Abstract

Words that have been learned early in life are responded to faster than words that have been acquired later. Subjective ratings of acquisition ages have been successfully employed to study the effect of age-of-acquisition (AoA). Whilst a large number of norms exist in many languages, fewer are available for German. Therefore, subjective AoA ratings for 3,259 German words were collected online, including 2,363 nouns and 473 verbs. Words were presented in lists of 140 words and participants rated the age in years that they first learned each word. A split-half correlation testified to a high internal reliability. There were high correlations with rated AoA values for sub-sets of items collected in previous studies in German and English. Age and gender were found to influence ratings very weakly: older and male participants tended to give slightly higher age ratings. Education, multilingualism and frequent usage of additional languages other than German did not exert an influence on rating values. These new ratings will extend current existent norms available for language and reading research across languages and will provide researchers with a wider choice of word stimuli. Ratings are available in two measurements, age-in-years and AoA rated on a 7-point-Likert scale.

Keywords: *Age-of-acquisition, AoA, ratings, norms, estimates*

Words (abstract): 198

Rated age-of-acquisition norms for over 3,200 German words

Age-of-acquisition (AoA) denotes the age at which a word and its meaning is first learned (Carroll & White, 1973). There is accumulating evidence that AoA exerts an influence on cognitive processes. Early acquired words are processed faster compared to words that are acquired later in life in pictured object naming (Holmes & Ellis, 2006; Morrison, Ellis, & Quinlan, 1992), in reading aloud (Cortese & Khanna, 2007; Cortese & Schock, 2013), lexical decision (Cortese & Khanna, 2007), in natural reading paradigms employing eye-tracking (Juhasz & Rayner, 2006), and in semantic categorization tasks (Brysbaert, Van Wijnendaele, & De Deyne, 2000). Moreover, in aphasic patients, earlier-acquired words seem to be more accessible for word production than late acquired words (De Bleser & Kauschke, 2003; Weekes, Davies, Wadey, & Bradley, 2004; **for a recent review also see Brysbaert & Ellis, 2015**). In Alzheimer patients, words which are learned earlier in life have also been found to remain intact for a longer time for word production (Cuetos, Gonzalez-Nosti, & Martínez, 2005) and word recognition (Cuetos, Herrera, & Ellis, 2010). AoA is now a widely accepted effect evident in lexical processing (Juhasz, 2005) and learning mechanisms more generally (Catling, Dent, Preece, & Johnston, 2013; Stewart & Ellis, 2008). AoA is thus critical to the investigation of language behaviour and needs to be taken into account in future language research.

AoA has been determined by averaging participants' subjective estimates of when they first learned a word. Such subjective AoA ratings have been collected in many languages. Some of these have been very extensive ratings collections for 30,000 words in English (Kuperman, Stadthagen-Gonzalez, & Brysbaert, 2012) and Dutch (Brysbaert, Stevens, De Deyne, Voorspoels, & Storms, 2014). Other studies have presented smaller sets of ratings, most of these for English (Bird, Franklin, & Howard, 2001; Carroll & White, 1973; Clark & Paivio, 2004; Cortese & Khanna, 2008; Gilhooly & Logie, 1980; Stadthagen-

1
2
3 Gonzalez & Davis, 2006). However, AoA rating estimates have also been collected in other
4
5 languages, including French (Ferrand et al., 2008), Portuguese (Cameirão & Vicente, 2010;
6
7 Marques, Fonseca, Morais, & Pinto, 2007), Spanish (Cuetos, Samartino, & Ellis, 2012;
8
9 Moreno-Martínez, Montoro, & Rodríguez-Rojo, 2014) and Italian (Barca, Burani, &
10
11 Arduino, 2002; Della Rosa, Catricalà, Vigliocco, & Cappa, 2010). In addition, the Snodgrass
12
13 & Vanderwart (1980) picture set of 260 objects have been rated for AoA, and at times
14
15 adjusted and extended with further drawings, in French (Alario & Ferrand, 1999), Icelandic
16
17 (Pind, Jónsdóttir, Gissuraadóttir, & Jónsson, 2000), Spanish (Cuetos, Ellis, & Alvarez, 1999),
18
19 and German (Schröder, Kauschke, & De Bleser, 2003). Finally, a selection of 824 rated AoA
20
21 estimates is available in German (Schröder, Gemballa, Ruppín, & Wartenburger, 2012). The
22
23 present AoA ratings extend the ratings available for German considerably and will thereby
24
25 aid word stimulus selection for future language research.
26
27
28

29
30 Early acquired words tend to be shorter in length, more frequent, more imageable,
31
32 more concrete and have more spelling neighbours than words which are learned later in life
33
34 (Morrison, Chappell, & Ellis, 1997; Stadthagen-Gonzalez & Davis, 2006). The high inter-
35
36 correlation with frequency has made it particularly difficult to distinguish frequency from
37
38 AoA effects (Brysaert & Ghyselinck, 2006; Zevin & Seidenberg, 2002).
39

40
41 The speeded naming task (reading aloud) requires participants to read words aloud as
42
43 quickly and accurately as possible, thus tapping into processes underlying the transformation
44
45 of the written word into its spoken form. Morrison & Ellis (1995) reported faster word
46
47 naming for early acquired than late acquired words (AoA effect) when frequency was taken
48
49 into account, but did not find a processing advantage for more frequent words (frequency
50
51 effect) when AoA was controlled for. They suggested that previously reported frequency
52
53 effects were actually due to AoA. However, other studies have reported effects of both
54
55 frequency and AoA effects in word production (Brown & Watson, 1987; Cortese & Khanna,
56
57
58
59
60

2007) and thus support the existence of independent AoA and frequency effects in reading aloud.

Studies examining the AoA effect in several tasks have indicated a stronger AoA effect in lexical decision than in word naming (Cortese & Khanna, 2007; Cortese & Schock, 2013). In the lexical decision task, participants are asked to discriminate between words and non-words and it is assumed that word meaning is thereby accessed (Balota, Cortese, Sergent-Marshall, Spieler, & Yap, 2004; Chumbley & Balota, 1984). Although early studies failed to find an AoA effect in the lexical decision task (see Gilhooly & Watson, 1981), subsequent investigations have reported independent effects of AoA and frequency (Cortese & Khanna, 2007; Ghyselinck, Lewis, & Brysbaert, 2004), as well as an interaction such that the AoA effect was stronger for low-frequency compared to high-frequency words (Bonin, Chalard, Méot, & Fayol, 2001; Gerhand & Barry, 1999). Importantly, Brysbaert & Cortese (2011) showed that the AoA effect remained present in both word naming and lexical decision when employing frequency norms based on larger text corpora.

In comparison, the AoA effect seems to be stronger in picture naming than in word naming (Lambon Ralph & Ehsan, 2006), and the AoA effect has been reliably shown in picture naming such that pictures of early acquired items are named faster than pictures of later acquired items (Holmes & Ellis, 2006). Conflicting evidence has been reported with regard to the role of frequency when AoA has been taken into account in picture naming. Barry, Morrison, & Ellis (1997) found both AoA and frequency effects in picture naming which interacted in such a way that late-acquired words produced a larger frequency effect than early-acquired words. In contrast, other studies concluded that frequency produced only a small effect (Carroll & White, 1973), or no effect (Chalard, Bonin, Méot, Boyer, & Fayol, 2003; Morrison et al., 1992).

1
2
3 The effect of AoA has been found to be larger in size and more clearly distinct from
4 frequency effects in tasks that require a mapping between language and semantics (but see for
5 example Chalard & Bonin, 2006). The semantic locus hypothesis (Brysbaert et al., 2000; van
6 Loon - Vervoorn, 1989) proposes that AoA effects in lexical processing occur because the
7 semantic system is organised according to when meanings are acquired. Early-acquired
8 words thus have an advantage and produce faster meaning associations and faster
9 categorisation than later acquired words. This is consistent with the model of semantic
10 growth presented by Steyvers & Tenenbaum (2005) in which AoA functions as an organising
11 factor of the semantic network. Earlier acquired word meanings have more connections to
12 other word meanings than later learned ones, and are consequently better connected. AoA
13 effects can then be understood to occur due to enhanced semantic connectivity and reflect the
14 underlying semantic network.

29 The network plasticity hypothesis (Ellis & Lambon Ralph, 2000) attributes AoA
30 effects to the diminution of network plasticity during the course of development. Ellis &
31 Lambon Ralph (2000) presented a series of simulation studies, where a connectionist system
32 was presented with patterns for learning in a cumulative and interleaved fashion. The
33 simulations reported by Ellis and Lambon Ralph (2000), and later by P. Monaghan & Ellis
34 (2010), demonstrated that as experience of input patterns accumulated and connection
35 weights were adapted, earlier introduced items tended to shape the network in their favour.
36 The adaptation of connections was found to be driven by both the frequency of occurrence of
37 input patterns but also, critically, by the order of entry of such patterns such that later-
38 acquired items were learnt less securely than earlier acquired items.

45
46
47
48
49
50

51 However, in a review of the computational evidence for AoA effects in reading
52 development, Zevin & Seidenberg (2002) identified the arbitrariness of the input-output
53 patterns deployed in the Ellis & Lambon Ralph (2000) simulations as critical to the
54
55
56
57
58
59
60

1
2
3 observation of AoA effects over and above the impact of pattern frequency. In the Zevin and
4
5 Seidenberg (2002) account (arbitrary mapping hypothesis), an enduring independent AoA
6
7 effect is less likely to be observed if input or output patterns have the rich structure possessed
8
9 by the orthography or phonology of English words, and if input-output mappings are
10
11 predictable as in the pronunciation of regular or consistent English word spellings. In this
12
13 analysis, strong AoA effects were observed by Ellis and Lambon Ralph (2000) because input-
14
15 output patterns were random and input-output mappings were arbitrary. Zevin and
16
17 Seidenberg (2002) argued that their simulations demonstrated that an AoA effect independent
18
19 of frequency is not observed even if spelling-sound mappings are inconsistent. However, in a
20
21 series of behavioural studies, J. Monaghan & Ellis (2002) showed that the AoA effect in
22
23 naming was greater for words with inconsistent compared to consistent spelling-sound
24
25 mappings. P. Monaghan and Ellis (2010) demonstrated in further simulations that AoA
26
27 effects emerge as an order effect when reading development is simulated using input-output
28
29 patterns and training regimes that more closely approximate those experienced in human
30
31 development. Importantly, the items with less consistent spelling – sound mappings incurred
32
33 greater AoA effects. Thus, AoA effects appear to be observable independent of frequency but
34
35 conditioned by spelling-sound consistency.
36
37
38
39

40
41 The finding of larger AoA effects for words in English with inconsistent spelling-
42
43 sound mappings predicts smaller AoA effects in languages where mappings are more
44
45 consistent (Davies, Wilson, Cuetos, & Burani, 2014; Ellis & Lambon Ralph, 2000).
46
47 However, word naming studies in transparent languages have reported mixed results. AoA
48
49 effects have been reported in transparent orthographies such as Turkish (Raman, 2006) and
50
51 Spanish (Cuetos & Barbón, 2006). Interestingly, Wilson, Ellis, & Burani (2012) showed that
52
53 AoA affects reading aloud of Italian words with irregular stress (arbitrary), but not words
54
55 with regular stress (consistent mapping) in an otherwise very consistent orthography.
56
57
58
59
60

1
2
3 However, in a naming study in Spanish, AoA showed an effect when words were highly
4 imageable (Davies et al., 2014). These findings suggest some form of semantic involvement
5 is required in reading for an AoA effect to occur (Davies, Barbón, & Cuetos, 2012; Davies et
6 al., 2014; Wilson, Cuetos, Davies, & Burani, 2013). AoA effects have been observed in
7 spelling systems varying in consistency. It is evident that AoA is a live area of enquiry and
8 that more AoA norms are needed to investigate the role of AoA in languages which differ in
9 the consistency of spelling-sound correspondences. This is a further motivation for collecting
10 AoA ratings for German words. German is considered a transparent language, and exception
11 words tend to be loan words from other languages or proper names of people and locations
12 (Ziegler, Perry, Coltheart, 2000). Within a comparison of several European languages,
13 German was considered to be a more consistent language in terms of grapheme – phoneme
14 correspondences (Seymour, Aro, & Erskine, 2003). One notable inconsistency in German is
15 found in vowel duration (e.g. Landerl & Reitsma, 2005).

31
32 As discussed in the foregoing, studies have successfully employed rated AoA norms
33 in accounting for variance in performance in various tasks. Alternatively, AoA has also been
34 determined by children's picture naming ages, which denote the age at which a child reliably
35 names a pictured object, in English (Morrison et al., 1997), French (Chalard et al., 2003),
36 Spanish (Álvarez & Cuetos, 2007) and Italian (Lotto, Surian, & Job, 2010). Whilst picture
37 naming ages are considered to be more objective estimates, they are also more difficult to
38 obtain for non-picturable words. AoA has therefore been collected as subjective ratings,
39 which has facilitated the determination of AoA values for much larger numbers of words.
40 Morrison et al. (1997) compared rated AoA with children's picture naming ages and
41 concluded that rated AoA was a good estimate of objective AoA, but that rated AoA differed
42 from objective measures in reduced reliance on imageability and was more influenced by
43 word length, word familiarity and word frequency when making a judgement. These findings

1
2
3 are consistent with comparisons of subjective and objective AoA norms in Icelandic (Pind et
4 al., 2000), French (Chalard et al., 2003) and Spanish (Álvarez & Cuetos, 2007). In a further
5 study in German, Schröder et al. (2003) compared rated AoA norms with children's picture
6 naming ages and spontaneous first speech production ages as reported by parents. Children
7 included words in their spontaneous production vocabulary at an earlier age than they were
8 able to use the same words to name pictures correctly. Schröder and colleagues found that
9 rated acquisition ages were more similar to children's picture naming ages than to
10 spontaneous speech production, suggesting that rated AoA does not indicate veridical first
11 acquisition age but reflects a more advanced form of lexical knowledge. Comparing rated and
12 objective AoA as predictors of picture naming latencies, Chalard et al. (2003) found that
13 although both rated and objective AoA were predictive of latencies, objective AoA accounted
14 for more variability than rated AoA. Morrison & Ellis (2000) also replicated both AoA and
15 frequency effects in naming and lexical decision tasks using objective AoA measures. These
16 results suggest that rated AoA is an adequate measure to investigate age-of-acquisition effects
17 in lexical processing, if objective measures are not available.

18
19 Rather than regarding AoA ratings as capturing the veridical age at which words are
20 learned, researchers have tended to conceptualise rated AoA as reflecting the order of
21 acquisition. Kuperman et al. (2012) compared their AoA ratings with an objective measure
22 which targeted the knowledge of word meanings in children (Biemiller & Slonim, 2001).
23 Kuperman and colleagues found that raters tended to overestimate at what age they had
24 learned very early-acquired words, specifically words learned in the first three years of life,
25 and highlighted that this is congruent with infantile amnesia. Kuperman et al. also observed a
26 tendency of raters to consider very few words to be learned after the age of 14/15. These
27 observations mirror previous reports of ratings underestimating the AoA of later learned
28 words (Morrison et al., 1997) and subsequent suggestions that AoA ratings should be

1
2
3 considered to reflect rank order rather than actual ages when words are learned. In this light,
4
5 recent research on AoA tends to refer to the order of acquisition rather than the age of
6
7 acquisition (Joseph, Wonnacott, Forbes, & Nation, 2014; Kuperman et al., 2012; P.
8
9 Monaghan & Ellis, 2010).

10
11 Whether AoA ratings can be taken to be age estimates or order estimates, how
12
13 might AoA values be influenced by participant characteristics? Previous ratings studies have
14
15 examined the impact of age, gender and education on ratings values. Kuperman et al. (2012)
16
17 reported that older participants tended to rate words as slightly later learned than younger
18
19 participants. Ratings by older participants were more predictive of Alzheimer patients' lexical
20
21 selection times than ratings from young participants (Cuetos et al., 2012). In contrast,
22
23 Schröder et al. (2012) compared their German ratings of older participants with that of the
24
25 younger group and did not find an age-related difference. Mixed results have also been found
26
27 with regard to gender. Whilst in Kuperman's sample, female respondents tended to rate
28
29 words as later learned than male respondents, the reverse was found in other studies
30
31 conducted in German (Schröder et al., 2003) and English (Winters Jr, Winter, & Burger,
32
33 1978). With regard to the influence of education level, Kuperman and colleagues did not find
34
35 a main effect of education, but noted that respondents with higher education tended to give
36
37 earlier word learning ages than participants with lower education, although the effect size was
38
39 very small. Multilingualism was also assessed by Kuperman et al. (2012), but few
40
41 participants had been raised with more than one language and ratings did not differ from the
42
43 rest. It thus appears that AoA ratings weakly correlate with age and may be influenced - with
44
45 varying direction - by gender, but seemingly not by education or multilingualism. With the
46
47 aim to ensure utmost comparability to other ratings, this study collected rater characteristics
48
49 and their relative influence on rating values were determined.

57
58
59
60

1
2
3 In the following we will present our AoA ratings for 3,259 German words. To
4
5 pave the way for more extensive research across languages, the ratings collection was
6
7 conducted using a methodological approach which resembled as closely as possible that
8
9 employed by Kuperman et al. (2012) to collect the current largest AoA dataset of 30,000
10
11 ratings in English using the Amazon Mechanical Turk
12
13 (<https://www.mturk.com/mturk/welcome>). In the present study, ratings were collected in
14
15 years and AoA values are presented in the resulting dataset both as AoA-in-years and as
16
17 converted values on a 7-point-Likert scale. The need for comparable psycholinguistic norms
18
19 has been previously highlighted by other researchers (Schmidtke, Schröder, Jacobs, &
20
21 Conrad, 2014) and the collection of German AoA ratings reported in the present article
22
23 endeavoured to broaden researchers' stimuli choice.
24
25
26

27 **Method**

28
29 Ratings were collected using online questionnaires (Qualtrics, 2014) advertised via a
30
31 large number of internet forums, mailing lists, flyers and personal communication between
32
33 January and September 2014. Respondents were encouraged to disseminate knowledge about
34
35 the study to attract further participants.
36
37

38 **Participants**

39
40 Eligibility for participation was confined to native German speakers, who were aged
41
42 18 years or over, and at the time of participation lived in a German-speaking country. At the
43
44 start of the questionnaire, all participants were invited to answer some questions on
45
46 demography, but it was not obligatory to provide any of this information and participants
47
48 were able to only complete the ratings section, if they so wished. First of all, participants
49
50 were asked to indicate their age and gender. Education level was probed twofold, both as
51
52 number of years receiving education, including primary schooling, and as a formalised level
53
54 of education with eight choices given: *weiterführende Schule* (secondary school), *Mittlere*
55
56
57
58
59
60

1
2
3 *Reife oder Äquivalent* (school qualification at age 16 or equivalent), *Abitur oder Äquivalent*
4 (school qualification at age 18 or equivalent), *nicht abgeschlossene Ausbildung nach Schule*
5 (not completed training after school), *abgeschlossene Ausbildung nach Schule* (completed
6 training after school), *abgeschlossenes Erststudium* (first degree), *Zweitstudium oder*
7 *weiterführendes Studium* (second degree or post-graduate studies), *nicht hier aufgeführt* (not
8 listed). Respondents' language environment was assessed by asking to indicate if they had
9 grown up speaking more than one language, and whether German was the language they
10 spoke most at the time of completing the questionnaire. The options given were *yes*, *no* and *I*
11 *don't know*. If respondents spoke other languages frequently, they were asked to specify
12 which ones. At the end of the questionnaire, respondents were invited to take part in a prize
13 draw to win one of five EUR25 – Amazon vouchers. Winners were determined and notified
14 in December 2014.

30 **Stimuli**

31
32 We aimed to collect AoA ratings for a varied set of German word stimuli to afford
33 experimenters as great a breadth as possible in future experimental stimulus selection.
34 Originally 3,260 words were selected for ratings data collection, but due to input error in
35 constructing the Qualtrics questionnaire one word was inputted twice, so that data were
36 obtained for 3,259 words including: 2,363 nouns, 473 verbs (in the infinitive form), 371
37 adjectives, and 17 adverbs. The remainder of the word forms fulfilled multiple grammatical
38 functions. For example, the word *allein* (alone) could be categorized as an adjective, adverb
39 or conjunction (Duden, <http://www.duden.de/suchen/dudenonline/allein>). Words were 2-17
40 letters long ($M = 6.73$), and had 1-7 phonological syllables ($M = 2.25$). Frequency ranged
41 between 0 and 2,839.84 ($M = 33.31$) occurrences per million (SUBTLEX -DE, Brysbaert et
42 al., 2011).

2
3 The set of words for which we collected AoA values shares 2,244 words with the
4 BAWL-R database for ratings of emotional arousal, valence and imageability (Vö et al.,
5 2009) and 425 words with the more recent German ANEW database for affective word norms
6 (Schmidtke et al., 2014). All words apart from *jauchzen* (shout for joy) and *All* (universe) can
7 be found in the cleaned version of the SUBTLEX-DE database (Brysbaert et al., 2011). This
8 considerable overlap in word choice with other psycholinguistic databases will be a useful
9 asset for researchers when choosing their stimuli.

18 **Data collection**

19
20 The original set of 3,260 words was divided into 3,240 rating items and 20 control
21 items. The 3,240 rating items were separated into 27 questionnaires each containing 120
22 words. Each participant completed one questionnaire only. A one-way independent ANOVA
23 showed that questionnaires did not differ in terms of log₁₀ frequency, $F(1,3238) = 0.07, p =$
24 $.79$. In each on-line questionnaire, the 120 items were distributed over 12 consecutive
25 question pages. In order to vary the items that were presented together on one question page,
26 we created three pseudo-randomized versions of each 120-item-questionnaire. (Note that
27 AoA values on the full dataset collected by the three different versions did not differ
28 significantly, Kruskal-Wallis test comparison, $H(2) = 5.66, p = .059$.) Further randomisation
29 occurred at two levels. The order of the question pages within each questionnaire and the
30 order of words within each question page were randomised for each participant.

38
39
40
41
42
43
44

45 The 20 control words (see Appendix 1) were chosen from the original word set for all
46 participants to rate, and appeared in all questionnaires. Kuperman et al. (2012) had also used
47 a set of 52 control words to be rated by all participants. In the current study, ratings for
48 control words were collected to have ratings given by all participants on the same 20 items,
49 which could then be used to 1) identify outliers and 2) to investigate the influence of rater
50 differences on AoA ratings. Items were selected to mirror a range of acquisition ages, whilst
51
52
53
54
55
56
57
58
59
60

1
2
3 having similar frequencies per million ($M = 33$, range = 29 to 35). The 20 control words were
4
5 randomly added to each questionnaire, one or two per question page. The addition of control
6
7 words meant that each participant rated 140 words.
8

9
10 Once participants had agreed to take part and answered the questions on demography,
11
12 they were asked to start with the rating task. At the top of each question page, participants
13
14 were shown instructions in German, a translation of those used by Stadthagen-Gonzalez &
15
16 Davis (2006) and Kuperman et al. (2012); instructions are reproduced in Appendix 2.
17
18 Participants were asked to estimate at what age they had learned each word with its meaning
19
20 by inserting the age estimates in years in a text box next to each presented item, or to indicate
21
22 with an “x” if they did not know an item.
23
24

25 Results

26
27 In the following, we report how raw data were prepared for inclusion in the ratings
28
29 database, how we derived our rated AoA estimates from the raw data and how we checked
30
31 their internal and external reliability. We further examined the validity of our estimates by
32
33 comparing them with German children’s production ages (Suchodoletz, 2010). In addition,
34
35 we assessed the relationship of the present AoA estimates with other psycholinguistic
36
37 variables. We then outline the characteristics of participants who contributed to the present
38
39 ratings. Lastly, we examine whether raters’ characteristics influenced AoA values and
40
41 explored the relative effects of lexical variables and participant characteristics on AoA
42
43 ratings. For all analyses, we used the R language and statistical computing environment (R
44
45 Development Core Team, 2014).
46
47
48

49
50 For the sake of clarity, we will make a distinction between the different types of rating
51
52 values which were used within data analysis. We distinguish between raw ratings, which
53
54 denote a single observation of one participant (one rating from one participant for one word),
55
56 and AoA ratings/estimates, which are all averaged raw ratings from all participants for that
57
58
59
60

1
2
3 word (our actual AoA norms). We will also refer to control word means (CWMs), which are
4
5 the average of raw AoA ratings given by each participant to the words in the control word
6
7 list.
8
9

10 **Database cleaning**

11
12 The questionnaires were accessed 1,056 times, but only 544 (51%) people submitted
13
14 their responses. Three completed questionnaires were excluded outright because they
15
16 contained only invalid entries or had marked all text boxes with crosses. Within the
17
18 remaining 541 completed questionnaires, each single raw rating was examined to detect any
19
20 non-valid entries. Nine raw ratings were deleted because they did not clearly indicate an age.
21
22 Where the age of learning had been given but additional text had been added (e.g., “years” or
23
24 a question mark), the additional text was deleted. This was the case for four raw ratings.
25
26 Where participants had indicated with an “x” that the item to be rated was unknown, this was
27
28 recorded and coded as a missing value. In total, 179 “x” (unknown) responses were recorded,
29
30 indicating that overall words in the stimulus set are likely to be known by adult speakers of
31
32 German. Information about which words were unknown was added to the final ratings
33
34 database. Four participants entered “x” (unknown) responses for more than 10% of the words
35
36 in the questionnaires that they completed. For these responses, the “x” seemed to function as
37
38 an indicator that the age-of-acquisition was not known, and not that words were unknown.
39
40 This assumption was supported by the fact that these participants did not leave any cells
41
42 blank to differentiate between not knowing the acquisition age and not knowing the meaning
43
44 of a word. The words marked with “x” for these four participants were not coded as unknown
45
46 but as missing values in the database. Where participants entered two different acquisition
47
48 ages for a word, we entered the mean of the ages in our database, provided the two values
49
50 were neighbouring integers, i.e. for the entry “5 and 6 years”, 5.5 years was used. These
51
52 entries were interpreted to signify that the participant indicated an approximate age, and was
53
54
55
56
57
58
59
60

1
2
3 applied for 57 raw ratings. For six further raw ratings, where two entries were made that were
4
5 separated by more than a year the lower age was used. For example, if “4 / 11 years” had
6
7 been entered, “4 years” was used. The different treatment seemed appropriate, because
8
9 greater differences were interpreted to indicate the learning of the different meanings of
10
11 polysemous words. For example, the word *Linse* could be have been interpreted to mean
12
13 ‘lentil’ or to refer to an optical lens, and it was assumed that these double entries had been
14
15 made to capture the acquisition of different word meanings.
16
17

18
19 Due to an input error, one word was lost and resulted in the reduction of the final
20
21 word count from 3,260 to 3,259 items. Three further items were erroneously presented for
22
23 rating twice within one of the three different order questionnaire versions. In one version, the
24
25 word *Parfum* was entered twice and the word *Nachteil* was left out. The word *mehr* was also
26
27 presented twice in one questionnaire version. On all occasions, we deleted at random one of
28
29 the two responses for the word accidentally presented twice.
30
31

32
33 In line with Kuperman et al. (2012), entries indicating acquisition ages above 25 years
34
35 were removed: this was done for 134 raw ratings. Checks showed that these had been
36
37 contributed by 73 different participants.
38
39

40
41 Following Kuperman et al. (2012), for some participants we removed all responses
42
43 from the dataset because the AoA values they supplied appeared to be outliers in comparison
44
45 to the responses supplied by other participants. The detection of outliers was based on data
46
47 collected using control words. All participants had been asked to rate 20 control words, and
48
49 for all but three participants (who had not provided enough control word ratings) we could
50
51 average across the ratings given for the 20 control words to obtain the mean of this person’s
52
53 control word ratings (CMWs). We then compared these to the sample’s overall CWM. We
54
55 identified four participants whose CMWs correlated below .4 with the mean. By removing
56
57 these four participants’ contributions, 459 raw ratings were excluded. Although the cut-off of
58
59
60

.4 is arbitrary, it emulates that used by Kuperman and colleagues who also removed lists that had a correlation below .4 with the Bristol norms. After these exclusions, we used the remaining 73,948 raw ratings of 537 participants to determine the average AoA ratings per word. The average correlation between the overall sample's CWM and each participants' CWM was $r = .83$.

Data Analysis

Age-of-acquisition ratings

Words (excluding control words) were rated on average 19.57 times (range = 7 to 27), a similar raw ratings per word ratio to that recorded for the Kuperman et al. (2012) and Schröder et al. (2012) datasets. (The twenty control words received an average of 528.7 raw ratings with a range of 518 to 534.) AoA estimates were computed by averaging across all raw ratings received per word, following the exclusions discussed previously. The overall mean AoA estimate was 7.01 years ($SD = 2.62$, range = 1.67 to 15.83 years). The ten words rated as latest acquired (including control words) were *Blog* (blog), *Quiche* (quiche), *Webcam* (webcam), *Fakultät* (faculty), *Kurator* (curator), *Mensa* (refectory), *Lobbyist* (lobbyist), *Veganer* (vegan), *Vektor* (vector) and *Webseite* (website). The 10 words which were rated as earliest acquired were *Papa* (dad), *Mama* (mum), *Bett* (bed), *Nase* (nose), *Bauch* (belly), *Mund* (mouth), *Hose* (trousers), *Kind* (child), *Hand* (hand) and *Puppe* (doll). The words which were the most often marked as unknown were *Quorum* (quorum), *Pomp* (pomp), *Alkoven* (alcove), *Charta* (charter), *Jade* (jade), *Noblesse* (nobility) and *Viola* (viola).

The frequency distribution in Figure 1 shows that averaged AoA estimates were slightly positively skewed (skew = 0.41, kurtosis = -0.45), peaking at around 6-7 years. Few items were rated as having been acquired before the age of two years. Acquisition was considered to occur mostly from age of 2.5 years onwards, with a slowly diminishing acquisition rate in later childhood and teenage years.

Figure 1. Distribution of AoA estimates in years for 3,259 German words

Internal reliability

A split-half correlation was performed to further examine internal reliability.

Participants were divided into two groups of even ($N=268$) and odd ($N=269$) numbered participants and the averaged AoA estimates were calculated for each group for all 3,259 words. Ratings from the two groups were found to correlate very highly ($r_s = .91, p < .001$).

External reliability

The present ratings were compared to other existing ratings to gauge external reliability. Schröder et al. (2012) presented the current largest set of German AoA ratings in Likert scale format (1 = 0-2 years, 2 = 3-4 years until 7 = 13+ years). For comparison purposes, we converted our raw ratings accordingly, as if respondents had used the Likert scale to issue a response. The by-items average AoA values were then computed to generate new AoA estimates on a 7-point Likert scale. These ratings in Likert scale can also be found

in the downloadable supplement. Our set included 203 of the words in Schröder et al.'s 824 items, and AoA values for these words in the Schröder et al. and in our data were highly correlated, $r_s = .91, p < .001$. In the present study, more words had been rated to be early acquired (between the ages of 3 – 8) and fewer had been rated as late acquired (after the age of 8) compared to Schröder's ratings.

The present ratings were also compared to AoA estimates which had been collected in English. Table 1 shows that cross-language comparisons yielded high correlations. The present stimulus set shared 2,683 words with the Kuperman et al. (2012) set of American English, and the AoA ratings were strongly, positively correlated, ($r_s = .74, p < .001$). Our stimulus set also had 782 words in common with the Cortese & Khanna (2008) norms, and correlated highly ($r_s = .70, p < .001$). Likewise, the AoA estimates for the 1,031 words appearing in both the Bristol norms (Stadthagen-Gonzalez & Davis, 2006) and our norms also correlated highly, $r_s = .77, p < .001$. (Note that we compared Likert-scale AoA estimates from the Bristol and the Cortese & Khanna norms with AoA estimates converted to Likert-scale values in our norms.)

Table 1

Correlation coefficients of present German age-of-acquisition (AoA) norms to extent rating collections

<i>Ratings study/collection</i>	<i>Language</i>	<i>Measurement</i>	<i>Number of words in common</i>	<i>correlation coefficient Spearman's rho</i>
Schröder et al. (2012)	German	Likert (1 - 7 scale)	203	.91***
Kuperman et al. (2012)	American English	years	2,683	.74***
Cortese & Khanna (2008)	American English	Likert (1 - 7 scale)	782	.70***
Stadthagen-Gonzalez & Davies (2006; Bristol norms)	British English	Likert (1 - 7 scale)	1,031	.77***

Note: *** $p < .001$, ** $p < .01$, * $p < .05$

External validity

We examined the external validity of our AoA estimates by comparing them to German data on early speech production. Suchodoletz (2010) had asked parents of 20 – 25-

month-old children which words their children produced. This resulted in a list of 406 words, and for each word the percentage of children who produced it was reported. The present dataset had 229 words in common with Suchodoletz' production word list and we found a moderate relationship of $r = -.53$ ($p < .001$) between the percentage of 20-25-month-olds who produced a word and our AoA estimates for those words (see Figure 2). Words estimated by adults as having been acquired earlier were more likely to have been produced by more children in spontaneous speech.

Figure 2. Scatterplot showing relationship between percentage of children aged 20-25 months producing a word and our present AoA ratings

Relationship of AoA with other word characteristics

As mentioned in the foregoing, previous research has shown that early acquired words tend to be shorter, more frequent and to have more orthographic neighbours. In order to inspect these relationships for our AoA estimates, a number of correlations with known word properties were performed. Frequency estimates (\log_{10}) were taken from the SUBTLEX-DE

database (Brysbaert et al., 2011). Word length was measured in letters and in number of phonological syllables. Two different measures were employed to capture the orthographic similarity neighbourhood characteristics of words. For each word, we calculated Coltheart's N (Coltheart, Davelaar, Jonasson, & Besner, 1977), an estimate of how many words of the same length can be created by changing one letter in a target word. As Coltheart's N has been argued to be insensitive to orthographic similarity neighbourhoods for longer words, for each word we also calculated the Orthographic Levenstein distance (Yarkoni, Balota, & Yap, 2008), a count of how many changes (insertions, deletions or substitutions) are needed to transform a word into its 20 nearest orthographic neighbours. Both measures were computed using the R package *vwr* (Keuleers, 2013) based on the Clearpond word list of 27,751 **DELETE most frequent DELETE END** German words (Marian, Bartolotti, Chabal, & Shook, 2012). As expected, words that were acquired earlier tended to be shorter, more frequent, and to have more orthographic neighbours (see Table 2). Both length measures were only weakly correlated with AoA.

Table 2

Correlation coefficients for multiple comparisons of present age-of-acquisition (AoA) norms for German words to other word characteristics

	AoAestimate	log frequency	length in letters	syllable number	old20
AoAestimate					
log frequency	-0.53***				
length in letters	0.29***	-0.26***			
syllable number	0.36***	-0.26***	0.75***		
old20	0.41***	-0.40***	0.81***	0.66***	
ColtN	-0.35***	0.33***	-0.49***	-0.42***	-0.58***

Note: log frequency (SUBTLEX-DE frequency estimates; Brysbaert et al., 2011), old20 (Orthographic Levenstein distance; Yarkoni et al, 2008), ColtN (Coltheart's N; Coltheart et al, 1977)

*** $p < .001$, ** $p < .01$, * $p < .05$

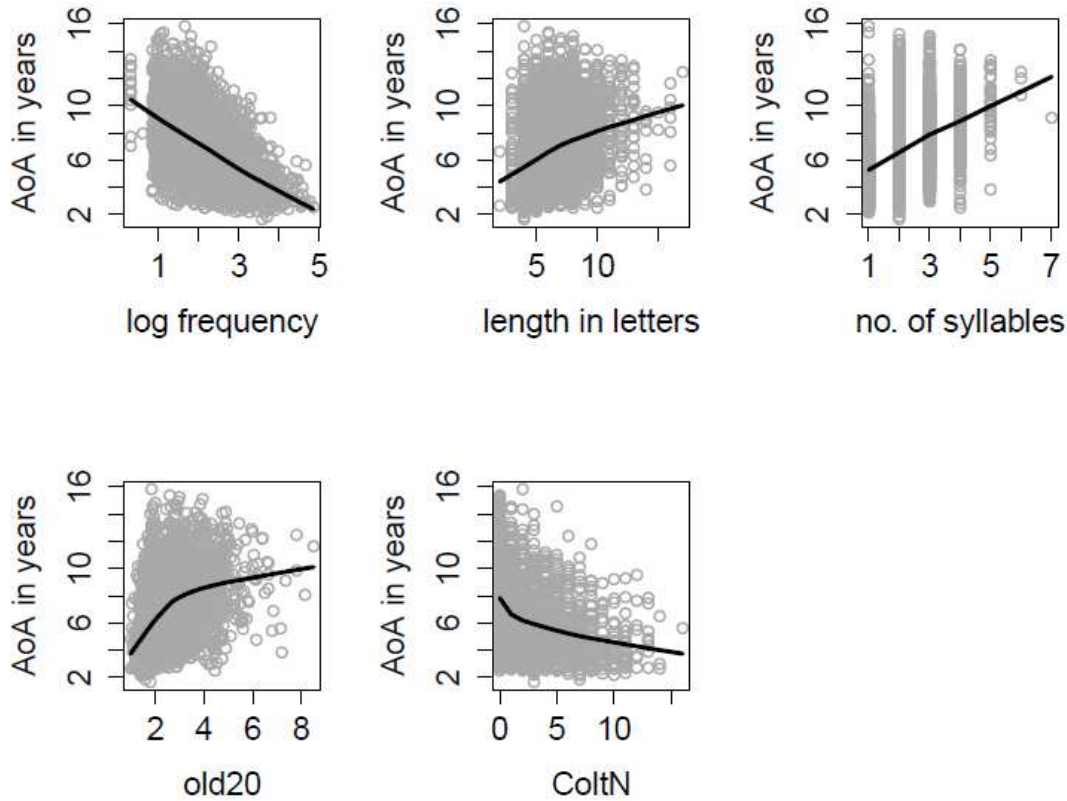

Figure 3. Scatterplots of AoA with lexical variables log frequency (SUBTLEX-DE frequency estimates; Brysbaert et al., 2011), length in letters, number of syllables, old20 (Orthographic Levenshtein distance; Yarkoni et al, 2008), and ColtN (Coltheart's N; Coltheart et al, 1977). Lowess smoothers are shown.

A regression analysis showed that variance in German age-of-acquisition estimates was explained, in part, by variation in word frequency, length in syllables and old20 as a measure of orthographic similarity, $R^2 = .34$, $F(3,3255) = 567.9$, $p < .001$ (see regression summary of Model 1 in Table 3). Given that old20 better captures orthographic similarity in long words (Yarkoni et al., 2008), we chose old20 rather than ColtN as a measure for orthographic similarity. However, substituting ColtN for old20 yielded similar results. We completed further analyses to check whether it would be useful to include the variable word length in letters as a predictor in the analysis of AoA values, either instead of or in addition to the inclusion of word length in syllables, and found that the inclusion of syllable length alone

1
2
3 accounted for most variance in AoA. The regression analysis with linear variables showed
4
5 that words were rated as earlier acquired when they were more frequent, shorter and more
6
7 orthographically similar to other words.
8

9
10 When inspecting the scatterplots in Figure 3, curvilinear relationships appeared likely
11
12 to explain added variance. Therefore, quadratic terms for old20 and syllable numbers were
13
14 gradually added to the model. Adding the term to describe nonlinearity for old20 improved
15
16 the model fit. With the inclusion of the quadratic term for syllable numbers, the linear term
17
18 for number of syllables was no longer predictive, but was retained in the model because
19
20 higher-order terms (like the quadratic term) cannot be estimated accurately without including
21
22 lower order terms (Cohen, Cohen, Aiken & West, 2003). This final model ($R^2 = .36$,
23
24 $F(5,3253) = 364.2$, $p < .001$; see Model 2 in Table 3) included all predictors (log frequency,
25
26 old20 and number of syllables) and the quadratic terms for old20 and syllable numbers. A
27
28 comparison between Model 1 which only estimated linear relationships and Model 2 which
29
30 also included the predictors' quadratic terms demonstrated a significance difference
31
32 ($F(2,3253) = 38.87$, $p < .001$). The fact that the inclusion of quadratic terms for all word
33
34 characteristics was beneficial for the model means that although early acquired words tend to
35
36 be shorter and have more neighbours, this relationship is attenuated for later acquired words.¹

Rater characteristics

Ratings from 537 participants (male = 170, female = 367) contributed to the final AoA estimates. Of the total sample, 531 participants volunteered age information ($M = 35.19$, $SD = 14.04$, range = 18 to 83 years). The age distribution is shown in Figure 4. The age group between 18 and 20 years old comprised 6.21% of all participants. The largest participant group were 21 – 30-year-olds with 44.63%, followed by 19.4% who were between 31 and 40 years old. 14.5% were aged between 41 and 50 years, and 7.91% were between 51 and 60 years old. Only 4.52% fell into the 61-70 age group, and the remaining 2.82% were aged 71 or older.

Figure 4. Age distribution of 531 participants who gave information about their age

Education was assessed in two ways, by asking for both years of education and formal level of education. All participants gave information about their formal level of education. Figure 5 shows the exact percentages for each possible choice given in the questionnaire. Overall, about a quarter of all participants (25.13%) were either still in secondary education or had not completed post-school education at the time of responding. The majority (70.19%) reported that they had completed job training or a first degree. This group included 20.48% who were educated to post-graduate level. Finally, 4.66% felt that their education level was not represented by the choices given.

Participants had also been asked to indicate the number of years in education including primary education and 506 respondents contributed this information (in years, $M = 17.5$, $SD = 3.33$, $\min = 6$, $\max = 33$). Not including the participants whose level of education was not represented, the two measures correlated moderately but significantly ($N = 481$, $r_s = .55$, $p < .001$). As more respondents had specified their formal level of education than number of years, the former measure was used for all further analysis.

Figure 5. Percentage of 537 participants within formal levels of education. *Mittlere Reife* oder *Äquivalent* (school qualification at age 16 or equivalent), *Abitur* oder *Äquivalent* (school qualification at age 18 or equivalent).

All but one participant gave information on whether they had grown up with more than one language, of which 9.51 % (51 participants) reported that they had been raised with languages additional to their mother tongue (German). Of 536 responses given, less than 1% stated that they did not use German as their main everyday language. 68% reported using other languages regularly, with English as the most common. Dialects were not included in the count.

Did ratings vary with rater characteristics?

In order to examine whether rating values varied with participants' age, gender, education, multilingualism or language usage, the control words' mean AoA (CWM) for each participant was computed. The CWM was the average of the AoA values assigned by the participant to the words in the control word list ($M = 5.63$ years, $SD = 1.49$). Only responses of participants who had rated all 20 control words and also given information on all

1
2
3 participant characteristics were included in this analysis. This reduced the number of
4
5 participants to 453.

6
7 Participant age was very weakly positively correlated with the CWM ($r = .16, p <$
8
9 $.001$) suggesting that older participants rated words as slightly later learned than younger
10
11 participants. This concurs with findings by Kuperman and colleagues in their American
12
13 English sample. We investigated this weak but significant correlation further and examined
14
15 the correlation between age and raw control word ratings (the original AoA values for each
16
17 control word given by each participant). Correlations varied between $r = -.15$ and $.38$.
18
19 Control words which showed the strongest positive association with age were *Karriere*
20
21 ($r = .38$, career), *Hubschrauber* (.33, helicopter) and *Urlaub* (.24, holidays), whilst at the other
22
23 end of the spectrum the words *Milch* (-.15, milk), *reparieren* (-.07, repair) and *Tier* (-.05,
24
25 animal) showed extremely low and negative age correlations. This demonstrates that the
26
27 positive direction of the association was not valid for all control words, but may arguably
28
29 have been influenced by more modern words. In order to examine whether the age correlation
30
31 would disappear if raw ratings from older participants were excluded, we computed CWMs
32
33 again for all participants up to the age of 59. The correlation between CWMs and age was
34
35 then no longer significant ($N = 426, r = .05, p = .285$).

36
37
38 We investigated whether the CWMs (control word means) differed between male and
39
40 female participants. In the present sample, female respondents ($N = 314, M = 5.51, SD =$
41
42 1.44) tended to give slightly lower ratings than male respondents ($N = 139, M = 5.90, SD =$
43
44 1.56). This result was significant, $t(245.664) = 2.53, p = .012$, but only had a small effect size
45
46 $r = .12$.

47
48
49 CWMs did not differ with regard to participants' formal education level (one-way
50
51 ANOVA, $F(7,445) = 1.75, p = .096$), although there was a tendency for participants with the
52
53 lowest formal education levels and those who had chosen the "not listed" option to rate words
54
55
56
57
58
59
60

as later acquired (see Table 4). However, there were very small participant numbers included in our sample for these education levels. A post-hoc Tukey multi-comparison between groups was conducted, where group was defined by education level and the observations were the CWMs (average AoA ratings of control words per participant). Participants in different education groups did not significantly differ in terms of CWMs.

Table 4Descriptives of control word mean AoA ratings by formal education level

<i>Education level</i>	<i>N</i>	<i>%</i>	<i>CWM</i>	<i>SD</i>
secondary school	3	0.66	6.70	0.87
<i>Mittlere Reife</i> or equivalent	7	1.55	6.64	1.86
<i>Abitur</i> or equivalent	96	21.19	5.46	1.37
uncompleted job training after school	9	1.99	4.84	0.92
completed job training after school	46	10.15	5.69	1.48
first degree	186	40.40	5.61	1.49
post-graduate	88	19.43	5.64	1.61
not listed	21	4.64	6.23	1.34

Note: N = number of participants, total $N = 453$; % = percentage of 453 participants; CWM = Control Word Mean (averaged AoA ratings in years of 20 control words of 453 participants)

Participants with multilingual ($N = 40$, $M = 5.75$, $SD = 1.72$) and monolingual upbringing ($N = 413$, $M = 5.62$, $SD = 1.46$) did not differ in the rating values they gave to control words (CWMs, $t(44.667) = 0.46$, $p = .644$). Equally, whether respondents regularly used other languages frequently ($N = 313$, $M = 5.57$, $SD = 1.43$) or not ($N = 140$, $M = 5.76$, $SD = 1.61$) did not impact on CMWs ($t(239.928) = -1.21$, $p = .227$).

In order to verify these results based on the means of 20 control words, we entered the full raw data set into a mixed-effects model using lme4 (Bates, Maechler, Bolker & Walker, 2014). Eliminating empty fields resulted in reducing participant numbers to 528. All of these participants had given all demographic information. The first model (Model 1) included only random effects for participants and words, but no fixed effects. Groups of predictor variables

1
2
3 were then added progressively to each new model, and models were compared with the
4
5 Likelihood Ratio Test (LRT). The following shows the order in which predictor groups were
6
7 added. Results comparing each model to its predecessor are given in brackets:

8
9 Model 2: log frequency, syllable numbers and old20 (LRT, $\chi^2 = 1400.9$, 3df, $p < .001$);

10
11 Model 3: syllable numbers² and old20² (LRT, $\chi^2 = 73.411$, 2df, $p < .001$);

12
13 Model 4: Questionnaire version, age, gender, formal education level, multilingual upbringing,
14
15 and frequent use of other languages (LRT, $\chi^2 = 29.847$, 13df, $p = .005$);

16
17 Model 5: age² (LRT, $\chi^2 = 9.5151$, 1df, $p = .002$);

18
19 Model 6: random slope for frequency (LRT, $\chi^2 = 1782.2$, 2df, $p < .001$)

20
21
22 In the final model (see Table 5, Model 6), the lexical variables log frequency, old20
23
24 and their quadratic terms syllable numbers², old20², and the participant characteristics gender,
25
26 age as well as age² emerged as significant predictors. Adding a term to capture the effect of
27
28 random participant variation in frequency made a significant difference to model fit. The
29
30 variable frequent-other-language-usage remained predictive until the inclusion of the random
31
32 slopes for frequency in Model 6, suggesting that participants who frequently spoke other
33
34 languages rated words as earlier learned.

35
36
37 The fact that model fit was significantly improved by the inclusion of the random
38
39 frequency effect of participants indicates that there is unexplained or unmeasured variation
40
41 among participants in the relationship between the frequency of words and participants' AoA
42
43 estimates. On average, higher frequency words are associated with earlier AoA ratings. For
44
45 some participants, however, the slope is steeper and for some the slope is shallower than the
46
47 average. We can conjecture that this effect may overlap with the impact of frequent-other-
48
49 language-usage. However, this is a subject for future research to investigate.

50
51
52 Until the inclusion of the quadratic age term, the linear term for the age effect was
53
54 associated with a positive coefficient, suggesting that older participants gave higher ratings.
55
56
57
58
59
60

1
2
3 With the inclusion of the quadratic age term, the linear age effect was estimated to have a
4
5 negative-signed coefficient, while the quadratic age effect was positive. As the inclusion of
6
7 age² significantly improved the model, this may indicate that participant age only affected
8
9 ratings in the older participants rather than all age groups. Whilst older participants showed a
10
11 slight tendency to rate words as later learned, there did not seem to be a systematic variation
12
13 amongst the younger participants. This finding concurs with our previous results when
14
15 inspecting control word means. However, the coefficient estimates for age are small,
16
17 especially for the quadratic term, indicating that the overall age effect is small.
18
19

20
21 Formal education level was not predictive of raw ratings in any of the models. We
22
23 also investigated whether age interacted with formal education level. We tested the
24
25 age:formal education level interaction twice. Adding it to Model 4 did not improve the model
26
27 (Likelihood Ratio Test (LRT), $\chi^2 = 5.7562, 7df, p = .569$). Adding the interaction after the
28
29 inclusion of the age² term into Model 5 also did not improve model fit (LRT, $\chi^2 = 3.8022, 7df,$
30
31 $p = .802$) and the interaction term was therefore not retained in the model. It may nevertheless
32
33 be noteworthy that age became non-significant when the age:formal_education was added to
34
35 the model. The fact that the age:education interaction did not have an effect may be due to
36
37 two reasons. First, there were very few individuals in the lowest education categories
38
39 “secondary school” and “Mittlere Reife”. Second, the education options given as choices to
40
41 participants could have been interpreted in a non-ordinal way. The choices “uncompleted
42
43 training after school” and “completed training after school” did not specify whether or not
44
45 previous school education had to have been completed. Arguably then, this option could
46
47 comprise participants both with and without previous completed formal school education, and
48
49 hence possibly include participants who have spent less time in education than those who
50
51 chose the preceding education level “*Abitur* or equivalent (A-levels or equivalent)”.
52
53
54
55
56 Consequently, formal education choices may then not describe incrementally ordered
57
58
59
60

1
2
3 education categories. Likewise, the last education level of “not listed” cannot be classified as
4
5 an education category. We examined whether the exclusion of the “not listed” education
6
7 category would reveal the formal education variable to be a significant predictor of AoA
8
9 ratings. After this exclusion, a linear mixed-effects model analysis on a reduced number of
10
11 503 participants indicated that the effects of predictor variables remained the same while
12
13 formal education did not emerge as a predictor. DELETE Future studies investigating the
14
15 interaction of age:education level on AoA estimates may usefully make the category
16
17 distinction clearer. DELETE END
18
19

20
21 The mixed-effects model analysis identified gender as a predictor for raw AoA ratings
22
23 with women showing a tendency to rate words as learned earlier. Interestingly, gender lost its
24
25 predictive power when we added an age:gender interaction term to Model 4. However, as
26
27 there was no age:gender interaction effect, the interaction term was not kept in the model.

Note. Number of obs: 72836, groups: Word, 3259; Part, 528; For categorical fixed effects variables, estimates indicate effect with regard to the reference variable, which were "Version 1" (for Version of questionnaire), "male" (for gender), "secondary school" (for formal.education.level), "yes to multilingual upbringing" (for multilingual.upbringing), and "yes to frequent.other.language.usage" (for frequent.other.language.usage).

Discussion

We have presented 3,259 AoA estimates for German words in years and in the form of points on a 7-point Likert scale. The present AoA collection extends existing norms and widens the choice of word stimuli for researchers. The present collection has a considerable

1
2
3 number of words in common with normative databases for other word properties.

4
5 Furthermore, high internal and external reliability of the current norms have been
6
7 demonstrated. Specifically, the high correlation of item ratings in common with Schröder et
8
9 al. (2012) suggests that the present ratings can be used in conjunction with Schröder's norms.
10
11 Correlations with AoA estimates collected in American and British English were high and
12
13 comparable to such cross-language correlations in other studies (Ferrand et al., 2008). In fact,
14
15 such high cross-language correlations are remarkable considering that translations are not
16
17 always unequivocally one-to-one. These translation difficulties naturally result in some
18
19 attenuation in the strength of the correlation.
20
21

22
23 AoA estimates were positively correlated with the frequency with which words
24
25 occurred in the spontaneous speech production of 20 to 25-month-old children (Suchodoletz,
26
27 2010). Although Schröder et al. (2003) had previously found that rated AoA was more
28
29 closely associated with picture naming ages than production ages, this association
30
31 nevertheless indicates the validity of the current set of AoA estimates. It may also be pointed
32
33 out, that the size of the correlation is even more striking, considering that the Suchodoletz
34
35 word production percentages are based on the vocabulary of children up to the age of two
36
37 years only. Furthermore, this lends support to the concept of rated AoA as an order of
38
39 acquisition.
40
41

42
43 We used **regression** to explore which lexical variables and which participant
44
45 characteristics accounted for variance in AoA estimates. In accordance with previous
46
47 research (Stadthagen-Gonzalez & Davis, 2006), the current rated AoA estimates were
48
49 influenced by word frequency and orthographic neighbourhood so that early learned words
50
51 tended to be more frequent and to be more similar in spelling with other words. The
52
53 curvilinear effect of word length in syllables indicates that later learned words tend to be
54
55 longer than early learned words, and that this relationship becomes more pronounced as
56
57
58
59
60

1
2
3 words become lengthier. This finding was further confirmed when exploring predictors of the
4
5 raw AoA ratings in a mixed effects model.
6

7
8 Previous studies have examined which factors other than word characteristics
9
10 influence AoA ratings. In the present study, we followed Kuperman et al.'s (2012) lead and
11
12 looked at the impact of age, gender, education and general language usage on ratings. This
13
14 was first examined by analysing participant characteristics effects on control word means
15
16 (CWMs).
17

18
19 Consistent with findings reported by Kuperman et al. (2012), older participants in this
20
21 sample tended to give slightly higher ratings, although the correlation was very weak.
22
23 Kuperman et al. had proposed that older participants have a greater age range available to
24
25 choose from and are therefore more prone to give higher ratings. Other research, however,
26
27 has suggested that ratings do not vary with age. Schröder et al. (2012) did not find an age
28
29 difference, but they had only employed a small sample size. Walley & Metsala (1992)
30
31 demonstrated that 5-year-old children give similar AoA estimates to adults.
32
33

34 In the current sample, age was confirmed as a predictor of AoA ratings, when added
35
36 to the mixed-effects model on raw estimates. The fact that model fit was improved by the
37
38 inclusion of the quadratic age term, corresponding to the nonlinear component in the age
39
40 effect, confirmed that the relationship between AoA estimates and age is curvilinear in such a
41
42 way that older participants tend to rate words as later learned. DELETE With age² in the
43
44 model, linear age turned into a negative predictor, possibly hinting at the fact that very young
45
46 adults also have a tendency to give higher AoA ratings. This could suggest that it was the
47
48 participants in intermediate age groups who tend to produce the earliest AoA ratings to
49
50 words. DELETE END
51
52
53
54
55
56
57
58
59
60

1
2
3 In the current sample, the correlation of participant age on AoA control word means
4
5 disappeared when ratings from older participants were no longer taken into account. This is
6
7 consistent with the findings of Cuetos et al. (2012) who showed that ratings from elderly
8
9 participants were better predictors of word recognition performance in Alzheimer patients.
10
11 Cuetos and colleagues found that although ratings from elderly and young adults correlated
12
13 highly, ratings also differed greatly for some words (e.g. robot, television), indicating that the
14
15 day-to-day vocabulary people use changes with time. In the present sample it may have been
16
17 possible that some of the later acquired words (career, helicopter) were driving the
18
19 association between age and AoA, and it is conceivable that this was due to a generational
20
21 change in day-to-day vocabulary. However, some caution may be advisable here, as De
22
23 Deyne and Storms (2007) found that participants, who were in their 50s, rated words as
24
25 significantly later learned than young participants in their 20s, and that this was true for both
26
27 common words and modern words. As suggested by an anonymous reviewer, the question of
28
29 whether the small age effect present in the current data was due to a genuine tendency of
30
31 older participants to rate words as later acquired or due to a generational difference in word
32
33 acquisition (common versus modern words) could be addressed more conclusively by taking
34
35 into account the appearance of the words in the general language vocabulary. Unfortunately,
36
37 this is beyond the scope of this paper.

38
39
40
41
42 We found that men tended to rate words as a little later acquired than women. This is
43
44 consistent with Winters Jr et al. (1978) who suggested that female respondents give lower
45
46 ratings because in contrast to male participants, female respondents may base their AoA
47
48 estimates on current children's usage and knowledge of words. DELETE It might then be,
49
50 that compared to the very young and the very old, the intermediate age group participants did
51
52 this also, with female respondents using their knowledge of children's speech the most.
53
54 Consistent with the Winters Jr et al. (1978) account, we found that men tended to rate words
55
56
57
58
59
60

1
2
3 as a little later acquired than women. If the curvilinear shape of the age effect can be
4
5 explained by the influence of female adult raters' greater reliance on knowledge about child
6
7 language then one would predict an interaction between age and gender effects. However, we
8
9 tested this by including the age:gender interaction additionally to the age² effect, but this did
10
11 not significantly improve the model. DELETE END The inclusion of an age:gender
12
13 interaction did not significantly improve the model. We note that the gender effect we
14
15 observed is opposite in direction to that observed by Kuperman et al. (2012), while Schröder
16
17 and colleagues did not find a gender difference, equally indicating inconsistency in the
18
19 empirical picture. We think that the precise shape of the relationship between age and AoA
20
21 ratings, and the potential modulation of the age effect by a gender effect, merits further
22
23 investigation in future research.
24
25
26

27 In the current analysis, education level did not affect ratings, in line with Kuperman's
28
29 findings, but we have highlighted that participant numbers were very unevenly distributed
30
31 over education categories. We also examined if respondents' language environment and
32
33 usage influenced ratings. Multilingualism has been linked to greater linguistic awareness
34
35 (Bialystok, 1988). Bilingual children tend to have smaller vocabularies than monolingual
36
37 children, when comparing word learning in one language only (Bialystok, 2009). In the
38
39 present study, almost 10% of participants had been raised with more than one language.
40
41 However, consistent with Kuperman et al.'s (2012) findings, AoA ratings did not differ as a
42
43 function of multilingualism. In the present sample, 68% used other languages frequently,
44
45 which intuitively could also be argued to lead to greater language awareness. However, a
46
47 simple group comparison showed that in the current sample the frequent use of languages
48
49 other than the mother tongue did not influence ratings given.
50
51
52

53
54 In the mixed-effects model, log frequency emerged as the strongest predictor for raw
55
56 AoA estimates. It is therefore interesting to note that model fit was significantly improved by
57
58
59
60

1
2
3 taking into account the random variation of the frequency effect between participants. This
4
5 indicates that while higher frequency words were, on average, associated with earlier AoA
6
7 ratings, there was a measureable variation among participants in the slope of that effect. The
8
9 reasons for such variation, we think, also merit further investigation in future research.
10

11 We have presented German age-of-acquisition ratings with high internal and external
12
13 reliability for 3,259 words comprising a number of word classes. A comparison to early
14
15 German word production ages provided evidence for the ratings' validity as reflecting the
16
17 order of word acquisition. Ratings were weakly influenced by gender, but not by education,
18
19 multi-lingualism or frequent use of other languages. Although a weak correlation with age
20
21 was found, this association may have been driven by modern words rated to be later acquired
22
23 by older participants. This may inform sampling for future ratings collections.
24

Appendix 2

Instructions given to participants. This is a direct translation into German from the instructions used by Stadthagen-Gonzalez & Davis (2006) and Kuperman et al. (2012).

Bitte geben Sie an, in welchem Alter (in Jahren) Sie jedes Wort in der Liste jeweils gelernt haben. Eine ungefähre Altersangabe ist ausreichend für diese Einschätzung. Wenn Sie die Bedeutung eines Wortes nicht kennen, dann schreiben Sie einfach ein X in den Textkasten. Mit „ein Wort lernen“ meinen wir das Alter, in dem Sie das Wort verstanden hätten, wenn es jemand in Ihrer Anwesenheit benutzt hätte, auch wenn Sie es nicht selbst zu diesem Zeitpunkt hätten benutzen, lesen oder schreiben können.

Original in English (Stadthagen – Gonzalez & Davis, 2006):

Please indicate (in years) the age at which you learned each of the words on the list. An approximate age is good enough for this rating. If you do not know the meaning of a word, just write an X on that space. By “learning a word” we mean the age at which you would have understood that word if somebody had used it in front of you, EVEN IF YOU DID NOT use, read or write it at the time.

Running head: RATED AOA FOR OVER 3,200 GERMAN WORDS

Appendix 3

Screenshot of downloadable German AoA database.

The following information is given in the columns: Word (original word), Upper (Word in capital letters), BE_TWord (British English translation), AM_TWord (American English translation), RatperWord (Number of ratings each word has received), AoAestimate (German AoA, computed as average from all individual ratings received), SD (standard deviation of AoAestimate), min (lowest individual rating received), max (largest individual rating received), unknown (number of times the word has been marked as not known), AoALikert (AoAestimate converted into score on 7-point-Likert scale), SDLikert (standard deviation of AoALikert), minLikert (lowest score received on Likert – scale), maxLikert (largest score received on Likert – scale).

Values are shown to two places after the decimal point where applicable.

Please note for German users: decimal mark used is the point (.)

Word	Upper	BE_TWord	AM_TWord	RatperWord	AoAestimate	SD	min	max	unknown	AoALikert	SDLikert	minLikert	maxLikert
