## **Abstract**

This study specifies and estimates a gravity model for inter-provincial migration in Indonesia. Using panel data for Indonesia's 26 provinces for 5 survey years between 1930 and 2000 we show that throughout the twentieth century economic factors were more important in the explanation of inter-provincial migration patterns in Indonesia than planned migration policy aimed at the redistribution of the population. In addition, our regression analysis demonstrates that the urban primacy of Jakarta, Indonesia's capital, had a strong effect on the direction and size of migration flows as well. Our findings thus suggest that the costly government-supported migration is not very successful and that a strongly centralized government induces migration flows to the capital. These findings have policy implications for other developing countries.

## **I. Introduction**

Immigration is a controversial issue in developed and developing countries alike, and increasingly economists have dealt with explaining its causes and effects (Lewer and Van den Berg (2008)). The economic approach to immigration has, however, been mainly applied to international migration, and mostly on migration flows between developed countries. The number of empirical studies that attempt to model internal migration in developing countries is still relatively limited, and the lion share of such studies has relied on the work Harris and Todaro (1970) which focuses on rural-urban migration (a two sector model). The present article has a different aim and methodology in that it studies developments in Indonesia's inter-provincial migration flows between 1930 and 2000 by applying a modified gravity model. Using Borjas' (1989) concept of immigrant markets and their gravitational behaviour we aim to study the main determinants of migration flows in Indonesia during a period where it changed from being part of the Dutch colonial empire to one of the largest economies in (Southeast) Asia. Specifically we ask the question which factors have driven internal population movements in Indonesia, and what the effect was of deliberate government programs to promote migration from specific provinces, and how the economic and social conditions in the sending and receiving provinces influenced the inclination to migrate.

To answer this question we specify and estimate a modified gravity model of migration using migration flows for five survey years covering seven decades: 1930, 1971, 1980, 1990 and 2000. The approach in estimating the model for internal migration is similar to that of Lewer and Van den Berg (2007) and Karemera *et al.*

(2000) who, however, applied a gravity model on international migration. In addition, following in particular Karemera *et al.*'s (2000) methodology of ranking the migration elasticities (or the beta-coefficients) for the five survey years, we aim to compare the importance of the determinants of internal migration in Indonesia diachronically.

This article is in five parts. Section II presents an outline of internal migration in Indonesia between 1930 and 2000. Section III lays out the theoretical assumptions of our model, and discusses the data and the econometric procedures we applied in this study. Section IV discusses the results. Finally, in section V we will present our conclusions.

## **II. Internal migration in Indonesia, 1930-2000**

Indonesia is an important case being the fourth most populous country in the world with more than 200 million inhabitants in 2000. Moreover, it is the world's largest archipelago, consisting of *ca* 17,000 islands which span more than 5,000 km eastward from Sabang in northern Sumatra to Merauke in Irian Jaya. If one would superimpose a map of Indonesia over one of Europe, one will find that it stretches from Ireland to Iran; compared to the United States, it covers the area from California to Bermuda.

The available sources for the twentieth century show that internal migration in Indonesia is far from a recent phenomenon. Already under Dutch rule – Indonesia declared independence in 1945, which was only acknowledged by the Dutch in 1949 – it already had a highly geographically mobile population. According to the 1930 population census no less than 11.5% of the total indigenous population of Indonesia

lived outside their district of birth (Volkstelling, 1930) although only half of this (5.6%) moved beyond the provincial borders. Still, in absolute figures this boils down to a number of 3.3 million inter-provincial migrants. Throughout the twentieth century, interprovincial migration increased significantly. While in 1971, with 5% of the total population living in another province than the province of birth, levels of internal migration were about equal to that of the colonial period, from the 1970s onwards inter provincial migration increased significantly. In the following decade the number of inter-provincial migration rose to 7.0 %, in 1990 it was 8.2 % and by 2000 it had increased to about double the share of 1930 and 1970: 10.1 %.

The – mostly sociological – literature on internal migration in colonial Indonesia points out at least three factors that contributed to inter-provincial population movements in Indonesia. Firstly, in the first half of the twentieth century the number of Dutch plantations in the Outer Islands increased strongly.<sup>1</sup> Since labour was scarce here, planters recruited people from Java. Secondly, in 1905 the Dutch government considered Java to be overpopulated and introduced a program to resettle people from Java to the Outer Islands. Migrant families were provided some money as a migration premium and could in addition get a credit, which had to be repaid. Thirdly, the concentration of colonial activity in Java also led to a number of growing urban centres such as Batavia (after independence it was renamed as Jakarta), Surabaya and Semarang (Hugo, 1980, 114). According to Pelzer (1945, 175) these cities attracted people from the crowded interior because of the employment opportunities they offered.

As the figures above pointed out, from the 1970s onwards inter-provincial migration in Indonesia remained to be an important phenomenon. The causes for

---

<sup>1</sup> Due to Java's importance as core region, other parts of the archipelago are usually referred to collectively as the 'Outer Islands'.

internal migration mentioned in the literature on *post*-colonial Indonesia are roughly similar to those mentioned in the studies on the Dutch period. The concentration of economic activity on Java and in particular in Jakarta, overall income differentials, and the government policy of transmigration are seen as the most important explaining factors for inter-provincial population movements in Indonesia since independence. Tirtosudarmo (2009), however, speculates that due to substantial reduction in the government capacity to move people under transmigration policy, in recent years migration has become predominantly a function of the labour market economy, this is something we will return to in our analysis.

This brief overview of the mostly qualitative literature on internal migration in Indonesia highlights a number of factors that are deemed to be important in determining migration patterns in Indonesia: relative income, migration policy in the shape of transmigration, but also the role of Jakarta as urban primate. In the following section we will not only test the hypotheses whether these factors had indeed a statistical effect, but also determine their relative importance and whether this changed over time.

### **III. A gravity model of internal migration in Indonesia, 1930-2000**

#### *Theoretical framework*

In this paragraph we evaluate the factors affecting migration flows between regions using a gravity model. The starting point of the gravity model of migration is the assumption that migration is driven by the attractive force between migrant source and destination location and impeded by the costs of moving from one country to another (Ravenstein, 1885, 1889; Zipf, 1946). The hypothesis that people migrate if

the expected earnings exceed the costs of the move (using distance as a proxy for the cost of migration) was further developed in the work of Greenwood (1975) and Borjas (1989). The latter proposed a model of immigration taking into account a set of variables in the host and destination country influencing the size and composition of the immigrant influx: economic performance; immigration policies, political orientation; and education levels.

Our model is based on the theoretical considerations of Borjas (1989), whose model is built on three basic equations: a wage earning function for the country of origin; one for the country of destination; and a function that takes into account the costs of moving between the two. However, as Karemera *et al.* (2000) have argued, neither Borjas nor Greenwood provides econometric estimates of the elasticities of migration with regard to the characteristics in their models. Therefore, in this article, we follow the successful approach of Karemera *et al.* (2000) and Lewer and Van den Berg (2007) in formulating and estimating a gravity model of migration. In doing so we aim to empirically derive migration impact elasticities for the five survey years in our Indonesia dataset. Subsequently, we will compare the impact of the elasticities diachronically, by means of ranking the beta-coefficients derived from the regression analyses for 1930, 1971, 1980, 1990 and 2000.

### *The gravity model*

Let us first look at formulation of the basic gravity model, which includes the theoretical assumption mentioned above. The starting assumption of our model is that migration is expected to be positively related to the population in the origin and destination. *Ceteris paribus*, the more people there are in a source region, the more people are likely to migrate; the larger the population in the destination region, the

larger is the labour market for immigrants. In addition, wage differentials between sending and receiving provinces are also likely to influence migration patterns. Following the neo-classical assumption of the labour market model in which migrants are regarded as rational actors who want to better themselves, differences in wages trigger population movements. At the same time, we assume migration to be negatively related to the distance between sending and receiving region since one is likely to incur higher costs if one needs to travel further. A final factor we control for in our basic model is that people are likely to move to neighbouring provinces – the concept of contiguity. To control for this phenomenon, we include a contiguity dummy in our model. This leads to the basic gravity equation

$$\ln(\text{mig}_{ij}) = \alpha_0 + \alpha_1 \ln(\text{pop}_i) + \alpha_2 \ln(\text{pop}_j) + \alpha_3 \text{rely}_{ij} + \alpha_4 \ln(\text{dist}_{ij}) + \alpha_5 \text{contig} + u_{ij} \quad (1)$$

where  $\text{mig}_{ij}$  represents the migration from source region  $i$  to destination region  $j$ ,  $\text{rely}_{ij}$  is the ratio of source region to destination region of log per capita incomes,  $\text{dist}_{ij}$  is the logged distance between source region  $i$  and destination region  $j$ ,  $\text{contig}$  is a dummy variable with the value of 1 if provinces have a common boundary and 0 otherwise, and  $u_{ij}$  is an error term. The expected signs of the coefficients are  $\alpha_1 > 0$ ,  $\alpha_2 > 0$ ,  $\alpha_3 < 0$ ,  $\alpha_4 < 0$  and  $\alpha_5 > 0$ .

The model can be improved by controlling for two other factors, namely transmigration and urban primacy. We will first deal with the issue of transmigration. The policy of transmigration policy was initiated under Dutch colonial rule during the early twentieth century and taken over by the Indonesian government after independence. Transmigration had three main goals. First of all,

the government aimed to use this policy measure to distribute the population more evenly by moving millions of Indonesians from the densely populated islands (Java, Bali, Madura) to the outer, less densely populated islands, indeed to achieve a more balanced demographic development and to alleviate demographic pressure.

Secondly, it was aimed at the reduction of poverty by providing land and (thus) new opportunities to poor landless settlers. Finally, the colonial and later national government used this measure to exploit more effectively the agricultural potential of the outer islands. To study the effect of transmigration we include a dummy variable

$$\ln(\text{mig}_{ij}) = \alpha_0 + \alpha_1 \ln(\text{pop}_i) + \alpha_2 \ln(\text{pop}_j) + \alpha_3 \text{rely}_{ij} + \alpha_4 \ln(\text{dist}_{ij}) + \alpha_5 \text{contig} + \alpha_6 \text{trans\_mig} + u_{ij} \quad (2)$$

in which *trans\_mig* is a transmigration dummy, which is 1 for migration from Java to a transmigration region and 0 otherwise.

The second influence on internal migration in Indonesia we want to control for is urban primacy. A primate city is the major city in a country, which as a result plays a dominant role on different levels. It not only is a city that encapsules a large proportion of the urban population of a country, but is also the political, economical, cultural and transportation center of a nation (Ades and Glaeser, 1995; Henderson, 2000). The general rule is that whenever the ratio of the size of the first to that of the second city exceeds two, the city size is said to be primate (Mutlu, 1989: 611).

Jakarta has clearly been the primate city of Indonesia throughout the twentieth century. At the beginning of the twentyfirst century it was more than twice

as populous as the second largest city Surabaya (in the province of East Java). Jakarta's population in 2005 was 8.8 million which is 3.2 times the population of Surabaya (2.75 million). Moreover, the combined population of Surabaya, Bandung (West Java) and Medan (North Sumatra) in 2005 – the second, third and fourth populous cities in Indonesia respectively – was only 7.1 million: still well below the number of inhabitants of Jakarta (United Nations, *World Population Prospects*). To study the influence of urban primacy on internal migration patterns in Indonesia we include a dummy variable for Jakarta in the basic gravity model (Equation 1), which suggest the following equation.

$$\ln(\text{mig}_{ij}) = \alpha_0 + \alpha_1 \ln(\text{pop}_i) + \alpha_2 \ln(\text{pop}_j) + \alpha_3 \text{rely}_{ij} + \alpha_4 \ln(\text{dist}_{ij}) + \alpha_5 \text{contig} + \alpha_7 \text{Jkt} + u_{ij} \quad (3)$$

in which Jkt is a dummy which is 1 for migration to Jakarta and 0 otherwise. Clearly, this dummy bears the risk of bringing in the problem of multicollinearity in the model, since Jakarta is also the province with relatively high per capita income. Yet, in estimating the model we do not find large changes in the estimated regression coefficients when a predictor variable is added or deleted, and we do not find a high R squared with low values for t-statistics (Alheety and Gore 2009; Bhattacharyya 2009).

The foregoing considerations combined suggests the following augmented gravity equation

$$\ln(\text{mig}_{ij}) = \alpha_0 + \alpha_1 \ln(\text{pop}_i) + \alpha_2 \ln(\text{pop}_j) + \alpha_3 \text{rely}_{ij} + \alpha_4 \ln(\text{dist}_{ij}) + \alpha_5 \text{contig} + \alpha_6 \text{trans\_mig} + \alpha_7 \text{Jkt} + u_{ij} \quad (4)$$

### *Data*

The migration data is based on lifetime migration flows for the survey years 1930, 1971, 1980, 1990 and 2000. This provided matrices of 650 migration flows between the 26 provinces of Indonesia for the respective benchmark years. For the years 1930 and 2000 we had to make some adaptations, because in these survey years Indonesia's provincial division differed from the intermediate ones.

The distance variable in our analysis was calculated between the geographic centres (or centroids) of the provinces using ArcGis software. Data on regional Gross Domestic Product (GDP) per capita has been published by the Indonesian Central Bureau of Statistics (BPS) since 1970 in the annual statistical yearbooks. For 1930 we had to rely on provincial wage data taken from Dros (1992).

## **IV. Results**

Table 1 provides the regression results for the 4 models in the 5 benchmark years. All estimated variables have the expected sign and almost all are statistically significant at the 1% level. In all cases the simple gravity model (Equation 1) already explains at least 57.2% of the observed variation in the depended variable inter-provincial migration, which increases when the dummy variables for transmigration (Equation 2) and urban primacy are estimated (Equation 3). In all instances the

highest R square is reached in the most elaborate model (Equation 4) with a minimum of 0.61 in 1971 and a maximum of 0.71 in 1990.

A number of interesting results emerge from the regression analysis, from which we want to point out three main issues. Firstly, our analysis demonstrates that the transmigration dummy is not significant for 1930, 1971 and 1980. This confirms more qualitative studies evaluating transmigration until the 1980s (Van der Wijst, 1985; World Bank, 1988). For 1990 and 2000, however, transmigration has a statistically significant effect on migration patterns. This can be attributed to renewed focus on transmigration since the 1980s. Substantial loans by the World Bank and the Asian Development Bank combined with bilateral financial assistance made it possible to expand the transmigration programme, as a consequence in the period 1980-1990 ten times more people were resettled than in the decades since the beginning of state-sponsored transmigration (Adhiati and Bobsien, 2001). Resettlement figures remained high in the first half of the 1990s, but the programme collapsed as a result of the Asian Crisis. Nevertheless, the ranking of the beta-coefficients in Table 2 reveals that although the effect of the transmigration policy – mainly due to massive financial input – might have become statistically significant from the 1990s onwards, its impact was still relatively limited compared to other factors. Table 2 shows that the beta rank of the transmigration dummy was seventh for the years 1930, 1971 and 1980, only fifth for 1990 to fall back again in 2000.

As the theory that underpins the basic gravity model would predict, wage differentials between sending and receiving regions are likely to be the main determinant in a well functioning, open economy and corresponding labour market. Interestingly, the results of our estimation show that this variable was indeed the most important determinant of inter-provincial migration in Indonesia in our first and

last survey year (1930 and 2000). Our regression analysis shows that the relative wage was a less important factor in 1971 and 1980. The most likely explanation for this is distortions in the (labour) market. Two causes for this can be identified: hyperinflation and a subsequent economic and political crisis in the 1960s, and windfall oil revenues in the 1970s. In 1990 income differentials become one of the leading determinants again. This supports findings that markets in Indonesia were relatively well integrated and functioned effectively in the late colonial period and the late 20<sup>th</sup> century, while integration and efficiency in the period in between was significantly lower (Marks, 2009). More generally, it also suggests that the basic migration model as proposed by Borjas (1989) as well as the gravity model of migration on which it is based has a universal applicability, not only in terms of political setting but also diachronically.

A third finding is that the variables contiguity and distance were significant throughout the entire period. This contrasts the findings of Lewer and Van den Berg (2007), whose dataset contained a large number of European countries, and which showed that contiguity was not significant. This finding stresses the fact that in contrast for Europeans in the twentieth century, where once the distance variable takes into account the transport costs the difficulty of moving to any other country was more or less the same, in Indonesia people did have a tendency to move to neighbouring provinces. This can probably be explained by the fact that for Indonesia we are looking at internal migration while Lewer and Van den Berg (2007) studied international migration. Compared to international migration cross border migration is much more likely to occur for internal migration because institutional and cultural barriers are lower.

Finally, a strikingly important determinant of migration patterns in Indonesia is the role of urban primacy, as proxied by our Jakarta dummy. Since Indonesia's independence in the 1940s this variable has become the dominant factor in explaining internal migration patterns. Clearly, the island of Java being Indonesia's economic core region, Jakarta has been the centre of this core. This explains its attractiveness for migrants through three channels. To begin with, as Krugman and Livas (1992) have shown for Mexico City, net transport costs are lower for domestic goods in the central city because firms are located in that city; workers then come to the city to pay lower prices for domestic goods. Another factor that explains the significant effect of the Jakarta dummy is Indonesia's trade and price intervention. In general, the Indonesian government adopts a policy of protecting manufacturing activities and has taxed primary sector based activities. This has led to protection of the urban sector of Java, and Jakarta especially (Garcia-Garcia, 2000). Finally, since its independence Jakarta has also been Indonesia's political core. As suggested by Ales and Glaeser (1995), urban giant leaders often extract wealth out of the hinterlands and distribute in the capital. This pulls migrants to the city because of the demand created by the concentration of wealth. Our analysis indicates that this theory can also be applied to Indonesia.

## **V. Concluding remarks**

This study applied a gravity model of model of migration on inter-provincial migration in Indonesia between 1930 and 2000. The theoretical framework of our study was Borjas' (1989) model of migration, while the application of the traditional gravity model on migration flows was based on the work of Lewer and Van den

Berg (2007) and Karemera *et al.* (2000). In order to capture the potential determinants of internal migration flows we augmented the traditional gravity model by including variables dealing with contiguity, migration policy and urban primacy.

This article demonstrated that the gravity model is very suitable for an analysis of internal migration flows in a large developing country such as Indonesia, not only for relatively recent migration flows, but also for more historical migration movements. Our analysis showed that all in all five survey years, from 1930 up until 2000, the signs of the coefficients was as expected, and the augmented gravity model explained a very large portion of the variation of the dependent variable, internal migration. Given that the number of empirical studies that apply gravity models on migration is still relatively limited, and the fact the application of the gravity model on Indonesian migration flows for over a period of 70 years – covering different political and economic settings – was successful, our study should thus be regarded as a next step in the testing of the robustness and overall validity of the model.

Our analysis showed that in Indonesia between 1930 and 2000 wage differentials between sending and receiving provinces and the presence of an urban primate in the shape of Jakarta were the most important determinants of migration. Nevertheless, the fact that other factors seemed to have had less influence is perhaps equally interesting. One of the main conclusions of this study is that a policy of supported migration (transmigration in the Indonesian case) is not only costly, but also of relatively limited effect. Our regression analysis showed that migrants have a tendency to base their decision on the more tangible prospect of economic betterment, either in the shape of improvements of one's (expected) income or the attractiveness of moving to a primate city, than on the less concrete prospect of moving to a region that lacks these features – even if this move is supported

financially by the government. This in turn suggests that in order to influence migration patterns, for instance as a means of alleviating demographic pressure or to even out the negative effects of lopsided regional economic growth, it seems more effective to focus on the development of less developed regions directly than simply to promote migration to them and thus create economic development in an in-direct way. Indonesia is in this respect an interesting case since it already has adopted decentralization measures since the beginning of the twenty-first century, and as such has begun to redistribute power and wealth; as a result in recent years Jakarta has already lost importance as economic and political core. Whether this will in fact result in different inter-provincial migration patterns, i.e. a less central role for Jakarta, and thus a more evenly distributed population, as indeed our analysis suggests, is yet too early to tell and is therefore a topic for future research.
