Abstract

Prior research reported that accounting conservatism has increased over time in developed countries. In this paper, we try to examine the time-series extent and shift of accounting conservatism in emerging countries over the period 2000-2012. We also analyze differences in conservatism level across countries, regions, legal regimes and industries and the effect of size, Market-to-Book and leverage on the degree of conservatism. We use a set of measures to assess the degree of conservatism. These include changing time-series properties of profitability, earnings, cash flows, accruals components, asymmetric timeliness, Market-to-Book ratio. We find that the degree of conservatism is declined during the period between 2000 and 2007 and increased over the period 2007-2012. In addition, we observe significant differences in accounting conservatism between countries, across regions and industries.

Keywords: Conservatism, Loss frequency, Earnings, Accruals, Market-to-Book, Emerging Markets, Time variation, Cross-section differences

1. Introduction:

Accounting conservatism is considered as one of the most important attribute of financial reporting and it has influenced accounting practice for at least five centuries (Basu, 1997; Watts, 2003a). Watts (2003a) argue that accounting practice is not only conservative, but it has become more and more conservative in the last 30 years. If the demand of conservatism has increased over time, the analysis of time-series financial statement needs to be adjusted in order to obtain more reliable interpretation of accounting numbers (Givoly and Hayn, 2000).

Previous studies have tried to define, measure conservatism and explain the reasons behind its existence (Basu, 1997; Givoly and Hayn, 2000; Watts, 2003a; Watts, 2003b). According to them, conservatism can be of two types: conditional and unconditional. Conditional conservatism is defined as “*the accountants’ tendency to require a higher degree of verification for recognizing good news than bad news in financial statements*” Basu (1997, p7). However, unconditional conservatism is defined as: “*the on average understatement of the book value of net assets relative to their market value*” Beaver and Ryan (2005, p269). The first type of conservatism is mainly related to the understatement of profits; however the second type is more related to the understatement of assets. In detail, when conservatism (both types) is set off, many implications arise. In fact, the presence of conservatism results in lower cumulative net income and assets values (Mason, 2004). In future periods, conservatism will induce an increase (decrease) in loss frequency (profitability) (Givoly and Hayn; 2000, Khan and Watts, 2009) by deferring the recognition of positive economic events until their effective realization, while negative economic events are immediately recognized to anticipate any future bad news. Roychowdhury and Watts (2007) point out that when asymmetric recognition of bad news vs. good news is observed cumulatively over long periods, the market value of equity will be overstated relative to the book value of equity, thus conditional conservatism leads to an understatement of assets value and overstatement of liabilities over time.

In this sense, studying the level and the extent of accounting conservatism becomes an important task in accounting research. Lai *et al.* (2012) denoted that understanding the shift and the trend in conservatism may have implications on financial statement analysis. In the same vein, Givoly and Hayn (2000) stated that if the degree of conservatism increases over time, a time-series analysis of financial statement should take in account the conservative characteristic by making adjustment for the varying level of conservatism in order to obtain more reliable analysis of accounting numbers. They also argued that understanding the time-series change in earnings, cash flows and accruals component is important for investors, researchers, auditors and regulatory bodies. For example, Basu (1997) stated that auditors will support more legal liability if recognition of bad news is late. Therefore, be aware of changes in conservatism level will help auditors to face their legal liability (Basu, 1997; Watts, 2003a). Prior studies supported the idea that accounting conservatism has increased over time in the context of developed countries. Givoly and Hayn (2000) studied the time-series change in accounting conservatism

by examining the changing time-series properties of earnings, cash flows and accruals by using four different measures of accounting conservatism. They reported that companies from US exhibit an increased level of conservative financial reporting over time especially during the period between 1950 and 1998. However Grambovas *et al.* (2006) found that conservatism has increased in European countries from 1989 to 1998 and declined both in US and Europe over the period 1998-2004. In other context, Lai *et al.* (2012) concluded that the degree of conservatism in Australia fluctuates without any obvious trend over the 17-year period from 1993 to 2009. Other studies have focused on international differences in accounting conservatism. For example, Gassen *et al.* (2013) reported that common law countries are likely to exhibit more conservative financial statements than code law countries. Their results coincide with earlier work initiated by Ball *et al.* (2000) who also found that the level of conservatism is higher in common law than in code law countries.

The objective of this paper is two-fold. First, we try to examine the time-series variation of accounting conservatism in developing markets including 47 countries belong to emerging and frontier emerging markets over the period of 2000 to 2012. Second we analyze the cross-sectional differences in the level of conservatism among different emerging regions, industries and legal regimes (common law and civil law). Our work is motivated by many reasons. First, to the best of our knowledge, no previous studies have examined the temporal variation of conservatism in emerging markets. Second, emerging market have recognized in last decade an economic and financial upheaval (crisis) which may rendered many businesses, accounts and auditors extremely prudent (conservative) in order to face any allegation, embezzlement or other misuses resources. Third, emerging markets have different institutional factors comparing to developed countries which means that the demand of conservatism according to taxation, litigation, regulation and contracting factors (Watts, 2003a) can be different from that in US and EU countries. Thus, the results of studying the trend and the extent of conservatism may differ in emerging markets comparing to developed countries.

We offered several novel contributions to existing literature. Following the same approach adopted by Givoly and Hayn (2000) and Lai et al (2012), we use four measures of conservatism: (1) loss frequency and profitability (Return-on-Asset), (2) distribution of cash flows and accruals, (3) market-to-Book ratio, (4) The Basu (1997) measure of timeliness to assess the time varying of the degree of conservatism over time. We find that the level of conservatism according to the profitability measure (ROA) has decreased from 2000 to 2007 and has increased during the period between 2007 and 2012. We find also the same result using the Market-to-Book ratio as a measure of unconditional conservatism. With regard to the distribution of accruals, we report a negative accumulation of non-operating accruals which is more pronounced in the period of 2007 to 2012.

Our study contributes to existing literature by examining also the cross-regions differences in the level of conservatism. We find that firms belong to countries from East Europe exhibit more conservatism than those from Asia and MENA/Africa countries. However, American countries firms do not produce conservatism earnings compared with firms from the other regions.

The remainder of the paper is organized as follows. Section 2 presents definitions of conservatism and how it can be measured. Section 3 presents our research design including sample selection, emerging market characteristics and variables measures. Section 4 shows the findings related to conservatism's time varying. Findings related to the cross-sectional differences in conservatism are discussed in section5. Section 6 concludes.

2. Conservatism measures

Conservatism has been viewed as one of the most important attributes of financial reporting and has been used over other accounting principles such as historical cost and realization conventions for centuries (Basu, 1997; Chan *et al.* 2009). Basu's (1997, p. 7) defined conservatism as: *"the accountant's tendency to require a higher degree of verification for recognizing good news as gains than to recognize bad news as losses"*. Under this interpretation, earnings will reflect bad news more quickly than good news. Beaver and Ryan (2005, p269) defined accounting conservatism as *"the on average understatement of the book value of net assets relative to their market value"*. Under this interpretation, conservatism will lead to the understatement of net assets comparing to their market value. Givoly and Hayn (2000, p292) argued that *"conservatism is a selection criterion between accounting principles that leads to the minimization of cumulative reported earnings by slower revenue recognition, faster expense recognition, lower asset valuation, and higher liability valuation"*. The first consequence of conservatism is that the observed number of losses will increase in time which means that the percentage of firms that report negative income will increase from year to year (Givoly and Hayn, 2000; Balkrishna et al., 2007; Khan and Watts, 2009). In the same sense, in period of conservatism the profitability as measured by ROA should increase over time. Another consequence of conservatism is that accruals tend to reverse (Givoly and Hyan, 2000). Indeed,

during the period in which net income exceeds cash flows from operations, the accruals tend to be negative and when net income falls below cash flows, accruals take positive sign. Therefore another measure of conservatism is the sign of and the magnitude of cumulative accruals. Persistence of negative accruals is a sign of conservatism practices. In detail, accruals (TOACC) are decomposed into operating accruals (OPACC) and non-operating accruals (NOPACC). Basu (1997), Givoly and Hayn (2000) and Watts (2003b) argued that the first, the second and the third moment of the distribution of TOACC and NOPACC vary with conservatism. In addition to those measures, Givoly and Hayn (2000) used the skewness of earning distributions.

The common used measure of conservatism was proposed by Basu (1997). Despite the criticism about this measure, it still widely used in accounting literature. Basu (1997) measured conditional conservatism using a reversal regression model which relates earnings to the return. The model is as follows:

$$EAR_i = \beta_0 + \beta_1 DR_i + \beta_2 RET_i + \beta_3 DR_i * RET_i + \varepsilon_i \quad (1)$$

Where i indexes the firm, EAR is earnings, RET is the return of firm i over the 12 months beginning nine months prior to the end of fiscal year t , DR is a dummy variable equal to 1 when $RET > 0$ and equal to 0 otherwise, and ε_i is the residual. According to Basu (1997), the magnitude of the coefficient on positive returns, β_1 , relates to the incremental response of accounting earnings to good news. Similarly, the degree of which bad news was impounded in earnings is measured by $\beta_2 + \beta_3$ and where β_3 and the total bad news timeliness. According to Basu (1997), if conservatism exists, β_3 should be significant and positive. Givoly and Hayn (2000) added another measure which is the relative sensitivity of earnings to bad news compared with their sensitivity to good news and which is measured by the ratio $(\beta_2 + \beta_3) / \beta_2$. In period of conservatism, this ratio should be greater than 1. However, the estimation value of the coefficient β_2 sometimes is close or below to zero, which can affect the interpretation of this ratio. For this reason, Gassen *et al.* (2013) have modified this ratio using trigonometric concept. The modified ratio is given by:

$$BASU = Arctang(\beta_2 + \beta_3) - Arctang(\beta_2) \quad (2)$$

We adopt this measure as an alternative to the ratio $(\beta_2 + \beta_3) / \beta_2$. The greater (lower) value of $BASU$ the greater (lower) the level of conservatism. In conclusion, following Givoly and Hayn (2000) and Lai *et al.* (2012) we mainly use five measures: (1) The loss frequency; (2) the distribution of ROA, TACC, OPACC, and NOPACC; (3) the Market-to-Book ratio; (4) the asymmetric timeliness.

For unconditional conservatism, the ratio market-to-book (MTB) can be used to measure the level of understatement of book values over their market value. A value of one of MTB is an indicator of presence of unconditional conservatism (Felthman and Ohlson, 1995; Roychowdhury and Watts, 2007).

3. Sample selection and variables measures:

To analyze the time variation and cross-sectional differences in conservatism, we use data collected from companies belong to 47 emerging countries over the period from 2000 to 2012. Countries are selected from both emerging markets and frontier emerging markets following MSCI and Standard and Poor's classifications. The preliminary sample includes all firms from 47 emerging markets; however the unavailability of data for some variables had limited the number of countries to 37 countries. Countries are classified according to four regions: (i) Americas countries; (ii) Asia countries; (iii) MENA/Africa countries and (iv) East Europe countries. The initial sample contains 46 223 firm-years observations. We exclude all firm-years with missing data for any variable used in the study. Besides, we eliminate financial firms from our analysis. In fact, some of used measures solely rely on accounting data (balance sheet, income statement) and financial firms report accounting numbers in different way from other firms. Therefore, our measures can be affected by these differences. In addition, we exclude firms with negative total assets. Indeed, the value of total assets is used as a deflator in measuring conservatism indicators (ROA, CFOA, TACC, OPACC and NOPACC). The negative value can biased our result interpretations. Furthermore the percentage of firms with negative total assets is negligible comparing to the whole sample. Thus eliminating them does not affect results. We also delete firms in the top and bottom 1% of earnings, cash flows, and accruals component to eliminate extreme values. The final sample contains 35,846 firm-years observations. The data for all variables are collected from Thomson Financial and Worldscope databases.

Consistent with Givoly and Hayn (2000), Ball and Shivakumar (2005) and Lai *et al.* (2012), the variable definitions and

measurement are defined in Table 1.

Table 1: List of variables

Variables	Abbreviation	Measures
Earnings	EAR	Earnings before extraordinary items
Return on asset	ROA	The ratio of net income-to-total assets
Total Accruals	TACC	Difference between earnings and cash flows from operation deflated by total assets
Operating Accruals	OPACC	The change non-cash current assets minus the change in current liabilities (excluding short-term debt) deflated by total assets
Non-operating Accruals	NOPACC	Difference between total accruals and operating accruals deflated by total assets
Cash flow from operations	CFOA	Income before extraordinary items + Depreciation and Amortization - change in working capital, deflated by total assets
Market-to-Book ratio	MTB	Ratio of market capitalization to book value of equity
Size	Size	Natural logarithm of market capitalization
Leverage	Lev	Total debt to market capitalization
Annual stock return	RET	calculated by cumulating monthly returns ending 3 months after the firm's fiscal year end

4. Time variation of conservatism:

The first objective of our study is to examine the time-series behavior conservatism's measures over the period 2000 to 2012. We provide descriptive statistics on the different measures discussed above. We also report results by subdividing our 13 years of data into two sub-periods (2000-2007 and 2008-2012). This allows us to test differences between these two periods.

4.1. Loss frequency and profitability:

The first measure that we use to examine the time variation in conservatism is the loss frequency calculated each year by counting the number of firms that reported negative income divided by the total number of firms in that year. However, the profitability across firms is measured using the ROA ratio. Table 2 shows the loss frequency for all years between 2000 and 2012 and for the two sub-periods. Results show that the loss frequency has decreased from 21% in 2000 to 13% in 2007. However the loss frequency has increased from 13% in 2007 to 17% in 2012 with peak in 2008 and 2009 to reach 20%. The mean difference of loss frequency between the two sub-periods is positive and significant which means that the number of losses is greater in the period between 2007 and 2012 than in the period between 2000 and 2007. The profitability as measured by ROA ratio, exhibit the same pattern as for the loss frequency. In fact we observe an increase in the mean of ROA from 4.23 per cent in 2000 to 7.17 per cent in 2007 after that we observe a decline of ROA throughout the period from 7.17% in 2007 to 5% in 2012. The difference in the mean of ROA is significant between the two sub-periods (6.31% vs. 5.35%). The median of ROA is lower than the mean, indicating that the distribution of ROA is left skewed. In conclusion and based on those measure we can say the level of accounting conservatism has decreased in the period between 2000 to 2007 and increased over the period 2007-2012.

Table 2: Distribution of Loss Frequency and profitability

Year	All Firms (N)	Loss (N)	Freq. of losses (%)	ROA		Sub-periods	Freq. of losses (%)	ROA	
				Mean	Median			Mean	Median
2000	1038	218	21.00	.0432	.0410				
2001	1301	273	20.98	.0495	.0502				
2002	1472	307	20.86	.0485	.0498				
2003	1809	295	16.31	.0552	.0526	2000-2007	15.60	.06313	.0585
2004	2075	307	14.80	.0641	.0612				
2005	2409	349	14.49	.0667	.0605

2009	3372	700	20.76	.0515	.0494	Difference P-value	2.85 (0.000)	-0.007 (0.000)	-0.0079 (0.000)
2010	3587	612	17.06	.0556	.0515				
2011	4051	706	17.43	.0555	.0532				
2012	5262	911	17.31	.0500	.0476				

4.2 Distribution of CFOA, TACC, OPACC and NOPACC

4.2.1 Mean and Median:

The mean and median of cash flows from operations, total accruals, operating accruals and non-operating accruals are displayed in table 4. The first indicator presented in the Table 3 is the cash flows from operation to total assets (CFOA) ratio which reflects the firms' economic performance (Healy *et al.*, 1992). According to the calculations, there is no obvious pattern over time. The result suggests that the increasing and the decreasing in the profitability observed in different periods are not related to the change in the distribution of cash flows from operation activities. The mean of TACC is negative in the 13-year period and most shifts in TACC come from NOPACC which also a negative mean over all years. The time-series pattern of the median of TACC, NOPACC are similar to the behavior of mean. Also we remark that median of all variables are less than the mean, indicating that variables are left skewed. In detail, the mean of TACC was -3 percent of total assets in 2000 and become -1.43 per cent in 2007 however in 2008 this ratio takes the value of -6.17% and -3.79 per cent in 2012. The mean of TACC has declined between the two periods, indeed the mean difference between the two sub-periods is negative and significant at 1% level. We observe the same result for the NOPACC. This result shows that the decreasing of profitability during the period between 2007 and 2012 can be attributed to the distribution of accruals over the same period that is the difference between earnings and cash flows.

4.2.2 Variance of CFOA, TACC, OACC, NOACC:

The time series change in the variances of ROA, TACC, OPACC and NOPACC is displayed in Table 4. The variance of ROA is constant over all years of the study. However, the TACC variance has increased from 1.43 per cent in 2000 to 7.13 percent in 2012 and the NOAPCC variance has increased from 1.49 per cent in 2000 to 6.49 in per cent in 2012. Comparing the variance of TACC and NOPACC between the two sub-periods, we find that the variance was increased in the period of 2007-2009 comparing to the period of 2000-2007. The increase in the TACC and NOPACC variances can suggest that the conservatism has increased after 2007.

Table 3: Mean and median of cash flows from operations and accruals deflated by total assets

4.3 Market-to-Book Ratio (MTB):

Our third measure is the market-to-book ratio. This index shows how much book value of equity is comparing to its market value. Recall that when conservatism is exercised, the MTB ratio should exceed the value of one. Figure 1 indicates the mean and the median of the MTB ratio. During the period between 2000 and 2007, the MTB mean has decreased from 1.6 in 2000 to 0.89 in 2007, however during the period of 2007-2012, the MTB ratio has increased in mean to reach the value of 1.07 with a peak in 2008 of 1.48. Overall, the MTB mean is significantly greater in the period 2007-2012 than the mean in the period 2000-2007. Those results confirm the remarks about the trend of conservatism. Again, according to MTB values, unconditional conservatism has increased since 2007 after a period of decreasing.

Figure 1: Meand and Median of MTB ratio

4.4 Asymmetric timeliness:

Table 6 shows the result of the annual regression estimation of the earning-return model presented above in equation (1). The estimations are made each year using all firms in all countries. Consistent with previous results in US, Europe and Australia, the first measure which is the asymmetric timeliness coefficient, is positive in all years. These results show that, in general, the financial reporting systems are conservative, indicating that bad news is recognized faster than good news. During the period between 2000 and 2012 the coefficient of asymmetric timeliness varies from year to year without any obvious trend. It ranges between 0.0192 and 0.2259.

Table 6: annual estimations of Asymmetric timeliness: Basu (1997) Model

$EAR_t = \beta_0 + \beta_1 DR_t + \beta_2 R_t + \beta_3 DR_t * R_t + \varepsilon_t$

5. Differences in conservatism level across regions, countries and industries

In this section we try to analysis cross-sectional differences in conservatism. To do so, we use the Basu's(1997) model. First, we compare the level of conservatism across regions and countries. Second we study the difference in conservatism level between industries.

5.1 Differences in conservatism across Regions and countries

Table 7 reports time-series averages of the estimated annual coefficients and the average of the annual regressions' adjusted R²s estimation of the Basu (1997) model given in equation (1). The estimations are computed for each country classified in four regions: AMERICA, ASIA, EAST EUROPE and MENA/AFRICA. Panel A of table 7 gives the estimations of the Basu (1997) model using firms which belong to America region. Only the following countries were retained in the analysis: Argentina, Brazil, Chili, Colombia, Mexico and Peru. Following the results, the asymmetric timeliness coefficient, β_3 , is negative for all countries except for Argentina where the coefficient is positive but not significant. Overall, countries in South America region do not exhibit conservatism in their financial reporting. In addition, the estimation of the model for the global region also shows that the asymmetric timeliness coefficient is negative.

Table 7: Panel A: Difference in accounting conservatism across country: AMERICAS region

Countries	β_0	β_1	β_2	β_3	BASU	Adj R ²
Argentina	0.048 (0.043)	0.042 (0.418)	0.185 (0.318)	0.157 (0.628)	8.401	20.05
Brazil	0.142 (0.039)	-0.017 (0.829)	-0.083 (0.312)	-0.066 (0.455)	-3.760	51.16
Chili	0.069 (0.000)	-0.000 (0.999)	0.043 (0.039)	-0.293 (0.411)	-16.537	18.85
Colombia	0.095 (0.000)	0.004 (0.644)	0.034 (0.678)	0.267 (0.214)	14.824	44.73

Mexico	-0.240 (0.436)	0.317 (0.314)	0.637 (0.297)	-0.170 (0.804)	-7.479	26.22
Peru	0.069 (0.041)	-0.084 (0.420)	0.045 (0.231)	-0.344 (0.447)	-19.259	31.85
AMERICAS	0.074 (0.000)	-0.116 (0.237)	0.004 (0.408)	-0.319 (0.477)	-17.726	8.1

Panel B of table 7 displays the result of estimations for countries from Asia region. They include China, India, Korea, Sri Lanka, Malaysia, Pakistan, Philippine, Thailand, and Taiwan. The results show that in all countries, the asymmetric timeliness coefficient is positive and significant except India, Pakistan (positive coefficient but not significant), Sri Lanka (negative coefficient). Overall, the financial reporting systems in Asia countries are conservative. Indeed the coefficient of asymmetric timeliness estimated for the entire Asia region is positive (0.1054) and significant (p-value=0.000). We also remark that Thailand firms report more conservative earnings ($\beta_3=0.2129$; BASU= 11.993 degrees; average adjusted R² of 9.06%) followed by Malaysia ($\beta_3=0.196$; BASU=11.118 degrees; Average adjusted R² of 8.81%). However, China firms exhibit the less degree of conservatism ($\beta_3=0.0512$; BASU=2.928 degrees; Average adjusted R² of 7.21%). The estimation results of the Basu's (1997) model for countries in Europe region are given in Table 7 Panel C. The model is estimated for firms belong to Greece, Hungary, Poland, Russia and Slovenia. According to the results, only firms in Greece report conservative financial statements. The coefficient β_3 is positive (0.230) and significant (p-value=0.076) at 10% level. Despite this result, overall the coefficient β_3 for the entire region is positive (0.270) and significant (p-value=0.051) at 10% level.

We will turn our attention to the countries from MENA/Africa region. The results are exhibited in Table 8 Panel D. Only firms from South Africa (Africa region) have conservative reporting system. The coefficient β_3 is positive (0.205; BASU=11.67 degrees) and significant (p-value=0.001) at 1% level. For countries in MENA region, only Israel presents a positive and significant coefficient ($\beta_3 =0.133$; BASU=7.57; Average Adj. R² =16.74%), however, for other countries (United Arab of Emirates; Qatar, Saudi Arabia and Turkey) the asymmetric timeliness coefficient β_3 is positive but not significant, and negative in Egypt, Jordan and Kuwait. Nevertheless, overall countries, the coefficient β_3 is positive (0.223) and significant (p-value=0.014) at 5% level indicating that firms in MENA/Africa have conservative reporting systems in general.

Between the four regions, we find that firms from East Europe report more conservative earnings ($\beta_3=0.27$; BASU=15.04 degrees, Average Adj R²= 13%) followed by MENA/Africa firms ($\beta_3=0.2236$; BASU=12.63 degrees; Average Adj. R²= 9.12%) and Asia firms ($\beta_3=0.1054$; BASU=6.02 degrees; Average Adj. R²=4.49%).

5.2 Difference in conservatism across industries:

Table 8 reports the estimation results of the Basu's (1997) model by industries using the Fama-MacBeth method. The asymmetric timeliness coefficient β_3 is positive and significant for all industries except for OilandGas and Utilities sectors where the coefficient is positive but not significant. Among sectors where the coefficient β_3 is positive and significant, we find that Telecommunications sector is the more conservative ($\beta_3=0.395$; BASU=22.34 degrees; Average Adj. R²=21.66%) followed by ConsumerandServices Technology and Basic Materials sector. Consumer Goods is the less conservative sector ($\beta_3=0.0826$; BASU=4.71 degrees; Average Adj. R²=4.27%).

Table 8: Annual cross-sectional Fama–MacBeth regressions of earnings regressed on returns by industries

6. Conclusion:

This paper examines the variation in time of conservatism in emerging countries over the period between 2000 and 2012. To do so, following Givoly and Hayn (2000) and Lai et al. (2012), we use five different measures to assess the pattern and the shift into the degree of conservatism over time. Overall, there is no obvious trend in the level of conservatism for the full period. However, we have observed that there mainly two patterns. The first one indicates a decrease of conservatism through the period between 2000 and 2007 and the second shows that financial reporting systems are become more conservative since 2007 until present day with a peak in 2012. The second objective of our paper was to examine differences in the level of conservatism across regions, countries, and industries and. We find that countries from East Europe are more conservative, followed by Asia countries and MENA/Africa firms. However, firms from America region produce non conservative financial statements. In addition, we find that firms belong to telecommunications sector has earnings that are more conservative than other sectors. Understanding the pattern and differences in conservatism level is important for financial statement analysis, standard setters, securities regulation, investors, firms and academic research. Our work is subject to some limitations. First, all the presented methods are subject to criticisms. For example, one of the limitations of Basu (1997) measure is that it depends on the association between return and market information and on how can return absorbs this information, this implies that the market is efficient which cannot be the case of emerging markets. In addition, in emerging markets financial statements are released several month after the closing date, therefore market return may reflect past performance that current earnings. We use different measures of conservatism to mitigate the weakness of some measures and to have a minimum of robustness of our results. Second, many countries have been eliminated from our analysis due to missing data which can affect our cross-section comparisons. Third, our study involves data gathered from many different countries with different institutional and culture factors which should be included in the analysis to more explain differences in our findings. Future research can be directed to examine the determinant factors of the change in the level of conservatism in time and across countries.
