Cardiovascular fitness: 1MWT Balance: Stork Balance Stand Test	• Praxis was the only cognitive outcome that significantly changed following RT • Improvements in attention and abstract reasoning, but not inhibitory control, mental flexibility, or praxis were observed following AE training • The cognitive benefits of exercise are moderated by the specific exercise modality being performed, • Combined, multiple modality exercise training programs may provide additive cognitive benefits
Best *et al.,* (2015)	12 month RCT	155 community-dwelling older women	Intervention: *2 RT groups* Machine-based and free weight RT (7 exercises	Brain volume: MRI	• Compared to BAT, improvements in EF were observed immediately following

	Follow-up at 24 months	MMSE >26 69.4 4 ± 2.8 years	focusing on major muscle groups) 2 sets, 8-10 reps each *I) 60 min/day, 1 day/week* *II) 60 min/day, 2 days/week* Control: BAT 60 min/day, 2 days/week	Cognition *EF:* Stroop Colour Word Test TMT A & B Digit Span backwards DSST *Verbal memory:* Rey's AVLT immediate recall, delayed recall, and recognition	the intervention and after 12 months of follow-up for those who performed RT once per week • Compared to BAT, improvements in memory were observed immediately following the intervention, and improvements in EF and reductions in cortical atrophy (BAT: 2.0% reduction vs. 2x RT: 0.8%) were observed after 12 months of follow-up for those who performed RT twice per week • Progressive RT can impart long-term benefits to cognition and brain volume in older women
Bolandzadeh *et al.,* (2015)	12 month RCT	155 community-dwelling older women MMSE >26 69.4 4 ± 2.8 years	Intervention: *2 RT groups* Machine-based and free weight RT (7 exercises focusing on major muscle groups) 2 sets, 8-10 reps each *I) 60 min/day, 1 day/week* *II) 60 min/day, 2 days/week* Control: BAT 60 min/day, 2 days/week	White matter lesion volume: MRI *EF:* Stroop Colour Word Test Mobility: Usual gait speed	• Compared to BAT, reductions in white matter lesion volume were only observed among those who performed RT twice per week • Reduced white matter lesion progression following once- or twice-weekly RT was associated with maintained usual gait speed, but not EF
Tsai *et al.,* (2015)	12 month RCT	48 cognitively healthy older men MMSE > 26 71.4 ± 3.8 years	Interventions: Progressive, high-intensity (75-80% 1RM) RT of the major muscle groups using machines and free weights 3 sets of 10 reps each 60 min/day, 3 days/week Control: Passive (maintained regular	*EF:* Oddball task reaction time Brain function: EEG Growth factors & blood markers: IGF-1, GH, Hcy	• 12 months of progressive RT stimulated improvements in reaction time to the oddball task, sustained P3a and P3b amplitudes during the oddball task, elevations in circulating IGF-1, and reductions in circulating Hcy • Elevations in serum IGF-1 were associated with improved

			lifestyle routine throughout the intervention)		• reaction time and sustained P3b amplitudes during the oddball condition • Attenuations in cognitive aging after RT are, in part, mediated by IGF-1
Fiatrone-Singh *et al.,* (2014) Suo *et al.,* (2016)	SMART Study 6 month RCT Follow-up at 18 months	100 older adults with MCI MMSE ≥ 26 70.1 ± 6.7 years	Interventions: Participants randomized to progressive RT, CT, combined progressive RT + CT, or sham control Resistance training: Machine-based group training of major muscle groups 3 sets, 8 reps each 45 min/day, 3 days/week Cognitive training: GOPACK computer-based Neurorehabilitation program 45 min/day, 3 days/week Combined RT + CT: Both interventions delivered each training day Control: Educational and stretching/seated calisthenics control 90 min/day, 3 days/week	Global Cognition: ADAS-Cog MMSE *Executive functions:* WAIS-III Matrices and Similarities subtests, verbal fluency *Memory:* WAIS-III Auditory Logical Memory immediate and delayed recall subtest, ADAS-Cog List learning subsection, Benton Visual Retention test-Revised, 5th Ed. *Attention:* Symbol Digit Modalities test *Global Function Domain:* Domain-specific and global cognitive functioning outcomes calculated using z-scores from tasks within each assessed cognitive domain Brain structure & function: Multimodal MRI	• RT (with or without CT) was associated with significant improvements in global cognitive functioning that were correlated with increased gray matter volume within the posterior cingulate cortex, improvements in EF and an attenuation in the decline of visual/constructional memory, but also worse performance on the delayed auditory memory task a reversion in the progression of white matter hyperintensities, • CT (with or without RT) demonstrated maintained memory-domain z-scores, which were associated with enhanced functional connectivity between the hippocampus and superior frontal cortex, but did not effect global cognitive functioning • Although improvements in attention and global cognitive function z-scores were observed following each intervention, the RT group displayed a 48% greater benefit than the combined RT+CT group at 18 months • Combined RT+CT was associated with worse performance on EF tasks and global cognitive functioning post-training • Future work is required to elucidate the neurophysiological

					and cognitive effects of combined training interventions
Cognitive training and cognitive health					
Study	Design	Sample	Treatments	Outcome(s) & Measure Used	Main Findings
Plassman *et al.*, (2007)	Population-based cross sectional study	856 older adults from the Aging, Demographics, and Memory Study 355: 71-79 years 366: 80-89 years 135: ≥ 90 years	Assessed prevalence of AD and other dementias, while attempting to identify predictors of cognitive health	Diagnosis of Alzheimer's, dementia, or vascular dementia: Abbreviated version of the TICS & the IQCODE	• Prevalence of dementia increases with age • Presence apolipotrotein ε4 significantly associated with increased risk of dementia • Higher education was associated with lower dementia risk
Lachman *et al.*, (2010)	Population-based cross-sectional study	3343 non-institutionalized adults from the second wave of the MIDUS study	Average of self-reported frequencies of cognitive activity on a 6-point scale <u>Where:</u> 1 = never 2 = once a month 3 = several times a month 4 = once a week 5 = several times a week 6 = daily	Global cognitive health: BTACT *Executive functions* Working memory: digit-span backwards, verbal fluency, inductive reasoning, processing speed Episodic memory: Immediate & delayed verbal recall (15 words) Attention switching and inhibitory control: Stop & Go Switch Task	• Higher education and frequent participation in cognitive activities were associated with higher episodic memory and EF • The disadvantages of lower education on episodic memory, but not EF, are attenuated by frequent cognitive activity across adulthood and older age
Klussman *et al.*, (2010)	6 month RCT	76 cognitively healthy older women MMSE ≥ 26 73.6 ± 4.2 years	Randomized to *1 of 3 groups*: I) *Mental exercise:* Computer-based exercises focused on creativity, coordination and memory e.g., learning how to operate common software and hardware, writing, playing game, calculating, surfing the Internet, emailing, drawing, image editing, and video taping II) *Physical exercise:* 30 min AE, with resistance and	General cognitive status: CERAD Fluid intelligence: Leistungs-Prüf-System-3/50+ *Executive functions* EF & working memory: TMT A & B Executive attention: Stroop task Episodic memory: Rivermead Behavioural Memory Test: story recall subtest & Free &	• Improvements and maintenance of episodic memory, working memory, and EF were observed at similar degrees following either mental or physical exercise training in older women • Mental exercise training has the potential to impact cognitive health to a similar degree as AE in older women

Study	Design	Sample	Treatments	Outcome(s) & Measure Used	Main Findings
			flexibility training III) *Non-exercising control* 90 min/day, 3 days/week	Cued Selective Reminding Test	
Rahe *et al.,* (2015)	1.5 month clinical trial	32 older adults with MCI 75.0 ± 5.2 years 50% female	Intervention: NEURO*vitalis* cognitive training program; targets attention, memory, and EF 90 min/day, 2 days/week, plus cognitive home work 10 min/day, 7 days/week	Global cognitive function: MMSE DemTect MCI screening tool *Memory* Verbal episodic memory: Memo Test Figural memory: Complex Figure Test delayed recall *Executive functions* Working memory: DemTec digit span backwards subtest Verbal fluency: semantic and phonemic fluency Executive control: TMT A & B *Visuo-construction abilities* Complex Figure Test *Number processing* DemTec number transcoding subtest	• There were no sex-specific baseline differences in cognitive performance • Women performed better than men on measures of immediate and delayed verbal episodic memory and working memory following 6 weeks of CT • CT produces more pronounced cognitive benefit among women when compared to men • There were no observable training effects when sex was omitted as a covariate within the analyses • Future research is required to elucidate the mechanisms of the observed sex-specific response to CT in MCI

Dual-task exercise training and cognitive health

Study	Design	Sample	Treatments	Outcome(s) & Measure Used	Main Findings
Erickson *et al.,* (2007)	2-3 week RCT	31 younger adults 23.74 years 61.2% female	Intervention: Single- and dual-task training with continuous and adaptive performance feed-back Control: Non-exercising control	Brain activity: fMRI during single- and dual-task performance	• Dual-task training produced a shift in the location of dual-task-related brain activity • The shift may represent a training-induced reorganization of the cortical areas involved while dual-tasking, resulting in more efficient task performance

			60 min/session, 5 sessions		
You *et al.,* (2009)	1.5 month RCT	13 older adults with a history of falls MMSE ≥ 24 68.3 ± 6.5 years 84.6% female	Intervention: Dual-task cognitive-motor intervention (walking + memory recall) Control: Dual-task placebo (walking + music) 30 min/day, 5 days/week	Memory: Correct number of items recalled while performing dual-task Dual-task gait analysis: Mean velocity & deviation	• Improvements in memory recall were observed after 6 weeks among those randomized to the intervention group • No significant improvements in gait performance were observed in the intervention group following the training period
Silsupado *et al.,* (2009*a*)	1 month RCT	23 cognitively healthy older adults with balance impairment MMSE ≥ 24 75.03 ± 6.2 years 80.9% female	Intervention: *1 of 3 groups:* I) *Single-task* balance training: focused on balance exercises II) *Fixed-priority dual-task* balance training III) *Variable-priority dual-task* balance training 45 min/day, 3 days/week	*Executive functions:* Single- & dual-task gait analysis Single-tasks: Narrow walking & Obstacle crossing Dual-tasks: Narrow walking + counting backwards by 3's, Obstacle crossing + auditory Stroop task	• Single- and dual-task training improves gait speed during single-task conditions • Individuals in either dual-task training group experienced greater improvements in dual-task gait speed compared to those training under single-task conditions • Dual-task training with variable-priority instructions produced improved dual-task gait speed after 2 weeks of training, which were maintained for 3 months following the intervention
Silsupado *et al.,* (2009b)	1 month RCT	23 cognitively healthy older adults with balance impairment MMSE ≥ 24 75.03 ± 6.2 years 80.9% female	Intervention: *1 of 3 groups:* I) *Single-task* balance training: focused on balance exercises II) *Fixed-priority dual-task* balance training III) *Variable-priority dual-task* balance training 45 min/day, 3 days/week	*Executive functions*: Single- & dual-task gait analysis Single-tasks: Narrow walking Obstacle crossing Dual-tasks: Narrow walking + counting backwards by 3's, Obstacle crossing + auditory Stroop task	• Variable priority dual-task balance training produced significant improvements in cognitive performance under dual-task conditions • Variable priority dual-task balance training is more effective in improving both balance and cognitive performance under a dual-task condition than either fixed-priority dual-task or single-task training strategies • Dual-task processing skills acquired during training did not transfer to a novel dual-task • Functional differences between the requirements of the practiced

					and novel dual-tasks may explain these discrepancies
Schwenk *et al.,* (2010)	3 month RCT	61 older adults with mild-to-moderate dementia MMSE: 21.4 ± 2.9 81.9 ± 7.5 years 63.9% female	Intervention: Dual-task training (walking while catching a ball, serial subtractions), with additional progressive resistance-balance and functional-balance training. 15 min/day dual-tasking, 120 min/day total, 2 days/week Control: Low-intensity AE focusing on flexibility, calisthenics, and seated ball games 60 min/day, 2 days/week	Cognitive health and dementia: CERAD Cognitive function: TMT A & B *Executive functions* Dual-task gait analysis (serial subtraction using 2's or 3's)	• No changes in cognitive health or function were observed • Significant improvements in dual-task motor performance were observed in the intervention group • Older adults with mild-to-moderate dementia can modify attentional control and improve performance during dual-task conditions to levels comparable to age-matched, cognitively healthy adults
Forte *et al.,* (2013)	3 month RCT	42 sedentary, community-dwelling older adults 69.8 ± 3.4 years 62% female	Interventions: *Randomized to 1 of 2 groups* I) Multicomponent training, involving group-based coordination, balance, strengthening, agility, stretching and relaxation exercises. Cognitive challenges were incorporated into the physical training components. II) Progressive (60 % 1RM to 80% 1RM) RT, involving a circuit of 12 exercises of the major muscle groups using machines and free weights 3 sets, 8 reps 60 min/day, 2 days/week	*Executive functions* *Inhibition* Random number generation task *Mental flexibility* TMT A & B Cardiorespiratory fitness VO$_2$max Muscular strength Isokinetic maximal knee extension & flexion Walking speed Max Walking Speed test	• Multicomponent and progressive RT can benefit inhibitory control and functional mobility • Mediation analyses suggest that each modality imparted benefits on inhibitory control along different pathways; multicomponent training directly effected inhibitory control, whereas gains were mediated by elevations in muscular strength following RT • Physical exercise training benefits executive control processes in older adults
Dorfman *et al.,*	1.5 month	10 older adults with	Intervention:	*Executive functions*	• Improvements in usual and dual-

(2014)	open label pilot study 1 month follow-up	a history of falls 78.1 ± 5.8 years 70% female	Progressive, treadmill-based AE with simultaneous verbal fluency and arithmetic tasks 15, progressed to 45 min/day, 3 days/week	Frontal Assessment Battery Verbal fluency TMT B *Scanning abilities* TMT A Mobility & Balance Usual and dual-task (serial 3's) gait speed, step length, and stride time variability	task gait speed and step length, and a reduction in usual stride time variability were observed following training; these were not maintained at follow-up • Improvements in EF (i.e., TMT B and serial subtractions while walking) were observed following training • Changes in performance on the other cognitive tasks did not reach significance • Dual-task treadmill training can benefit cognition and mobility in elderly fallers • Longer duration interventions may be required to impart the greatest cognitive benefit
Eggenberger *et al.,* (2015)	6 month RCT 12 month follow-up	71 cognitively healthy older adults MMSE ≥ 22 78.9 ± 5.4 years 65% female	Interventions: *Randomized to 1 of 3 groups* I) Combined cognitive + physical training 1; Impact Dance Platforms and StepMania Software, participants replicate stepping patterns in response to real-time visual cues II) Combined cognitive + physical training 2; dual-task treadmill walking with verbal memory tasks III) Physical training; moderate intensity (7 RPE) treadmill-based AE 60 min/day, 2 days/week	*EF* TMT B *Working memory* Executive Control Task *Short- and long-term verbal memory* WMS-R Digit Forward & backward, WMS-R Logical Memory subtest *Attention* Age Concentration Tests A & B *Information Processing speed* TMT A, WAIS-R DSST	• Improvements on all of the cognitive tasks, aside from Digit Forward, were observed following each on the 3 interventions • Changes in EF were apparent after 3 months of dual-task treadmill walking, but regressed back to baseline by intervention endpoint • Improvements in EF were apparent following 3 months and 6 months of virtual dance training • Improvements in cognition following the interventions were maintained at follow-up • The combined training interventions provided a subtle advantage to performance on measures of EF (switching attention and working memory) when compared to physical training alone • Longer duration, combined cognitive and physical training

					interventions may be most efficacious at improving cognition in older adults

226   Results from several randomized controlled trials (RCT) do suggest that the

227   cognitive functioning of older adults can benefit from AE training. Relatively short

228   duration (i.e., ≤3 months), moderate intensity (i.e., 40-70% heart rate reserve; 65-75%

229   maximal heart rate) AE training has stimulated increased hippocampal perfusion and

230   volume, which were both associated with improved cardiorespiratory fitness and

231   improved memory performance among older adults with objective cognitive impairment

232   (Maass et al., 2015).

233   Longer duration (i.e., ≥ 6 months), moderate intensity (i.e., 40-70% heart rate

234   reserve; 75-85% of their maximum heart rate; 60% of their maximum heart rate; 65-75%

235   maximal heart rate) AE training has also led to improvements in perceptual speed and EF,

236   which were correlated with elevations in cerebral oxygenation (Voelcker-Rehage, Godde,

237   & Staudinger, 2011), greater flanker task-related activation within the attentional

238   networks of the prefrontal and parietal cortices (Colcombe et al., 2004), increased

239   prefrontal and temporal cortical volume, and attenuated brain volume loss by magnitudes

240   of 27 - 42% (Colcombe et al., 2006) among cognitively healthy older adults. The benefits

241   of AE training are not reserved solely for those with intact cognitive functioning. A

242   number of studies have reported cognitive improvements following AE training among

243   those with objective cognitive impairment, including global cognitive functioning

244   (Lautenschlager et al., 2008), psychomotor and information processing speed

245   (Williamson et al., 2009), verbal learning and memory (Nagamatsu et al., 2013), and EF

246   (Baker et al., 2010; Nagamatsu et al., 2013). Furthermore, AE training can also lead to

247   physiological improvements within the brain of those with objective cognitive

248   impairment, including increased hippocampal perfusion (Maass et al., 2015) and volume

249   (Erickson et al., 2011; Maass et al., 2015; Ten Brinke et al., 2014), and a reduction the

250   number of circulating vascular risk factors associated with the development of AD (i.e.,

251   systolic BP, total cholesterol, and total cholesterol/high density lipoprotein C risk ratio;

252   Uemura et al., 2012).

253   Several observations from these studies are of particular interest. First, the

254   exercise-induced changes in hippocampal volume were associated with a number of

255   physiological phenomenon, including elevated concentrations of circulating brain-derived

256   neurotropic factor (Erickson et al., 2011), improved cardiorespiratory fitness (Maass et

257   al., 2015) and improved memory performance in some studies (Erickson et al., 2011;

258   Maass et al., 2015), but also reduced verbal learning and memory performance in others

259   (Ten Brinke et al., 2014). Although exercise-induced changes in brain structure and

260   function can be rationalized as beneficial, the discrepancies in the observed association

261   between exercise-induced changes in hippocampal volume and memory performance

262   suggest that the nature of the relationship between AE, memory-related cortical structural

263   changes, and memory performance remains equivocal. Second, although AE and

264   resistance training (RT) appeared to benefit EF (i.e., reaction time to a complex spatial

265   memory task) to a similar extent in the RCT conducted by Nagamatsu and colleagues

266   (2013), the improvements in verbal learning and memory (i.e., loss after interference on

267   the auditory verbal learning test) were greater following AE compared to RT (43.4% vs.

268   32.5%, respectively). This comparison suggests that although some aspects of cognition

269   appear to be responsive to a number of different types of exercise training, certain

270   cognitive domains (i.e., EF) may be more sensitive to change following the practice of

271   specific exercise training modalities (i.e., AE). Last, the majority of the AE intervention

272   trials have utilized a progressive exercise training paradigm (Colcombe et al., 2004;

273   Colcombe et al., 2006; Erickson et al., 2011; Nagamatsu et al., 2013; Ten Brinke et al.,

274   2014; Voelcker-Rehage et al., 2011; Williamson et al., 2009), which suggests that

275   monitoring progression in fitness and modifying the exercise training intensity to reflect

276   this progression may contribute to sustained elevations in the physiological stimuli [(i.e.,

277   increased cerebrovascular perfusion; (Colcombe et al., 2004)] that are required to benefit

278   the health and functioning of the brain.

279   Nevertheless, it would appear that AE training can benefit brain health and

280   functioning in older adults with or without cognitive impairment. The preserving effects

281   of AE on cognition are likely related to some combination of an exercise-induced

282   reduction in CVD risk-factor profiles (Uemura et al., 2012), increased cerebral perfusion

283   (Ribeiro, Alves, Duarte, & Oliviera, 2010; Voelcker-Rehage et al., 2011) or hippocampal

284   perfusion and volume (Maass et al., 2015; Ten Brinke et al., 2014), elevations in

285   circulating neural and vascular growth factors (Lista & Sorrentino, 2010), or improved

286   neurotransmission or the maintenance of prefrontal and subcortical structural or

287   functional integrity (Colcombe et al., 2004; Colcombe et al., 2006); however, the specific

288   mechanisms responsible remain equivocal. Although there is a large evidence base

289   supporting the association between previous or current AE training and maintained or

290   improved cognitive functioning in later life, issues related to differences in exercise

291   program prescription, small sample sizes, lack of control groups, short study durations

292   without follow-up assessments, lack of participant adherence reports, a lack of consensus

293   on which standardized measures represent clinically meaningful outcomes, and which

294   outcomes should be used to monitor the effectiveness of an intervention remain {Gregory

295   et al., 2013, #3710}. The majority of studies investigating the effect of exercise training

296   on brain health have primarily focused on AE training; however, evidence suggests that

297   other forms of exercise training can also benefit the brain.

298   *Resistance Exercise Training and Brain Health in Aging*

299   For older adults who may not be functionally capable of participating in AE, there

300   is a possibility to obtain cognitive benefits from resistance training (RT) as well.

301   However, due to the relatively recent nature of scientific inquiry into the matter, the

302   available literature is sparse but nevertheless promising.

303   Previous meta-analyses have identified a significant effect of RT on broad

304   cognitive functioning (Heyn et al., 2004), reasoning but not attention or memory (Kelly et

305   al., 2014b), and memory but not EF (Gates et al., 2013) among older adults with objective

306   cognitive impairment. These observations should be considered preliminary, however, as

307   the reviews were limited by the low number of studies that were available for inclusion in

308   the meta-analyses. Increased attention has been recently directed towards the

309   investigation of the effects of RT on cognition in older adults. Short-duration (i.e., ≤ 3

310   months) moderate intensity RT has led to improvements in memory (Lachman, Neupert,

311   Bertrand, & Jette, 2006; Perrig-Chiello, Perrig, Ehrsam, Staehelin, & Krings, 1998) and

312   EF (Anderson-Hanley, Nimon, & Westen, 2010) among cognitively healthy older adults,

313   and has been found to benefit global cognition (Lü et al., 2016) and stimulate

314   improvements in verbal memory that were associated with improved resting frontal lobe

315   neurophysiology (Yerokhin et al., 2012) among those with objective cognitive

316   impairment. Of particular interest, the improvements in memory performance following

317   RT among cognitively healthy older adults were associated with progressive RT

318   (Lachman et al., 2006) and preliminary evidence suggests that the benefits of short

319   duration RT can persist for up to 1 year post-training (Perrig-Chiello et al., 1998).

320   Longer duration (i.e., ≥ 6 months) RT programs have also been associated with

321   improved cognition. Specifically, improvements in praxis (Iuliano et al., 2015), memory

322   (Best, Chiu, Liang Hsu, Nagamatsu, & Liu-Ambrose, 2015; Cassilhas et al., 2007), verbal

323   concept formation (Cassilhas et al., 2007), and EF (Liu-Ambrose et al., 2010; Tsai, Wang,

324   Pan, & Chen, 2015) have been observed following 6 months of RT. RT can also benefit

325   the function of the brain, as RT has been associated with sustained event-related potential

326   (i.e., P3a and P3b amplitudes) during executive tasks over 1-year (Tsai et al., 2015), a

327   reduction in the progression of white matter lesions (Bolandzadeh et al., 2015), a

328   attenuation in cortical white matter atrophy (Best et al., 2015), and elevations in

329   circulating growth factors [i.e., insulin-like growth factor 1 (IGF-1; Cassilhas et al., 2007;

330   Tsai et al., 2015)] among cognitively healthy older adults. Of particular interest, the

331   improvements in EF (i.e., oddball task reaction time) and sustained EEG activity

332   following RT have been associated with elevations in circulating concentrations of IGF-1

333   (Tsai et al., 2015). IGF-1 mediates exercise-induced neurogenesis within the

334   hippocampus (Lista & Sorrentino, 2010), a region of the brain that is intimately involved

335   with memory processes. Taken together, these observations suggest that the cognitive

336   benefits of RT among cognitively healthy older adults are at least, in part, mediated by

337   elevations in circulating growth factors, specifically IGF-1. Longer duration RT can also

338   benefit the brain health and functioning of older adults with objective cognitive

339   impairment, and has been associated with elevations in global cognition, increased gray

340   matter volume within the posterior cingulate cortex, and revert the progression of white

341   matter hyperintensities (Fiatarone Singh et al., 2014; Suo et al., 2016) in these

342   individuals.

343   Collectively, these studies demonstrate that the beneficial cognitive effects of RT

344   are possible following progressive, moderate to high intensity (50-80% 1RM) RT ,

345   performed at least at least once per week for 3- to 6-months. Furthermore, these

346   observations suggest that RT can provide the appropriate physiological stimulus, by

347   means of modifications in resting cerebral perfusion (Xu et al., 2014) and elevations in

348   circulating growth-factor profiles, specifically IGF-1 (Cassilhas et al., 2007; Tsai et al.,

349   2015), to initiate improvements in cognition. However, it appears that certain aspects of

350   cognitive functioning differ in how they are influenced by RT, depending upon the

351   duration, intensity, and specific modality of RT. Furthermore, the cognitive benefits

352   provided through RT may be selective and sex-specific; specifically, improved memory

353   and verbal concept formation may be more pronounced in males (Cassilhas et al., 2007;

354   Yerokhin et al., 2012), while elevations in cerebral perfusion (Xu et al., 2014), reductions

355   in white matter lesion volume (Bolandzadeh et al., 2015), attenuated cortical atrophy

356   (Best et al., 2015), and improved EF may be more likely to occur in females (Anderson-

357   Hanley et al., 2010; Liu-Ambrose et al., 2010). Specific characteristics of the RT program

358   may help mitigate these sex-specific differences; improvements in EF have been observed

359   in previously sedentary older men who performed 6 months (Cassilhas et al., 2007) and

360   12 months (Tsai et al., 2015) of high intensity RT. Furthermore, there has been

361   heterogeneity in the effect of RT on EF, where some have observed improvements

362   following RT that were specific for verbal fluency outcomes (Anderson-Hanley et al.,

363   2010), while others have identified an effect of RT on other executive sub domains,

364   including conflict resolution (Liu-Ambrose et al., 2010), reasoning (Fiatarone Singh et al.,

365   2014), reaction time (Tsai et al., 2015), and central (Cassilhas et al., 2007) EF, and still

366   others did not observe any significant effect of RT on EF (Jensen & Rohwer, 1966;

367   Yerokhin et al., 2012). The heterogeneity in the effect of RT on EF can likely be

368   attributed to differences in the design of these studies, including: i) the population under

369   investigation (i.e., cognitively healthy vs. objective cognitive impairment, males vs.

370   females), ii) the duration of the interventions, and iii) the relative nature of the RT

371   program (i.e., intensity and progression). Nevertheless, these observations suggest that

372   certain aspects of EF may be differentially affected by exercise training modality, and that

373   the effect of RT on certain cognitive domains depends upon the duration, intensity, and

374   specific modality of RT. Further research is needed to elucidate the mechanisms that

375   drive the sex-specific response to RT, and to determine the characteristics of a RT

376   program (i.e., training intensity, frequency of training, duration of the training program)

377   that will impart the greatest cognitive benefits.

378   ***Cognitive Training and Brain Health in Aging***

379   Cognitive training (CT) and the performance of cognitively challenging activities

380   requires the organization and direction of a significant number of neurological processes,

381   such as attention, perception, memory, and EF, and has also been found to benefit

382   intellectual wellness in aging (Kramer, Bherer, Colcombe, Dong, & Greenough, 2004).

383   The potential therefore exists for CT to influence the health and functioning of the aging

384   brain.

385   It is well understood that years of formal education has a direct correlation with

386   cognitive functioning in older age {Plassman et al., 1995, #81937; Brickman et al., 2011,

387   #34955}. Observational studies have demonstrated that the participation in multiple forms

388   of cognitively stimulating activities has the potential to maintain or improve cognitive

389   functioning in late-life (Verghese et al., 2003; Wang et al., 2013), and has been associated

390   with a reduced risk of MCI when combined with physical exercise training (Hughes,

391   Becker, Lee, Chang, & Ganguli, 2015). Furthermore, a recent review by Plassman and

392   colleagues (2007) found that individuals who had at least 12-years of formal education

393   exhibited stronger cognitive functioning and a reduced risk of AD in later life. However,

394 recent work by Lachman *et al.,* (Lachman, Agrigoroaei, Murphy, & Tun, 2010) suggests

395 that the influence of less education on cognitive functioning, specifically episodic

396 memory, can be compensated for in later life through the participation in cognitively

397 stimulating activities (e.g., reading, solving word games or puzzles, attending educational

398 lectures or courses, writing) at least once per week across adulthood and into old age.

399 Taken together, these observations suggest that although the participation in certain

400 cognitively stimulating activities throughout life can provide considerable protective

401 benefit to the brain, CT can serve as a method to impart additional cognitive benefits.

402　　Cognitive function has also been shown to improve following CT interventions.

403 Previous meta-analyses have reported a positive effect of CT on memory and subjective

404 cognitive function when compared to non-exercising controls, and also EF and global

405 cognitive composite scores when compared to active (i.e., educational training, health-

406 promotion, or unstructured learning) controls (Kelly et al., 2014a). Of particular interest,

407 the discrepancies in the observed cognitive effects of CT when compared to passive and

408 active controls suggests the possibility that the mentally stimulating activities performed

409 by the active control participants (i.e., health and educational programs) may also benefit

410 certain aspects of cognition, specifically memory performance, to a similar extent as CT.

411 Nonetheless, these observations have led to the implication of CT and mental stimulation

412 as potentially powerful methods to improve cognition in aging (Lehert et al., 2015).

413　　Results from several RCTs have also identified a beneficial cognitive effect of

414 CT. Participation in ≤ 3 months of CT has been associated with improvements in episodic

415 and working memory in older women with MCI (Rahe et al., 2015), while participation in

416 longer duration (i.e., ≥ 6 months) CT interventions has led to improvements in composite

417 memory scores (Fiatarone Singh et al., 2014) that were associated with enhanced

418   functional connectivity between the hippocampus and superior frontal cortex (Suo et al.,

419   2016), as well as episodic memory, working memory, and EF (Klusmann et al., 2010)

420   among older adults with cognitive impairment. Of particular interest, the improvements in

421   episodic memory in the study by Klussman and colleagues (2010) occurred to a similar

422   degree following both the cognitive and physical training interventions, suggesting that a

423   6-month CT intervention holds the potential to benefit the brain and reduce the risk of

424   developing dementia to a comparable degree as AE in older women. There may also be

425   sex-specific effects to the cognitive response of CT, as improvements in episodic and

426   working memory following computerized CT for older adults with MCI were specific for

427   women (Rahe et al., 2015). Taken together, these observations support the use of CT in

428   older adults to prevent cognitive impairment, and suggest that the effect of CT on

429   cognitive health may be similar to that seen following participation in habitual exercise

430   training. Although CT can benefit cognition, there is currently uncertainty related to

431   whether cognitive improvements following CT are specific to the trained task or if

432   transfer effects are possible (Bherer, 2015). Furthermore, cross-sectional observations

433   suggest that the most pronounced cognitive benefits might be reserved for those who

434   participate in both CT and physical exercise training (Hughes et al., 2015). Therefore,

435   investigating the effects of interventions that combine physical exercise and cognitive

436   training is warranted.

437   ***Novel Exercise Modalities and Brain Health in Aging - Dual-task Exercise***

438   Dual-task (DT) training is a multi-dimensional type of intervention that combines

439   simultaneous cognitive and motor-tasks, and evidence implicated DT training as a

440   potential method to improve physical function in older adults (Pichierri, Wolf, Murer, &

441   de Bruin, 2011). According to task-coordination and management theory, single-task

442   training has fewer processing demands compared with DT training, since single-task

443   training does not require a participant to practice the coordination of two tasks performed

444   concurrently {Pashler, 1994, #40296}. In contrast, DT training allows for the practice and

445   efficient integration of DT coordination (Kramer, Larish, & Strayer, 1995), such as

446   walking while talking. DT training reflects the demands often experienced during daily

447   living and can provide an appropriate platform for training effects to be carried over to

448   daily life (Yogev-Seligmann, Hausdorff, & Giladi, 2008). The cognitive demands of dual-

449   tasking relates to the cognitive demands of the DT exercise and the cognitive capacity of

450   a given individual; if the demands of performing two tasks simultaneously exceeds the

451   cognitive capacity of the individual, performance in either one or both tasks is reduced

452   (Yogev-Seligmann et al., 2008).

453   DT coordination is controlled by EF (Yogev-Seligmann et al., 2008). This control

454   has been localized to networks within the dorsolateral prefrontal and superior parietal

455   cortices (Szameitat, Schubert, Muller, & Von Cramon, 2002), and research suggests that

456   executive control processes and their underlying brain regions are plastic and can be

457   modified by training. For instance, Erickson and colleagues (2007) demonstrated a DT

458   training-related 'shift' in the location of DT-related brain activity in younger adults, and

459   suggest that this may represent a training-induced reorganization of the cortical areas

460   involved in dual tasking which resulted in more efficient task performance. In lieu of

461   these observations, numerous small-scale studies have attempted to discern the cognitive

462   benefits associated with DT exercise training. Short duration (i.e., < 6-months) DT

463   exercise training programs have been shown to benefit memory (You et al., 2009), EF

464   (Forte et al., 2013), global cognition (Silsupadol et al., 2009a), and DT gait performance

465   (Pichierri, Coppe, Lorenzetti, Murer, & de Bruin, 2012; Silsupadol et al., 2009a;

466   Silsupadol et al., 2009b) among cognitively healthy older adults. Longer duration (i.e., ≥

467   6 months) DT training interventions have also been shown to benefit EF in cognitively

468   healthy older adults (Eggenberger, Schumacher, Angst, Theill, & de Bruin, 2015). Of

469   particular interest, improvements in EF following DT training were significantly larger

470   than that which was observed among those performing treadmill-based AE alone

471   (Eggenberger et al., 2015), suggesting that DT training holds the potential to provide the

472   most pronounced benefits to EF when compared to single-modality exercise training

473   programs. The impact of short duration (i.e., < 3 months) DT exercise has also been

474   investigated in older adults with pre-existing health issues and cognitive impairment.

475   Short-duration DT training has been shown to improve EF, improve gait (i.e., increase

476   usual and DT gait speed and reduce usual gait stride time variability; (Dorfman et al.,

477   2014), and improve DT gait performance (i.e., reduced DT cost on gait speed; Schwenk,

478   Zieschang, Oster, & Hauer, 2010) among older adults with a history of falls (Dorfman et

479   al., 2014) and those with dementia (Schwenk et al., 2010). Collectively, these preliminary

480   findings are indeed promising; however, there are a number of limitations that are specific

481   to DT exercise training programs that must be considered when interpreting these results.

482   First, there is considerable heterogeneity in the design of the DT interventions used, and

483   the majority of studies investigate the effects of a unique DT intervention. Second, each

484   of these DT interventions imposes unique cognitive and motor requirements that are

485   specific to the given DT exercise, which ultimately impact the cognitive and

486   neurophysiological response to the exercise program. Third, although preliminary

487   evidence exists, the effect of longer duration DT interventions remains relatively

488   understudied. Last, diversity of the populations within current available literature (i.e.,

489   previously sedentary, cognitively healthy, MCI, and dementia) limits the ability to draw

490   firm conclusions regarding the cognitive and physiological benefits associated with DT

491   training in any population of older adults. Nevertheless, these results suggest that DT

492   training can benefit EF and other aspects of cognition, as well as usual and DT gait

493   characteristics in a number of geriatric populations. DT exercise interventions may be of

494   particular importance to those with cognitive impairment, as these individuals can

495   experience post-training improvements in DT performance that allow them to reach levels

496   that are comparable to cognitively intact older adults (Schwenk et al., 2010). Together,

497   these studies have provided an exciting foundation for the inclusion of DT training in

498   cognitive rehabilitation and other exercise programs for older adults, particularly those at

499   increased risk for cognitive impairment and further pathological cognitive decline..

500   **Limitations and Future Directions for Investigating Cognitive Health and Exercise**

501   Although a number of exercise training modalities can benefit the structure and

502   function of the aging brain, a number of limitations to the current literature base must be

503   identified and overcome before definitive recommendations can be made (Daviglus et al.,

504   2011). First, there is considerable heterogeneity in the neuropsychological tests used to

505   evaluate the cognitive effects of exercise training interventions. In order to effectively

506   compare the impact of various exercise-training modalities on cognition and to avoid the

507   potential for practice effects, a comprehensive cognitive battery that includes a diverse set

508   of tests with alternate forms that evaluate cognition across a number of domains should be

509   developed and endorsed for use (Anderson-Hanley et al., 2010; Daviglus et al., 2011;

510   Yerokhin et al., 2012). Second, in order to elucidate the association between exercise-

511   induced improvements in cognition and structural and functional changes to the brain,

512   interventions that assess cognition should include neurophysiological and neuroimaging

513   outcomes (e.g., EEG, perfusion CT, transcranial Doppler, fMRI) and determine whether

514   structural and functional outcomes mediate improvements in cognition following training.

515   Third, although a number of long duration (i.e., $\geq$ 6 months) and large (i.e., > 150

516   participants) intervention trials exist, more large-scale RCTs are required to determine

517   whether physical, cognitive, and particularly DT exercise training can benefit aspects of

518   cognition that have remained undetected due to low statistical power (Daviglus et al.,

519   2011), and to identify the dosage of exercise (i.e., frequency, intensity, time, and type)

520   that is required to benefit cognition. Fourth, although several RCTs have suggested the

521   presence of sex-based differences in the cognitive response to exercise training (Baker et

522   al., 2010; Xu et al., 2014), the presence of sex-specific and other population-specific (i.e.,

523   cognitive status, ethnicity) responses to physical and cognitive exercise training has not

524   yet been definitively determined. Fifth, although observations suggest that each specific

525   type of exercise training modality (i.e., AE, RT, CT, DT) can provide unique and

526   potentially complimentary cognitive benefits, the impact of combined exercise training

527   programs remains relatively understudied and equivocal (Fiatarone Singh et al., 2014;

528   Suo et al., 2016). Sixth, due to the relatively high drop-out rate among the oldest

529   participants within exercise-training programs (Oswald, Gunzelmann, Rupprecht, &

530   Hagen, 2006), interventions should include methods to increase adherence and

531   compliance to the exercise program among the oldest-old through higher level of

532   engagement or the use of novel exercise training components (Silveira, van het Reve,

533   Daniel, Casati, & de Bruin, 2013). Seventh, the brain appears to be less responsive to

534   exercise as neuropathological changes accumulate and cognitive impairment progresses.

535   Intervention efforts that are focused on the prevention of cognitive decline through risk

536   factor management earlier in life may be the most effective strategy to protect and benefit

537   the aging brain. If prevention is the goal of the intervention, longitudinal studies

538   incorporating extended follow-up periods may be required to determine the beneficial

539   effects of an exercise program on the basis of when impaired cognitive functioning is

540   identified. Thom and colleagues (Thom & Clare, 2011) suggested that older adults with

541   declining physical function may be able to sustain the associated benefits of a brief

542   exercise intervention ($\geq$ 3-months) for longer durations if booster sessions are performed

543   at regular intervals; however, the nature and frequency of these booster sessions have yet

544   to be defined.

545

546 **Table 1.2**

547

548 *Limitations within the Current Literature and Recommendations for Future Research*

Limitations	Recommendations
Non-standardized use of neuropsychological tests • A given test administered by multiple groups is used to assess different domains of cognition • Results in confusion as to what is being measured and what domain of cognition responds to an intervention • Different tests are being used across studies making comparisons difficult	Standardize the use of the neuropsychological batteries employed, and determine which domain of cognition each test most closely represents
Simple neuropsychological batteries often employed • Assessments employing single outcome measures may not capture significant changes across all domains of cognition • Training effects on certain domains of cognition are missed	Identify single assessments that best represent functioning in a given cognitive domain Include comprehensive neuropsychological batteries that assess multiple domains of cognition
Practice effects can be encountered • Repeat testing using the same version of an outcome assessment may promote practice effects • Resulting in skewed/biased results	Use multiple valid versions of neuropsychological tests for pre- and post-assessments
A lack of association between neuropsychological performance and neurophysiological structure and/or functioning • Association between neuropsychological test performance and cerebral functional integrity have not been captured • A definitive association between an intervention and improvements in cognitive health have not been identified	Couple novel imaging techniques with neuropsychological assessment batteries within randomized controlled trials • Perfusion CT scan, transcranial Doppler, fMRI
Vascular health, cognitive functioning, and neurophysiological outcomes are often not incorporated together within intervention studies • Vascular risk factors have been identified as potentially modifiable risk factors for cognitive decline in aging • Whether improvements in vascular health mediate exercise-induced benefits to brain health and function has yet to be determined	Incorporate vascular risk factor outcomes within interventions trials aimed at improving cognitive functioning • Resting and ambulatory BP • Indices of arterial stiffness • Phlebotomy and blood chemistry • Glucose metabolism • Cardiac functioning
Dropout rates for exercise interventions in older adults are high • Older adults have the lowest cognitive functional reserve, and maybe removing themselves from an intervention prior to the realization of any associated benefits	Include novel training modalities • Engaging and stimulating interventions may promote adherence
Longitudinal and follow-up studies are lacking • Long duration interventions are labour intensive and often result in high dropout rates • Unable to determine whether the effects of an intervention persist for prolonged periods of time	Incorporate de-training periods with extended and multiple follow-up assessments to evaluate the prolonged effect of an exercise intervention on cognitive health
Small sample sizes • Studies to date lack statistical power to detect significant effects of an intervention	Large-scale trials employing recruitment strategies aimed towards larger sample sizes should be encouraged and employed
The potential for "booster" training sessions performed to maintain cognitive benefits that are obtained following an intervention remains to be investigated	Develop and incorporate a "booster" training regimen into future randomized controlled trials

549   Lastly, the majority of studies have focused on examining the cognitive effects of

550   exercise in relatively healthy, predominantly Caucasian older adults. Although several

551   studies have recruited previously sedentary (Cassilhas et al., 2007; Colcombe et al., 2006;

552   Maass et al., 2015; Williamson et al., 2009) and ethnically-diverse populations (Varma et

553   al., 2015; Varma et al., 2016), future works should aim to include these and other clinical

554   and cognitively healthy populations in order to identify those who stand to achieve the

555   greatest benefits, and to determine whether the cognitive response to exercise training

556   differs between populations. If these current limitations are collectively addressed, future

557   studies would have the potential to identify the most effective exercise regiment to

558   improve cognition in aging while shedding light on the possible mechanisms that drive

559   improved brain health and functioning following exercise training.

560   **Conclusions**

561   Leading a physically active and cognitively engaged lifestyle can have a

562   beneficial influence on cognitive health as individuals advance in age. Exercise training is

563   relatively inexpensive, tolerable, safe, and is readily accessible to the majority of older

564   adults. Identifying interventions that could effectively delay the onset cognitive decline

565   would lead to significant reductions in the incidence of dementia after several decades,

566   and the prevention of approximately 1 million fewer cases by 2050 (Brookmeyer et al.,

567   2007; Camelli et al., 1997). Therefore, attempts should continue to be made to further our

568   understanding of the beneficial impact that exercise training (i.e., physical and CT

569   programs) and other simple lifestyle modifications (i.e., nutrition and diet, risk factor

570   reduction, etc.) have on brain health and functioning and the prevention of cognitive

571   impairment in aging.

572   The cardiovascular benefits of physical exercise and the cognitively demanding

573   requirements of CT have been proposed as the driving factors that influence the

574   underlying mechanisms responsible for the preservation of cognitive functioning and

575   improved cognition. While recent evidence suggests that motor tasks combined with a

576   cognitive stressor (i.e., DT training) can provide additive cognitive benefits, a specific

577   exercise program aimed at preserving cognitive health has yet to be endorsed by the

578   scientific community. Nonetheless, it appears that the AE-induced benefits to memory

579   and EF can be maximized with individualized or progressive, moderate-to-high intensity

580   AE training over a period of 6- to 12-months. Although the evidence supporting the

581   beneficial effect of RT on the aging brain is promising, future research is required to

582   further determine the effectiveness of RT at maintaining and improving brain health and

583   functioning in older adults. Further investigations that are focused on determining the

584   individual and combined cognitive benefits of multiple exercise training modalities (i.e.,

585   AE, RT, CT, and DT) that utilize a standardized and comprehensive battery of

586   neuropsychological and neurophysiological outcomes will provide the most robust

587   evidence related to the benefits of exercise in aging, and will help to further define the

588   mechanisms by which cognitive functioning may be preserved in advancing age

589   **Overarching Purpose**

590   The overarching purpose of this thesis was three-fold: (i) to determine whether

591   CVD risk factors and gait are associated with poor cognitive functioning, (ii) to determine

592   whether blood pressure dipping status (a novel CVD risk factor) was associated with

593   cognitive and gait impairments (iii) to examine the impact of a dual-task gait training and

594   aerobic exercise (DAE) intervention on cognition, gait, and vascular health in

595   community-dwelling older adults without dementia. Specifically, Chapter 2 sought to

596   retrospectively determine whether cumulative CVD risk (i.e., QRISK2 risk score) and

597   gait performance can contribute to the prediction of global cognition and executive

598   functioning above and beyond age, education, depression, and the presence of

599   uncontrolled hypertension. Chapter 3 sought to retrospectively and cross-sectionally

600   determine whether group differences in cognition, gait, and vascular health exist between

601   older adults with normal BP dipping status and those with reduced BP dipping status.

602   Chapter 4 investigated the longitudinal effect of a novel 26-week dual-task gait training

603   and aerobic exercise (DAE) program on cognition, usual and DT gait, and vascular health

604   in community-dwelling older adults without dementia.

Disclosures: A portion of this work was presented at the Alzheimer Association Annual Conference (2016) that took place in Toronto ON, July 24th-28th, 2016. The abstract will be published in the summer 2016 issue of *Alzheimer's & Dementia*

1   **Vascular Health and the Pathophysiology of Cognitive Function in Aging**

2   Vascular cognitive impairment and vascular dementia (VaD) describe older adults

3   who exhibit impaired cognition that occur as a result of vascular-related brain pathology

4   (Sachdev et al., 2014). VaD is the second leading form of dementia in Western nations

5   and the most prevalent form of dementia in the Orient (Fratiglioni, De Ronchi, &

6   Agüero-Torres, 1999). Subclinical vascular-related brain pathology is common; the

7   prevalence of unsuspected infarction of the cerebral deep small vessels in the elderly

8   ranges from 15% (Bryan et al., 1999) to 28% (Price et al., 1997), and lesions within the

9   deep subcortical and periventricular white matter were present in 95% of the individuals

10   included in the neuroimaging extension of the Rotterdam study (de Leeuw et al., 2001).

11   The frontal-subcortical circuits that control both cognitive and motor processes are

12   located in close proximity; thus, vascular lesions in the frontal cortices may

13   simultaneously cause dysfunction in both systems (Pugh & Lipsitz, 2002). Developing a

14   greater understanding of the link between vascular risk factors and cognitive impairment

15   is imperative, as they are considered the most readily modifiable risk factors for dementia

16   (Smetanin et al., 2009).

17   **Cumulative Cardiovascular Risk and Cardiovascular Disease**

18   Although individual cardiovascular disease (CVD) risk factors have been

19   associated with cognitive impairment and brain pathology in aging (e.g., hypertension,

20   type 2 diabetes) (Langbaum et al., 2012), cumulative CVD risk may aid in the

21   identification of individuals who are at increased risk for future cognitive impairment.

22   Cumulative CVD risk scoring systems, such as the QRISK2 (Hippisley-Cox et al., 2008),

23   utilize predictive algorithms to estimate an individual's 10-year CVD risk, and can

24   identify populations who may garner the greatest benefit from interventions. The

25   algorithms that are at the core of these scoring systems consider a collection of

26   appropriately weighted clinical characteristics (i.e., age, medical history, smoking status,

27   presence and severity of CVD risk factors) to provide a comprehensive representation of

28   an individual's overall CVD risk when compared to the consideration of a single CVD

29   risk factor in isolation (Hippisley-Cox et al., 2008). The QRISK2 is a well-established,

30   reliable and validated CVD risk calculator (Hippisley-Cox et al., 2008), and recent

31   analyses suggest that the QRISK2 outperforms other established CVD risk scores (i.e.,

32   Framingham score and Scottish ASSIGN score) (Collins & Altman, 2012). Although the

33   QRISK2 can provide considerably accurate and reliable prognostic information regarding

34   CVD health, the relationship between QRISK2 scores and cognitive function in aging is

35   currently unknown.

36   **Vascular Health and Pathological Mobility Impairments in Aging**

37   Mobility impairments are characteristic of underlying cognitive impairment

38   (Annweiler & Montero-Odasso, 2012), and vascular brain injury has been implicated as

39   one of the mechanisms that drive age-related changes in gait (Annweiler & Montero-

40   Odasso, 2012; Rosano, Brach, Studenski, Longstreth, & Newman, 2007). Despite these

41   observations, the specific factors that directly contribute to the identification of those with

42   cognitive impairment (i.e., those related to vascular health, mobility, or otherwise) remain

43   equivocal.

44   Thus, this study sought to determine whether cumulative CVD risk and UG

45   performance independently contribute to the prediction of global cognition and EF, after

46   controlling for potential confounders (i.e., age, education, depression, uncontrolled

47   hypertension).

48   **Methods**

49   *Study Design*

50   This retrospective analysis used pooled baseline data collected from two, 6-month

51   exercise interventions designed to investigate the cognitive, mobility, and vascular

52   responses to exercise among community-dwelling older adults; the inclusion and

53   exclusion criteria for each study were identical.

54   *Eligibility*

55   Following consent, eligibility was determined during a screening visit via a

56   medical history review, resting BP measures, and a sensory and motor function

57   neurological exam. Older adults (55-90 years) without dementia [i.e., no previous

58   dementia diagnosis and a Mini-Mental State Examination (MMSE) score > 24 (Folstein,

59   Folstein, & McHugh, 1975)] and preserved instrumental activities of daily living (IADL)

60   (Lawton & Brody, 1969)] were enrolled. Individuals with significant neurological

61   (Parkinson's) or orthopaedic (severe osteoarthritis) conditions, clinical depression [>16

62   on the Centre for Epidemiological Studies-Depression Scale (CES-DS) (Radloff, 1977) or

63   based on the clinical judgement of the study physician], BP unsafe for exercise [i.e., >

64   180/100 mmHg or < 100/60 mmHg (Thompson, Gordon, & Pescatello, 2010)], a recent

65   (< 6 months) severe cardiovascular event (i.e., myocardial infarction, congestive heart

66   disease), and those who were unable to comprehend the questionnaire material were

67   excluded.

68

69   *Primary Outcomes*

70   **Cognition:** Global cognition (i.e., MoCA (Nasreddine et al., 2005)) and EF (i.e.,

71   Trail Making test Part B; TMT-B (Reitan, 1958)) were considered as the primary

72   outcomes for this study. The MoCA is a valid and reliable (Freitas, Simões, Alves,

73   Vicente, & Santana, 2012) 13-item, 30-point cognitive screening questionnaire that

74   assesses 8 cognitive domains, including attention and concentration, orientation, short-

75   term memory, visuospatial abilities, EF, working memory, and language. The maximum

76   total score is 30, with higher scores indicating better cognition (Nasreddine et al., 2005).

77   The TMT-B is a valid and reliable (Hagen et al., 2014) assessment of EF, and requires

78   participants to draw a line between alternating numbers and letters (e.g., 1, A, 2, B, 3, C,

79   etc.) as quickly and accurately as possible. The time to test completion in seconds

80   represents the outcome score for this test, with higher scores indicating worse

81   performance.

82   *Primary Predictor Variables*

83   **Gait:** Spatiotemporal gait characteristics were collected using a valid and reliable

84   (Brach, Perera, Studenski, & Newman, 2008) portable electronic walkway system

85   [GAITRite® System and software version 4.7.1, CIR Systems, Peekskill, NY, USA].

86   Participants completed three standard ("usual") walking trials at preferred speed. The

87   performance from the final two trials were averaged and used for analysis. Start and end

88   points were positioned 1.5 metres from either end of the mat in order to avoid recording

89   the acceleration and deceleration phases of the gait cycle, and footfalls that did not

90   entirely fall on the walkway at the start and the end of each trial were removed prior to

91   analyses. Three gait outcomes, specifically gait velocity (m/sec), step length (cm), and

92   stride time variability were used to create a UG composite score for analysis. The

93   composite score was derived by converting the parameters to standardized z-scores (i.e.,

94   subtracting the baseline group mean from the raw score and dividing by the baseline

95   standard deviation), which were then averaged to create the standardized UG composite

96   score for analysis.

97   **Cardiovascular Risk:** CVD risk was quantified using the QRISK®2-2015

98   cardiovascular risk calculator (available at: www.qrisk.org). QRISK2 uses participant

99   demographics (i.e., age, sex and ethnicity) and clinical information (i.e., smoking status,

100   previous diagnoses of type 2 diabetes, kidney disease, atrial fibrillation, or rheumatoid

101   arthritis, the use of antihypertensive medications, and BP measures) to identify the

102   likelihood of experiencing a significant cardiovascular event (i.e., stroke, transient

103   ischaemic attack, myocardial infarction, or angina pectoris) over the subsequent 10 years

104   (Collins & Altman, 2012). The QRISK2 is a well-established, valid, and reliable (Collins

105   & Altman, 2012; Hippisley-Cox, Coupland, & Brindle, 2014) CVD risk calculator,

106   whose predictive ability has surpassed that of other established CVD risk scores [i.e.,

107   National Institutes for Health and Clinical Excellence (NICE) modified Framingham

108   score (Collins & Altman, 2010; Collins & Altman, 2012) and Scottish ASSIGN score

109   (Hippisley-Cox et al., 2007)].

110   *Covariates*

111   *Demographic and Clinical Characteristics*

112   Participant demographics and anthropometrics, including age, sex, ethnicity,

113   education, medical history, body mass index, predicted cardiovascular fitness level, and

114   the presence of self-reported cognitive complaints (SCC) were collected. Predicted

115   cardiovascular fitness was determined using the Step Test for Exercise Prescription

116   (STEP) tool (Stuckey, Knight, & Petrella, 2012), which required participants to ascend

117   and descend a standardized set of two stairs at a self-selected pace; cardiorespiratory

118   fitness was calculated using a prediction algorithm that utilized time to test completion,

119   post-test radial heart rate, age, and sex. The presence of SCC was determined by asking

120   the question "Compared to yourself five years ago, do you think that your memory is:

121   much better (1), better (2), about the same (3), worse (4), or much worse (5)? Responses

122   that were ≥ 4 were coded as a subjective cognitive complaint. Uncontrolled hypertension

123   and was identified using ambulatory BP monitoring. Participants were fitted with an

124   appropriately sized ambulatory BP cuff and monitor (Spacelabs^{TM} 90207 Ambulatory BP

125   Monitor, SpaceLabs Inc), and ambulatory BP was recorded over a 24-hour period: twice

126   per hour during the day (i.e., 06:00 to 22:00), and once per hour during the night (i.e.,

127   22:00 to 06:00). Mean 24-hour systolic BP values > 135mmHg and hypertensive

128   medication status were used together to create a binary variable that identified

129   participants with uncontrolled hypertension (i.e., 0 = controlled hypertension or

130   normotensive; 1 = uncontrolled hypertension). The covariates used for analysis included

131   age, education, CES-DS, and uncontrolled hypertension.

132   *Analysis*

133   Analyses were performed using SPSS version 20 (SAS Institute Inc., Cary, NC,

134   USA). Following the removal of any significant outliers, hierarchical regression models

135   were used to determine the predictive utility of QRISK2 and UG performance on

136   cognition. Specifically, global cognition (i.e., MoCA score) and EF (i.e., TMT-B score)

137   were considered as the dependent variable within their respective models, while QRISK2

138   score and the UG composite score were considered as the primary predictor variables

139   within each model. Covariates (age, education, CES-DS, uncontrolled hypertension) were

140   entered at the first, second, third, and fourth steps, respectively, to account for the

141   variance in the dependent variables that are attributable to these covariates. QRISK2

142   score and the UG-composite score were entered into the models at the fifth, and sixth

143   step, respectively, in order to account for the variance in the dependent variables that is

144   uniquely attributable to QRISK2 and UG performance in isolation, after controlling for

145   the influence of the covariates. The increment in explained variance (R^2 change) was

146   obtained and tested for significance at each step of the analysis. Means and standard

147   deviations were determined and two-sided p-values less than 0.05 were claimed as

148   statistically significant.

149   **Results**

150   Participants were enrolled starting on June 26th, 2012, and data collection ended

151   on September 23rd, 2014 (Figure 2.1). A total of 167 individuals were assessed for

152   eligibility, and 48 were excluded from participation (30 did not meet inclusion criteria, 14

153   declined to participate, 4 were missing baseline data). This left 119 individuals who were

154   enrolled and had complete baseline data.

1
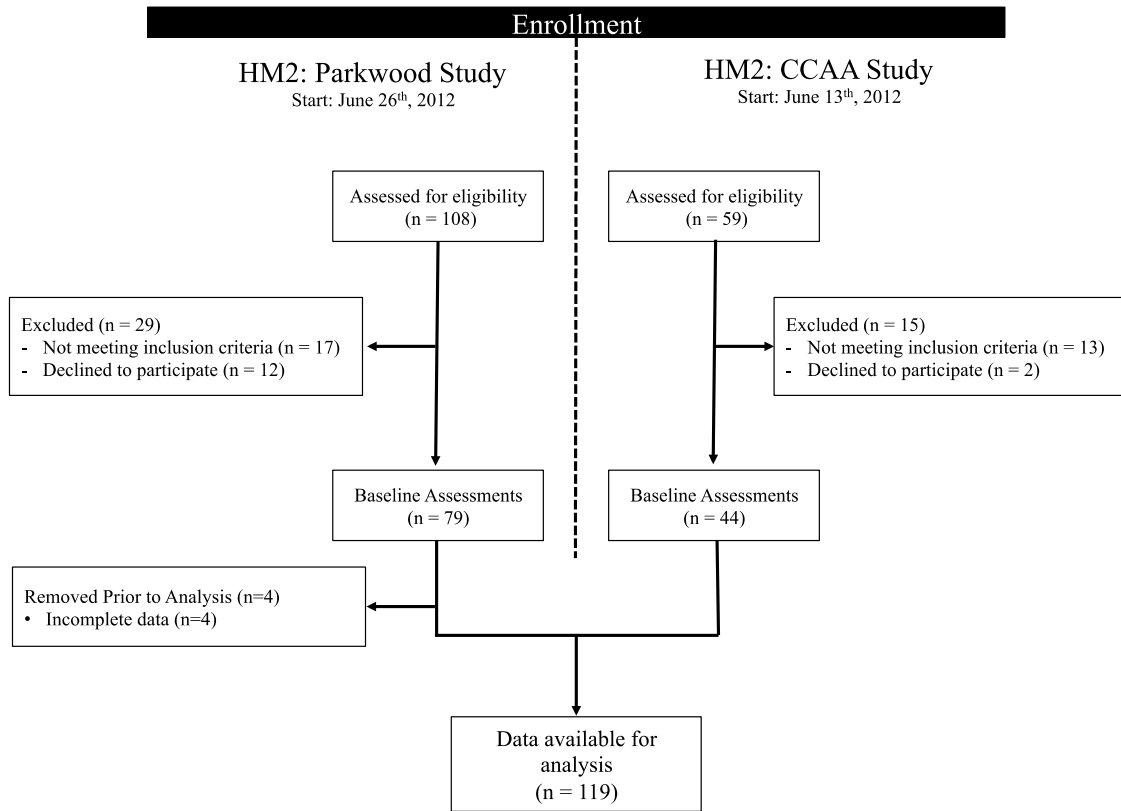

Figure 2.1. Participant Recruitment and Enrollment for the Laboratory- and Community-based Arms of the Healthy Mind, Healthy Mobility (HM2) trial.

280   Participant characteristics are presented in Table 2.1. Participants had a mean age

281   of 71.5 (SD 7.0) years, 63% were female, most (96%) were Caucasian, and all were

282   highly educated [mean (SD): 15.5 (3.2) years]. Slightly more than half (54.5%) of the

283   participants reported a SCC, and, on average, CES-D scores were well below the cut-off

284   of 16 [mean (SD): 6 (5)]. Participants had subtle indications of underlying cognitive

285   impairment [MoCA scores, mean (SD): 25.0 (2.2)] but not dementia [MMSE scores,

286   mean (SD): 28.5 (1.3)]. On average, performance on the TMT-B was similar to what

287   could be expected for the participant's age and education level (Tombaugh, 2004), and

288   UG performance (i.e., speed, step length, and stride time variability) was also comparable

289   to normative data (Hollman, McDade, & Petersen, 2011). QRISK2 scores ranged from

290   6.8% to 59.4%, and were, on average, higher than the >20% threshold that is required to

291   identify individuals at high 10-year CVD risk (Collins & Altman, 2012).

292   **Table 2.1**

293   *Baseline Characteristics of the 119 Participants Enrolled in the HM2 Studies[a]*

Characteristic	Participants (n = 119)
Age, mean (SD), yr	71.4 (7.0)
Female sex, no. (%)	77 (58.3)
Education, mean (SD), yr	15.5 (3.2)
Caucasian, no. (%)	115 (87.1)
Cognitive complaint (ref: 5 yr ago)[b], no (%)	66 (55.5)
MMSE score, mean (SD)	28.6 (1.3)
MoCA score, mean (SD)	25.0 (2.2)
Body mass index, mean (SD)	28.8 (4.5)
Fitness (pVO_{2max}) score[c], mean (SD)	28.0 (8.0)
QRISK2 score (%), mean (SD)	22.7 (12.6)
Usual gait performance, mean (SD)	
Velocity (m/sec)	1.14 (0.17)
Step length (cm)	63.0 (7.3)
Stride time variability (CoV)	2.4 (2.6)
Usual gait composite	-0.01 (0.34)
Medical history, no. (%)	
Hypertension-total[d]	54 (45)
Hypertension-uncontrolled[d]	36 (30)
Hypercholesterolemia	42 (35)
Type 2 diabetes	15 (13)
Myocardial infarction	9 (8)
Angina/coronary artery disease	8 (7)
Atrial fibrillation	4 (3)
Cerebrovascular disease	11 (9)
Depression[f]	7 (6)
Current smoker	4 (3)
Former smoker	63 (53)

Abbreviations: MMSE, Mini-Mental State Examination; MoCA, Montreal Cognitive Assessment; pVO_{2max}, predicted maximal oxygen uptake

[a]Data is preseted as mean (SD) or frequency (%), where applicable

[b]Participants rated their memory on a scale of 5 (1 = much better, 5 = much worse)

[c]pVO_{2max} was determined using the Step Test and Exercise Prescription tool

[d]Total hypertension was defined as those who displayed systolic ambulatory BP measures >135 mmHg *or* those taking antihypertensive medication

[e]Uncontrolled hypertension was defined as 24-hour ambulatory systolic blood pressure >135 mmHg, regardless of medication status.

[f]Depression was defined as scores >16 on the Centre for Epidemiological Studies-Depression Scale

294

295   ***Bivariate Analysis***

296   MoCA scores were negatively correlated with age (r = -.233, p<.01) and QRISK2

297   scores (r = -.213, p<.02), and positively correlated with education (r = .188, p<.04) and

298   the UG composite score (r = .210, p=.02). CES-DS and uncontrolled hypertension were

299   not correlated with MoCA scores (all p>.05). TMT-B scores were negatively correlated

300   with the UG composite score (r = -.275, p<.01), and positively associated with age (r =

301   .462, p<.001), and QRISK2 scores (r = .469, p<.001). Education, depressive status, and

302   the presence of uncontrolled hypertension were not associated with TMT-B scores (all

303   p>.05).

304   ***Hierarchal Regression***

305   The results from the regression models are summarized in Table 2.2. All

306   applicable assumptions were met for the two regression models. When examining the

307   explained variance in MoCA scores provided by QRISK2 and UG performance, only age

308    $[F_{(1,117)}=7.003, p=.009]$ and years of education $[F_{(1,116)}=7.159, p=.009]$ contributed to the

309   explained variance in MoCA scores. Age contributed the highest degree of explained

310   variance in global cognition (5.6%, R^2 change = 0.056), while years of education

311   explained an additional 5.5% of the variance (R^2 change = 0.055). The overall model

312   explained 13.9% of the variance in MoCA scores (R^2 = 0.139, or 13.9%, p<.01; Adjusted

313   R^2 = .093 or 93%).

314   When examining the explained variance in TMT-B scores provided by QRISK2

315   and UG performance, only age $[F_{(1,117)}=31.637, p=<.001]$ and QRISK2 scores

316    $[F_{(1,113)}=4.89, p<.03]$ contributed to the explained variance in TMT-B scores. Age

317   contributed the highest degree of explained variance in executive function (21.3%, R^2

318   change = 0.213), while QRISK2 scores explained an additional 3.2% of the variance (R^2

319   change = 0.032). The overall model explained 28.4% of the variance in TMT-B scores

320   ($R^2 = 0.284$, or 28.4%, p<.03; Adjusted $R^2 = .245$ or 24.5%).

321

322   **Table 2.2**

323   *Summary of hierarchal regression analyses for Montreal Cognitive Assessment and Trail*

324   *Making Test Part B scores.[a]*

Model	Step	Variable	R	R^2	R^2 Change	F Change	p-value
1[b]	1	Age	.238	.056	.056	7.003	.009
	2	Education	.334	.111	.055	7.159	.009
	3	Depression	.337	.114	.002	.289	.592

325

326   **Discussion**

327   *Cardiovascular Disease Risk, Gait, and Global Cognition*

328   The presence of chronic CVD risk factors has been implicated as a mechanism

329   responsible for vascular-related neuropathological changes within the aging brain

330   (Knopman et al., 2001). Recently, the management of CVD risk (Langa, 2015) and also

331   gait dysfunction (Lord, Galna, & Rochester, 2013; Mielke et al., 2013) have emerged as

332   promising avenues to prevent cognitive impairments in aging; however, specific risk

333   factors that share the strongest relationship with cognition remain unknown.

334   In this study, QRISK2 scores and UG-composite scores were associated with

335   MoCA scores in bivariate analyses; however, multivariable analyses suggest that neither

336   provide a meaningful contribution to the explanation of variance in MoCA scores. Aging

337   coincides with a gradual decline in the functioning of a number of cognitive domains

338   (Sperling et al., 2011), and higher educational attainment is considered a protective factor

339   against cognitive impairment (Brickman et al., 2011). The lack of contribution of either

340   QRISK2 score or the UG-composite scores to the explained variance in MoCA scores

341   was, however, in contrast to the a priori hypothesis and previous observations (Liu et al.,

342   2013; McLennan et al., 2011). Liu and colleagues (2013) identified an association

343   between a number of cardiovascular conditions (i.e., previous stroke, type 2 diabetes,

344   history of smoking, and systolic hypertension) and global cognitive functioning among a

345   large cohort (n = 3,145) of older, community-dwelling African Americans, while

346   McLennen and colleagues (2011) observed low MoCA scores [mean (SD), 22.8 (3.8)]

347   among a cardiovascular outpatient population. The discrepancies between these studies

348   can be attributed to differences in the recruited populations and study design. There is a

349   higher incidence and prevalence of CVD among African Americans compared to

350   Caucasians (Yusuf, Reddy, Ounpuu, & Anand, 2001), and the relationship between

351   vascular health and cognition may be higher among CVD outpatient populations.

352   However, the participants herein were predominantly Caucasian, attained higher levels of

353   formal education [mean (SD), 15.5 (3.2) years], demonstrated relatively preserved

354   cognitive functioning (i.e., MoCA scores), and had lower pre-existing CVD than those

355   previously studied. Furthermore, the present study utilized the QRISK2 as an index of

356   cumulative CVD risk rather than assessing the relationship between individual CVD risk

357   factors. Although QRISK2 is an effective method to identify individuals at increased risk

358   for CVD, its utility as an index of CVD risk to be used for the investigation of the

359   relationship between vascular health and cognition remains uncertain. Furthermore, age is

360   the strongest weighted factor when calculating the QRISK2. Although these variables did

361   not share multicolinearity, having age entered in to the models first may have masked a

362   portion of the relationship between QRISK2 and cognition.

363   In contrast to the current study, previous investigations have identified an

364   association between gait dysfunction and poor cognitive functioning in older adults

365   (Allali, Ayers, & Verghese, 2016; Mielke et al., 2013). These conflicting observations are

366   also conceivably related to discrepancies in participant characteristics and study design,

367   including differences in: i) the measure of global cognition, ii) the proportion of

368   participants reporting SCCs, and iii) the methods used to quantify usual gait (i.e., raw

369   data vs. composite performance score). The relatively well-preserved cognitive

370   functioning of the older adults in the present study may have blunted the likelihood of

371   observing a relationship between gait and cognition. Furthermore, previous studies have

372   focused on individual measures of gait performance (Allali et al., 2016; Mielke et al.,

373   2013) rather than a multifactorial composite score. Although gait speed, step length, and

374   stride time variability have been independently associated with poor global cognitive

375   function (Allali et al., 2016; Mielke et al., 2013) the creation of a UG-composite score for

376   use in this study may have masked these relationships.

377   ***Cardiovascular Disease Risk, Gait, and Executive Function***

378   In bivariate analyses, TMT-B scores were positively associated with age, QRISK2

379   scores, and were negatively associated with UG-composite scores. Linear multiple

380   regression analysis identified age and QRISK2 were the only dependent variables to

381   contribute to the explained variance in TMT-B scores.

382   Intact EF is dependent upon the integrity of a number of neural networks;

383   however, the prefrontal and dorsolateral prefrontal cortices are heavily relied upon for

384   successful completion of the TMT tests (Hagen et al., 2014; Shibuya-Tayoshi et al.,

385   2007). Thus, vascular-related neuropathology within these regions of the brain could

386   contribute to impaired performance on the TMT-B. In addition to age, the QRISK2 score

387   was the only additional factor that contributed to the explained variance in TMT-B

388   scores. Although associations between TMT-B performance, age, and education have

389   been previously reported (Tombaugh, 2004), the relatively high level of formal education

390   attained by the participants in the current study likely diminished the possibility of

391   observing this relationship. These observations are, however, aligned with previous

392   works that identified an association between a number of indices of vascular health (i.e.,

393   aortic stiffness, hypertension, stroke, congestive heart failure and Framingham

394   cardiovascular risk scores) and EF (i.e., TMT-B and Stroop task performance) (Gauthier

395   et al., 2015; Viswanathan et al., 2015). Taken together, these observations suggest that

396   EF, but not global cognition, is most sensitive to vascular health and CVD risk in aging.

397   These observations are critically important, as EF is one of the first cognitive domains

398   affected by pathological cognitive decline (Li et al., 2004), and is the cognitive domain

399   whose intact functioning is necessary for the maintenance of functional independence in

400   aging (Mitchell & Miller, 2008). However, the low percentage of explained variance in

401   TMT-B scores provided by QRISK2 suggests that other vascular risk factors that are not

402   captured by CVD risk-scoring systems must be identified. Identifying novel vascular risk

403   factors, determining their impact on brain health, and addressing CVD risk may serve to

404   protect and benefit EF in older adults.

405   Gait performance reflects underlying neuropathology within the frontal cortices

406   (Rosano et al., 2008), and thus, may be associated with cognitive functions that rely upon

407   these regions. In contrast to the current study, previous research has identified an

408   association between usual gait and measures of EF (Hajjar et al., 2009). This discrepancy

409   can be attributed to a number of factors: i) the use of a composite score rather than a

410   single gait characteristic (Hajjar et al., 2009), ii) the EF outcome used in the analysis, as

411   well as iii) the relatively preserved cognitive functioning, and iv) the lack of gait

412   dysfunction within participants. The UG-composite score was envisioned to

413   comprehensively account for gait performance across a number of gait parameters that

414   are affected as cognition declines (Mielke et al., 2013). However, the relatively preserved

415   cognitive functioning of the participants within the current study could have diminished

416   the previously reported relationship between UG performance and EF. Recent evidence

417   suggests that UG performance is dependent upon the integrity of cortical regions that are

418   associated with information processing rather than EF (Rosano et al., 2008). The

419   relationship between UG and EF becomes most pronounced while performing more

420   complex motor tasks (i.e., walking while responding to cognitively challenging

421   questions) (Springer et al., 2006), and among those with pre-existing gait dysfunction

422   (Holtzer, Verghese, Xue, & Lipton, 2006). A lack of an observed association between our

423   UG-composite score and TMT-B test performance likely arose from the single task

424   requirements of the gait assessment, and the preserved functional status of the

425   participants. In order to overcome these issues, a comprehensive evaluation of gait under

426   a number of conditions, and investigating the relationship between usual and complex

427   gait performance and cognitive functioning within a wide breadth of cognitive domains

428   should be explored.

429   **Conclusions**

430   Identifying which risk factors contribute to increased risk for cognitive

431   impairment, and whether the modification of these risk factors contribute to the

432   prevention of cognitive impairment remains a significant priority in clinical practice

433   (Smetanin et al., 2009). Although there is an increasing consensus on the role of vascular

434   risk factors and gait in the establishment of cognitive impairment (Smetanin et al., 2009),

435   the factors that are the most suitable targets for dementia-risk reduction remains

436   equivocal. The observed relationship between cumulative CVD risk and EF suggests the

437   potential for vascular risk factor management and CVD prevention to be the most

438   promising strategies for the preservation of EF in aging.

1   *Cognitive Impairment in Aging*

2   Despite considerable efforts being directed towards the maintenance of cognitive

3   health in aging, cognitive impairment continues to impart considerable strain on health

4   care systems (Fisher et al., 2011; Werner, 2012) and the global economy (Brookmeyer,

5   Johnson, Ziegler-Graham, & Arrighi, 2007; Prince et al., 2015). As such, the

6   identification of modifiable risk factors for dementia and the development of effective

7   methods to reduce the incidence and prevalence of cognitive impairment remains a

8   significant priority for cognitive research and clinical practice (Lancet Neurology, 2012).

9   Although cardiovascular disease (CVD) risk factors are not the sole contributors

10 to the development of cognitive impairment, they do appear to be some of the most

11 promising modifiable dementia risk factor candidates (Chen et al., 2014; Hughes et al.,

12 2014; King, 2014; Langbaum et al., 2012; Norton, Matthews, Barnes, Yaffe, & Brayne,

13 2014). Indeed this notion appears to have taken hold, as population-based studies suggest

14 that recent reductions in the incidence of dementia in high-income nations can be

15 attributed, in part, to increased rigor in the identification and management of CVD risk

16 factors (Langa, 2015). A number of CVD risk factors (i.e., hypertension and arterial

17 stiffening) contribute to progressive damage to the cortical microvasculature and have

18 been associated with the development of lesions within the frontal and subcortical regions

19 of the brain (Pugh & Lipsitz, 2002). The neural networks that are responsible for

20 cognitive and motor control lay within close proximity to one another within these

21 regions; thus, when these lesions accumulate within these regions, cognitive impairments

22 and gait dysfunction can manifest (Pugh & Lipsitz, 2002). In addition to CVD risk

23 factors, these observations have led to the identification of gait abnormalities as a

24   potentially modifiable dementia risk factor, and have solidified the importance of the

25   interplay between vascular risk factor management, cognitive functioning, and gait.

26   However, intervention efforts aimed at prevention would benefit from the further

27   identification and characterization of other vascular risk factors that are potentially

28   associated with cognitive and gait impairments in aging (Canavan et al., 2014; Langa,

29   2015; Prince et al., 2015).

30   *Novel Vascular Risk Factors for Cognitive Impairment*

31   Due to the intimate relationship between CVD risk factors and brain health, it is

32   reasonable to surmise that a myriad of CVD risk factors may impose a significant

33   negative impact on the aging brain. However, questions regarding the specific

34   mechanisms of action by which these risk factors detrimentally affect the aging brain

35   have yet to be answered. Furthermore, as a large number of vascular risk factors have

36   also been implicated as dementia risk factors, it stands to reason that other novel vascular

37   risk factors may also impose a pernicious effect on the aging brain and may play an

38   equally important prognostic role.

39   *Blood Pressure Dipping Status as a Risk Factor for Chronic Conditions in Aging*

40   Ambulatory blood pressure (BP) monitoring has become an integral component of

41   the clinical management of hypertension (National Institute for Health and Clinical

42   Excellence, 2011; Public Health Agency of Canada, 2010), as it collects mean,

43   maximum, and minimum 24-hour, daytime, and night time systolic and diastolic BP and

44   heart rate. This data provides unique and comprehensive insight into a patient's diurnal

45   BP pattern that reaches far beyond what could be obtained during resting office BP

46   measures. Indeed, ambulatory BP monitoring consistently out-performs office BP

47   measures as an index of overall cardiovascular risk (Krakoff, 2013; O'Brien et al., 2013;

48   Verdecchia, 2000), and has led to the identification of mean nocturnal BP as the most

49   potent predictor of cardiovascular events (ABC-H Investigators et al., 2014; O'Brien et

50   al., 2013).

51   BP dipping characterizes the diurnal BP pattern, and is expressed as the

52   percentage-drop in mean systolic BP from day to night or the systolic day-to-night ratio

53   (O'Brien et al., 2013). Several BP dipping patterns are commonly observed, including

54   normal dipping status (DS; i.e., those who experience a 10% to 20% drop in mean

55   systolic BP from day to night), extreme dipping status (i.e., those who experience a

56   greater than or equal to 20% drop in mean systolic BP from day to night), non-dipping

57   status (N-DS; i.e., those who experience a drop of less than 10% in mean systolic BP

58   from day to night), and reverse dipping status (i.e., those who experience higher mean

59   systolic BP levels at night compared to day, expressed as a negative blood pressure

60   dipping percentage) (O'Brien et al., 2013; Salles et al., 2016). N-DS is considered an

61   independent CVD risk factor (Salles et al., 2016), and has been associated with an

62   increased risk of severe cardiovascular events, cerebrovascular events, and all-cause

63   mortality (Fagard et al., 2008; Verdecchia, 2000; Salles et al., 2016). It is assumed that

64   because of the exposure to higher BP levels during night time hours when individuals lie

65   supine while sleeping, the brain is less protected from hydrostatic forces and the cerebral

66   vasculature is exposed to pathologically higher pulsatile flow (Fagard et al., 2008). The

67   sustained elevation in pulsatile flow subsequently damages the cerebral microvasculature

68   and contributes to the development of vascular-related brain injury, including

69   microbleeds, lacunar infarcts, and white matter hyperintensities (O'Rourke & Safar,

70   2005). Previous observations have also identified a negative relationship between N-DS

71   and cognition. N-DS has been associated with worse global cognitive functioning among

72   older adults with various degrees of cognitive and functional impairments (Ohya et al.,

73   2001). In older hypertensive adults, N-DS has been associated with smaller total brain

74   volumes (Nagai, Hoshide, Ishikawa, Shimada, & Kario, 2008), poorer global cognitive

75   functioning (Bellelli et al., 2004), worse memory, and information processing speed (van

76   Boxtel et al., 1998). Abnormal BP dipping may also be associated with the development

77   of mild cognitive impairment (MCI), as the prevalence of MCI is greatest among

78   community-dwelling older adults who are extreme dippers (32%), N-DS (30%), and

79   reverse-dippers (50%) when compared to DS (13.2%; Guo et al., 2010). Although these

80   initial observations suggest a negative relationship between N-DS and brain health,

81   questions regarding the mechanisms that drive the association between N-DS and

82   cognition remain. For instance, some have failed to identify an association between N-DS

83   and cognitive functioning in older adults, and have suggested that this apparent

84   association is mediated by the development of vascular-related cerebral lesions (van

85   Boxtel et al., 2006). Although the mechanistic evidence to implicate N-DS as a

86   pathological mechanism of cognitive impairment in aging exists, the relationship between

87   diurnal BP variation and cognitive functioning in older adults remains equivocal.

88   Thus, the purpose of this study was two-fold: i) to determine whether differences

89   in cognitive performance [i.e., global cognitive functioning, executive functioning (EF),

90   information processing speed, verbal fluency, and memory] exist between community-

91   dwelling older adults who display a diurnal BP dipping profile greater than 10% (DS),

92   and those who do not (N-DS), and ii) to determine whether group differences exist

93   between DS (including extreme dippers) and N-DS (including reverse dippers) on usual

94   and dual-task gait speed, step length, and stride time variability, 24-hour ambulatory

95   systolic and diastolic BP, carotid intima-media thickness (cIMT), and carotid arterial

96   compliance (CAC). It was hypothesized that compared to DS, N-DS would: i) perform

97   worse on all cognitive tasks, and ii) demonstrate slower usual and dual-task gait speed,

98   shorter usual and dual-task gait step length, greater usual and dual-task stride time

99   variability, higher 24-hour ambulatory BP and cIMT, and lower CAC.

100   **Methods**

101   *Study Design*

102   A retrospective analysis was performed using pooled data collected from two, 6-

103   month exercise interventions that took place in London, Ontario. Targeted recruitment

104   efforts were focused on town-hall announcements, calls to past research participants, and

105   the distribution of advertisements to other locations (i.e., Retirement Research

106   Association of Western University, Boys & Girls Clubs, Kiwanis Clubs, and newspaper

107   ads) within London Ontario, and the surrounding communities.

108   *Participants*

109   The inclusion and exclusion criteria for each of the parent studies were identical.

110   Following consent, eligibility was determined during a pre-therapy visit via a medical

111   history review, seated resting office BP measures, and a comprehensive sensory and

112   motor function neurological exam (Hachinski et al., 2006), which included the Mini-

113   Mental State Examination (MMSE; Appendix C; Folstein, Folstein, & McHugh, 1975),

114   Montreal Cognitive Assessment (MoCA; Appendix D; Nasreddine et al., 2005), Centre of

115   Epidemiological Studies-Depression scale (CES-D; Appendix E; Lewinsohn, Seeley,

116   Roberts, & Allen, 1997), and the Lawton-Brody Instrumental Activities of Daily Living

117   scale (IADL; Appendix F; Lawton & Brody, 1969).

118   Older adults (60-90 years) without dementia [i.e., no previous dementia diagnosis

119   and a MMSE score > 24 (Folstein et al., 1975)] and preserved IADLs [i.e., Lawton Brody

120   IADL score ≥ 6 (Lawton & Brody, 1969)] were invited to participate. Individuals who

121   presented with significant neurological conditions (Parkinson's), recent severe

122   cardiovascular conditions (myocardial infarction, congestive heart disease), significant

123   mobility limitations (severe osteoarthritis), clinical depression [i.e., >16 on CES-D scale

124   (Lewinsohn et al., 1997) or at the discretion of the study physician], BP unsafe for

125   exercise [i.e., > 180/100 mmHg or < 100/60 mmHg (Thompson, Gordon, & Pescatello,

126   2010)], or those unable to comprehend the questionnaire material were excluded. All

127   participants provided written informed consent and the Western University Health

128   Sciences (Appendix A) and Lawson Health Research Institute (Appendix B) Research

129   Ethics Boards approved these studies.

130   ***Participant Characteristics***

131   Participant demographics and anthropometrics were collected upon entry to each

132   study, including: age, sex, ethnicity, education, self-reported cognitive complaints, and

133   body mass index. Medical history and current prescribed medications were recorded and

134   used to determine the presence of hypertension, type 2 diabetes, hypercholesterolemia,

135   osteoarthritis, and a previous cardiovascular or cerebrovascular event within each group.

136   Previous cardiovascular events included myocardial infarctions or bypass surgery;

137   previous cerebrovascular events included stroke or transient ischemic attacks.

138   Cardiovascular fitness [i.e., predicted maximal oxygen uptake] was determined using the

139   Step Test and Exercise Prescription (STEP; Appendix M) tool (Petrella, Koval,

140   Cunningham, & Paterson, 2001).

141   ***Outcomes***

142   All outcomes were collected over a span of two days, with cognition and gait

143   evaluated on the first day of assessments, and vascular health evaluated on the second day

144   of assessments. Each assessment session lasted approximately 60 minutes.

145   **Cognition**

146   Global cognition and domain-specific cognitive function (i.e., EF, information

147   processing speed, verbal fluency, and memory) were assessed using traditional

148   neuropsychological evaluations.

149   *Global Cognition*

150   MoCA scores that were collected during the screening and eligibility visit were

151   used as a surrogate of global cognitive functioning. The MoCA is a valid and reliable

152   (Costa et al., 2012; Freitas, Simões, Alves, Vicente, & Santana, 2012) cognitive screening

153   questionnaire that assesses cognitive functioning within 8 sub-domains, including

154   attention and concentration, orientation, short-term memory, visuospatial abilities, EF,

155   working memory, and language. The maximum total score is 30, with higher scores

156   indicating better global cognitive functioning.

157   *Executive Function*

158   EF was assessed using the Trail Making Tests (TMT) part B (Appendix H), TMT-

159   B minus A (B-A), and TMT-B to A ratio (B/A), which has been deemed a valid and

160   reliable method to evaluate set-shifting and executive control (Arbuthnott & Frank, 2000;

161   Hagen et al., 2014). The TMT-B requires participants to draw a line between alternating

162   numbers and letters (e.g., 1, A, 2, B, 3, C, etc.) as quickly and accurately as possible. The

163   time to test completion in seconds represents the outcome score for the test.

164   *Information Processing Speed*

165   Information processing speed was assessed using the TMT-A (Appendix G) and

166   the Digit Symbol Substitution Test (DSST; Appendix J). The TMT-A requires

167   participants to draw a line between consecutive numbers spanning from 1 to 25 as

168   quickly and accurately as possible. Time to complete the TMT-A is used as the outcome

169   score for the test. For the purposes of this study, the decision to include the TMT-A as a

170   measure of information processing speed was due to the specific cognitive requirements

171   of the TMT A task (i.e., simple motor task with lower perceptual complexity when

172   compared to TMT B; Arbuthnott & Frank, 2000).

173   The DSST is a 120 second task that requires participants to decode a test section

174   by using a legend to sequentially match numbers with their corresponding symbols as

175   quickly and accurately as possible. Performance on the DSST is dependent upon a

176   number of cognitive processes, including incidental memory, visuomotor coordination,

177   perceptual organization, sustained attention, psychomotor speed, and information

178   processing (Wechsler, 2003). The DSST has high test-retest reliability (Matarazzo &

179   Herman, 1984) and a maximum total score is 133, with higher scores indicating better

180   performance.

181   *Verbal Fluency*

182   Verbal fluency was assessed using semantic (Appendix K) and phonemic

183   (Appendix L) verbal fluency tasks. For the semantic verbal fluency outcome, participants

184   were required to provide as many unique responses to a category fluency task (i.e.,

185   naming animals) as possible in 60 seconds (Tombaugh, Kozak, & Rees, 1999). The

186   Controlled Oral Word Association (COWA; Benton, Lester, DeSandoz Hamsher, &

187   Sivan, 1994) test was used to evaluate phonemic verbal fluency, which required

188   participants to provide as many unique words that started with the letter "C", excluding

189   proper nouns, numbers, and suffix substitutions (e.g., love, loves, lover, loving, etc.). The

190   total numbers of unique responses provided over 60 seconds for each test were used as

191   the verbal fluency outcomes.

192   *Memory*

193   Memory was assessed using the Auditory Verbal Learning Test (AVLT; Van der

194   Elst, Van Boxtel, Van Breukelen, & Jolles, 2005). The AVLT (Appendix I) requires

195   participants to listen to a list of 15 monosyllabic words and provide as many correct

196   responses as possible over five independent trials. After the fifth trial, an interference list

197   containing 15 new monosyllabic words is presented, and participants are required to

198   recall as many items from the interference list as possible. Approximately five minutes

199   (immediate recall) and 30 minutes (delayed recall) after the administration of the

200   interference trial, participants are required to provide as many items from the original 15

201   item list as possible without having received any cues. Responses from each of the five

202   trials and the immediate and delayed recall trials were used as a measure of verbal

203   learning and memory, respectively.

204   **Gait**

205   Spatiotemporal gait characteristics were collected using an electronic walkway

206   system [GAITRite® System, Software version 4.7.1, CIR Systems, Peekskill, NY, USA]

207   following previously published techniques (Gregory et al., 2016). Briefly, participants

208   completed two standard (i.e., usual gait, UG) walking trials across the GAITRite mat at

209   usual preferred speed. Participants then performed three separate DT walking trials: one

210   "familiarization" (i.e., counting backwards from 100 by 1's) and two separate

211   experimental (i.e., naming animals and subtracting serial 7's from 100) DT conditions.

212   Gait characteristics were collected over two walking trials for each experimental

213   condition (i.e., usual, naming animals, serial 7's) and were averaged and used for

214   analysis. In order to avoid capturing the acceleration and deceleration phases of the gait

215   cycle, participant start and end points were positioned 1.5 metres from either end of the

216   mat (Montero-Odasso et al., 2009). Footfalls that did not entirely fall on the walkway at

217   the start and the end of each walk were removed prior to analyses. No instructions

218   regarding task prioritization were provided during the DT trials.

219   **Vascular Health**

220   In an attempt to avoid the effect of extrinsic factors on ambulatory BP and the

221   vascular ultrasonography assessments being performed on day 2, participants were asked

222   to avoid the participation in vigorous intensity exercise for 24 hours, the consumption of

223   alcohol and tobacco products for the final 12 hours, and the consumption of food for four

224   hours prior to the ultrasonography assessments (Pickering et al., 2005).

225   *Ambulatory Blood Pressure*

226   Upon completion of the first assessment day, participants were fitted with an

227   appropriately sized, valid and reliable (Iqbal, Fotherby, & Potter, 1996) ambulatory BP

228   cuff and monitor (Spacelabs^{TM} 90207 Ambulatory Blood Pressure Monitor, SpaceLabs

229   Inc), which they wore over the subsequent 24 hours. Ambulatory BP measures were

230   collected twice per hour during the day (i.e., 06:00 to 22:00) and once per hour at night

231   (i.e., 22:00 to 06:00), and the percent drop in daytime to nighttime mean systolic BP was

232   used to calculate DS. For instance, a participant would demonstrate a 10.4% dip in

233   systolic BP if they presented with a mean daytime systolic BP of 135 mmHg and a mean

234   night time systolic BP of 121 mmHg. Although mean daytime and night time systolic BP

235   were used to determine DS, mean 24-hour systolic and diastolic BP were considered as

236   outcomes for this study Participants were identified as N-DS if they demonstrated a <

237   10% reduction in systolic BP from daytime (i.e., 06:00 to 22:00) to night time (i.e., 22:00

238   to 06:00; O'Brien et al., 2013; Salles et al., 2016).

239   *Carotid Arterial Compliance and Intima-Media Thickness*

240   Immediately following the 24-hour ambulatory BP period, carotid arterial

241   stiffness measures were obtained using B-mode ultrasonography following previously

242   published techniques (Gregory et al., 2016). Briefly, participants were fitted with a 3-lead

243   ECG and underwent 5 to 10 minutes of supine rest in a quiet, temperature controlled (20

244   to 23°C) room. A longitudinal B-mode image (Vingmed, GE Ultrasound A/S, Horton,

245   Norway) of the cephalic portion of the right common carotid artery was then obtained 1-2

246   cm proximal to the carotid bifurcation (Gregory et al., 2016). Arterial diameters were

247   measured leading-edge-to-leading-edge at peak systole and end diastole over three

248   cardiac cycles and subsequently averaged. Following image acquisition, a single measure

249   of resting supine brachial arterial systolic and diastolic BP was recorded using automated

250   oscillometry (BPTru, Coquitlam, BC, Canada). Carotid arterial compliance (CAC) and

251   carotid intima-media thickness (cIMT) were considered as outcomes for this study;

252   arterial compliance was determined using the following equation:

253    $$\left[\pi \left(\frac{Dmax}{2}\right)^2 - \pi \left(\frac{Dmin}{2}\right)^2\right] \Delta P \qquad \text{(Equation 2)}$$

254   where D_{max} was the systolic carotid arterial diameter, D_{min} was the diastolic carotid

255   arterial diameter, and ΔP was resting brachial pulse pressure. cIMT was determined by

256   subtracting the carotid arterial lumen diameter from the outer arterial diameter at diastole

257   from the far wall of the carotid artery (Gregory et al., 2016).

258   **Analysis**

259   All analyses were performed using SPSS version 20 (SAS Institute Inc., Cary,

260   NC, USA). Participant characteristics and anthropometrics (i.e., age, sex, ethnicity,

261   education, body mass index, cardiovascular fitness, CES-D scores, MoCA and MMSE

262   scores) were compared between DS and N-DS using one-way ANOVA for continuous

263   data, and Chi-squared tests for categorical data. The prevalence of vascular risk factors,

264   mobility limitations (i.e., osteoarthritis), and previous cardiovascular or cerebrovascular

265   events were compared between DS and N-DS using Chi-squared tests. For the primary

266   outcomes, differences in cognitive performance (i.e., TMT-B, TMT-A, DSST, semantic

267   fluency & COWA, and AVLT) between DS and N-DS were investigated using one-way

268   ANOVA. For the secondary outcomes, differences in usual and dual-task (i.e., serial 7's)

269   gait and vascular health (i.e., 24-hour ambulatory SBP & DBP, cIMT, and CAC) between

270   DS and N-DS were investigated using one-way ANOVA. Means and standard deviations

271   (SD) were determined and two-sided P-values less than 0.05 were claimed as statistically

272   significant.

273   **Results**

274   *Participant Characteristics*

275   Participant enrolment began June 26th, 2012, and data collection was finalized

276   September 23rd, 2014. Across studies, of the 167 individuals who responded to the

277   recruitment efforts (Figure 3.1), 44 were excluded from the studies (30 did not meet

278   inclusion criteria, 14 declined to participate). An additional 8 participants did not have

279   complete ambulatory BP data, which precluded the determination of their dipping status

280   and resulted in their removal from this study. The remaining 115 individuals had

281   complete baseline data and were included in the analyses. All of the data that was used

282   for this study (i.e., ambulatory BP data used for group and outcome measures) was

283   collected at baseline within their respective intervention studies.

284
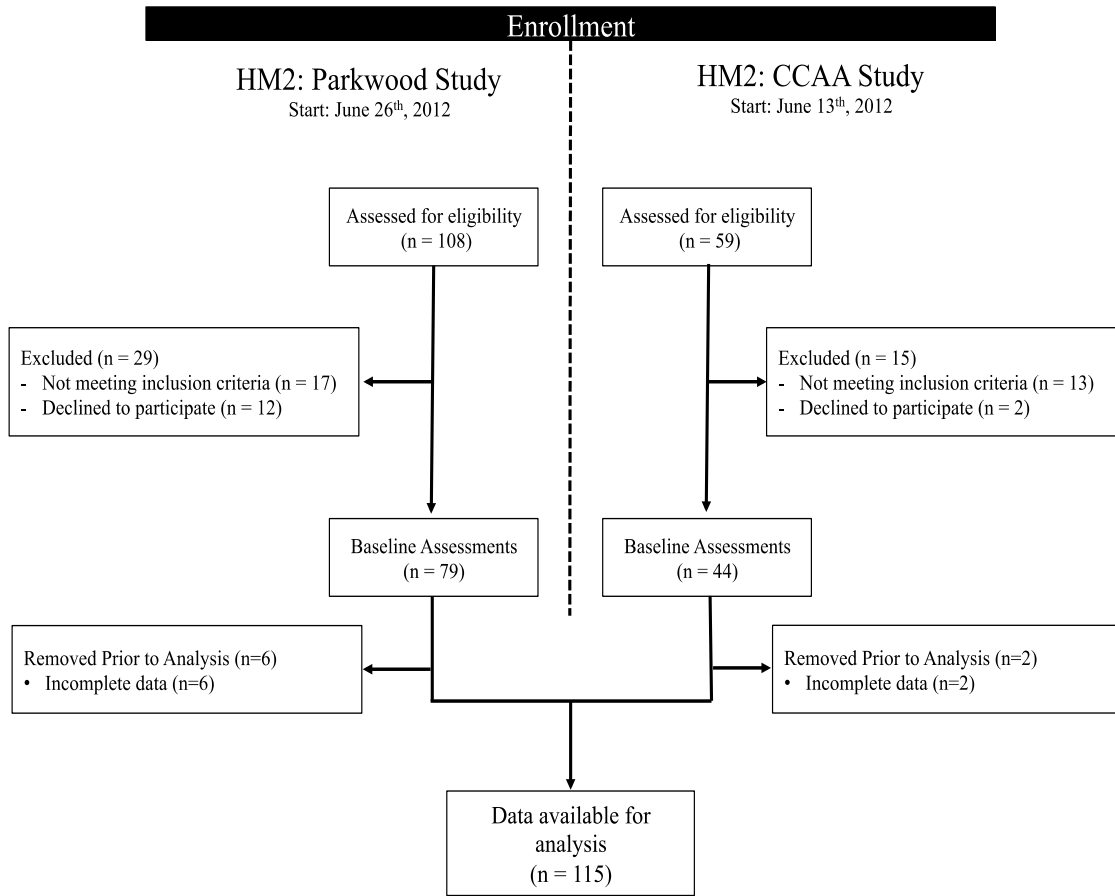

285

286   *Figure 3.1.* Participant recruitment for the Healthy Mind, Healthy Mobility (HM2)

287   Laboratory- and Community-based Exercise Interventions.

288

289   Participant characteristics are presented in Table 3.1. Participants were older

290   [mean (SD), 71.7 (6.9) years] and approximately 73% were female; most (96%) were

291   Caucasian, and all were highly educated [mean (SD): 15.5 (3.3) years of formal

292   education]. Educational attainment was the only participant characteristic that differed

293   between groups, with N-DS achieving a higher level of formal education compared to DS

294   [mean (SD); DS: 16.1 (3.3) vs. N-DS: 14.9 (3.1), p = .04]. On average, the participants in

295   the study scored well within the range to indicate the absence of clinical depression on

296   the CES-D [mean (SD): 5.8 (5.2)]. Over half (54.7%) of the participants reported that

297   their memory was worse than 5 years earlier. Objective cognitive screening corroborated

298   these subjective concerns, as participants had, on average, subtle indications of

299   underlying cognitive impairment [MoCA scores, mean (SD): 24.8 (2.2)] but not dementia

300   [MMSE scores, mean (SD): 28.5 (1.3)]. Vascular risk factors and medical comorbidities

301   were also prevalent among participants in this study; approximately half (47%) had

302   hypertension, 37% had hypercholesterolemia, 17% had type 2 diabetes, and 15% had

303   osteoarthritis. The occurrences of previous cardiovascular or cerebrovascular events were

304   rare among participants (6% and 10%, respectively). The prevalence of hypertension and

305   the occurrence of a previous cardiovascular events were the only two clinical

306   characteristics to differ between groups, with a higher proportion of those with N-DS

307   having hypertension [n (%); DS: 17 (35) vs. N-DS: 37 (56), p = .02] and only N-DS

308   reported having experienced a previous cardiovascular event [n (%); DS: 0 (0) vs. N-DS:

309   7 (11), p = .02].

Abbreviations: DS, Dippers; N-DS, Non-Dippers; SD, Standard Deviation; MMSE, Mini-Mental Status Examination; MoCA, Montreal Cognitive Assessment; CES-D, Centre for Epidemiological Studies Depression Scale

[a] Body Mass Index measured in kg/m^2

[b] Baseline fitness was estimated using the Step Test and Exercise Prescription (STEP) tool, and is measured in $mlO_2/kg/min$. Four participants from the N-DS group did not complete the STEP test and were missing data for this outcome

[c] Range from 0 to 30; lower scores indicate greater cognitive impairment

[d] Scores above 15 indicate clinical depression. Four participants from the N-DS group did not complete the CES-D and were missing data for this outcome

[e] Previous cardiovascular events included myocardial infarction, bypass surgery, or coronary artery stent implantation

[f] Previous cerebrovascular events included strokes or transient ischemic attacks (TIA)

314

315   *Group Differences in Cognition*

316   Differences in cognitive performance between DS and N-DS are presented in

317   Figure 3.2 and Table 3.2. N-DS performed worse on measures of EF [TMT B, mean

318   (SD); DS: 71.5 (29.2) sec vs. N-DS: 88.1 (31.8) sec, p=.005; TMT B-A, mean (SD); DS:

319   36.5 (21.6) sec vs. N-DS: 50.5 (28.0) sec, p=.004], information processing speed [DSST,

320   mean (SD); DS: 60 (14) correct vs. N-DS: 54 (13) correct, p=.03], and memory [AVLT

321   delayed recall, mean (SD); DS: 8 (3) correct vs. N-DS: 7 (4) correct, p=.02].

322   Performances on measures of verbal fluency, as well as other measures of information

323   processing speed and memory (i.e., TMT A and AVLT immediate recall) were not

324   significant (all p>.05).

Immediate recall (no. correct)[d]	8 (3)	9 (3)	7 (3)	.08
Delayed recall (no. correct)[e]	7 (4)	8 (3)	7 (4)	**.02**

Abbreviations: TMT, Trail Making Test; BmA, TMT B score minus A score; BdA, TMT B score divided by A score; DSST, Digit Symbol Substitution Test; COWA, Controlled Oral Word Association Test

[a] All data is presented as mean (standard deviation)

[b] Semantic verbal fluency was assessed using "animals" as the category

[c] COWA required participants to provide unique words starting with the letter "C", excluding proper nouns, numbers, and simple suffix changes

[d] Immediate verbal recall was performed approximately 5 minutes following the interference trial

[e] Delayed verbal recall was performed approximately 30 minutes following the interference trial

339

340   *Group Differences in Usual and Dual-task Gait*

341   Differences in usual and dual task (i.e., naming animals and serial 7's) gait

342   performance between DS and N-DS are presented in Figure 3.3 and Table 3.3. Compared

343   to DS, N-DS had slower usual gait speed [mean (SD); DS: 1.17 (.16) vs. 1.09 (.18) m/sec,

344   p=.01] and greater usual gait stride time variability [CoV (%), mean (SD); DS: 1.9 (.6)

345   vs. N-DS: 2.2 (.9) %, p=.03]. Compared to DS, N-DS also demonstrated shorter step

346   length while performing both dual tasks [naming animals, mean (SD); DS: 60.4 (7.2) vs.

347   N-DS: 56.8 (9.6) cm; serial 7's mean (SD); DS: 59.2 (7.2) vs. N-DS: 55.4 (9.6) cm, both

348   p=.02]. N-DS also demonstrated slower gait speed while performing the verbal fluency

349   task but not the serial 7's subtraction task, and greater stride time variability while

350   performing the serial 7's subtraction task but not the verbal fluency task when compared

351   to DS.
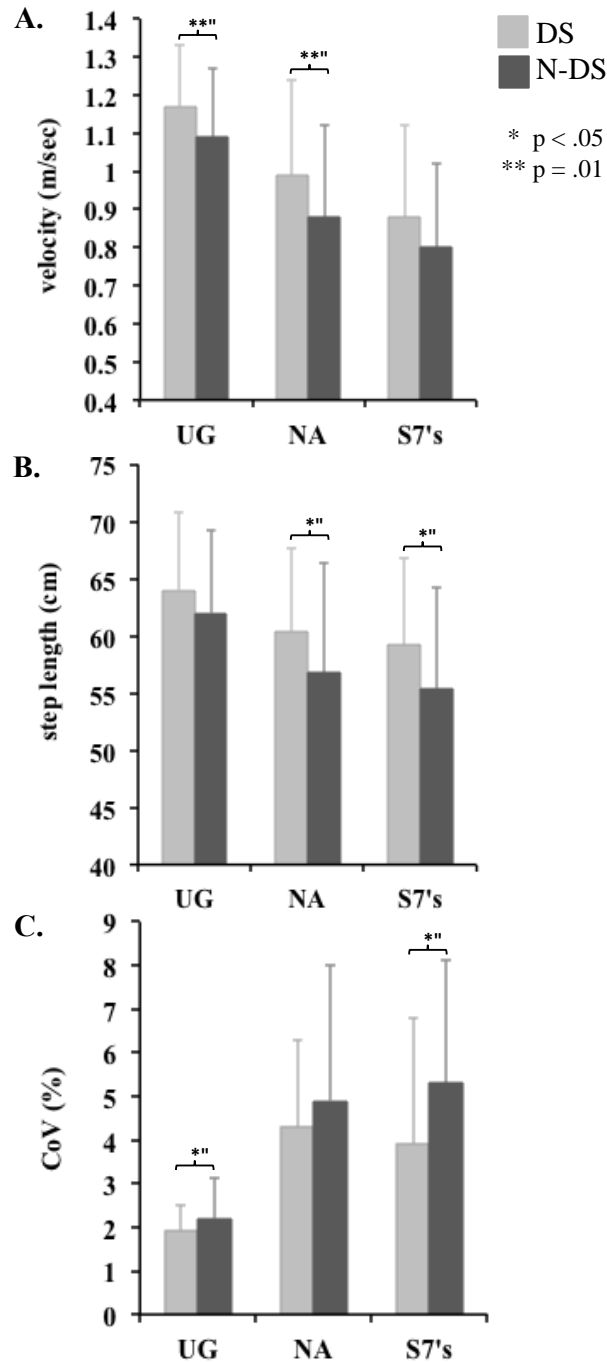

352
353
354   Abbreviations: UG, usual gait; NA, naming animals, S7's, serial sevens; m/sec, metres per second; cm,
355   centimetres; CoV, coefficient of variation (%). A. Usual and dual-task gait speed, B. Usual and dual-task
356   step length, C. Usual and dual-task stride time variability. Naming animals and serial seven subtractions
357   were used as verbal fluency and arithmetic dual-task conditions during the gait assessments.
358

359   *Figure 3.3.* Group differences in usual and dual-task gait performance between older

360   adults with normal blood pressure dipping status (DS) and those with reduced blood

361   pressure dipping status (N-DS).

362   **Table 3.3**

363   *Usual and Dual-task Gait Characteristics for the Total Sample, Older Adults with*

364   *Normal Blood Pressure Dipping Status (DS), and Those with Reduced Blood Pressure*

365   *Dipping Status (N-DS).[a]*

Characteristic	Total (n=115)	DS (n=49)	N-DS (n=66)	Group difference (p-value)
Usual gait				
Velocity (m/sec)	1.13 (.18)	1.17 (.16)	1.09 (.18)	**.01**
Step length (cm)	62.6 (7.1)	64.0 (6.8)	62.0 (7.3)	.11
Stride time variability (CoV, %)[b]	2.2 (1.0)	1.9 (.6)	2.2 (.9)	**.03**
Dual-task (naming animals) gait				
Velocity (m/sec)	.93 (.23)	.99 (.25)	.88 (.18)	**.01**

Stride time variability (CoV, %)[c]	4.7 (2.8)	4.3 (2.0)	4.9 (3.1)	.25
Dual-task (serial 7's) gait				
Velocity (m/sec)	.83 (.24)	.88 (.25)	.80 (.24)	.11
Step length (cm)	57.0 (8.8)	59.2 (7.2)	55.4 (9.6)	**.02**
Stride time variability (CoV, %)[d]	4.7 (3.1)	3.9 (2.0)	5.3 (3.1)	**.03**
Vascular Health				
24-hour systolic BP (mmHg)	129 (12)	127 (12)	131 (12)	.10
24-hour diastolic BP (mmHg)	72 (8)	71 (8)	73 (8)	.20
Carotid IMT (mm)	.65 (.13)	.66 (.12)	.65 (.14)	.88
Carotid AC (mm^2/mmHg x 10^{-1})	.86 (.54)	.89 (.67)	.83 (.43)	.57

Abbreviations: AC, arterial compliance; CoV, coefficient of variation; mmHg, millimeters of mercury; IMT, intima-media thickness

[a] All data is presented as mean (standard deviation)

[b] n = 47 for Dippers and n = 64 for Non-Dippers following the removal of outliers

[c] n = 44 for Dippers and n = 62 for Non-Dippers following the removal of outliers

[d] n = 41 for Dippers and n = 63 for Non-Dippers following the removal of outliers

366

367   *Group Differences in Vascular Health*

368   Differences in 24-hour ambulatory systolic and diastolic BP, cIMT and CAC

369   between DS and N-DS are also presented in Table 3.3. Despite participants having been

370   stratified into groups by ambulatory BP dipping status (a known CVD risk factor), there

371   were no differences between DS and N-DS on 24-hour systolic and diastolic BP, cIMT,

372   or CAC (all p > .05).

373   **Discussion**

374   Until effective prevention and management strategies for cognitive impairment

375   are developed, dementia is expected to continue to place a significant burden on the

376   global health-care systems and economy (Brookmeyer et al., 2007; Fisher et al., 2011;

377   Prince et al., 2015; Werner, 2012). Thus, developing a thorough understanding of the

378   pathological processes and risk factors that are associated with the development of

379   subclinical cerebrovascular disease and dementia is of significant clinical importance.

380   CVD risk factors have been implicated as mechanisms that drive the development and

381   progression of neuropathological changes in the brain, which predispose individuals to

382   cognitive impairment and an increased risk of dementia. Despite these observations, the

383   specific mechanisms by which traditional CVD risk factors impart detrimental effects on

384   the aging brain have yet to be fully elucidated.

385   Hypertension is a known risk factor for a number of chronic conditions in aging,

386   including cardiovascular morbidity (i.e., left ventricular hypertrophy), coronary heart

387   disease, and stroke (ABC-H Investigators et al., 2014; Verdecchia et al., 1990;

388   Verdecchia et al., 1994); recent evidence also implicates hypertension as a risk factor for

389   neuropathological changes to the brain and dementia (Beauchet et al., 2013; Brickman et

390   al., 2010; Dai et al., 2008; Dufouil et al., 2001; Goldstein, Bartzokis, Hance, & Shapiro,

391   1998; Langbaum et al., 2012; Petrovitch et al., 2000; van Dijk et al., 2004). In addition to

392   poor BP control, other CVD risk factors (i.e., arterial stiffness, diabetes) contribute to the

393   development and accumulation of vascular-related brain injury and subsequent cognitive

394   impairment (Crane et al., 2013; Daviglus et al., 2011; Hooshmand et al., 2013; Tsao et

395   al., 2013). Collectively, these observations suggest that the health of the cardiovascular

396   and cognitive systems is intimately linked, and the accumulation of any given CVD risk

397   factor can detrimentally affect the brain. Thus, investigating the association between

398   cognitive functioning and the presence of other established and novel CVD risk factors

399   may help to characterize the mechanisms by which vascular health influences cognitive

400   health and functioning in aging.

401   Although N-DS has been identified as an independent CVD risk factor

402   (Verdecchia et al., 1994; Verdecchia et al., 1990) and has been implicated as a

403   mechanism that contributes to the development white matter hyperintensities (Goldstein

404   et al., 1998), the association between blunted BP dipping and cognitive functioning

405   remains poorly understood. In the current study, community-dwelling older adults with

406   N-DS scored worse on a number of diverse cognitive outcomes, including measures of

407   EF, information processing speed, and verbal memory delayed recall when compared to

408   their DS peers, despite having significantly higher levels of formal education. These

409   results are, however, aligned with previous observations that have suggested that specific

410   components of BP regulation may be more appropriate to consider when evaluating

411   chronic disease risk than merely systolic BP in isolation. For instance, recent meta-

412   analyses and observational studies have suggested that nighttime systolic BP outperforms

413   day time systolic BP as a predictor of all-cause mortality, cardiovascular mortality,

414   coronary heart disease and stroke in older hypertensive adults (ABC-H et al., 2014;

415   Fagard et al., 2008). Higher pulse pressure (i.e., the difference between systolic and

416   diastolic BP) has also been associated with the accumulation of fibrillar amyloid beta

417   burden and impaired glucose metabolism within the cortex (Langbaum et al., 2012), both

418   of which are hallmarks of Alzheimer's disease pathology. Last, higher BP variability (i.e.,

419   a greater degree in the fluctuations of BP) at baseline has also been associated with a

420   higher prevalence of cerebral infarctions and white matter hyperintensities over 6 years of

421   follow-up (Brickman et al., 2010). Collectively, these observations and those presented

422   within the current study support the notion that discrete BP characteristics may provide

423   additional prognostic utility for the development of CVD and neuropathological changes

424   to the aging brain, beyond what can be achieved using systolic BP alone. Indeed,

425   previous studies have identified a negative relationship between N-DS and global

426   cognition, memory, and information processing speed that were not apparent when

427   considering other measures of BP in older adults with and without hypertension (Bellelli

428   et al., 2004; Nagai et al., 2008; Ohya et al., 2001; van Boxtel et al., 1998). However,

429   questions regarding the specific association between N-DS and brain health and

430   functioning, and the mechanisms that drive the association between N-DS and cognition

431   in aging remain. Further research is required to characterize the relationship between

432   specific components of BP and brain health and function in those with and without pre-

433   existing CVD and cognitive impairment.

434   The exposure to both protective and risk factors for dementia over the course of

435   one's life differentially affect the probability of developing dementia in aging

436   (Fratiglioni, Winblad, & von Strauss, 2007). However, the relationship between these

437   protective and risk factors, and the nature by which they cumulatively affect the aging

438   brain remains poorly understood. In the current study, participants with N-DS

439   demonstrated worse cognitive performance despite having achieved significantly higher

440   levels of formal education. This observation suggests two likely possibilities: i) that

441   physiological risk factors are of greater clinical and prognostic importance to brain aging

442   than experiential factors or ii) the time course of exposure to protective and risk factors

443   influences the degree by which these factors affect brain health; the benefits of higher

444   formal education in young adulthood are undone by the sustained exposure to risk factors

445   in middle to older age. However, this observation must be replicated, and further study

446   into the interplay between physiological and experiential dementia risk factors is required

447   to definitively determine how these factors cumulatively influence the aging brain.

448   Mobility impairments, specifically gait dysfunction, manifest as cognitive function

449   declines. For instance, impaired gait, specifically, reductions in gait speed, step length,

450   and elevations in stride time variability is a common characteristic of those with mild

451   cognitive impairment and dementia (Muir et al., 2012; Verghese et al., 2008), and is

452   amplified under dual-task conditions (Hausdorff, Schweiger, Herman, Yogev-Seligmann,

453   & Giladi, 2008). Gait abnormalities have also been suggested as potentially modifiable

454   dementia risk factors (Mielke et al., 2013). For instance, reductions in gait speed develop

455   prior to the establishment of objective cognitive impairment (Mielke et al., 2013), and

456   have been linked with the presence of CVD risk factors (Rosano et al., 2011), vascular-

457   related neuropathological changes to the brain (Holtzer, Epstein, Mahoney, Izzetoglu, &

458   Blumen, 2014; Rosano, Brach, Studenski, Longstreth, & Newman, 2007; Rosano, Rosso,

459   & Studenski, 2014), and poorer objective cognitive functioning (Mielke et al., 2013;

460   Holtzer, Verghese, Xue, & Lipton, 2006; Montero-Odasso, Verghese, Beauchet, &

461   Hausdorff, 2012; van Iersel, Kessels, Bloem, Verbeek, & Olde Rikkert, 2008). EF

462   appears to play a specific and intimate role in gait performance, as the cognitive control

463   of gait has been localized within the regions of the brain that are involved with executive

464   control processes (Persad, Jones, Ashton-Miller, Alexander, & Giordani, 2008; Montero-

465   Odasso et al., 2012; Rosano et al., 2008). Collectively, these observations suggest that the

466   control of gait under usual and dual-task conditions is dependent upon the functional and

467   structural integrity of the regions of the brain associated with EF, and the accumulation of

468   vascular-related injury within these regions can contribute to the simultaneous

469   development of gait dysfunction and cognitive impairment.

470   Results from the present study corroborate these previous observations, as N-DS

471   exhibited slower gait speed and higher gait variability under usual and dual-task

472   conditions, and reduced step length under dual task conditions when compared to DS. Of

473   particular interest, the participants within the current study did not exhibit significant

474   objective cognitive impairment [total sample MMSE = 29 (1); total sample MoCA: 26

475   (2)] and there were no observable differences in global cognitive functioning between

476   older adults with DS and N-DS.

477   Together, these observations suggest that N-DS may be a risk factor that drives

478   the initial development subclinical cerebrovascular disease that can affect both cognition

479   and mobility in older adults prior to the establishment of significant objective cognitive

480   impairment. Thus, BP dipping status may be more a more effective surrogate of vascular-

481   related cognitive risk in aging than ambulatory BP indices or central arterial health (i.e.,

482   cIMT and CAC). Future prospective cohort studies are required to definitively determine

483   the temporal relationship between BP dipping and changes in cognition and mobility in

484   older adults with and without cognitive impairment.

485   **Future Directions and Recommendations**

486   N-DS is associated with poor objective cognitive functioning and gait dysfunction

487   in community-dwelling older adults without dementia. However, several limitations must

488   be addressed before the nature of the relationship between N-DS and brain health in

489   aging can be thoroughly understood. First, this secondary analysis was cross-sectional

490   and is thus limited by an inability to determine causality. Furthermore, the predominantly

491   Caucasian, relatively healthy, well-educated and functionally independent older adults

492   within this study will limit the ability to generalize these findings. Prospective cohort

493   studies that define their objectives *a priori*, incorporate appropriately spaced longitudinal

494   follow-up visits, and recruit a number of clinical populations will be required to

495   overcome these issues (Goldstein et al., 1998). Second, other BP dipping phenotypes

496   (i.e., extreme dippers, reverse dippers) have been associated with the incidence of total

497   cardiovascular events, but their relationship with brain health and functioning has yet to

498   be investigated. In the current study, only three of the 49 DS participants were extreme

499   dippers (i.e., >20% drop is systolic BP from daytime to night time) and only 14 of the 66

500   N-DS participants were reverse dippers (i.e., rise in systolic BP from daytime to night

501   time). The small sizes of these two dipping phenotypes precluded the ability to perform

502   meaningful subgroup analyses. In order to comprehensively characterize the influence of

503   diurnal BP variation on brain health, the recruitment of older adults who demonstrate

504   other BP dipping phenotypes should be a priority. Third, previous observations suggest

505   that the relationship between N-DS and cardiovascular health may be sex-specific, with

506   N-DS women being at greater risk for cardiovascular morbidity than men (Verdecchia et

507   al., 1994; Verdecchia et al., 1990); future works should be specifically designed and

508   powered to investigate the possibility of sex-specific relationship between N-DS,

509   cognition, and mobility. Fourth, the possibility for confounders and covariates to

510   influence the relationship between dipping status and cognition were not accounted for in

511   this investigation, and should be considered when interpreting these findings. Finally, the

512   relationship between N-DS, dementia risk factor candidates, and brain health remains

513   relatively understudied. Future work should aim to determine the extent by which N-DS

514   drives neuropathological changes in the aging brain, and to determine the degree by

515   which N-DS pathologically influences brain health in aging when compared to other

516   potential vascular-related dementia risk factors (i.e., hypertension, type 2 diabetes,

517   hypercholesterolemia, etc.).

518   **Conclusions**

519   The establishment and progression of pathological cognitive decline in aging is

520   intimately linked with cardiovascular health and the detrimental influence of the presence

521   of chronic CVD risk factors. Continuing to define the risk factors for dementia and

522   determining the specific mechanisms by which known risk factors influence the brain

523   remains a significant research and clinical priority. Diurnal BP variation appears to be a

524   promising potential candidate, as N-DS was associated with poorer performance on

525   measures of EF, information processing speed, and memory, and usual and dual-task gait

526   impairments in this sample of community-dwelling older adults without dementia in this

527   study. However, this work is cross-sectional and does not allow for the establishment of

528   causality in this relationship; further work is required in order to solidify blunted BP

529   dipping as a risk factor for cognitive and functional impairment in aging. The

530   development of interventions that can beneficially impact BP control while

531   simultaneously mitigating the burden of other CVD-related dementia risk factors in older

532   adults prior to the establishment of vascular-related cerebral pathology (i.e., middle-aged)

533   may be one of the most promising strategies to prevent pathological cognitive impairment

534   in the elderly. Lifestyle modifications, including a well-balanced diet (Bacon, Sherwood,

535   Hinderliter, & Blumenthal, 2004) and the habitual participation in physical exercise

536   training (Wang, Li, Dong, Zhang, & Zhang, 2015) can reduce vascular risk factor burden,

537   and evidence suggests that these interventions and cognitive training can also benefit

538   brain health and functioning (Gregory, Gill, & Petrella, 2013). Future work should aim to

539   determine whether combined lifestyle interventions (i.e., nutritional or dietary counseling

540   with multiple modality exercise training) could benefit vascular health and restore diurnal

541   BP variation, and whether these improvements mediate the maintenance of or beneficial

542   changes to the structure and function of the brain.

1   *The Global Burden of Cognitive Impairment in Aging*

2   As the global population continues to age, the incidence of dementia is expected

3   to continue to rise. Currently, there are more than 46 million cases of dementia

4   worldwide, a number that is expected to double every two decades to reach

5   approximately 131.5 million by 2050 (Prince et al., 2015). This forecast is coupled with

6   projections that estimate 9.9 million new cases of dementia will be diagnosed globally

7   each year, and suggests that there will be one new case of dementia diagnosed every 3.2

8   seconds (Prince et al., 2015). These predictions are also accompanied by a considerable

9   economic burden; the global costs of dementia have risen by 35.4% over the past five

10   years, reaching $818 billion dollars (United States dollars) in 2015 (Prince et al., 2015).

11   Dementia has gained considerable global recognition, as recent work from the G7 has led

12   to a "Global Action Against Dementia" plan that aims to identify effective dementia

13   treatment and prevention strategies within the next 10 years (Prince et al., 2015). An

14   integral component to dementia prevention efforts will be the identification of modifiable

15   risk factors for dementia (Daviglus et al., 2010; Daviglus et al., 2011; Lehert, Villaseca,

16   Hogervorst, Maki, & Henderson, 2015; Prince et al., 2015; Xu et al., 2015) and the

17   development of interventions that can reduce risk factor burden and benefit brain health

18   and functioning in older adults who are at risk for future cognitive impairment (Gregory,

19   Gill, & Petrella, 2013).

20   *Risk Factors for Cognitive Impairment and Dementia*

21   Cardiovascular disease (CVD) risk factors have been recognized as some of the

22   most readily modifiable risk factors for dementia (Montine & Larson, 2009; Xu et al.,

23   2015); developing a thorough understanding of the link between CVD and cognitive

24   impairment is a significant research priority. Indeed, an association between heart and

25   brain health has been identified, as greater vascular risk factor burden is associated with

26   greater task-related activation and poorer task performance on executive function (EF)

27   tasks in community-dwelling older adults (Chuang et al., 2014), and has been found to

28   increase the risk of incident dementia over five years of follow-up among older adults

29   with mild cognitive impairment (Li et al., 2011).

30   *Exercise Training and Cognitive Function in Older Adults*

31   Healthy lifestyle choices, such as the habitual participation in aerobic exercise

32   (AE), consistently reduces CVD risk factor burden, and evidence suggests that exercise

33   may also be an important strategy to reduce the risk of cognitive impairment and slow the

34   progression of dementia (Barnes, Yaffe, Satariano, & Tager, 2003; Xu et al., 2015).

35   Previous meta-analyses suggest that AE can improve cognitive function within a number

36   of cognitive domains, including processing speed, memory, and EF in healthy older

37   adults (Colcombe & Kramer, 2003; Hindin & Zelinski, 2012; Smith et al., 2010) and can

38   improve verbal fluency in those with indications of underlying cognitive impairment

39   (Gates, Fiatrone Singh, Sachdev, & Valenzuela, 2013). Of particular interest, EF appears

40   to be particularly responsive to AE training (Colcombe & Kramer, 2003) and can also

41   improve following cognitive training (CT; Kelly et al., 2014a). Furthermore, cognitive

42   training (or cognitive exercise) has also been found to lead to improvements in EF and

43   memory in healthy older adults (Kelly et al., 2014a; Willis et al., 2006) and in those with

44   cognitive impairment (Klusmann et al., 2010). Although the evidence from these reviews

45   is promising, recent meta-analyses have revealed inconsistencies regarding the impact of

46   AE interventions and improvements in aerobic fitness on cognitive functioning in older

47   adults, and the specific exercise training modality that is best suited to benefit the brain

48   remains to be determined (Kelly et al., 2014b; Snowden et al., 2011; Young, Angevaren,

49   Rusted, & Tabet, 2015).

50   *Novel Exercise Modalities to Improve Cognition in Older Adults*

51   In addition to AE and CT, the effect of novel exercise modalities [i.e., dual-task

52   (DT) training] on cognition and mobility in older adults has received increasing attention.

53   DT training is a multi-dimensional intervention that combines physical and cognitive

54   tasks in order to directly train the parieto-frontal networks of the brain (Collette et al.,

55   2005) to divide attention and co-ordinate actions more efficiently (Erickson et al., 2007;

56   Kramer, Larish, & Strayer, 1995). For instance, Erickson et al. (2007) observed a DT

57   training-related 'shift' in the location of DT-related brain activity (i.e., reduced activation

58   within the right ventral inferior gyrus, right and left superior parietal lobules, and right

59   dorsal inferior gyrus accompanied by increased activation within the dorsolateral

60   prefrontal cortex from pre- to post-training), and suggested that this may represent a

61   training-induced reorganization of the cortical areas involved in dual-tasking processing.

62   DT exercise training has been found to benefit memory (Eggenberger, Schumacher,

63   Angst, Theill, & de Bruin, 2015; Nishiguchi et al., 2015), EF (Eggenberger et al., 2015;

64   Forte et al., 2013; Nishiguchi et al., 2015; Silsupadol et al., 2009a), and global cognition

65   (Gill et al., 2016), and can reduce the activation within regions of the brain associated

66   with short-term memory functioning (Nishiguchi et al., 2015), and increase DT gait speed

67   (Silsupadol et al., 2009b) in cognitively healthy older adults. DT exercise training has

68   also been shown to benefit memory and EF, as well as usual and dual task gait speed

69   among elderly fallers (Dorfman et al., 2014) and improve DT performance (i.e., reduced

70   DT cost on gait speed while walking and performing serial 3 subtractions) among older

71   adults with dementia (Schwenk, Zieschang, Oster, & Hauer, 2010). Collectively, these

72   observations suggest that DT exercise programs can benefit neural functioning, which

73   may in turn mediate improvements in objective cognitive functioning, dynamic balance,

74   and usual and DT gait performance among older adults.

75   Despite these initial observations, several limitations within the current literature

76   must be addressed before the cognitive benefits of aerobically based exercise training can

77   be fully understood. Specifically, longer duration interventions that incorporate well-

78   validated cognitive outcome measures and longitudinal follow-up are required to

79   determine the trajectory of cognitive change throughout the course of the intervention,

80   and whether any cognitive benefits are maintained following the cessation of exercise

81   training (Gregory et al., 2013; Kelly et al., 2014b; Snowden et al., 2011; Young et al.,

82   2015). Furthermore, it is crucial to determine the efficacy of interventions aimed at

83   simultaneously reducing the burden of modifiable dementia risk factors (i.e., CVD risk

84   factors) and improving cognition and mobility in older adults at increased risk for future

85   cognitive decline.

86   Thus, the primary objective of this study was to determine whether 26 weeks of

87   DT gait training and aerobic exercise (DAE) training can improve performance on an EF

88   task. It is hypothesized that 26 weeks of DAE training will stimulate improvements in

89   EF. The secondary objectives include determining whether 26 weeks of DAE training

90   can: i) improve performance on cognition tasks across multiple domains, including,

91   information processing, verbal fluency, and memory; ii) improve usual and DT gait

92   performance; iii) reduce 24-hour ambulatory systolic and diastolic blood pressure (BP),

93   and decrease vascular stiffness (i.e., carotid arterial compliance and intima media

94   thickness; and iv) stimulate changes in cognition, mobility, and vascular outcomes that

95   are maintained six months following the cessation of training. It is hypothesized that

96   DAE training will: i) improve performance across all of the measured cognitive domains;

97   ii) improve usual and DT gait performance; iii) reduce 24-hour ambulatory BP and

98   decrease vascular stiffness (i.e., increase compliance and reduce intima media thickness);

99   and iv) provide cognitive, mobility, and vascular benefits that will be maintained for six

100   months following training.

101   **Methods**

102   *Study Design*

103   This study was a 6-month experimental case series coupled with a 6-month no-

104   contact follow-up. Participants were assessed at four time points throughout the

105   intervention and follow-up period: i) baseline, ii) interim (3 months), iii) intervention

106   endpoint (6 months), and iv) study endpoint (12 months).

107   *Participants*

108   Participants were recruited from London, ON through the use of town hall

109   announcements, calls to past research participants, and the distribution of advertisements

110   to various locations throughout the community (i.e., Boys & Girls Clubs, Kiwanis Clubs,

111   media outlets). Community-dwelling older adults (60-90 years) without dementia [i.e., no

112   previous dementia diagnosis and a Mini Mental State Examination (MMSE) score > 24

113   (Appendix C; Folstein, Folstein, & McHugh, 1975)], and preserved instrumental

114   activities of daily living [Lawton-Brody Instrumental Activities of Daily Living (IADL)

115   scale (Appendix F; Lawton & Brody, 1969)] were invited to participate. Older adults who

116   demonstrated significant neurological (i.e., Parkinson's) or orthopaedic (i.e., severe

117   osteoarthritis) conditions, clinical depression [i.e., >16 on Center for Epidemiologic

118   Studies-Depression (CES-D) Scale (Appendix E; Radloff, 1977)] or at the discretion of

119   the study physician), or BP unsafe for exercise [i.e., 180/100 mmHg or < 100/60 mmHg

120   (Thompson, Gordon, & Pescatello, 2010)], and those who reported a recent severe

121   cardiovascular complication (i.e., congestive heart failure, stroke), or could not

122   comprehend the questionnaire material were excluded from participation.

123   *Sample Size*

124   No study to date has observed the impact of laboratory-based DAE on EF in older

125   adults; however, following reviews of studies using AE (Baker et al., 2010; Colcombe &

126   Kramer, 2003) and other cycle-based exergaming (Anderson-Hanley et al., 2012) to

127   improve cognition [i.e., EF measured via the Trail Making Test Part B (TMT B;

128   Appendix H)] in older adults allowed for the selection of an effect size of d=0.66 for our

129   calculations. The valid and reliable TMT-B (Arbuthnott & Frank, 2000; Reitan, 1958;

130   Shibuya-Tayoshi et al., 2007) is specific to EF processes due to its requirements for

131   switching sets and mental tracking throughout the task (Arbuthnott & Frank, 2000;

132   Hagen et al., 2014) and was considered the primary outcome measure. Assuming an

133   alpha of 0.05, 80% power, and a drop out rate of 10%, 84 participants were required for

134   this study [G*Power ver. 3.1.9.2 (Faul, Erdfelder, Lang, & Buchner, 2007)].

135   *Baseline Variables*

136   Participant medical history and demographics were collected at baseline, and

137   include: age, sex, ethnicity, years of formal education, body mass index, global cognitive

138   functioning, the presence of subjective cognitive complaints, and estimated

139   cardiorespiratory fitness [i.e., predicted maximal oxygen uptake (VO_2 max)]. Global

140   cognitive functioning was assessed using the Montreal Cognitive Assessment (MoCA;

141   Appendix D; Nasreddine et al., 2005). Predicted VO_2max was estimated using the Step

142   Test and Exercise Prescription (STEP) tool (Appendix M; Stuckey, Knight, & Petrella,

143   2012), which requires participants to climb and descend a set of standardized steps

144   twenty times at a self-selected moderate pace, and uses time to completion, post-test heart

145   rate, age, and sex within the prediction algorithm to estimate VO_2 max.

146   <u>Cognition:</u> Cognition was assessed across 4 domains, including EF, information

147   processing speed, verbal fluency, and memory.

148   EF was assessed using Trail Making Tests (TMT), which requires participants to

149   draw a line between 25 consecutive encircled numbers on a piece of paper (TMT-A;

150   Appendix G), and between alternating numbers and letters (TMT-B; Appendix H). The

151   time to test completion in seconds represents the outcome score for each part of the test.

152   For the purposes of this study, TMT-B served as a surrogate of EF and the primary

153   cognitive outcome, while TMT-A served as an index of information processing and a

154   secondary cognitive outcome.

155   Information processing speed was also assessed using the valid and reliable

156   (Matarazzo & Herman, 1984) Digit-Symbol Coding (DSC; Appendix J) from the

157   Weschler Adult Intelligence Scale, 3rd Ed. (Wechsler, 2003). The DSC required

158   participants to decode the test section by using a legend to sequentially match the

159   numbers with the corresponding symbols as quickly and accurately as possible.

160   Maximum total score obtained in 120 seconds was used as the outcome.

161   Semantic (animal naming; Appendix K) and phonetic [Controlled Oral Word

162   Association Test; Appendix L; Benton, Hamsher, & Sivan, 1994)] fluency tasks were

163   used to evaluate lexical verbal fluency. For the phonetic verbal fluency task, participants

164   were required to exclude proper nouns and suffix substitutions (i.e., love, loves, lover,

165   loving, etc.) from the responses that were provided. The total number of correct responses

166   provided over 60 seconds was used as the outcome score for each task, and repeated

167   responses were not considered in the final score.

168   Memory was assessed using the Auditory Verbal Learning Test (AVLT;

169   Appendix I; Van der Elst, Van Boxtel, Van Breukelen, & Jolles, 2005). This test contains

170   15 monosyllabic words that are presented over five subsequent trials. After each trial,

171   participants were required to freely recall as many words from the list as possible without

172   receiving any cues from the administrator. Following the fifth trial, an interference trial

173   was performed, whereby a new 15-item word list was read and participants were required

174   to freely recall as many items from this list as possible. Approximately five minutes after

175   the interference trial, an immediate recall trial was performed, where participants were

176   required to provide as many items from the original 15 word list as possible, without

177   receiving cues by the administrator. Approximately 30 minutes following the immediate

178   recall trial, a delayed recall trial of the original list was performed. Responses from the

179   immediate and delayed recall trials were tallied separately and served as the memory

180   outcomes.

181   Mobility (gait): Usual and DT gait analysis was used to assess mobility.

182   Spatiotemporal gait characteristics were collected using a valid and reliable

183   (Brach, Perera, Studenski, & Newman, 2008) portable electronic walkway system

184   [GAITRite® System; 580 x 90 x .63cm (L x W x H), that has an active electronic surface

185   area 792 x 610 cm (L x W), with a total of 29,952 pressure sensors, and scanning

186   frequency of 60 Hz, Software version 4.7.1, CIR Systems, Peekskill, NY, USA]. In order

187   to avoid capturing acceleration and deceleration phases of the gait cycle, participant start

188   and end points were placed 1.5 metres before and after the mat. Participants were

189   required to complete two usual walking trials at a comfortable pace, and then performed

190   three separate DT walking trials: a "sham" DT condition (i.e., counting backwards from

191   100 by 1's), and two experimental DT conditions (i.e., naming animals and subtracting

192   serial 7's from 100). For the usual and two experimental DT conditions, gait performance

193   over two walks were averaged and used for analysis. The sham DT condition was

194   incorporated as an attempt to familiarize the participants to the requirements of the DT

195   condition and was not considered for analysis. There was no instruction to prioritize gait

196   or responses to the cognitive tasks during the DT trials, and any footfalls that did not

197   entirely fall on the walkway during data collection were removed prior to analysis.

198   A total of three outcomes for each gait condition were considered as outcomes: i)

199   velocity (m/sec), ii) step length (cm), and iii) stride time variability (CoV, %). Gait

200   performance during the second experimental condition (serial 7s from 100) was selected

201   to serve as the DT gait outcome for two reasons: i) recent literature followed a similar

202   approach for the DT condition used during a gait assessment (i.e., arithmetic-based task)

203   following an treadmill based exercise intervention (Dorfman et al., 2014); and ii) as an

204   attempt to reduce the probability of false-positive results or committing a Type I error by

205   reducing the number of gait outcomes considered for analysis.

206   Vascular Health: 24-hour ambulatory BP and carotid ultrasonography were used to

207   evaluate vascular health.

208   Following the gait assessment, participants were fitted with an appropriately

209   sized, valid and reliable (Iqbal, Fotherby, & Potter, 1996) ambulatory BP cuff and

210   monitor (Spacelabs^{TM} 90207 Ambulatory Blood Pressure Monitor, SpaceLabs Inc.).

211   Measurements were recorded two times an hour during the daytime (i.e., 06:00 to 22:00),

212   and once an hour during the nighttime (i.e., 22:00 to 06:00) over the subsequent 24-hour

213   period, and mean 24-hour systolic and diastolic BP were considered as outcomes.

214   Following the ambulatory BP assessment, carotid arterial diameters were following

215   previously published techniques (Gregory et al., 2016). Briefly, after 10 minutes of

216   supine rest, a 10 MHz linear array B-mode ultrasonography (Vingmed, GE Ultrasound

217   A/S, Horton, Norway) transducer was used to collect a longitudinal two-dimensional

218   image of the cephalic portion of the right common carotid artery, 1-2 cm proximal to the

219   carotid bifurcation. Arterial diameters were measured leading-edge-to-leading-edge at

220   peak systole and end diastole and averaged across three cardiac cycles. Following the

221   acquisition of the arterial diameters, carotid arterial pulse pressure was inferred through

222   the collection of a single measure of resting supine brachial pulse pressure obtained using

223   automated oscillometry (BPTru, Coquitlam, BC, Canada). Anatomical land marking was

224   used to ensure accurate comparisons over time. Carotid arterial compliance (CAC) was

225   determined using the following equation:

226   $$\left[\pi\left(\frac{Dmax}{2}\right)^2 - \pi\left(\frac{Dmin}{2}\right)^2\right]\Delta P \qquad \text{(Equation 1)}$$

227   where D_{max} was the systolic carotid arterial diameter, D_{min} was the diastolic carotid

228   arterial diameter, and ΔP was resting brachial pulse pressure (Gregory et al., 2016).

229 Carotid intima-media thickness (cIMT) was determined by subtracting the carotid arterial

230 lumen diameter from the outer arterial diameter at end diastole. In attempts to control for

231 external factors, vascular assessments were performed in a quiet, temperature controlled

232 room (20 to 23°C), and participants were asked to refrain from the consumption of

233 alcohol or participation in moderate-vigorous intensity exercise in the preceding 24

234 hours, and the consumption of caffeine over the preceding 12 hours (Pickering et al.,

235 2005).

236 **Intervention**

237   Laboratory-based DAE Program: Exercise training utilized a Biodex GaitTrainer2

238 treadmill (providing visual-spatial feedback related to the user's step length on a screen

239 fixed atop of the treadmill) under the supervision of research personnel.

240   During each session, participants worked through a 5-minute (min) warm-up

241 period, one 15-min stage of DAE, one 15-min stage of moderate intensity AE [i.e., 75-

242 85% maximal heart rate determined using the STEP test protocol (Knight, Stuckey, &

243 Petrella, 2014; Petrella, Koval, Cunningham, & Paterson, 2003; Stuckey et al., 2012)],

244 and a 5-min cool down stage. During the DAE stage, participants walked at a self-

245 selected pace while receiving visuospatial step-length feedback and answering

246 cognitively challenging questions (i.e., verbal fluency and arithmetic). The variable

247 priority DT training was used during DAE portion of the exercise sessions (Silsupadol et

248 al., 2009a); for the first 7-min, participants prioritized providing correct responses to the

249 verbal fluency and arithmetic tasks, and after a 1-min break (walk without answering

250 questions), participants prioritized modifying their step length to achieve or surpass an

251 individualized step length goal (for the remaining 7-min).

252   Following the DAE component, the visuospatial step length feed back was

253   removed and participants performed 15-min of moderate intensity AE. The incline and

254   speed of the treadmill was increased until training heart rate was achieved, and the

255   training intensity was monitored every 5-min throughout the 15-min of AE using a 10-

256   point RPE scale and the built-in handgrip heart rate monitor on the Biodex treadmill.

257   Duration/Frequency/Length of Intervention: _40-min/session; 3x/week; 26-weeks_.

258   **Analysis**

259   All analyses were performed using SPSS version 20 (SAS Institute Inc., Cary,

260   NC, USA). Demographic variables at baseline were summarized as means and standard

261   deviations or medians and interquartile ranges, where applicable.

262   Primary Analysis: To determine the efficacy of DAE on EF and whether changes

263   in TMT-B scores were maintained after the no-contact follow-up, changes in TMT-B

264   scores (time to complete test in seconds) were compared from baseline (V0) to 12-weeks

265   (V1; interim assessment), 26-weeks (V2; intervention endpoint) and 52-weeks (V3; study

266   endpoint) using a one-way repeated measures analysis of variance (ANOVA) using time

267   as a main effect and post hoc tests that employ Bonferroni alpha adjustments.

268   Secondary and Tertiary Analyses: Secondary and Tertiary efficacy parameters

269   included: i) change in other cognitive tests [information processing: DSC and TMT-A;

270   verbal fluency: semantic (animal naming) & phonemic (COWA) fluency; memory:

271   AVLT immediate and delayed recall]; ii) change in mobility measures [usual and DT gait

272   speed, step length, and strive time variability]; and iii) change in vascular measures [24-

273   hour systolic and diastolic BP; CAC and cIMT] at V2 and V3. The same analysis

274   approach was followed to determine the efficacy of DAE on the secondary and tertiary

275   outcome measures.

276   Outliers for each outcome were identified and removed prior to analyses, and

277   Greenhouse-Geiser epsilon adjusted degrees of freedom were interpreted from the

278   omnibus ANOVA tests. Friedman tests with alpha adjusted Wilcoxon sign ranked tests

279   were used when violations of normality were encountered.

280   **Results**

281   Participant enrollment began June 26th, 2012, and data collection was completed

282   on October 8th, 2015. Figure 4.1 describes participant flow through the intervention. A

283   total of 109 participants were assessed for eligibility, and 30 were excluded from

284   participation (n = 17 did not meet the inclusion criteria; n= 12 declined to participate,

285   primarily due to the time commitment required for the intervention). This left 79

286   participants who were enrolled for the study. Following attrition throughout the

287   intervention and follow-up period, 56 participants completed the entire 52-week study.

288   There were no study-related adverse events experienced by any of the participants

289   throughout the intervention and follow-up period.
290

291   *Figure 4.1.* Participant flow through the dual-task and aerobic exercise (DAE)

292   intervention and follow-up period.

293   Participant characteristics are reported in Table 4.1. Participants had a mean age

294   of 70.4 (SD 6.2) years, were just under two-thirds female, and were primarily (96%)

295   Caucasian. Participants were on average highly educated [mean (SD) years: 14.7 (3.2)],

296   and just over half reported that their memory has gotten worse over the past five years.

297   On average, the participants had relatively preserved objective cognition [MoCA score,

298   mean (SD): 25 (3.2)] and did not display any indications of the presence of unidentified

299   dementia [MMSE score, mean (SD): 28.5 (1.3)].

300

301 **Table 4.1**

302 *Baseline characteristics of the 56 participants who completed the 26-week dual-task gait*

303 *training and aerobic exercise (DAE) intervention and the 24-week no-contact follow-up.*

Characteristic	Participants (n = 56)
Age, mean (SD), yr	70.4 (6.2)
Female sex, no. (%)	22 (61)
Education, mean (SD), yr	14.7 (3.2)
Caucasian, no. (%)	53 (95)
Body mass index[a], mean (SD)	29.6 (4.7)
Fitness (pVO_{2max}) score[b], mean (SD)	28.9 (7.8)
Cognitive complaint (ref: 5 yr ago)[c], no (%)	31 (55)
MMSE score[d], mean (SD)	29 (1.3)
MoCA score[d], mean (SD)	25 (2.5)
CES-D score[e], mean (SD)	6.4 (5.3)
Medical history, no. (%)	
Hypertension	32 (57)
Hypercholesterolemia	23 (41)
Type 2 diabetes	7 (12.5)
Previous cardiovascular event	3 (5)
Previous stroke	6 (11)
Osteoarthritis	9 (16)

Abbreviations: SD, Standard Deviation; MMSE, Mini-Mental Status Examination; MoCA, Montreal Cognitive Assessment; CES-D, Centre for Epidemiological Studies Depression Scale

[a] Body Mass Index measured in kg/m^2

[b] pVO_{2max} was determined using the Step Test and Exercise Prescription tool, and is measured in $mlO_2/kg/min$

[c] Participants rated their memory on a scale of 5 (1 = much better, 5 = much worse)

[d] Range from 0 to 30; lower scores indicate greater cognitive impairment

[e] Scores above 15 indicate clinical depression

304

305   *Cognition Outcomes*

306   Baseline cognitive scores are summarized in Table 4.2. Compared to age and

307   education-matched normative data, the study participants demonstrated on average better

308   baseline performance on TMT-A and -B (Tombaugh, 2004) and semantic verbal fluency

309   task (letters starting with "C"; Tombaugh, Kozak, & Rees, 1999), comparable

310   performance on the DSC (Van der Elst, Van Boxtel, Van Breukelen, & Jolles, 2006) and

311   the AVLT (Van der Elst et al., 2005), and poorer performance on the phonemic verbal

312   fluency task (naming animals; Tombaugh et al., 1999).

313

314   **Table 4.2**

315   *Baseline performance on all outcome measures for participants in the dual-task gait*

316   *training and aerobic exercise (DAE) intervention.*

Outcome[a,b]	Score
Executive Function	
TMT-B[c], median (IQR), (n = 51)	65.6 (53.9 to 87.0)
Information Processing Speed	
TMT-A[c], median (IQR), (n = 50)	30.5 (26.7 to 36.2)
DSC[d], mean (SD), (n=55)	56.9 (13.8)
Verbal Fluency	
Semantic VF[e], mean (SD), (n = 53)	20.4 (5.1)
COWA[e], mean (SD), (n = 53)	13 (4.5)
Memory	
AVLT immediate recall[f], median (IQR), (n = 51)	7 (5.3 to 10.8)
AVLT delayed recall[f], median (IQR), (n = 56)	8 (4.3 to 10)
Usual Gait	
Speed[g], mean (SD), (n = 56)	1.11 (.19)
Step length[h], mean (SD), (n = 56)	62.2 (7.1)
Stride time variability[i], median (IQR), (n = 45)	1.8 (1.5 to 2.3)
Dual-task Gait	
Speed[g], mean (SD), (n = 55)	.81 (.27)
Step length[h], mean (SD), (n = 53)	56.1 (8.3)
Stride time variability[i], median (IQR), (n = 44)	3.5 (2.5 to 7)
Vascular Health	
24-hour systolic BP[j], mean (SD), (n = 45)	128 (10)
24-hour diastolic BP[j], mean (SD), (n = 50)	71 (6)
CAC[k], median (IQR), (n = 54)	.73 (.54 to .96)
cIMT[l], median (IQR), (n = 54)	.63 (.55 to .74)

Abbreviations: IQR, Interquartile Range; TMT-A, Trail Making Test Part A; TMT-B, Trail Making Test Part B; DSC, Digit Symbol Coding; SD, Standard Deviation; VF, verbal fluency; COWA, Controlled Oral Word Association test; VLT, Verbal Learning Test

[a] Data that violated normality are presented as median and IQR

[b] Differing sample sizes for outcomes were due to the identification and removal of outliers prior to analysis

[c] Units for the TMT tests are seconds; lower time to completion indicates greater performance

[d] Scores range from 0 to 144; higher scores indicate greater performance

[e] Scored as the correct number of unique responses provided in 60 seconds

[f] Range from 0 to 15; higher scores indicate greater performance

[g] Units are in metres per second (m/sec)

[h] Units are in centimetres (cm)

[i] Units are the CoV, expressed as a percentage

[j] Units are in millimetres of mercury (mmHg)

[k] Units are in millimetres squared per millimetre of mercury (mm^2/mmHg x 10^{-1})

[l] Units are in centimetres (cm)

317

318

319   The effects of 26-weeks of DAE training on the primary and secondary cognitive

320   outcomes are reported in Table 4.3a. The observed change in TMT-B performance from

321   V0 to V1, V2, and V3 is shown in Figure 4.2. A significant difference between TMT-B

322   scores was observed ($\chi^2_{(3)}$ = 19.49, p < .001). Post hoc tests with Bonferroni corrections

323   (significance set at p < .008) revealed significant reductions in the time to complete

324   TMT-B from baseline to intervention endpoint [median (IQR); V0: 65.6 (53.9 to 87.0),

325   V2: 57.7 (42.6 to 78.4), p = .002], and a significant difference from baseline was

326   maintained through the no-contact follow-up period [median (IQR): V0: 65.6 (53.9 to

327   87.0), V3: 55.8 (41.6 to 74.5), p<.001]. There were no significant differences in TMT-B

328   scores at any other time points (all p > .05).

329

334   *Figure 4.2.* Trail Making Test (TMT) Part B performance at baseline, interim (12-weeks),

335   intervention endpoint (26-weeks), and study endpoint (52-weeks).

336

337   The observed changes in the secondary cognitive outcomes from V0 to V2 are

338   summarized in Table 4.3a are presented in Figure 4.3. Significant reductions in TMT-A

339   scores were observed following 26-weeks of DAE training [median (IQR); V0: 30.5

340   (26.7 to 36.2), V2: 26.0 (23.0 to 32.3), p < .001], and these changes were maintained over

341   the 6-month follow-up [median (IQR); V3: 25.8 (22.3 to 29.8), p = .005]. At 26-weeks,

342   the participants showed significant improvements DSC scores [mean (SD); V0: 56.9

343   (13.8), V2: 61.7 (15.0), p = .001], phonemic verbal fluency [mean (SD); V0: 13.2 (4.6),

344   V2: 17.0 (4.7), p < .001], and immediate [median (IQR); V0: 7.0 (5.3 to 10.8), V2: 11.0

345   (9.3 to 13.8), p < .001] and delayed recall [median (IQR); V0: 8.0 (4.3 to 10.0), V2: 12.0

346   (7.3 to 14.0), p < .001], but not semantic verbal fluency [mean (SD); V0: 20.4 (5.1), V2:

347   21.8 (5.1), p > .05). Compared to baseline performance, the observed improvements DSC

348   scores, phonemic verbal fluency, and immediate and delayed recall following DAE

349   training were maintained after 6-months of follow-up (all ≤ .001).
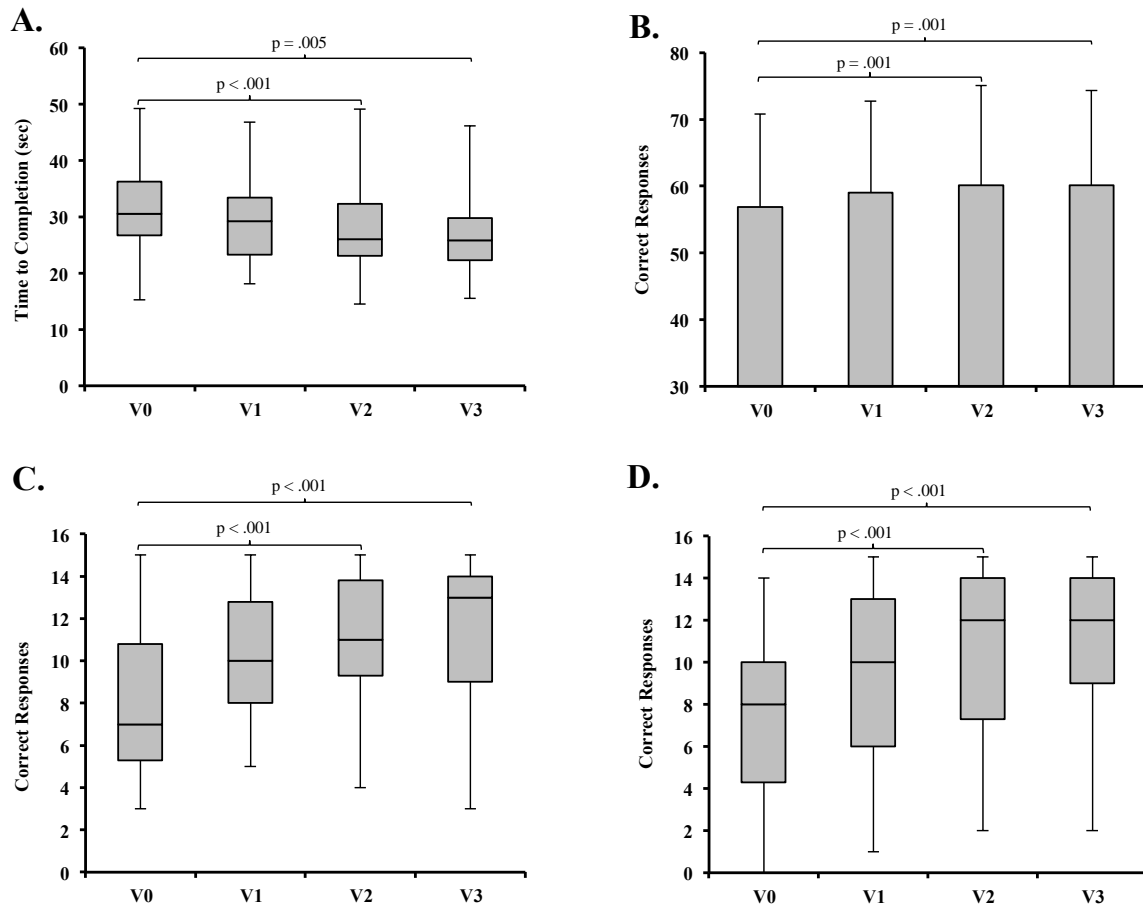

Abbreviations: sec, seconds. A. Trail Making Test Part A; B. Digit Symbol Coding; C. Auditory Verbal Learning Test immediate recall; D. Auditory Verbal Learning Test delayed recall; E. Semantic and Phonemic verbal fluency.

Figure 4.3. Performance on secondary cognitive outcomes at baseline, interim (12-weeks), intervention endpoint (26-weeks), and study endpoint (52-weeks).

358   ***Usual and Dual-Task Gait Outcomes***

359   Changes in usual and DT gait speed, step length, and stride time variability from

360   V0 to V2 are summarized in Table 4.3b. Changes in usual and DT gait and stride-time

361   variability from V0 to V1, V2, and V3 are presented in Figure 4.4. Compared to age-

362   matched data, the study participants demonstrated on average comparable usual gait

363   speed, step length and stride time variability (Verlinden et al., 2013), and dual task gait

364   speed, step length, and stride time variability (Gregory et al., 2016).

365   Increased usual gait speed [mean (SD); V0: 1.11 (.19) m/sec, V2: 1.18 (.18)

366   m/sec, p = .002] and step length [mean (SD); V0: 62.2 (7.1) cm, V2: 64.3 (6.8) cm, p =

367   .001] were observed following 26-weeks of DAE training; however, after the 6-months of

368   follow-up the improvements in usual gait speed and step length no longer remained

369   [mean difference (95% CI); gait speed: .41 (.90 to -.078) m/sec, p = .15; step length: .96

370   (2.5 to -.54), p = .51]. Increased DT (serial 7's subtraction) gait speed [mean (SD); V0:

371   .81 (.27) m/sec, V2: .91 (.25) m/sec, p < .001] and step length [mean (SD); V0: 56.1 (8.3)

372   cm, V2: 59.2 (8.1) cm, p = .003] were observed following 26-weeks of DAE training.

373   After the 6-month follow-up, the improvements in DT gait speed and step length no

374   longer remained [mean difference (95% CI); gait speed: .63 (.13 to - .08) m/sec; step

375   length: 1.3 (3.6 to -1.1) cm, all p > .05]. There were no observable reductions in usual

376   stride time variability [median (IQR); V0: 1.87 (1.47 to 2.45), V2: 1.88 (1.51 to 2.37)] or

377   dual task stride time variability [median (IQR); V0: 3.5 (2.5 to 7.0), V2: 3.5 (2.0 to 4.4)]

378   following 26-weeks of DAE training (both p > .05).
Abbreviations: CoV, coefficient of variation; m/sec, metres per second; cm, centimetres. A. Usual and dual-task gait speed; B. Usual and dual-task step length; C. Usual gait stride time variability; D. Dual-task gait stride time variability.

Figure 4.4. Changes in usual and dual-task (serial 7 subtraction) gait speed, step length, and stride time variability from baseline (V0), interim (V1; 12-weeks), intervention endpoint (V2; 26-weeks), and study endpoint (V3; 52-weeks).

388   *Vascular Health Outcomes*

389   Differences in 24-hour systolic BP, diastolic BP, CAC and cIMT from V0 to V2

390   are summarized in Table 4.3c. Changes in vascular health outcomes from V0 to V1, V2,

391   and V3 are presented in Figure 4.5. Compared to age-matched data, the study participants

392   demonstrated on average lower cIMT (Lim, Lim, Dwivedi, Kooner, & Senior, 2008), and

393   similar 24-hour systolic BP, 24-hour diastolic BP, and CAC (Gregory et al., 2016). There

394   were no significant changes in 24-hour systolic BP, 24-hour diastolic BP, or CAC

395   following 26-weeks of DAE training (all p > .05). Compared to baseline, cIMT was

396   higher after 26-weeks of DAE training [median (IQR); V0: .63 (.55 to .74) mm, V2: .69

397   (.63 to .80) mm, p = .002], but not after the 6-month follow-up (p >.05).

413   **Discussion**

414   *The Effect of DAE Training on Cognition*

415   Following 26 weeks of treadmill based DAE for older adults without dementia,

416   improvements in EF were observed and were maintained over 26 weeks of follow-up.

417   Performance on the EF task was not significantly different from baseline following 12

418   weeks of training. Improvements in other cognitive processes, including information

419   processing speed, verbal fluency, and memory were also observed following 26 weeks of

420   DAE training, and these improvements were maintained for at least 26 weeks following

421   the completion of the intervention. Performance on the semantic verbal fluency task was

422   the only outcome that remained unchanged following the intervention, as well as the 26-

423   week no contact follow-up period.

424   Evidence continues to suggest that AE training alone (Chapman et al., 2013;

425   Colcombe & Kramer, 2003; Erickson & Kramer, 2009; Iuliano et al., 2015), or in

426   combination with cognitive or DT training (Gill et al., 2016) can benefit brain health and

427   improve cognition in cognitively healthy older adults, and even among those with

428   objective cognitive impairment (Baker et al., 2010; Nagamatsu et al., 2013; Ten Brinke et

429   al., 2014). Although recent meta-analyses have suggested that there is limited high-

430   quality evidence to support the use of AE training alone as a method to improve cognition

431   in older adults with (Gates et al., 2013) or without (Young et al., 2015) cognitive

432   impairment, recent observations suggest that combined cognitive and physical exercise

433   training interventions may provide the greatest cognitive benefit (Gregory et al., 2013;

434   Law, Barnett, Yau, & Gray, 2014).

435   The results from the current study expands our understanding of the influence of

436   combined physical and cognitive exercise training on cognitive functioning in older

437   adults. The 26-week DAE training program combined moderate intensity AE with a DT

438   gait training component that required participants to actively modify their step length

439   using real-time biofeedback while simultaneously responding to a variety of verbal

440   fluency and arithmetic tasks. Although this is the only study that the authors are aware of

441   that has investigated the cognitive effects of such a unique DT stimulus in combination

442   with an AE intervention, previous studies have investigated the cognitive benefits

443   associated with other combined cognitive and physical exercise training interventions

444   (Barnes et al., 2013; Dorfman et al., 2014; Fabre, Chamari, Mucci, Masse-Biron, &

445   Prefaut, 2002; Gill et al., 2016; Nishiguchi et al., 2015; Rahe et al., 2015; Shah et al.,

446   2014; Theill, Schumacher, Adelsberger, Martin, & Jancke, 2013). Although a number of

447   exercise training modalities can benefit the brain, previous observations and those from

448   the current study collectively suggest that the cognitive response to these interventions

449   appear to be unique and is likely dependent upon several key factors: i) the duration of

450   the intervention, ii) the exercise intensity, and iii) the specific task requirements of the

451   cognitive training components of each intervention. In contrast to several previous shorter

452   duration studies (Barnes et al., 2013; Dorfman et al., 2014; Fabre et al., 2002; Nishiguchi

453   et al., 2015; Rahe et al., 2015; Shah et al., 2014; Theill et al., 2013), improvements in

454   cognitive functioning following DAE training were not apparent after 12 weeks of

455   training, and did not emerge until the completion of the 26-week intervention. In lieu of

456   these observations, several methodological differences may have contributed to the

457   delayed cognitive response to DAE training, specifically: i) the cognitive and functional

458   status of the participants in the current study was relatively preserved and exercise-related

459   improvements may have required more time to manifest; ii) the AE component was

460   relatively short; iii) the use of a moderate intensity AE component, which was gradually

461   progressed over the first two weeks of the intervention until the proper training intensity

462   could be comfortably performed; and iv) the evaluation of cognition using different

463   neuropsychological tests where performance may be more responsive to exercise training.

464   For instance, Dorfman and colleagues (2014) observed significant reductions in TMT B

465   scores following 12 weeks of treadmill-based DT exercise training for older idiopathic

466   fallers. Although the participants in both studies were of similar age, education, and

467   cognitive status (i.e., MoCA scores), the participants did differ on their previous falls

468   history. Cognition, especially EF, is highly associated with the control of gait, balance,

469   and falls prevention (Amboni, Barone, & Hausdorff, 2013; Herman, Mirelman, Giladi,

470   Schweiger, & Hausdorff, 2010); thus, when compared to those without a history of falls,

471   older adults with a history of falls may have a greater degree of underlying executive

472   dysfunction, which would be more sensitive and responsive to interventions directed

473   towards mitigating falls risk. Differences in baseline TMT-B scores between the

474   participants in the Dorfman study and the present study [mean (SD): 148.8 (65.3) vs. 69.9

475   (24.7) seconds] suggests greater executive deficit among the idiopathic fallers of the

476   former study, which may have allowed for a more immediate EF response to training.

477   The observations presented herein are also aligned with previous work that

478   investigated the additional cognitive benefit that is provided by including a DT training

479   component to a standardized senior's fitness program (Gill et al., 2016). For instance, a

480   previous study reported by our group (Gill et al., 2016) employed a 26-week randomized

481   controlled trial whereby participants performed a standardized senior's fitness program

482   and mind-motor exercise (i.e., Square Stepping Exercise) in isolation, or with the addition

483   of a cognitive task (i.e., verbal fluency or arithmetic). Following the intervention,

484   improved global cognitive functioning was observed among those who performed the

485   standardized fitness program and the DT mind-motor exercise when compared to those

486   who performed the standardized fitness program and single-task mind-motor training. In

487   contrast to the results of the present study, improvements in global cognition were driven

488   by increased performance on verbal fluency and memory tasks, but not EF. The

489   differences in the executive cognitive response between these interventions can be

490   attributed in part to discrepancies in the DT requirements of the interventions. The DT

491   component within the study by Gill and colleagues was a group-based Square Stepping

492   Exercise with additional cognitive tasks. Briefly, the participants who performed the

493   cognitive motor task were split into groups of six and were provided a demonstration of a

494   foot-placement pattern that was to be memorized and replicated in order to progress

495   across a gridded floor mat. While these participants were replicating the foot-placement

496   pattern, they were also required to respond to verbal fluency and arithmetic tasks. In the

497   present study, each individual participant was required to actively monitor and modify

498   their gait while simultaneously answering verbal fluency and arithmetic tasks for the

499   entire duration of the DT portion of the intervention. Participants in the HM2 study were

500   subject to an intermittent DT training stimulus during 15 minutes of DT exercise rather

501   than 15 minutes of consistent DT exercise training as was performed in the present study.

502   Furthermore, individuals who quickly became proficient with the motor demands of the

503   square stepping exercise could have moved across the mat more quickly than others,

504   which would have resulted in a reduced DT load than what was provided within the

505   current study. Although DT training can benefit cognition, and specifically EF (Dorfman

506   et al., 2014; Gill et al., 2016; Gregory et al., 2013), questions regarding which type of DT

507   stimulus and the intensity of that stimulus are best suited to improve cognition, still

508   remain. The relationship between EF and the control of gait may have allowed for the

509   current intervention to more directly influence EF than those that employ an unrelated DT

510   condition during training.

511   The longitudinal observation of the decay of the cognitive benefits that are

512   obtained through exercise training has received little attention (Gregory et al., 2013).

513   Recently, Rahe and colleagues (Rahe et al., 2015) observed the maintenance of improved

514   attention up to after 1 year of follow-up, while the LIFE trial (Sink et al., 2015) did not

515   detect any maintenance and suggest that the cognitive benefits of exercise training

516   dissipate after 2 years of follow-up. Findings from the present study suggest that the

517   cognitive benefits garnered through the participation in DAE training persist for up to 6

518   months following the cessation of the intervention. Taken together, it appears that mid to

519   long duration (i.e., 12- to 26-weeks) exercise training interventions can provide cognitive

520   benefits that persist for 6 to 12 months post-training; however, sustained participation in

521   exercise training programs may be required to prevent the decay of any cognitive benefits

522   that are achieved. Further work is required to determine the trajectory of the decay in the

523   cognitive benefits that are garnered through exercise training.

524   ***The Effect of DAE Training on Usual and Dual-task Gait***

525   Improvements in usual and DT gait speed and step length were observed

526   following 26 weeks of DAE training, while stride time variability remained unchanged.

527   Despite the beneficial effect of training, the improvements in usual and DT gait speed and

528   step length were not maintained after 26 weeks of no contact follow-up. Recent meta-

529   analyses have identified increased gait speed as the primary mechanism by which

530   exercise benefits gait performance (Howe, Rochester, Neil, Skelton, & Ballinger, 2011;

531   Plummer, Zukowski, Giuliani, Hall, & Zurakowski, 2015). Indeed, these suggestions are

532   aligned with the results of the current study and those from previous works, which

533   observed increased usual and DT gait speed following 12 weeks of treadmill-based DT

534   training (Dorfman et al., 2014) and DT gait speed following 26 weeks of standard

535   senior's fitness training combined with single or DT mind-motor exercise training

536   (Gregory et al., 2016). The influence of exercise training on usual and DT step length is

537   less definitive, as improvements in step length have not been consistently found

538   (Dorfman et al., 2014; Gregory et al., 2016). In contrast to results reported from Gregory

539   and colleagues (Gregory et al., 2016), observations from treadmill-based training

540   interventions suggest that these programs can increase usual and DT step length

541   (Dorfman et al., 2014). Compared to other novel cognitive-motor interventions,

542   treadmill-based interventions involve a repetitive stepping requirement that is readily

543   comparable to the demands of usual gait, and thus provide benefits that are more readily

544   translatable to daily locomotion. Differences in the motor requirements of the DT

545   between these studies (i.e., treadmill-based versus Square Stepping Exercise) likely

546   contributed to the discrepancies in the effect of the interventions on usual gait

547   performance.

548   Stride time variability under usual and DT conditions was not influenced by the

549   DAE intervention. Increased gait variability has been identified as a falls risk factor

550   (Hausdorff, Rios, & Edelberg, 2001; Springer et al., 2006) and is a common characteristic

551   of mild cognitive impairment (Montero-Odasso et al., 2009; Verghese et al., 2008).

552   Participants in the present study were, on average, cognitively healthy and functionally

553   independent community-dwelling older adults. Furthermore, these individuals

554   demonstrated relatively preserved stride time variability at baseline [stride time

555   variability %, median (IQR): 1.8 (1.5 to 2.3) %]. Beauchet and colleagues (2013)

556   determined that only those with the greatest variability at baseline (i.e., > 4.4%)

557   experience reductions in stride time variability following exercise training. The relatively

558   preserved cognitive and functional status of the participants in the current study likely

559   contributed to the lack of observed change in the gait variability outcomes following the

560   DAE intervention.

561   ***The Effect of DAE Training on Vascular Health***

562   　　　Following 26 weeks of DAE training, 24-hour ambulatory systolic and diastolic

563   BP, and CAC remained unchanged, while cIMT increased. After 26 weeks of no-contact

564   follow-up, 24-hour systolic and diastolic BP, CAC, and cIMT were not significantly

565   different from baseline. CVD risk factors, specifically hypertension (Tsao et al., 2013)

566   and the associated exacerbations in age-related arterial stiffening (Seals, Desouza,

567   Donato, & Tanaka, 2008) have been implicated as mechanisms that drive

568   neuropathological changes (i.e., reduced brain volume, white matter hyperintensities, and

569   silent cerebral infarct) in the aging brain and the establishment of dementia (Akinyemi,

570   Mukaetova-Ladinska, Attems, Ihara, & Kalaria, 2013). However, recent reductions in the

571   incidence of cognitive impairment have been attributed in part to increased efforts to

572   prevent and manage CVD risk factors (Langa KM, 2015; Shatenstein B, 2015). Exercise

573   training is a cornerstone lifestyle modification used for CVD risk factor management, and

574   increasing evidence suggests that exercise can benefit cognition (Gregory et al., 2013).

575   Although exercise-induced adaptations to vascular structure and function and improved

576   neurovascular coupling have been suggested as primary mechanisms that drive improved

577   cognition post-training (Barnes, 2015), the cognitive benefits that were observed within

578   the current study emerged without concurrent changes in vascular health.

579   The lack of an observed change in ambulatory BP and CAC within the current

580   study may be attributed to the level of baseline fitness of the study participants and the

581   lack of change in predicted VO_{2max} following the intervention [mean (SD); V0: 29.2

582   (7.9); V2: 30.3 (8.1) mLO_2/kg/min]. There was no requirement for a history of recent

583   sedentary living within the inclusion criteria, nor was habitual exercise participation

584   quantified upon entry to the study; the blunted vascular response to training could have

585   occurred as a result of participants substituting previously performed exercise training

586   with the DAE intervention. In addition, although aerobically based exercise training has

587   been shown to impart both cardiovascular and cognitive benefits, very little is known

588   regarding whether these benefits occur alongside one another. Other mechanisms (i.e.,

589   elevations in circulating growth factors, cortical volume, neurogenesis, neural efficiency,

590   or cerebral glucose metabolism, and reductions in oxidative stress, beta amyloid burden,

591   etc.; Garcia-Mesa et al., 2015; Griffin et al., 2011; Lange-Asschenfeldt & Kojda, 2008;

592   Lista & Sorrentino, 2010; Tsai, Wang, Pan, & Chen, 2015) that are able to act in a

593   manner independent to changes in vascular physiology remain under investigated and

594   may be equally as important to consider.

595   Observational studies have identified cIMT as an index of vascular stiffness, and

596   elevations in cIMT over time have been associated with adverse cardiovascular events

597   (i.e., myocardial infarction; O'Leary et al., 1999), the development of white matter

598   hyperintensities (Bots et al., 1993) and stroke (Bots, Hoes, Koudstaal, Hofman, &

599   Grobbee, 1997). Although exercise training has consistently been shown to benefit

600   traditional indices of vascular health (i.e., BP and arterial compliance), its influence on

601   cIMT remains equivocal. Reductions in cIMT have been observed, but this response has

602   only been found following high-intensity and long duration exercise training (Thijssen,

603   Cable, & Green, 2012). In the current study, due to baseline fitness levels and lack of

604   change in predicted VO_{2max} post-training, we did not expect to see significant changes in

605   cIMT. The observed elevations in cIMT post-training are likely the result of normal age-

606   related changes to vascular wall structure that occur in order to maintain intra-arterial

607   pressure and flow homeostasis (Engelen et al., 2013). Furthermore, these observed

608   elevations in cIMT are well within what is considered the "normal" range for older adults

609   without established CVD (Engelen et al., 2013). Taken together, these observations

610   suggest that the intensity of the DAE intervention was insufficient to prevent the natural

611   progression of age-related elevations in cIMT.

612   ***Limitations***

613   The majority of the participants in the current study were Caucasian (95%), nearly

614   two-thirds female, and they were highly educated, all of which should be considered

615   when interpreting and generalizing these findings. The current investigation followed a

616   case study design, and there were no controls or comparison groups included. The

617   omission of a comparison group does not allow for the determination of whether or not

618   the changes in cognition that were observed during the study occurred as a result of other

619   extraneous factors (i.e., increased socialization). There were also limitations associated

620   with the specific outcomes used in this study. Cognition was assessed using traditional

621   pen and paper-based neuropsychological outcomes, which may have contributed to the

622   occurrence of practice effects. However, as previous observations suggest, the likelihood

623   of encountering practice effects on cognitive testing is significantly diminished if

624   assessment sessions are spaced at least 12 weeks apart (Bartels, Wegrzyn, Wiedl,

625   Ackermann, & Ehrenreich, 2010). Furthermore, environmental and contextual cues can

626   also serve as a primer for cognitive performance. For instance, Hupbach and colleagues

627   (2008) found that memories could be automatically reactivated when an individual

628   returns to an original learning context. The participants in the current study performed the

629   cognitive assessments in a small clinical room that was not used for any other study-

630   related purposes, and this unique assessment environment may have served to

631   subconsciously prime cognitive performance. The possibility for contextually cued

632   cognitive performance during follow-up assessments and the absence of an inactive

633   control group for appropriate comparisons of cognitive performance over time must be

634   considered when interpreting these results. Furthermore, mechanistic outcomes that could

635   allow for a more thorough interpretation of the mediators of the observed cognitive

636   benefit (i.e., blood borne growth factors, cerebral spinal fluid, beta amyloid

637   concentrations etc.] were not included in the study. Future work should aim to include a

638   comprehensive battery of neuropsychological and neurophysiological outcomes. Several

639   limitations related to the dual-task gait assessments must also be identified, including i)

640   the task delivery was not randomized (i.e., usual gait followed by 3 DT conditions:

641   counting backwards from 100 by 1, semantic verbal fluency task, and serial 7's

642   subtraction from 100), ii) the starting point for the serial subtraction DT was not modified

643   between visits, and iii) performance on the secondary tasks within the DT gait assessment

644   was not methodologically controlled (i.e., performance on serial 7's subtraction in

645   isolation, without the walking task). Furthermore, this study contained a large number of

646   outcome variables, which resulted in a large number of statistical analyses, and these

647   analyses were not adjusted for any potential confounders. The large number of analyses

648   may have increased the likelihood of committing Type I error. Finally, although ideal

649   vascular testing conditions and the associated participant responsibilities were outlined

650   and verbally communicated 24 hours prior to the vascular assessments (Pickering et al.,

651   2005), adherence to these requirements was not evaluated or enforced.

652   **Conclusions**

653   Recent reductions in the age-specific prevalence and incidence of cognitive

654   impairment can be attributed to a number of lifestyle factors, including attaining a higher

655   level of formal education, leading a healthy lifestyle, and effective CVD risk factor

656   management (Langa KM, 2015; Shatenstein B, 2015). These observations suggest that

657   the risk of cognitive impairment and the progression of cognitive decline can be mitigated

658   through interventions aimed at these and potentially other modifiable risk factors.

659   Exercise training is regarded as a gold standard for CVD risk factor management, and

660   increasing evidence supports the role of exercise alone, or in combination with cognitive

661   training as a promising strategy to preserve brain health and functioning in aging.

662   Numerous studies continue to support the use of cognitive and physical exercise training

663   as an effective non-pharmacological intervention to mitigate CVD risk factor burden,

664   improve physical function, and benefit cognition (Bherer, 2015; Gregory et al., 2013).

665   During pathological cognitive aging, EF and memory are often the first cognitive

666   domains affected (Carlson, Xue, Zhou, & Fried, 2009); therefore, identifying

667   interventions that aim to prevent incipient cognitive decline through the simultaneous

668   targeting and training of these cognitive domains is of considerable importance.

669   Treadmill-based DT gait training and AE may be an attractive choice, as the cognitive

670   requirements of this exercise program (i.e., DT control of gait while providing responses

671   to the verbal fluency task) targets and trains both EF and memory processes. Results from

672   this study indicate that 26 weeks of DAE training can improve functioning within a

673   number of diverse cognitive domains and benefit usual and DT gait performance, but not

674   influence vascular health, in community-dwelling older adults without dementia. These

675   observations support the notion that combined exercise training interventions impart

676   diverse cognitive and motor benefits, and that DT gait training may be an effective

677   method to directly target and train EF and memory. Future work is required to determine

678   whether the cognitive benefits that are associated with DAE training are greater than what

679   can be achieved following other exercise training modalities, and whether these

680   observations can be replicated in a community-based setting.

1   **Thesis Summary**

2   The global purpose of this thesis was to explore the relationship between cognition,

3   cardiovascular health, and gait, and to determine whether a novel dual-task gait training

4   and aerobic exercise intervention could benefit cognition, cardiovascular health, and gait

5   in community-dwelling older adults without dementia. In particular, the three studies

6   included in ths thesis were conducted to:

7   i.   Retrospectively investigate the relationship between: (i) global cognition, (ii)

8   executive functioning (EF), (iii) cumulative cardiovascular disease (CVD) risk

9   (i.e., QRISK2 score), and (iv) usual gait (UG) performance (i.e., UG

10   composite score) (Chapter 2).

11

12   ii.   Determine whether differences in: (i) cognition (i.e., global cognition, EF,

13   information processing speed, verbal fluency, verbal learning and memory),

14   (ii) gait (i.e., usual and dual-task gait speed, step length, and stride time

15   variability), and (iii) vascular health [i.e., 24-hour systolic and diastolic blood

16   pressure (BP), carotid intima-media thickness (cIMT), and carotid arterial

17   compliance (CAC)] exist between older adults with normal BP dipping status

18   and those with non-dipping status (Chapter 3).

19

20   iii.   Examine the effect of a novel dual-task gait training and aerobic exercise

21   (DAE) program on: (i) cognition (i.e., EF, information processing speed,

22   verbal fluency, verbal learning and memory), (ii) gait (i.e., usual and dual-task

23   gait speed, step length, and stride time variability), and (iii) vascular health

24   [i.e., 24-hour systolic and diastolic blood pressure (BP), carotid intima-media

25   thickness (cIMT), and carotid arterial compliance (CAC)] (Chapter 3).

26   **Scientific Contributions**

27   Chapter 2 provided insight into the relationship between cumulative CVD risk,

28   usual gait performance, and cognitive functioning. Further characterizing the relationship

29   between these variables is of considerable clinical importance, as CVD risk factors

30   (Dufouil et al., 2001; Hughes et al., 2014; Langbaum et al., 2012) and gait dysfunction

31   (Mielke et al., 2013; Verghese et al., 2002) have been identified as two of the most

32   promising dementia risk factors candidates. Although the relationship between brain

33   health and specific CVD risk factors or gait parameters have been investigated and

34   established, the association between cognition and cumulative CVD risk or overall gait

35   performance has not been previously determined. The results from Chapter 2 suggest that

36   addressing cumulative CVD risk would benefit cognition, specifically EF, to a greater

37   degree than managing gait dysfunction. Furthermore, when considering these results with

38   previous observations that have found associations between individual gait components

39   (i.e., speed and variability) and cognitive impairment (Mielke et al., 2013; Watson et al.,

40   2010) or pathological changes to the brain (Rosano, Brach, Studenski, Longstreth, &

41   Newman, 2007; Rosano et al., 2008; Rosano et al., 2012), it appears that specific aspects

42   of gait, rather than composite gait performance, may be most repflective of underlying

43   cognitive dysfunction. Therefore, the management of cumulative CVD risk rather than

44   gait dysfunction may provide the greatest benefit to cognitive functioning, specifically

45   EF, in older adults who are at risk for future cognitive decline.

46   Building on previous work from Chapter 2, Chapter 3 retrospectively determined

47   whether community-dwelling older adults who demonstrate reduced BP dipping (i.e.,

48   non-dippers, N-DS) was associated with worse performance on measures of cognition

49   and gait and vascular health than those who demonstrate normal BP dipping. Specifically,

50   baseline data from two exercise intervention studies were pooled, and N-DS participants

51   were identified as those who demonstrated a > 10% reduction in 24-hour ambulatory

52   systolic BP from daytime to nighttime. Despite having achieved a significantly higher

53   level of formal education, N-DS participants performed worse on measures of EF,

54   information processing speed, and memory, and demonstrated slower usual gait speed,

55   shorter dual-task step length, and greater usual and dual-task stride time variability.

56   Furthermore, although the participants were stratified by a known CVD risk factor and N-

57   DS participants had previously experienced a significantly higher number of

58   cardiovascular events, there were no between group differences for any of the measured

59   vascular outcomes (i.e., 24-hour ambulatory systolic or diastolic BP, cIMT or CAC).

60   Although these observations are aligned with previous work what have found

61   associations between N-DS and cognitive function (Bellelli et al., 2004; Nagai, Hoshide,

62   Ishikawa, Shimada, & Kario, 2008; Ohya et al., 2001; van Boxtel et al., 1998), this is the

63   first study to investigate the relationship between N-DS, cognition, and gait in relatively

64   healthy, functionally independent community-dwelling older adults. These results suggest

65   that N-DS can influence the health and functioning of the brain regardless of an

66   individual's hypertensive status and prior to the establishment of significant objective

67   cognitive impairment, which highlights the potential impact that the restoration of the

68   diurnal variation in BP could impart on cognitive functioning. Collectively, these

69   observations suggest that BP dipping status can provide additional prognostic utility for

70   the development of cognitive impairment and neuropathological changes to the aging

71   brain beyond what can be achieved using systolic BP alone, and implicates this

72   independent vascular risk factor as a potential dementia risk factor candidate.

73   Chapter 4 explored the effect of a 26-week DAE training program on multiple

74   domains of cognition (i.e., EF, information processing speed, verbal fluency, verbal

75   learning and memory), usual and dual-task gait (i.e., speed, step length and stride time

76   variability), and a number of traditional CVD risk factors (i.e., 24-hour ambulatory

77   systolic and diastolic BP, cIMT, and CAC) in community-dwelling older adults without

78   dementia. This novel DAE program was designed in an attempt to maximize the potential

79   benefit to EF by combining two exercise modalities (i.e., dual-task and aerobic exercise

80   training) that have been shown to preferentially benefit the functioning of this cognitive

81   domain and the health of its associated brain structures (Colcombe & Kramer, 2003;

82   Erickson et al., 2007). In line with previous work investigating the cognitive effects of 26

83   weeks exercise training interventions (Barnes et al., 2013; Dorfman et al., 2014; Gill et

84   al., 2016), 26 weeks of DAE training was found to benefit EF, information processing,

85   phonemic verbal fluency, and memory. Moreover, while the DAE program did not

86   influence vascular health or cardiorespiratory fitness, improvements in usual and dual-

87   task gait speed and step length were also observed. Previously Dorfman and colleagues

88   (2014) observed improvements in EF and usual and dual-task gait speed following a

89   similar, yet shorter-duration (i.e., 6 weeks) dual task and aerobic exercise training

90   intervention in idiopathic fallers; however, improvements in EF failed to emerge prior to

91   the completion of the full 26-week intervention in the current study. These discrepancies

92 suggest that certain patient populations may be more readily receptive to the cognitive

93 benefits of exercise training interventions. For instance, a surmounting body of evidence

94 suggests that intact cognitive functioning is required for the control of gait and falls

95 prevention (Amboni, Barone, & Hausdorff, 2013); thus, a history of falls reflects

96 underlying brain pathology and cognitive impairment. The presence of idiopathic fallers

97 in Dorfman and colleagues (2014) work suggest that, despite having similar objective

98 cognitive screening (i.e., MoCA) scores, these participants may have had a greater degree

99 of underlying cognitive impairment at baseline when compared to the participants in the

100 current study. An additional noteworthy contribution of this work was the inclusion of a

101 longitudinal evaluation of the maintenance of cognitive change following the cessation of

102 the DAE intervention. Previous studies have been limited by their omission of

103 longitudinal follow-up, and the degree by which cognitive benefits are maintained

104 following exercise training remains equivocal (Gregory, Gill, & Petrella, 2013). Results

105 from this study suggest that the cognitive benefits provided by 26-weeks of DAE training

106 can be maintained for at least 26-weeks following participation in the program. Despite

107 the intrinsic gait requirements of the intervention and the observed benefit to cognition,

108 the improvements in usual and dual-task gait that were observed following the

109 intervention were not maintained at follow-up. These seemingly contradictory

110 observations may be due to a number of factors: i) the possibility of having observed

111 practice effects on the cognitive outcomes, ii) the requirements of the gait training portion

112 of the DAE program did not effectively impact the cognitive control of gait during

113 untrained tasks, and/or iii) the relationship between cognition and gait is dependent upon

114 the degree of pre-existing cognitive impairment. Nevertheless, the observations from

115   Chapter 4 have helped to define the trajectory of cognitive change in older adults without

116   dementia following exercise training interventions, as well provided preliminary evidence

117   related to the maintenance of changes in cognition and gait following the cessation of

118   training.

119   **Future Directions**

120   Higher cumulative CVD risk was associated with worse EF in a cohort of

121   community-dwelling older adults without dementia. However, the relatively low total

122   explained variance of the regression model in Chapter 2 (i.e., 28.4%, see Table

123   2.2)suggest that other CVD risk factors that are not captured by CVD risk composite

124   scores may also contribute to cognitive impairment in aging. Future efforts should focus

125   on the identification and characterization of novel CVD risk factors that are associated

126   with neuropathological changes to the brain and cognitive impairment. Furthermore, the

127   relationship between gait and EF becomes most pronounced while under dual-task

128   conditions (Yogev-Seligmann, Hausdorff, & Giladi, 2008), and the control of gait is

129   dependent upon not only EF, but also attention, memory, and visuospatial skills (Amboni

130   et al., 2013). Thus, future work should investigate the relationship between cognition and

131   dual-task gait, as well as the realtionship between gait performance and the functioning of

132   a wide breadth of cognitive domains.

133   A number of exercise training modalities have been found to benefit the health

134   and function of the aging brain. The results from Chapter 3 suggest that 26-weeks of

135   DAE training can benefit ususal and dual task gait, and provide cognitive benefits that are

136   maintained for at least 26-weeks followoing the cessation of training. Although there has

137   recently been increasing attention paid to the evaluation of the maintenace of exercise-

138 induced cognitive benefits (Gill et al., 2016; Best, Chiu, Liang Hsu, Nagamatsu, & Liu-

139 Ambrose, 2015; Rahe et al., 2015; Sink et al., 2015; Eggenberger, Schumacher, Angst,

140 Theill, & de Bruin, 2015; Ngandu et al., 2015; Fiatarone Singh et al., 2014), future

141 studies should include longitudinal follow-up periods with appropriately spaced

142 assessment visits in order to definitively support these findings. The cognitive response to

143 exercise training interventions is quite heterogeneous and appears to be dependent upon a

144 number of factors, including: i) the specific exercise training modality employed, ii) the

145 intensity of the training program (i.e., low, moderate, vigorous, progressive or static

146 intensity), iii) the frequency of training, iv) the overall duration of the intervention, and v)

147 the clinical characteristics of the study population (Gregory et al., 2013). Although the

148 results from Chapter 3 suggest that DAE can benefit the functioning of a number of

149 diverse cognitive outcomes, further work is required to determine the specific modality,

150 training intensity, and overall duration of training that will provide the greatest beneit to

151 the health and functioning of the aging brain. Furthermore, despite the intrinsic gait

152 requirements of the intervention the observed benefit to cognition, the improvements in

153 usual and dual-task gait that were observed following the intervention were not

154 maintained at follow-up. These seemingly contradictory observations may be due to a

155 number of factors, including: i) the possibility of having observed practice effects on the

156 cognitive outcomes, ii) the requirements of the gait training portion of the DAE program

157 did not effectively impact the cognitive control of gait during untrained tasks, and/or iii)

158 the relationship between cognition and gait is dependent upon the degree of pre-existing

159 cognitive impairment. Future efforts aimed at developing interventions to benefit

160 cognition and mobility in aging should strive to further delineate the relationship between

161   cognition, gait, and vascular health in preclinical populations, and develop exercise

162   interventions that are of sufficient intensity to stimulate the maintenance of improvements

163   in gait outcomes following the cessation of the program. Last, although the results from

164   Chapter 4 implicate BP dipping status as a potential vascular-related dementia risk factor,

165   further research is required to define the relationship between N-DS as well as other BP

166   dipping phenotypes and brain health and functioning in those with and without pre-

167   existing CVD and cognitive impairment.

This is to notify you that the University of Western Ontario Health Sciences Research Ethics Board (HSREB) which is organized and operates according to the Tri-Council Policy Statement: Ethical Conduct of Research Involving Humans and the Health Canada/ICH Good Clinical Practice Practices: Consolidated Guidelines; and the applicable laws and regulations of Ontario has reviewed and granted approval to the above referenced study on the approval date noted above. The membership of this HSREB also complies with the membership requirements for REB's as defined in Division 5 of the Food and Drug Regulations.

The ethics approval for this study shall remain valid until the expiry date noted above assuming timely and acceptable responses to the HSREB's periodic requests for surveillance and monitoring information. If you require an updated approval notice prior to that time you must request it using the University of Western Ontario Updated Approval Request form.

Member of the HSREB that are named as investigators in research studies, or declare a conflict of interest, do not participate in discussions related to, nor vote on, such studies when they are presented to the HSREB.

The Chair of the HSREB is Dr. Joseph Gilbert. The HSREB is registered with the U.S. Department of Health & Human Services under the IRB registration number IRB 00000940.

Appendix C
Mini-Mental State Examination (MMSE)

The Mini-Mental State Exam

Patient_____ Examiner _____ Date_____

Maximum   Score
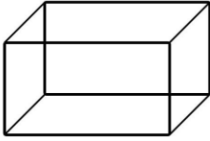

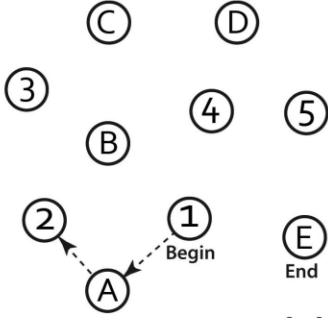

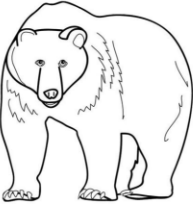

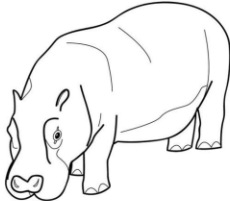

Orientation
5   ( )   What is the (year) (season) (date) (day) (month)?
5   ( )   Where are we (state) (country) (town) (hospital) (floor)?

Registration
3   ( )   Name 3 objects: 1 second to say each. Then ask the patient
                    all 3 after you have said them. Give 1 point for each correct answer.
                    Then repeat them until he/she learns all 3. Count trials and record.
                    Trials _____

Attention and Calculation
5   ( )   Serial 7's. 1 point for each correct answer. Stop after 5 answers.
                    Alternatively spell "world" backward.

Recall
3   ( )   Ask for the 3 objects repeated above. Give 1 point for each correct answer.

Language
2   ( )   Name a pencil and watch.
1   ( )   Repeat the following "No ifs, ands, or buts"
3   ( )   Follow a 3-stage command:
                    "Take a paper in your hand, fold it in half, and put it on the floor."
1   ( )   Read and obey the following: CLOSE YOUR EYES
1   ( )   Write a sentence.
1   ( )   Copy the design shown.

_____   Total Score
              ASSESS level of consciousness along a continuum _____
                                    Alert   Drowsy   Stupor   Coma

Appendix E
Centre for Epidemiological Studies-Depression Scale (CES-D)

Center for Epidemiologic Studies Depression Scale (CES-D), NIMH

Below is a list of the ways you might have felt or behaved. Please tell me how often you have felt this way during the past week.

	During the Past Week			
	Rarely or none of the time (less than 1 day)	Some or a little of the time (1-2 days)	Occasionally or a moderate amount of time (3-4 days)	Most or all of the time (5-7 days)
1. I was bothered by things that usually don't bother me.	☐	☐	☐	☐
2. I did not feel like eating; my appetite was poor.	☐	☐	☐	☐
3. I felt that I could not shake off the blues even with help from my family or friends.	☐	☐	☐	☐
4. I felt I was just as good as other people.	☐	☐	☐	☐
5. I had trouble keeping my mind on what I was doing.	☐	☐	☐	☐
6. I felt depressed.	☐	☐	☐	☐
7. I felt that everything I did was an effort.	☐	☐	☐	☐
8. I felt hopeful about the future.	☐	☐	☐	☐
9. I thought my life had been a failure.	☐	☐	☐	☐
10. I felt fearful.	☐	☐	☐	☐
11. My sleep was restless.	☐	☐	☐	☐
12. I was happy.	☐	☐	☐	☐
13. I talked less than usual.	☐	☐	☐	☐
14. I felt lonely.	☐	☐	☐	☐
15. People were unfriendly.	☐	☐	☐	☐
16. I enjoyed life.	☐	☐	☐	☐
17. I had crying spells.	☐	☐	☐	☐
18. I felt sad.	☐	☐	☐	☐
19. I felt that people dislike me.	☐	☐	☐	☐
20. I could not get "going."	☐	☐	☐	☐

SCORING: zero for answers in the first column, 1 for answers in the second column, 2 for answers in the third column, 3 for answers in the fourth column. The scoring of positive items is reversed. Possible range of scores is zero to 60, with the higher scores indicating the presence of more symptomatology.

Appendix F
Lawton-Brody Instrumental Activities of Daily Living (IADL) Scale

---

Instrumental Activities of Daily Living (IADL)

Instructions: Circle the scoring point for the statement that most closely corresponds to the patient's current functional ability for each task. The examiner should complete the scale based on information about the patient from the patient him-/herself, informants (such as the patient's family member or other caregiver), and recent records.

A. Ability to use telephone	Score
1. Operates telephone on own initiative; looks up and dials numbers, etc.	1
2. Dials a few well-known numbers	1
3. Answers telephone but does not dial	1
4. Does not use telephone at all	0

B. Shopping	
1. Takes care of all shopping needs independently	1
2. Shops independently for small purchases	0
3. Needs to be accompanied on any shopping trip	0
4. Completely unable to shop	0

C. Food preparation	
1. Plans, prepares, and serves adequate meals independently	1
2. Prepares adequate meals if supplied with ingredients	0
3. Heats and serves prepared meals, or prepares meals but does not maintain adequate diet	0
4. Needs to have meals prepared and served	0

D. Housekeeping	
1. Maintains house alone or with occasional assistance (e.g., "heavy work domestic help")	1
2. Performs light daily tasks such as dishwashing, bed making	1
3. Performs light daily tasks but cannot maintain acceptable level of cleanliness	1
4. Needs help with all home maintenance tasks	1
5. Does not participate in any housekeeping tasks	0

E. Laundry	Score
1. Does personal laundry completely	1
2. Launders small items; rinses stockings, etc.	1
3. All laundry must be done by others	0

F. Mode of transportation	
1. Travels independently on public transportation or drives own car	1
2. Arranges own travel via taxi, but does not otherwise use public transportation	1
3. Travels on public transportation when assisted or accompanied by another	1
4. Travel limited to taxi or automobile with assistance of another	0
5. Does not travel at all	0

G. Responsibility for own medications	
1. Is responsible for taking medication in correct dosages at correct time	1
2. Takes responsibility if medication is prepared in advance in separate dosages	0
3. Is not capable of dispensing own medication	0

H. Ability to handle finances	
1. Manages financial matters independently (budgets, writes checks, pays rent and bills, goes to bank), collects and keeps track of income	1
2. Manages day-to-day purchases, but needs help with banking, major purchases, etc.	1
3. Incapable of handling money	0

(Lawton & Brody, 1969)

Scoring: The patient receives a score of 1 for each item labeled A – H if his or her competence is rated at some minimal level or higher. Add the total points circled for A – H. The total score may range from 0 – 8. A lower score indicates a higher level of dependence.

Auditory Verbal Learning and Memory Test

Auditory Verbal Learning Test (A.V.L.T.) Version A
Baseline Visit

START TIME: ☐ ☐ ☐ ☐
(24-hour clock)

Trial 1 Instruction:

Say, "I am going to read a list of words. Listen carefully, for when I stop you are to repeat back as many words as you can remember. It doesn't matter in what order you repeat them, just try to remember as many as you can."

Trial 2-5 Instructions:

Say, "Now I am going to read the same words again, and once again when I stop I want you to tell me as many words as you can remember, including words you said the first time. It doesn't matter in what order you say them, just as many words as you can remember, whether or not you said them before."

List B Instructions:

Say, "Now I'm going to read a second list of words. Listen carefully, for when I stop you are to repeat back as many words as you can remember. It doesn't matter in what order you repeat them, just try to remember as many as you can."

Trial 6 Instructions:

Say, "Now tell me all the words you can remember from the first list, the list I repeated a number of times."

Appendix K
Semantic Verbal Fluency Test

Semantic Fluency (Animal Naming):

Instructions: I am going to give you one minute to name to me as many animals as you can think of. They can be animals from the farm, the zoo, the jungle, underwater animals, house pets, or any kind of animal that you can think of. Any Questions? (Pause) "Now, name for me as many animals as you can think of. (Time for 60 seconds) "Stop".

Phonemic Verbal Fluency Test – Controlled Oral Word Association (COWA) Test

Phonemic Fluency [Controlled Oral Word Association (COWA) Test]:

Instructions: The examiner gives the following instructions" Tell me as many words as you can think of that begin with a certain letter of the alphabet that I will tell you in a moment. You can say any kind of word you want, except for proper nouns (like Bob or Boston), numbers, or words that begin with the same sound but have a different suffix, for example, love, lover, loving, etc. I will tell you to stop after one minute. Are you ready? (Pause) Now, tell me as many words as you can think of that begin with the letter "C". (Time for 60 seconds) "Stop".

Record exact responses
Responses within the first 15 seconds

Responses within the last 45 seconds

Appendix M
Step Test for Exercise Prescription (STEP) Stepping Unit and Predicted VO₂max
Equation

pVO2max = 3.9 + (1511/time)*((weight/HR)*0.124) – (age*0.032) – (sex*0.633)

Where pVO2max is the predicted maximal oxygen uptake (L/min); time is the time to complete the stepping test; weight is body mass (kg); heart rate is beats per minute palpated immediately upon completion of the stepping test; age is the participant's age (years); and sex is 1 for males and 2 for females. The predicted VO2max (mL/kg/min) is used to determine fitness classification for the prescription of individualized and appropriate aerobic exercise intensity during the intervention.

Curriculum Vitae

CURRENT POSITION

Doctor of Philosophy Candidate (PhD), Rehabilitation Sciences (RS)   Sept. 2012 – present
London ,ON
  - with distinction in collaborative musculoskeletal health research (CMHR)

Health & Rehabilitation Sciences, University of Western Ontario
Thesis title: "Dual-task gait training and aerobic exercise for community-dwelling older adults without dementia"

Thesis committee: Dawn P. Gill, Kevin Shoemaker, Jeff Holmes, Cheri L. McGowan, Robert J. Petrella (advisor)

EDUCATION

Master's of Human Kinetics (M.H.K.), **Cardiovascular Physiology**   September 2012
Windsor, ON
Department of Kinesiology, University of Windsor
Thesis title: "The effects of isometric handgrip training in carotid arterial compliance and resting blood pressure in postmenopausal women"
Thesis committee: Kevin Milne, Huimung Zhang, Cheri McGowan (advisor)

Bachelor's of Science (B.Sc.) Honour's, Biological Sciences (BIOS)   February 2010
Guelph, ON
College of Biological Sciences, University of Guelph

RESEARCH EXPERIENCE

Graduate Research Assistant   Sept. 2012 – Current
London, ON
Parkwood Research Institute
Parkwood Institute, in affiliation with Lawson Health Research Institute
(Primary Affiliation)

Multi-site Study Coordinator, Isometric handgrip training and the   Oct. 2011 – Aug. 2012
neurovascular control of blood pressure
Physical Activity and Cardiovascular Research Lab (PACR), University of Windsor
Vascular Dynamics Laboratory, McMaster University
Principle Investigator: Michael Gregory (with Cheri McGowan, Philip Millar, and Maureen MacDoanald)

Research Assistant, Biological Mass Spectrometry Facility   Dec. 2009 – Dec. 2010
Advanced Analysis Centre, University of Guelph
Supervisor: Dyanne Brewer and Armen Charchoglyan
Training time: 550 hours

SCHOLARSHIPS, AWARDS, & DISTINCTIONS

1. **Registration Fellowship ($989)**, Alzheimer's Association International Conference (2014)
2. **Early Researcher Award ($400)**, Ontario Long-Term Care Association (2014)
3. **Travel Grant ($170)**, Canadian Association on Gerontology (2013)

4. **Neuroscience Conference Poster Award ($300)**, Baycrest 23rd Annual Conference (2013)

SCHOLARSHIPS, AWARDS, & DISTINCTIONS (cont'd)

5. **Graduate Research Scholarship ($14,268)**, Western University (2012-2013, 2013-2014)
6. **Verdecchia Family Scholarship in Health Sciences ($1500)**, University of Windsor (2012)
7. **Department of Human Kinetics Master's Honour Roll**, University of Windsor (2012)
8. **Graduate Student Society Scholarship ($500)**, University of Windsor (2011)

$356,547 CAD total (Oct. 2013 – Sept. 2016)

RESEARCH FUNDING - HISTORY

Healthy Mind, Healthy Mobility (HM^2): Dual-task and aerobic gait-training for community-dwelling older adults with and without cognitive impairment, but not dementia (CIND)
Mary Elizabeth Horney Fellowship in Rehabilitation Research
St. Joseph's Health Care Foundation
Role: Principal Applicant, Co-Investigator
$33,692 CAD total (Sept. 2014 – Aug. 2015)

Healthy Mind, Healthy Mobility (HM^2): Dual-task exercise for older adults
Fellowship in Care of the Elderly Research Endowment
St. Joseph's Health Care Foundation
Role: Principal Applicant, Co-Investigator
$30,000 CAD total (Sept. 2012 – Aug. 2013)

BIBLIOGRAPHY

Published Refereed Papers (6 Total)

1. Silva NBS, **Gregory MA**, Gill DP, Petrella RJ. Multiple-modality exercise and mind-motor training to improve cardiovascular health and fitness in older adults at risk for cognitive impairment: a randomized controlled trial. Accepted for publication: Arch Gerontol Geriatr, Oct 20th, 2016.

2. Heath M, Weiler J, **Gregory MA**, Gill DP, Petrella RJ. A six-month aerobic exercise intervention improves executive control in persons with objective cognitive impairment: evidence from the antisaccade task. Accepted for publication in *Journal of the Alzheimer's Disease,* Aug. 2016.

3. **Gregory MA**, Gill DP, Shellington EM, Liu-Ambrose T, Shigematsu R, Zou G, Shoemaker K, Owen AM, Hachinski V, Stuckey M, Petrella RJ. Group-based exercise and cognitive-physical training in older adults with self-reported cognitive complaints: The multiple-Modality, Mind-Motor (M4) study protocol (2016). *BMC Geriatr*; 16(1):17.

4. **Gregory MA**, Gill DP, Zou G, Liu-Ambrose T, Shigematsu R, Fitzgerald C, Hachinski V, Shoemaker K, Petrella RJ. Group-based exercise combined with dual-task training improves gait but not vascular health in active older adults without dementia (2016). *Arch Gerontol Geriatr*; 63:18-27.

5. Gill DP, **Gregory MA**, Zou GY, Liu-Ambrose T, Shigematsu R, Hachinski V, Fitzgerald C, Petrella RJ. The Healthy Mind, Healthy Mobility (HM2) Trial: A Proof-of-Concept Randomized Controlled Trial of a Novel Exercise Program to Improve Cognition in Older Adults (2015). *Med Sci Sports Exerc*; 48(2):297-306.

6. **Gregory MA**, Gill DP, Petrella RJ. Brain health and exercise for older adults (2013). *Current Reviews in Sports Medicine*, 2013 12(4):256-271.

Submitted Refereed Papers (5 total: 1 under review; 4 in progress)

1. **Gregory MA**, Felfeli T, Holmes J, Johnson A, and Petrella RJ. The impact of cognitive impairment on psychosocial functioning in community-dwelling older adults: a scoping review. In preparation for submission to: *Journal of Alz Dis.*

2. **Gregory MA**, Gill DP, Petrella RJ. Vascular risk, mobility, and brain health in aging: a targeted review. In preparation for submission to: *Med Sci Sports Exerc.*

3. **Gregory MA**, Gill DP, Liu-Ambrose T, Shigematsu R, Hachinski V, Shoemaker K, Holmes J, Petrella RJ. Cardiovascular risk contributes to the prediction of executive function but not global cognition in community-dwelling older adults at risk for future cognitive decline. In preparation for submission to: *J Alz Dis*.

4. **Gregory MA**, Gill DP, Liu-Ambrose T, Shoemaker K, Holmes J, Hachinski V, Petrella RJ. The effect of combined dual-task gait training and aerobic exercise on cognition, mobility, and vascular health in community-dwelling older adults at risk for future cognitive decline. In preparation for submission to: *Arch Phys Med Rehabil.*

5. **Gregory MA,** Gill DP, McGowan CL, Petrella RJ. Diurnal blood pressure dipping status as a novel risk factor for cognitive and mobility impairments in older adults without dementia. In preparation for submission to: *Journ Hypertens.*

Refereed Oral Presentations (6 Total; Presenting author is underlined)

1. **Gregory MA**, Gill DP, McGowan CL, <u>Petrella RJ</u>. Diurnal blood pressure dipping status as a novel risk factor for cognitive and mobility impairments in community-dwelling older adults without dementia. Abstract submitted to: European Council for Cardiovascular Research Annual Meeting (Lake Garda, ITY, October 14-16, 2016). To be published in: *High Blood Pressure & Cardiovascular Prevention*.

2. <u>Silva NCBS,</u> Gill DP, **Gregory MA**, De Cruz A, Petrella RJ. The effects of a multi-modality exercise program combined with mind-motor task training for older adults at risk of cognitive impairment on usual gait and balance: a randomized trial. Bodies of Knowledge Graduate Conference 2016, University of Toronto (Toronto, ON, CAN. May 5-6, 2016). *Note: also delivered as a poster presentation at London Health Research Day 2016, Schulich School of Medicine and Dentistry and Lawson Health Research Institute (London, ON, CAN).*

3. <u>Shellington EM</u>, **Gregory MA**, Gill D, and Petrella RJ. Dual-task gait training and aerobic exercise improves information processing, memory, and gait in older adults with cognitive impairment. Canadian Society for Exercise Physiology (CSEP) Annual Meeting (Hamilton, ON, Oct 2015). Published in: *Appl Phys, Nutr, & Metab* 2015, 40(S1):S57.

4. <u>**Gregory MA**</u>, Gill DP, Petrella RJ. Investigating the effects of dual-task gait training and aerobic exercise on cognition and vascular health in older adults with cognitive impairment, no dementia (CIND). Canadian Society for Exercise Physiology (CSEP) Annual General Meeting (St. John's, Newfoundland; October 22-25, 2014). Published in *Appl Phys, Nutr, & Metab* 2014, 39(S1):S20.

5. Gill DP, **Gregory MA**, Liu-Ambrose T, Hachinski V, Zou GY, Fitzgerald C, Shigematsu R, De Cruz A, Petrella RJ. A randomized controlled trial to examine combined multiple-modality and mind-motor exercise on cognitive functioning in community-dwelling older adults: A Pilot Study. Submitted to: Alzheimer's Association International Conference (Copenhagen, Denmark; July 12-17, 2014). Published in: Alz & Dem 2014, 10;(4 Suppl):P210.

6. <u>Gill DP</u>, **Gregory MA**, Koblinsky N, Morton H, De Cruz A, Gonzalez L, Fitzgerald C, Shigematsu R, Petrella RJ. Effects of an Aerobic Exercise and Dual-Tasking Intervention on Cognition and Balance In Older Adults. 2014 American College of Sports Medicine Annual Meeting (Orlando, FL. May 27-31, 2014). Published in: Med Sci Sports Exercise 2014, 46;(5 Suppl).

Refereed Poster Presentations (14 Total; Presenting author is underlined)

1. <u>Silva NCBS</u>, Gill DP, De Cruz A**, Gregory MA**, Petrella RJ. Multi-Modality Exercise Training May Decrease Risk for Dementia and Improve Mobility in Older Adults with Subjective Cognitive Complaints. Abstract submitted to: Canadian Association on Gerontology 45th Annual Meeting (Montreal, QC, CAN, Oct 20-22, 2016).

2. <u>**Gregory MA**</u>, Gill DP, McGowan CL, Petrella RJ. Cardiovascular risk contributes to the prediction of executive function, but not global cognition in older adults at risk for future cognitive decline. Abstract submitted to: Alzheimer's Association International Conference (Toronto, ON, CAN, July 24-28, 2016). To be published in: *Alz & Dem* 2016.

3. <u>**Gregory MA**</u>, Gill DP, De Cruz A, Petrella RJ. Dual-task gait training and aerobic exercise improves cognition in older adults with early indications of cognitive impairment. Abstract submitted to: Alzheimer's Association International Conference (Toronto, ON, CAN, July 24-28, 2016). To be published in: *Alz & Dem* 2016.

4. <u>Silva NCBS</u>, Gill DP, **Gregory MA**, De Cruz A, Petrella RJ. The efficacy of a multi-modality exercise program combined with mind-motor task training for older adults at risk of cognitive impairment on gait parameters: a randomized controlled trial. Abstract submitted to: Alzheimer's Association International Conference (Toronto, ON, CAN, July 24-28, 2016). To be published in: *Alz & Dem* 2016.

5. <u>Heath M</u>, **Gregory MA**, Gillen C, Gill DP, Petrella RJ. A six-month exercise-training program improves cognitive-motor control in persons with an identified cognitive complaint: Evidence from the antisaccade task. Abstract presented at: Society for Neuroscience Annual Meeting. Chicago, IL. October 17-21, 2015.

6. <u>**Gregory MA**</u>, Gill DP, De Cruz A, Shigematsu R, Petrella RJ. A multiple-modality exercise program plus dual-task training improved mobility but did not impact vascular health in active older adults without dementia. Alzheimer' Association International Conference

(Washington, DC, USA, July 18-23, 2015). Published in: *Alz & Dem* 2015, 1(7, Suppl):P742. *Note: also presented at the Western University Annual Bone and Joint Research Retreat (May. 6th, 2015)*

7. **Gregory MA**, Gill DP, Morton H, De Cruz A, Gonzalez L, Petrella RJ. The effects of mind-motor and aerobic exercise on cognition and mobility in older adults with cognitive impairment but not dementia. Alzheimer's Association International Conference (Copenhagen, DN, July 12-17, 2014). Published in: *Alz & Dem* 2014, 10;(4 Suppl):P448-449.

8. **Gregory MA**, Koblinsky N, Morton H, Gonzalez L, DeCruz A, Fitzgerald C, Shigematsu R, Liu-Ambrose T, Gill DP, Petrella RJ. HM2: Healthy Mind, Healthy Mobility - Dual-task Aerobic Gait-Training for Older Adults with Cognitive Impairment but Not Dementia (CIND). American College of Sports Medicine's (ACSM) 61st Annual Meeting, 5th World Congress on Exercise is Medicine®, Orlando, FL, May 25-30, 2014. Published in: *Med Sci Sports Exercise* 2014, 46;(5 Suppl).

9. **Gregory MA**, Koblinsky N, Morton H, Gonzalez L, Gill DP, Petrella RJ. HM2: Healthy Mind, Healthy Mobility: Dual-task aerobic exercise for older adults with cognitive impairment. Canadian Association of Gerontology 23rd Annual Meeting, Halifax, NS, Oct-17-19th, 2013.

10. Deosaran A, **Gregory MA**, Gill DP, Koblinsky N, Morton H, De Cruz A, Gonzalez L, Fitzgerald C, Shigematsu R, Petrella RJ. Effects of combined aerobic exercise and dual-task training on vascular health in older adults. American College of Sports Medicine's (ACSM) 61st Annual Meeting, 5th World Congress on Exercise is Medicine®, Orlando, FL, May 25-30, 2014. Published in *Med Sci Sports Exerc* 2014, 46;(5 Suppl). *Note: also presented at the 2014 FHS-ARGC Symposium at Western University (Feb. 7th, 2014)*

11. De Cruz ARL, **Gregory MA**, Gonzalez L, Gill DP, Petrella RJ. The effects of a combined program of mind-motor and aerobic exercise on gait performance in older adults with cognitive impairment, but not dementia (CIND). Baycrest/Rotman Research Institute 24th Annual Conference. Toronto, ON, Mar 11th, 2014. *Note: this presentation won the annual poster award competition, and was also presented at the 2014 FHS-ARGC Symposium at Western University (Feb. 7th, 2014).*

12. Gill DP, Koblinsky N, **Gregory M**, Morton H, Fitzgerald C, Petrella RA. Preliminary findings from a 6-month randomized controlled trial of combined dual-task gait training and aerobic exercise in older adults with cognitive impairment but no dementia. Alzheimer's Association International Conference 2013. Boston, MA, USA. July 13-18, 2013. Published in: *Alz & Dem* 2013;9(4, Suppl): P480. *Note: also presented at Dementia Care @ AAIC 2013: Translating Research to Practice – with the Alzheimer's Association Massachusetts/New Hampshire Chapter. Boston, MA, USA. July 17, 2013. [Invited Poster Presentation]*

13. **Gregory MA**, Koblinsky N, Morton H, Gonzalez L, Gill DP, Petrella RJ. Dual-task aerobic exercise for older adults with cognitive impairment. Baycrest 23rd Annual Rotman Research Institute Conference, Toronto, ON, March 4-6th, 2013.

14. **Gregory M**, Kovecavic M, Millar PJ, McGowan CL. Isometric leg training delays time to claudication in patients with type II diabetes and peripheral arterial disease: a pilot study. Canadian Society for Exercise Physiology Annual Meeting, Quebec City, QC, October 2011. Published in: *Appl Phys, Nutr & Metabol* 2011;36(S2): S323.

Other Presentations (5 Total; Presenting author is underlined)

1. Bocti JP, **Gregory MA**, Gill DP, De Cruz A, Gonzalez L, Koblinsky N, Petrella RJ. Effects of combined aerobic exercise and dual-task training on gait variability in community-dwelling older adults. 2014 FHS-ARGC Symposium at Western University. Feb. 7th, 2014.

2. **Gregory MA**, Koblinsky N, Morton H, Gonzalez L, Gill DP, Petrella RJ. Healthy Minds, Healthy Mobility: Dual-task aerobic exercise for older adults with cognitive impairment. 2013 FHS-ARGC Symposium at Western University. Feb. 1st, 2013. *Note: this was also presented at the Faculty of Health Sciences Graduate Research Forum, Western University, Feb 6th, 2013.*

3. **Gregory M**, Kovecavic M, Millar PJ, McGowan CL. Isometric leg training increases claudication distance without improvements in local blood flow in a diabetic patient with peripheral arterial disease: a case study. Department of Kinesiology Research Day, University of Windsor, ON, 2012.

4. Hanik S, **Gregory MA**, Seifarth J, Clarke D, MacDonald M, Millar P, Petrella R, Zinszer K, Milne K, McGowan CL. Effects of isometric handgrip training on ambulatory blood pressure and muscle sympathetic nerve activity in post-menopausal women: a proposal. Department of Kinesiology Research Day, University of Windsor, ON, 2012.

5. **Gregory MA**, Seifarth J, Clarke D, MacDonald M, McCartney N, Millar P, Zinszer K, Milne K, McGowan CL. The Effect of Isometric Handgrip Training on Ambulatory Blood Pressure and Neurovascular Function in Post-Menopausal Women: A Thesis Proposal. Department of Kinesiology Research Day, University of Windsor, ON, 2011.
