Keywords: Quantum dots, germanium, Cd-Se/ZnS, bio-labelling, cell toxicity

Colloidally stable Ge quantum dots around 3 nm in size were synthesized and suspended in water and ethanol. In the ethanol solution, the photoluminescence emission of the Ge quantum dots was observed between 650 and 800 nm. Structural and optical properties of these colloidal Ge quantum dots were investigated by utilizing X-ray diffraction, X-ray absorption spectroscopy, Raman spectroscopy, and photoluminescence spectroscopy and transmission electron microscopy. The structure of as-prepared Ge quantum dots that was found is best described by a core/shell model with a small crystalline core and an amorphous outer shell with a surface that was terminated by hydrogen-related species. As-prepared Ge quantum dots

1 were suspended in cell growth medium, and then loaded into Cervical Carcinoma (HeLa)
2 cells. The fluorescent microscopy images were then collected using 405 nm, 488 nm, 561 nm
3 and 647 nm wavelengths. We observed that, based on fluorescence measurements, as-
4 prepared Ge quantum dots can remain stable for up to 4 weeks in water. Investigation of
5 toxicity, based on a viability test, of as-prepared uncoated Ge quantum dots in the HeLa cells
6 was carried out and compared with the commercial carboxyl coated CdSe/ZnSe quantum dots.
7 The viability tests show that Ge quantum dots are less toxic when compared to commercial
8 carboxyl coated CdSe/ZnS quantum dots.

21 1. Introduction

22
23 Real time monitoring of a cell's function and state can be carried out by using visible and
24 near-infrared emitting luminescent nano-scale particles, which are also known as quantum
25 dots (Qdots) ^[1,2]. The repetition and reliability of the luminescence at room temperature from
26 various inorganic qdots make them excellent candidates for the detection of biomolecular
27 interplay and imaging applications in vivo ^[2-6]. Qdots also have a high resistivity to
28 photobleaching and their narrow emission and broad absorption bands can be tuned by
29 varying the particle size and composition. Thus, quantum yield, small size and lack of
30 photobleaching are some of the reasons why qdots are becoming a popular alternative to
31 fluorescent organic dyes for biological fluorescent imaging ^[4,7]. CdSe/ZnS-based qdots
32 currently hold the dominant position in bio-imaging applications. However, CdX (X=Se, Te)
33 qdots show significant levels of cytotoxicity when used in cell imaging/diagnostics ^[8,9]. When
34 CdSe has been coated with ZnS there is still a considerable cytotoxic effect ^[10]. At the end of
35 24 hours, approximately 40 % of the macrophage cells was observed as killed even with small
36 concentrations of CdSe/ZnS qdots (e.g. 2.5 nM).

48
49
50
51
52
53
54
55
56
57

58 An alternative system is the InP qdots, however, production of high quality qdots is more
59 challenging for these materials than for the Cd-based systems ^[3]. Group 4 materials (C, Si and
60
61
62
63
64
65

1 Ge) can offer a viable alternative due to relatively low toxicity^[6,11,12]. Their optical properties
2 can also be radically enhanced by exploiting the quantum confinement effect (QCE)^[13-16]. Ge
3
4 qdots are expected to show these unique properties in accordance with the QCE for relatively
5
6 large particles due to the fact that its exciton Bohr radius is estimated to be larger ($R_B=24.3$
7
8 nm) than that of Si ($R_B = 4.9$ nm)^[17]. One of the fundamental problems that preclude the
9
10 wider use of Si and Ge in imaging application is an indirect band gap that results in a
11
12 relatively inefficient light emission. However, this can be improved by the QCE as has
13
14 originally been demonstrated for porous Si by L. Canham in 1991^[13,14]. Modifying the
15
16 surface species can also alter the optical properties of these qdots and can improve their
17
18 stability by saturating the dangling bonds for instance by hydrogen or carbon atoms^[18,19]. For
19
20 over 20 years various physical and chemical routes of the synthesis of Ge qdots have been
21
22 reported^[15,17,20-29]. A novel and significant method of colloidal synthesis, particularly
23
24 reducing the halides (GeI_2/GeI_4), was recently reported as the most elegant method in terms of
25
26 size/shape modification and the stability of Ge qdots^[28-30]. However, this method requires the
27
28 high temperature Schlenk technique which makes it rather elaborate. Recently, colloidal
29
30 synthesis methods^[26,30] have become available using room temperature benchtop chemistry.
31
32 These methods seem to yield small Ge qdots and allow for some control over size selectivity
33
34 as well. However, potential suitability of these Ge qdots for bio-applications would
35
36 significantly depend on their atomic structure, morphology and surface termination as each of
37
38 these physiochemical properties are essential to understand the toxicity of qdots^[31]. For
39
40 example, oxygen-terminated Ge qdots may have limited use in bio-application due to water
41
42 solubility of germanium oxide. It has been suggested^[26] that, following the benchtop colloidal
43
44 synthesis, the structure of as-prepared Ge qdots is amorphous (based on the X-ray diffraction),
45
46 while the sample seems to be crystalline according to the selective area electron diffraction
47
48 (SAED) results^[27]. The latter may suggest a transformation to a crystalline phase due to
49
50 annealing in the highly energetic electron beams used in TEM. The nature and stability of the
51

65

1 surface is also unclear. Furthermore, there are some reports suggesting a Ge tetragonal phase
 2 (ST-12 phase) may be obtained upon deposition by the cluster beam evaporation technique
 3
 4 [32,33], releasing of high pressure [34] or annealing at high temperature. There are also some
 5
 6 studies including lithiation [35] and aging [36] that show ST-12 phases mixed together either
 7
 8 with lithium atoms or the diamond cubic phase of Ge. The ST-12 phase has a potential for
 9
 10 opto-electronic applications since it is predicted to be a direct band gap material ($E_g=1.47$ eV)
 11
 12 [37].
 13
 14
 15

16
 17 Despite the potential in the biomedical applications of Ge qdots there are few studies on
 18
 19 biological imaging and the toxicity of Ge qdots [38,39]. Herein we present a slightly modified
 20
 21 method of the preparation of Ge qdots to yield colloiddally stable Ge qdots. We use a
 22
 23 combination of direct visual techniques, such as TEM, together with short range (X-ray
 24
 25 absorption spectroscopy, Raman) and long range (XRD, Raman) sensitive structural methods
 26
 27 to investigate atomic arrangements on the sub-nanoscale. We test biocompatibility of Ge
 28
 29 qdots using the viability test and compare it with the commercial carboxyl coated CdSe/ZnS
 30
 31 qdots. We also assess the potential of Ge qdots for cell imaging applications.

 37

38 2. Results and Discussion

39
 40 **Scheme 1** demonstrates how the experiment was conducted and a brief formation mechanism
 41
 42 of Ge qdots (CS_1) reduced from $GeCl_4$. CS_1 were prepared by nucleation of Ge atoms
 43
 44 liberated by the reduction of $GeCl_4$ [27] with a slight modification as designated in the scheme.
 45
 46
 47
 48

49 A possible formation mechanism of Ge qdots reducing from $GeCl_4$ is outlined as follows:
 50
 51

In the process of the production of Ge qdots by the colloidal synthesis route, the reaction is initiated upon a hydrophilic attack of BH_4^- to GeCl_4 as a source of a hydride ion (**Equation 1**) which can then lead to the formation of GeCl_3H (**Equation 2**). Then, the removal of HCl from GeCl_3H (**Equation 3**) could form reactive germanium(II) species such as GeCl_2 , which could then be inserted into GeH_xCl_y molecular clusters (**Equation 4**) to act as intermediates in the formation of Ge nanoparticles.

The images of CS_1 immediately after production, suspended in the chemical solution, and suspended in ethanol, are shown in **Figure 1(a)**. CS_1 , which was then placed onto a quartz boat after being dried by Ar gas, can also be seen in **Figure 1(b)**. The particles are yellow in color.

Raman spectroscopy was used as a first analysis technique to understand the structural properties of CS_1 as well as to estimate the average size of particles. Raman spectroscopy measurements are shown together with the analysis of the data in **Figure 1(d)**. We observed a broad asymmetric peak just below 300 cm^{-1} as expected for diamond-type Ge qdots^[20]. In addition to the shift in the peak position relative to the bulk Ge optical phonon mode (300 cm^{-1})^[40], the Raman spectrum of free-standing CS_1 (see **Figure 1(d)**) has an asymmetrical Lorentzian-like shape which is an indication that the sample is nanocrystalline^[23,41]. We used the well-known Richter-Fauchet-Campbell (RFC) model^[42,43] based on phonon confinement to estimate the mean size of CS_1 by fitting the corresponding phonon confinement expression to the data. We obtained the particle size to be approximately 3.2 nm for the Raman spectrum given in **Figure 1(d)**. The residual signal between the RFC model and the experimental

spectrum is also shown in Figure 1(d). There is a broad peak close to 250 cm^{-1} . Possible origins of this residual might be due to (i) limitation of the phonon confinement model for very small nanoparticles^[44], (ii) amorphous component^[45] or (iii) a metastable phase^[36,46].

The inset in Figure 1(d) shows a broad peak centered at about 2000 cm^{-1} that was assigned to the Ge-H stretch mode of CS_1 . Hydride termination of Ge nanocrystals using FT-IR studies was reported by several authors with a broad stretching mode between 1900 cm^{-1} to 2100 cm^{-1} ^[18,47–49].

In **Figure 2(a)**, the TEM results are shown for CS_1 . The TEM micrograph of CS_1 in Figure 2(a) shows the mean size of CS_1 to be $3.89\text{ nm} \pm 0.61\text{ nm}$ with a very narrow size distribution from out of 200 qdots of CS_1 in Figure 2(c). Comparison of the size analysis of CS_1 by TEM and the RFC model using Raman spectroscopy results are given in **Table S1** (see the supplementary material).

X-ray diffraction (XRD) is frequently used to determine the size and structure of CS_1 ^[19,20]. Figure 1(e) shows the background subtracted XRD signal for CS_1 . The broad peak may suggest a large degree of disorder in samples, but may also be due to the small size of particles. XRD of amorphous Ge (a-Ge) qdots ($\text{FWHM}=12.68^\circ$)^[27] are found to give a somewhat broader peak compared to the XRD here (5.48° , Figure 1(e)). Using the Scherrer expression^[21], we obtained the size of CS_1 as 1.54 nm . This is to be compared with 3.20 nm and 3.89 nm values extracted from the Raman and TEM respectively. Thus there is a clear discrepancy among TEM, the Raman and XRD results. Given that we do not observe any appreciable number of particles of sizes below 2 nm for CS_1 in TEM (see histogram in Figure 2(b)), this suggests a degree of disorder in our samples, but not as much as in typical a-Ge. One possibility that may explain the result is a core-shell model with a small crystalline core and an amorphous outer layer (see the inset of Figure 1(e)). This would certainly be consistent with the theoretical modelling of small Ge qdots reported previously^[50].

1 Extended X-ray absorption fine structure (EXAFS) at Ge *K*-edge was used to examine the
2 local environment around Ge atoms and shed light on the possible atomic arrangements.
3
4 **Figure 3** shows the magnitude of the Fourier transform (MFT) of the k^2 -weighted EXAFS
5 signal, which provides a convenient way to visualize the average local environment around
6 Ge. One can see that only a single peak corresponding to a Ge-Ge bond in the MFT of the
7 EXAFS signal (the first coordination shells at $2.437 \pm 0.011 \text{ \AA}$ for the diamond cubic
8 structure -see the supplementary material for the details of the fit) exists. The presence of only
9 the first coordination shell in the MFT of the EXAFS signal is due to a structural disorder
10 beyond the first coordination shell and the small size. The lack of the Ge-O related signal (at
11 around 1.73 \AA) indicates no significant amount of oxides are present in the as-prepared
12 sample. Still, the surface must be terminated and the Ge-H symmetric stretching vibrational
13 mode was observed (as evidence by the Raman data, see inset Figure 1(e)). Clearly, pure H-
14 terminated Ge qdots are unlikely to be colloiddally stable due to the hydrophobic nature of the
15 surface. Therefore, it's quite possible that colloidal stability can be achieved through the
16 bonding of surface hydrogen to other species (e.g. ethoxide as discussed, for example, in other
17 reports^[51]).

18
19 Crystalline bulk Ge has an indirect band-gap that lies within the infrared region of energies
20 ($E_g = 0.67 \text{ eV}$, 1850 nm)^[52]. In order to determine the optical absorption/emission properties
21 of any qdots, such as Ge or CdSe/ZnS, UV-Vis absorption spectroscopy and the PL
22 spectroscopy is widely used^[20,21,28]. Broad UV-Vis absorption spectrum of CS₁ suspended in
23 ultra-pure water is shown in Figure 1(f). The data show that the absorption has a shoulder at
24 ca. 400 nm (3.1 eV). However, the PL emission peak is found in Figure 1(f) at 680 nm (1.82
25 eV) suggesting that the nature of emission and absorption events are different. One reason for
26 this could be due to GeH_xCl_y molecular clusters instead of Ge particles. This would be
27 consistent with the Raman signatures and more importantly explain the presence of the
28 narrow emission spectrum. Moreover, it will yield the stable emission of these molecular

1 clusters in a cell growth environment. It is well-known that the surface contribution to the
2 emission spectra ^[19,53–55] may be significant due to the high probability of excitons being
3 captured by the surface states with a subsequent recombination. On the other hand, H-
4 terminated a-Ge ^[56] (1.1 eV) was found to have larger band gaps than that of a-Ge ^[57] (0.5 eV)
5 or bulk Ge (0.67 eV). Thus, both the large amorphous intermediate region inside the qdot and
6 the surface affect the light emission in CS₁.

7 CS₁ synthesized here represents a novel fluorescent product with a potential for bio-
8 applications. Therefore, the biocompatibility and stability of CS₁ for fluorescent imaging was
9 tested on HeLa cells. First, it was necessary to understand the concentrations of Ge qdots that
10 can be suitable for live cell applications. Cell viability as a function of Ge qdot concentration
11 in cell growth medium is shown in Figure 4(a). The results suggest that concentrations below
12 100 nmole give values of viability close to the qdot free reference. Cell number and viability
13 were found to depend on Ge qdot concentrations and reduced relatively quickly when seeded
14 with a higher concentration of Ge qdots of 200 nmole (see Figure 4(a)). We further compared
15 the viability of our un-coated as-prepared Ge qdots with commercially available (Invitrogen)
16 carboxyl coated CdSe-ZnS qdots. Figure 4(b) shows the results of the viability tests that were
17 taken over 72 hours and clearly indicates a higher level of biocompatibility of uncoated as-
18 prepared Ge qdots as compared to the commercial carboxyl coated CdSe/ZnS qdots. When
19 using smaller concentrations of the commercial carboxyl coated CdSe/ZnS qdots (e.g. 10
20 nmole), then the viability results show very little impact on cell viability (see Figure S4 in
21 supplementary part).

22 There are a number of mechanisms ^[58] reported which are related to CdSe based qdots which
23 might affect their toxicity. Along with the leaking of Cd ions, the CdSe/ZnS qdot degradation,
24 due to an oxide enriched environment, may result in free radicals formation which are
25 understood to contribute to toxicity. Coating CdSe qdots with ZnS helps to decrease Cd ions
26 desorption, although it does not stop the CdSe qdots degradation. In addition to the ZnS

1 coating, commercial carboxyl coated CdSe/ZnS qdots might help slow the CdSe qdot
2 degradation even further. Nevertheless, about 50% of all HeLa cells were killed after 72 hours
3 as shown in Figure 4(b). However, this is not the case for Ge. It has been reported in a wide
4 range of studies ^{[59,60],[61]} that Ge can play a therapeutic role by binding free radicals in cells
5 via oxidation. Ge
6

7
8
9
10 We tested the CS₁ suitability as a marker for the long term fluorescent imaging of the HeLa
11 cells by using the spinning disk confocal microscopy. The luminescent images from the HeLa
12 cells loaded with CS₁ seem to suggest that the Ge qdots have a higher emission efficiency
13 with the excitation wavelength of 405 nm rather than that of 647 nm, at which there is nearly
14 no emission. This result is consistent with our optical absorption measurement (Figure 2(f)).
15
16 Based on the fluorescent images in Figure 4 it is clear that CS₁ has reasonably good emission
17 brightness when excited with an appropriate wavelength, despite having relatively lower
18 luminescence efficiency compared to commercial carboxyl coated CdSe/ZnS qdots.

32 3. Conclusion

33
34
35 Reflecting upon our collected data, we were able to synthesize colloiddally stable Ge qdots.
36
37 Combined EXAFS, XRD, Raman and TEM measurements suggest a core-shell structure of
38 Ge qdots with a crystalline core, an amorphous outer layer and a surface with hydrogen-
39 related species. Using Ge qdots, the luminescent images of HeLa cells were obtained for
40 various excitation wavelengths, which indicate that using Ge qdots as a fluorescence probe is
41 applicable in light microscopy. We tested toxicity of Ge qdots on HeLa cells. The toxicity of
42 Ge qdots and commercial carboxyl coated CdSe/ZnS qdots were investigated using a viability
43 test and from this the Ge qdots were found to be the least toxic of the two. Cells with Ge qdots
44 survived even after 3 days, which suggests that, as well as basic research, the qdots could be
45 used in medical research, clinical imaging and drug screening trials.

4. Experimental Section

Materials: The chemicals, GeCl_4 (>%99), ethylene glycol (ETG, %99), and 2 M of sodium borohydride solution in triethylene glycol dimethyl ether ('the triglyme') were used as purchased from Sigma-Aldrich. Polyvinylpyrrolidone (PVP) (MW=630.000) were used as purchased from Tokyo-chemicals.

Synthesis of Ge qdots (CS_1): Ge qdots, named as CS_1 , were synthesized by a slight modification of a benchtop colloidal synthesis route ^[27] which produces CS_1 suspended in water and ethanol. In the first part of the synthesis 265 μL of GeCl_4 were reduced using a solution of 10 mL of ETG and 50 mg of PVP. 6 mL of the triglyme was then added at a rate of 90 ml/hour for the first 2 ml and then 9 ml/hour for the remaining 4 ml. This controlled addition process of the triglyme was performed with a syringe pump into a 3 neck round bottom beaker in which the solution was bubbled using a continuous Ar gas flow with an inlet of a micro-tube through the solution. The formation process took approximately 1 hour and the final product was separated from the colloidal chemical solution by 10 minutes of centrifugation at 10,000 rpm.

Characterization of Ge qdots: After the synthesis, Raman spectroscopy and photoluminescence (PL) spectroscopy measurements were conducted with a Renishaw 1000 spectrometer. A diode laser at a wavelength of 473 nm was used for CS_1 , whereas for the Ge-H stretching mode of CS_1 , a He-Ne laser at a wavelength of 633 nm was used. TEM measurements were taken using a JEOL 2010 to characterize the morphology and the size of CS_1 . Gatan digital micrograph software was used for the size analysis by TEM. XRD and EXAFS measurements were conducted in the beamline B18 ^[62] at Diamond Light Source in the UK. The EXAFS measurement was carried out at T=100 K using a cryojet system. ATHENA ^[63] was used to extract the absorption spectrum from the raw data. Then, the structural parameters were determined using the least squared fit of the EXAFS data in r-

1 space with ARTEMIS^[63] by FEFF6 code^[64] within the fitting range of the photoelectron
2 momentum (k) and the non-phase corrected radial distribution distance (r) of 3-16 Å⁻¹ and
3
4 1.67-2.55 Å respectively. Energy resolution of EXAFS experiment was 1 eV.
5
6

7
8 *Cell Culture:* The Cervical Carcinoma cells (HeLa cells) were cultured in a growth medium
9 (89% high glucose DMEM, 10 % Foetal Calf Serum, 1 % Penicillin & Streptomycin) with
10 various densities inside 6-well plates according to the following trials. Cells were split once a
11 week and incubated in a 5% CO₂ atmosphere at 37 °C. In the fixation steps, cells were firstly
12 washed 2 times with Phosphate Buffered Saline solution (PBS), and incubated with 2 mL of 4
13 % Paraformaldehyde solution (PFA) per well for 10 minutes at room temperature, followed
14 by washing 3 times with PBS. Fixed cells dishes or plates were then stored in a fridge for 24
15 hours before post procedures.
16
17

18
19 *Visualization of Ge qdots in HeLa Cells:* In order to investigate the Ge qdots impacts on HeLa
20 cells, sample of HeLa cells with Ge qdots were prepared and imaged. HeLa cells were seeded
21 on a glass coverslip in a 6-well plate at a density of 5.0×10^3 cells ml⁻¹ well⁻¹, incubated
22 overnight with 50 nmole of Ge qdots per well. Ge qdots were synthesized, suspended in water
23 and sterilized under UV light for 15 minutes. Ge qdots were re-suspended in growth medium.
24 Ge qdots with different concentrations suspended in growth medium were loaded to the HeLa
25 cells. The cells were fixed with PFA prior to fluorescence imaging.
26
27

28
29 Fluorescence images were acquired on a spinning disk confocal microscopy (consisting of a
30 Nikon ECLIPSE TE2000-s microscope, a YOKOGAWA CSU-x1 spinning disk, and a 100X
31 objective, NA 1.4). Sample was excited with four different wavelength lasers (405 nm, 488
32 nm, 561 nm and 640 nm). Images were captured using an Andor-iXon3 885 camera and data
33 were post processed on ImageJ.

1 The incoming laser was modulated through an acousto-optical tunable filter (AOTF) before
2 being recorded by CCD camera. The reflected light from a mirror sample slide were recorded
3
4 using an optical power meter (Newport 1916-C).
5
6

7
8 *Cell Viability Test:* Once the optical stability of Ge qdots (CS₁) in cells was confirmed the
9
10 toxicity test was performed. Series of viability test were taken and each test were repeated 3
11
12 times.
13

14
15
16 To examine the toxicity, fresh CS₁ samples were produced and tested on HeLa cells. HeLa
17
18 cells were cultivated as described in section 2.3. Cells were seeded into a 12-well plate at a
19
20 density of 5.0×10^3 cells ml⁻¹ well⁻¹. Ge qdots were added into different wells after a whole
21
22 night, at the concentration of 0, 10, 100, 200, 300, 400, 500, 600 nmole. Viability of HeLa
23
24 cells were tested on a Muse™ Analyser after 24 hours. In every viability measurement, at
25
26 least 1000 cells were counted.
27
28

32 Regarding the long term effect of Ge qdots on live cells viability, HeLa cells were cultivated
33
34 on a 12-well plate at a density of 15.0×10^3 cells ml⁻¹ well⁻¹. CS₁ was diluted into two
35
36 concentration solutions of 25 nmole, 250 nmole. Cell viability was analysed at 24, 48 and 72
37
38 hours. Simultaneously, comparison tests were performed with commercial qdots (Qdot 625
39
40 ITK Invitrogen A10200: CdSe/ZnS core and shell structure, emission peak at 625 nm). In
41
42 every viability measurement, at least 1000 cells were counted.

Scheme 1. Schematic illustration of formation of luminescent Ge qdots by colloidal synthesis. (a) GeCl₄, PVP and ethylene glycol mixed before infusing NaBH₄ in the triglyme into the solution (see experimental procedure for the details) Here, instead of Ar gas 26, H₂Ar (5%/95%) gas were used to purge the solution in order to prevent possible oxide formation (b) 2 ml of NaBH₄ in the triglyme was added to the solution initially with the rate of 90 ml/min using a syringe pump. Then, the rate was reduced to 9 ml/min for the rest 4 ml of NaBH₄ in the triglyme.

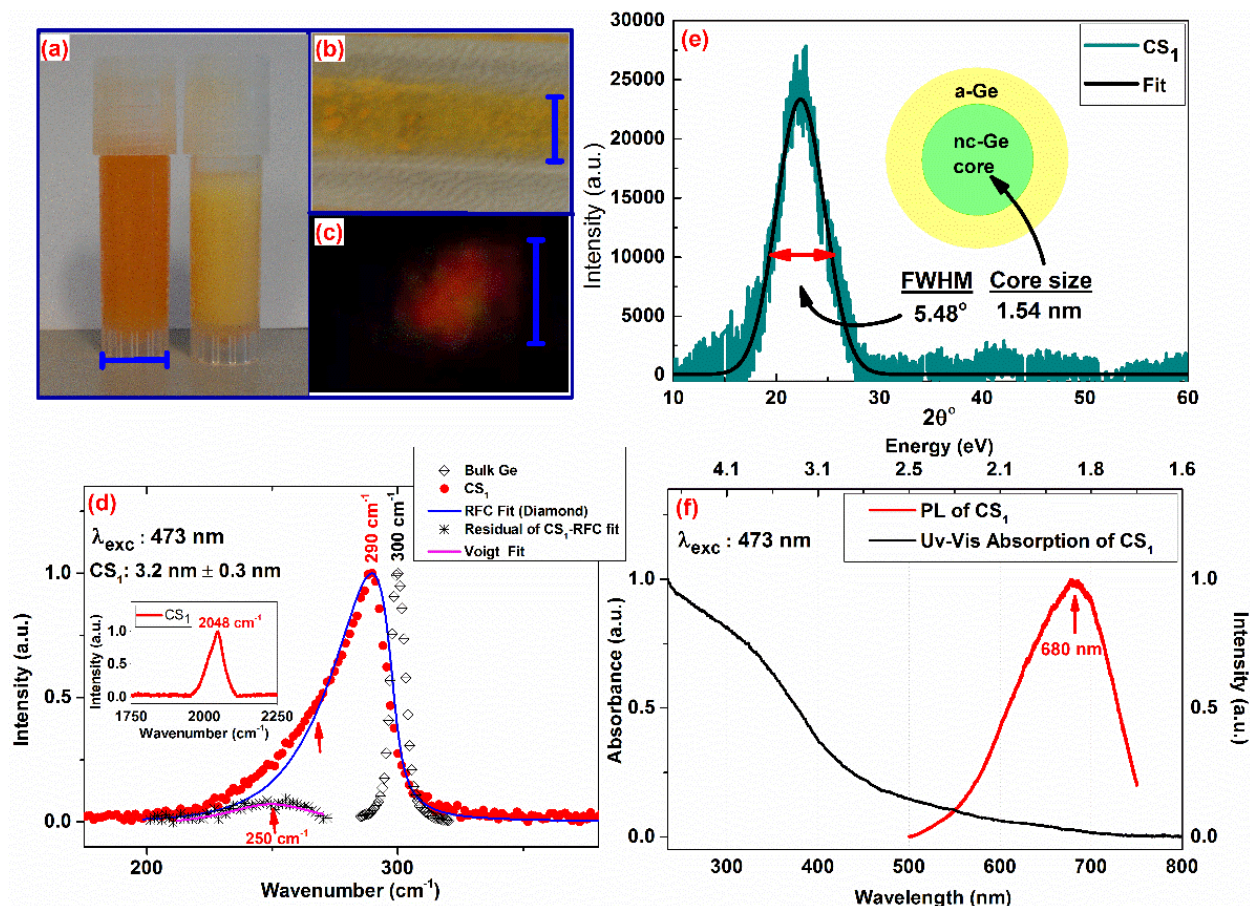

Figure 1. (a) Picture of Ge qdots (CS₁) as-prepared suspended in chemical solution and in ethanol after centrifugation (b) Ge qdots in powder form after dried with Ar gas (c) Luminescent picture of red emitting Ge qdots (the excitation wavelength was 325 nm). Scale bars (all with blue colors) in (a), (b) and (c) are 10 mm, 17 mm and 0.75 mm respectively. (d) Raman shift of CS₁ (red circles) shows an asymmetric Lorentzian peak positioned at 290 cm⁻¹ obtained after the RFC fit (blue color). Residual between Raman data of CS₁ and the RFC fit is shown and fitted with a Voigt fit (magenta color) which results in peak position of 250 cm⁻¹. Raman of bulk Ge (black colored diamond) is shown to have a peak position at 300 cm⁻¹. In a-Ge, there is one but a very broad and asymmetric peak^[64] at 275 cm⁻¹. (See supplementary for Raman of a-Ge reproduced from reference^[64]). The inset in (d) shows stretching mode at 2048 cm⁻¹ between Ge and H. For Raman shift and photoluminescent spectroscopy measurements, an excitation wavelength of 473 nm was utilized. (e) X-ray diffraction (XRD) ($\lambda=1.544 \text{ \AA}$, $E=8047 \text{ eV}$) (f) Normalized Uv-Vis absorption spectroscopy and Photoluminescence spectroscopy measurements. The inset core-shell schematic in (e) clarifies the discrepancy between Raman and XRD size calculations such as 3.2 nm and 1.54 nm respectively.

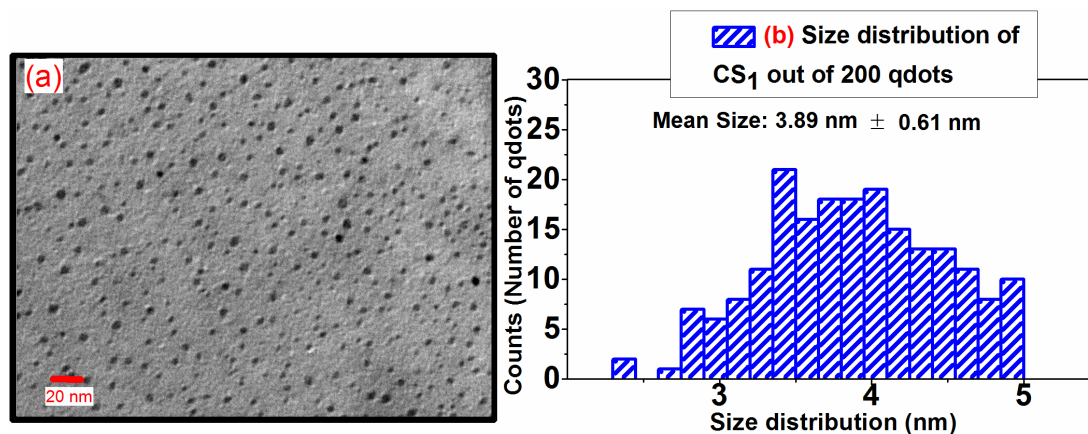

Figure 2. (a) TEM micrograph of CS₁. The graph in (b) is the size distribution of Ge qdots out of 200 qdots. The mean size of Ge qdots was found to be 3.89 nm ± 0.61 nm.

Figure 3. FT modulus of k^2 -weighted EXAFS spectrum of Ge qdots as-prepared (CS₁) at Ge K-edge shows only one peak attributed to local disorder and oxide-free surface. The figure also shows the fit, the residual between the fit and the data and the window of the fit. The models of the diamond cubic type of Ge is also demonstrated. The range of the models were chosen between 0-3 Å for the first shells only.

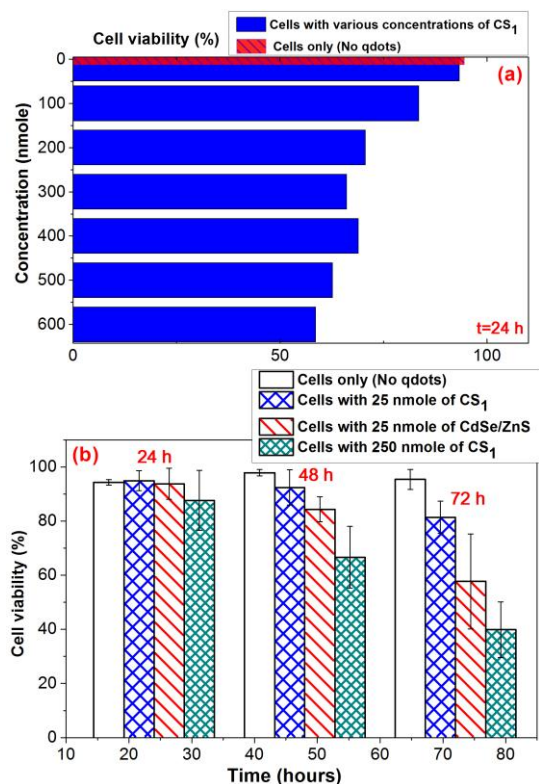

Figure 4. Cell viability of CS₁ when cultured with various concentrations of CS₁ at the end of 24 h is shown in Figure 4(a). Confirmation of the viability test of CS₁ and its comparison with commercial Invitrogen (carboxyl coated CdSe/ZnS) qdots at 25 nmole concentration at different time points show Ge qdots are relatively promising as given in Figure 4(b) Fluorescence images of CS₁ in Figure 4(c) to 4(f) acquired at various excitation wavelengths; 405, 488, 561, 647 nm shows respectively the range of optical usability The detected laser power was around 550 nW in the fluorescence images (see also the supplementary material).

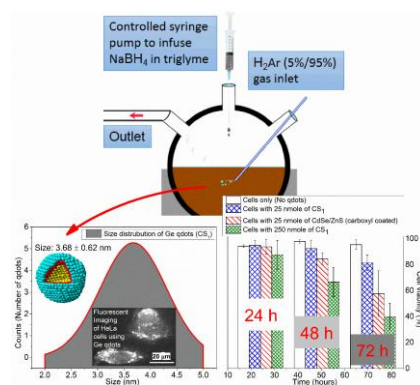

1 **Non-toxic luminescent Ge quantum dots** are synthesized with colloidal stability, narrow
 2 size distribution and core/shell structure via a room temperature benchtop chemistry. Cells
 3 with Ge qdots can stay alive even after 3 days suggests that Ge qdots are a viable bio-imaging
 4 probe and have a great potential to be used in medical research, clinical imaging and drug
 5 screening trials. Luminescent Ge qdots as-prepared can be stored in water for a month.

S1. Experimental Section

S1.1 Laser Power Measurements in Fluorescent Imaging

The laser power, P_L used in taking fluorescent images in Figure 5(c), (d), (e), (f) using spin disk confocal microscopy are shown in Table S1. The values of the laser power at each wavelength such as 647 nm, 561 nm, 488 nm and 405 nm were recorded using an optical power meter (Newport 1916-C). In the measurement of the reflecting light from the sample glass slide, the power meter replaced by the camera and then the corresponding laser power for each wavelength was recorded.

Table S1 Table of the laser power values used in the measurement of wavelength dependent fluorescence images using spin disk confocal microscopy. For each wavelength utilized such as 647 nm, 561 nm, 488 nm and 405 nm, the incident and reflected laser power are represented.

| $\lambda_{exc} = 647$ nm | $\lambda_{exc} = 561$ nm | $\lambda_{exc} = 488$ nm | $\lambda_{exc} = 405$ nm |

S2 Results

S2.1 EXAFS Fit

EXAFS spectrum of crystalline bulk Ge at the Ge K-edge was recorded between 11 keV and 12 keV in energy space and is shown in **Figure S1**. This was done as a reference measurement in order to determine the amplitude reduction factor, S_0^2 of c-Ge and use it as a set parameter for Ge qdots before conducting any EXAFS measurements of formed nanoparticles.

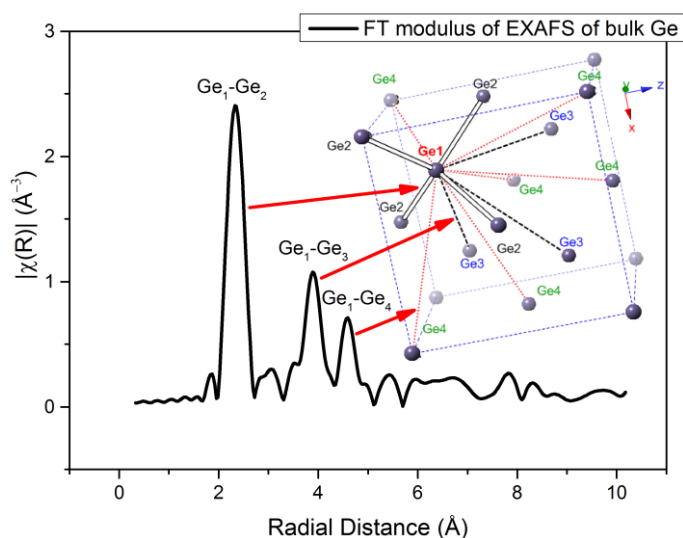

Figure S1 Reference bulk Ge. The three nearest neighbour distances ($\text{Ge}_1\text{-Ge}_2$, $\text{Ge}_1\text{-Ge}_3$ and $\text{Ge}_1\text{-Ge}_3$) were obtained using FT modulus of EXAFS of bulk Ge and are compared with those of the diamond cubic Ge structure (ICDS No. 43422). In the model, $\text{Ge}_1\text{-Ge}_2$ bonds, $\text{Ge}_1\text{-Ge}_3$ bonds and $\text{Ge}_1\text{-Ge}_4$ bonds are shown with white cylinders, black dashed lines and red dotted lines respectively. The values of the interatomic distances measured are shown in **Table S2**.

Table S2 The fit quality and the parameters obtained at the end of multiple shell fit of the FT modulus of the k^2 -weighted EXAFS spectrum of crystalline bulk Ge.

| The | fitting | Bulk Ge |
|--------------|-------------------------------------|---------------------|
| quality and | | |
| Parameters | | |
| R-factor | | 0.023 |
| N | (Ge ₁ -Ge ₂) | 4 |
| | (set) | |
| S_0^2 | | 0.843 ± 0.054 |
| ΔE_0 | | 2.095 ± 0.619 |
| σ^2 | | 0.0020 ± 0.0003 |
| ΔR | | -0.007 ± 0.002 |
| N | (Ge ₁ -Ge ₃) | 12 |
| | (set) | |
| σ^2 | | 0.0035 ± 0.0004 |
| ΔR | | -0.010 ± 0.005 |
| N | (Ge ₁ -Ge ₄) | 12 |
| | (set) | |
| σ^2 | | 0.0038 ± 0.0005 |
| ΔR | | -0.016 ± 0.006 |

Table S3 shows the R-factor and fitting parameters obtained after the fit of FT modulus of EXAFS of CS₁ using the first coordination shell of the diamond cubic structure of Ge. The fitting parameters includes the amplitude reduction factor, S_0^2 , the energy shift, ΔE_0 , the

debye-waller factor, σ^2 and the shift between the theoretical structural model and the experimental measurement, ΔR are shown.

Table S3 The fit quality and the parameters obtained at the end of fit of the FT modulus of the k^2 -weighted EXAFS spectrum of Ge qdots (CS_1).

| The fitting | CS_1 |
|------------------------|--------------------|
| quality and parameters | |
| R-factor | 0.029 |
| N (Ge_1 - Ge_2) | 4 |
| (set) | |
| S_0^2 (set) | 0.843 |
| ΔE_0 | 2.175 ± 2.427 |
| σ^2 | $0.0062 \pm$ |
| | 0.0005 |
| ΔR | -0.013 ± 0.012 |

S2.2 Raman Spectroscopy Results

Raman of a-Ge [1] were compared with the bulk Ge (the diamond cubic structure) in Figure S1.

In a-Ge (black square), there is one peak at 275 cm^{-1} which is very broad and asymmetric.

Crystalline bulk Ge has a symmetric peak at 300 cm^{-1} .

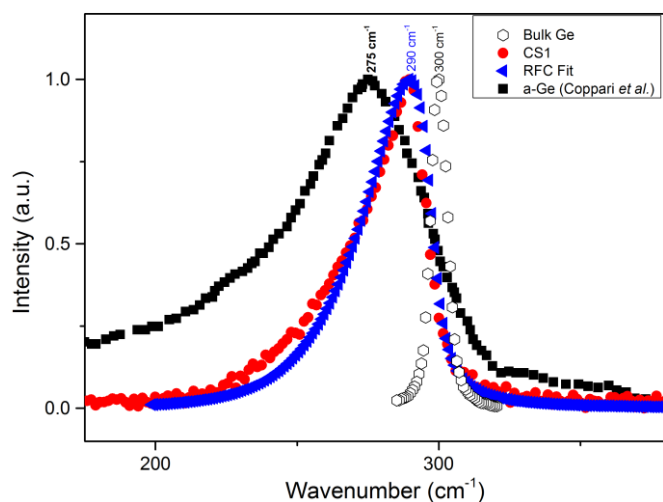

Figure S2. Raman shift of CS1 and RFC fit to CS1 are shown for comparison with Raman of crystalline bulk Ge (black sphere) and that of a-Ge (black square). Raman shift of bulk Ge is shown to have a peak position at 300 cm^{-1} . In a-Ge, there is one but a very broad and asymmetric peak at 275 cm^{-1} (reproduced from reference [1]).

The particle size of CS1 by Raman, TEM and XRD is shown in Table S1.

Table S4. Particle Size by Raman, TEM and XRD

| Method | Particle size (nm) |
|--------|--------------------|
| Raman | 3.2 ± 0.3 |
| TEM | 3.89 ± 0.61 |
| XRD | 1.54 |

In order to test long-term stability of CS₁ in water, CS₁ was stored in water for 35 days. Then, photoluminescence spectrum was collected and is given in Figure S3.

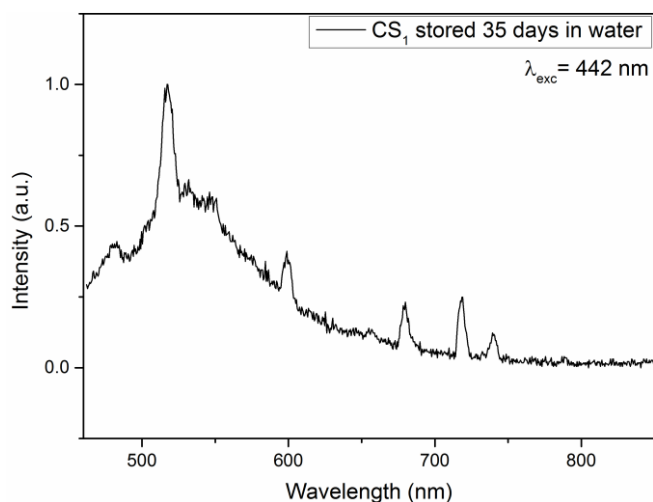

Figure S3. Photoluminescence spectrum of CS₁ stored 35 days in water. The excitation wavelength is 442 nm.

Concentrations dependent viability results of CS₁ and the carboxyl coated CdSe/ZnS qdots are shown in Figure S4. In very small concentrations such as 10 nmole, the CdSe qdots can also be considered to be viable.

Figure S4. Cell viability of CS₁ and the commercial carboxyl coated CdSe/ZnS qdots when cultured with various concentrations of CS₁ at the end of 24 h, 48 h and 72 h.
