Physical activity and health in adolescence

Authors: Bhavesh Kumar,^A Rebecca Robinson^B and Simon Till^C

ABSTRACT

Adolescence represents a critical period of development during which personal lifestyle choices and behaviour patterns establish, including the choice to be physically active. Physical inactivity, sedentary behaviour and low cardiorespiratory fitness are strong risk factors for the development of chronic diseases with resulting morbidity and mortality, as well as economic burden to wider society from health and social care provision, and reduced occupational productivity. Worrying trends in adverse physical activity behaviours necessitate urgent and concerted action. Healthcare professionals caring for adolescents and young adults are ideally placed and suited to deliver powerful messages promoting physical activity and behaviour change. Every encounter represents an opportunity to ask about physical activity, provide advice, or signpost to appropriate pathways or opportunities. Key initial targets include getting everyone to reduce their sedentary behaviour and be more active, with even a little being more beneficial than none at all.

KEYWORDS: Physical activity, physical inactivity, sedentary behaviour, cardiorespiratory fitness, adolescence, young adults, health promotion, chronic disease

There is overwhelming evidence for the lifelong health benefits of a physically active lifestyle and the health risks of inactivity and sedentary behaviour.¹ England's Chief Medical Officer has acknowledged that the benefits of regular physical activity on health, longevity, and wellbeing 'easily surpass the effectiveness of any drugs or other medical treatment'.²

The process of cardiovascular disease (CVD) begins in childhood, and associated risk factors, including inactivity and obesity, track through adolescence (ages 11–25 years³) into adulthood, imparting heightened risk of premature mortality. Since physical activity (PA) patterns are established during

childhood and adolescence, every consultation represents an opportunity to promote PA.

The burden of physical inactivity and obesity

In England, only 21% of boys and 16% of girls meet minimum PA recommendations for their health⁴ (Table 1), a trend that remains in decline.⁵ Half of the UK's population of 11–25 year olds (4.5 million) are inactive.⁶ Those from lower socioeconomic groups and ethnic minorities have less access to environmentally safe PA and sports.⁷

The proportion of active individuals declines significantly in adolescence (Table 2), with girls less active than boys (56 vs 39%). This tallies with the continued rise in obesity rates among 11–15 year olds, with 38% being overweight.⁸

Increased self-consciousness and peer pressure through adolescence and puberty may be factors in declining PA involvement and therefore timely, sensitive engagement with this group is essential.

50–75% of obese children and adolescents will become obese adults with associated higher rates of metabolic, vascular and musculoskeletal disease.^{9–11} Obesity increases the risk of type-2 diabetes five-fold in men and over ten-fold in women, triples the risk of cardiovascular disease and colon cancer, and increases risk of liver disease and osteoarthritis.⁴

The economic burden of physical inactivity (PIA) in England is immense. The lifetime cost to the UK economy is an estimated £53.3 billion for today's 11–25 year olds, with £8.1 billion directed towards care for inactivity-related disease. Impact from reduced quality of life and life expectancy costs around £10,000 per child.⁶

Table 1. The recommended 'dose' of PA in adolescents.²

Exercise prescription using FITT	PA guidelines for young people aged 5–18 years
Frequency	Daily
Intensity	Moderate to vigorous
Type	All PA, exercise or sport. Muscle strengthening and bone loading activity three times weekly
Time	At least 60 minutes daily. Minimise prolonged sedentary time

PA = physical activity.

Authors: ^Aconsultant physician in sport and exercise medicine, Institute of Sport Exercise and Health, University College London, London, UK; ^Bregistrar in sport and exercise medicine, Royal Hallamshire Hospital, Sheffield, UK; ^Cconsultant rheumatologist and reader in physical activity medicine, Sheffield Teaching Hospitals and Sheffield Hallam University, Sheffield, UK

Table 2. Proportion of children and adolescents meeting current UK PA guidelines.⁴

Age group, years	Percentage meeting guidelines, %	
	Males	Females
5–7	24	23
13–15	14	8

PA = physical activity.

Physical activity behaviours and health risk

Physiologically, there exists a complex dynamic between the ‘dose’ of regular PA undertaken, level of sedentariness, body mass index (BMI), fitness and the link with non-communicable disease. Box 1 explains some of the terminology relating to these key concepts.

PIA is the fourth leading cause of global mortality.¹ PA plays a key role in developing healthy cardiorespiratory fitness (CRF), which in turn correlates inversely with morbidity and mortality. However, within groups with similar fitness, the risk is higher for inactive individuals compared with those meeting PA guidelines. Furthermore, active overweight and obese people have around 50% lower non-communicable disease risk compared with unfit normal weight counterparts.

If everyone had a ‘moderate’ level of CRF, overall mortality would be reduced by about 17%, whereas if no one were obese, the risk reduction would be only 2–3%.¹⁰ It is therefore imperative to increase both PA and CRF levels to offset the adverse effects of inactivity, sedentary time and associated obesity.

The challenging reality is the common co-presentation of PIA and obesity. Current guideline PA levels for adolescents⁴ remain insufficient to offset weight gain associated with today’s

sedentary lifestyles, highlighting the need for promotion of an active lifestyle and healthy diet.¹² The inactive adolescent with normal BMI is at heightened risk of chronic disease relative to an overweight, active peer.

Sedentary lifestyles and adolescent health

Public Health England (PHE) advise that all children and young people should minimise sedentary time.¹³

Sedentary behaviour is an independent cause of chronic disease and one in six deaths in the UK. This cluster of behaviours, characterised by very low energy expenditure, is highly prevalent in modern society. The adolescent playing sport for an hour three times per week is still likely to lead a ‘sedentary’ lifestyle relative to their peers 50 years ago.¹⁴ Young adolescents spend an average of 6.1 hours each day watching television, using a computer or other smart technology, referred to as screen time. A child born in 2012 will accrue three years of screen time by age 18. Screen time is positively associated with obesity, CVD and mortality.¹⁵

Studies indicate continuous periods of sedentariness pose more potent health risks than obesity. Independent of BMI, the most physically active people reduce their risk of developing CVD by 40%, compared with the most sedentary.¹⁶ Engaging in moderate and vigorous PA at current guideline levels without further interrupting sedentary behaviour is likely to be insufficient to offset health risks.¹⁷

Advancing technology which is associated with sedentary behaviour compounds the challenges of PIA. While current recommendations to limit screen time may be unrealistic, paradoxically there may be opportunity to engage young people in PA through technology, for example with apps and virtual training partners. Wearable technology within smartphones, watches and tablets can monitor PA levels and track biometric data.

Box 1. Glossary of PA terms.

- > PA: Any body movement that increases energy expenditure. Includes activities of daily living, occupation, active transport, play, exercise and sport.
- > Exercise: Planned, structured, repetitive body movement undertaken to improve physical fitness.
- > Physical fitness: Ability to perform physical activity. Requires physiological health and neuromotor skills.
- > CRF: Ability of the body’s circulatory and respiratory systems to supply fuel and oxygen during sustained PA.
- > PIA: Insufficient amount of PA according to Department of Health guidelines.¹⁰
- > METs: A measure of energy expenditure. The amount of oxygen required for a given activity in relation to sitting (1 MET). 1 MET varies between individuals, though a mean approximation is 3.5 ml O₂/kg/min = 1 kcal/kg/h
- > Sedentary behaviour: Very low energy expenditure (<1 MET) eg TV viewing, computer use, motorised transport.
- > Light-intensity PA: 1–3 METs; sustained PA where heart rate, respiratory rate and body temperature rise above resting levels (eg standing, strolling).
- > Moderate-intensity PA: 3–6 METs. Able to talk but not sing (eg brisk walking, steady pace cycling).
- > Vigorous-intensity PA: 6–9 METs (eg running, shovelling).
- > Very vigorous PA: >9 METs (eg squash, cross-country skiing, stair running).
- > Moderate and vigorous PA: most beneficial for health at population level.

CRF = cardiorespiratory fitness; METs = metabolic equivalent; PA = physical activity; PIA = physical inactivity.

Box 2. The health benefits of PA in adolescence. ^{18,19}

- > Optimising muscular strength and flexibility
- > Maintaining healthy weight
- > Attaining peak bone mass
- > Developing cardiovascular health
- > Developing neuromuscular awareness
- > Benefiting cognition and mental health, mood, sleep and academic attainment
- > Improving wellbeing and social behaviour

PA = physical activity.

Health benefits of physical activity

PA is potent medicine that promotes healthy development in adolescence. Box 2 summarises some of the key benefits.

There is a clear inverse correlation between PA and all-cause mortality. Regular PA in youth improves cardiovascular physiology, including blood pressure, lipid profile, insulin sensitivity and endothelial function. Furthermore, the resulting higher calorie expenditure helps weight control.¹²

Weight-bearing and resistance exercise play vital roles in developing muscle mass and attaining peak bone density in early adulthood, important for musculoskeletal health in later life.

PA increases cerebral blood flow and circulating levels of norepinephrine and endorphins, positively affecting mood,

self-confidence and concentration, while moderating anxiety, stress and anger. Cognitive development, skill acquisition and behaviour are also improved.¹⁸

Sport participation can help develop social skills, teamwork and leadership. PA is associated with reduced levels of risk-taking behaviours, smoking and excessive alcohol consumption.²⁰

Every healthcare professional's role

The healthcare professional is ideally placed to engage adolescents in healthy lifestyle choices involving optimal PA to improve health and wellbeing. Healthcare professionals can also actively engage families, schools and local authorities to support young people in an active environment.

Every patient encounter is an opportunity to elicit PA and sedentary behaviour levels, and offer advice. This should be recorded within the social history, documenting daily minutes engaged in moderate and vigorous PA and time spent sedentary. Information and advice offered to the adolescent must be relatable in context of their lifestyle and any coexistent medical conditions.

We advocate a PA 'prescription' for all young people within their healthcare plan. A useful tool for providing specific advice is the FITT principle. Table 1 demonstrates how current guideline levels of PA can be prescribed according to FITT. Fig 1 illustrates a model for integrating PA within the consultation and Table 3 provides key strategies for successful PA promotion.

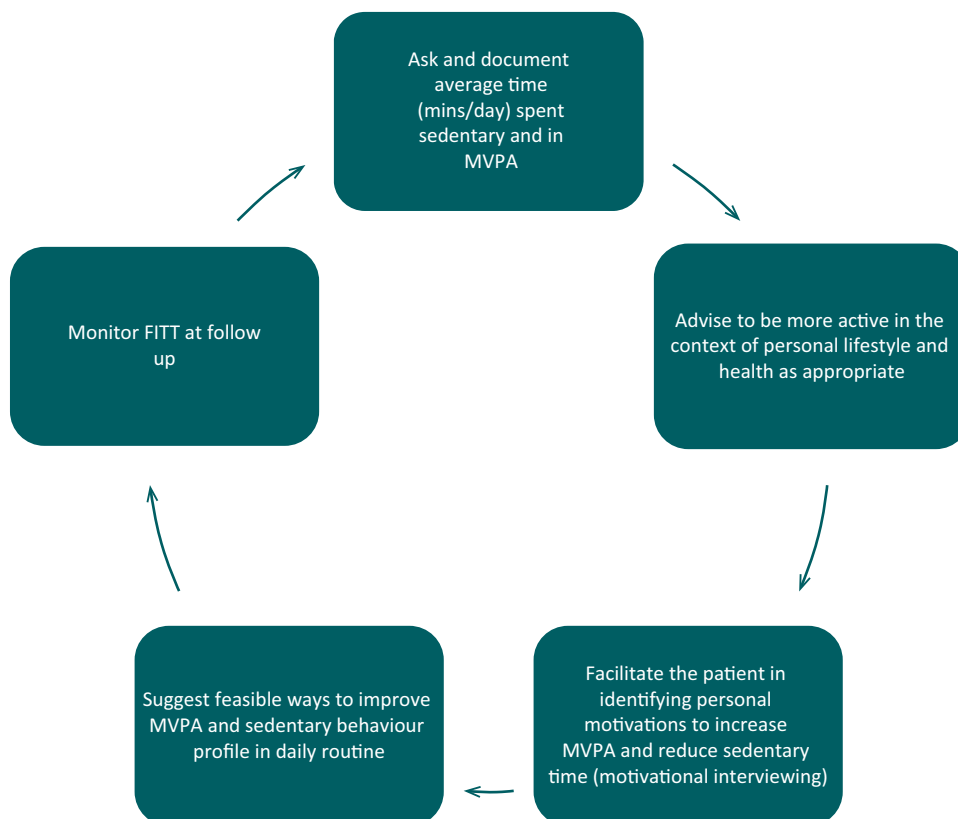

Fig 1. Incorporating PA into every consultation. MVPA = moderate and vigorous physical activity; PA = physical activity.

Table 3. Key strategies for PA promotion.

Aims	Tips	Practical steps
Incorporate small increments into daily routine	10 minute moderate and vigorous PA bouts are most beneficial to health, but light PA is more beneficial than none at all ²¹	<ul style="list-style-type: none"> > Active breaks at school or work to reduce uninterrupted sedentary behavior > Take the stairs > Stand up from sitting and stretch every 20–30 minutes
Ascertain baseline activity levels and measure intra-individual changes	Remember the capacity for PA naturally increases through maturation and growth	<ul style="list-style-type: none"> > Involve and educate to enable self-efficacy in PA management
Encourage family-based activity	Children of physically active parents are more physically active than children of inactive parents ²²	<ul style="list-style-type: none"> > Involve family in management
Advocate active transport	Promote PA as part of daily life	<ul style="list-style-type: none"> > Encourage walking part way to school or work > Use cycle routes
Engage a wide range of stakeholders	Support safe, sociable environments and green spaces	<ul style="list-style-type: none"> > Include schools, parents and the local authority > Signpost to useful web-based PA information hubs, such as the local council or British Heart Foundation
Enable children to work together	Establish schools as physical activity hubs	<ul style="list-style-type: none"> > Encourage links between adolescents, school, family and community
Establish links to local services	Be aware of local referral pathways	<ul style="list-style-type: none"> > Consult NICE PA overview 2014²³

PA = physical activity.

The case study in Box 3 exemplifies PA prescription for an adolescent, where PIA is impacting negatively upon health and wellbeing.

The risks from physical activity

Risks are very low compared with potential health benefits, but practitioner awareness is key. The general physician should enquire about:

- > a history of exercise-associated dizziness, presyncope or collapse
- > family history of sudden cardiac death, unexplained death or drowning, especially in those under 35
- > comorbidities, for example asthma or diabetes, where additional specialist advice and initial monitoring may be required.

Commencing purposeful light PA and instigating sedentary behaviour reduction is very safe. Progressing to moderate-intensity PA is safe in the vast majority of patients with well managed comorbidities, in the context of salient advice regarding safe self-management for exacerbation of their symptoms, when to seek help and the principle of gradual progression. In a small number of cases deemed higher risk, onward referral to a sport and exercise medicine physician or other appropriate specialist is recommended for formal screening and risk stratification.

Implementing physical activity advice in practice: the inactive and obese adolescent

The risk factors of PIA in adolescence are highly relevant to the case presented in Box 3 and are presented in Box 4. PA is

Box 3. Emma, 14, advised to see her doctor by the school nurse concerned about Emma’s weight gain and withdrawn behaviour.

Emma’s growth has been mapped to the 90th percentile since age 10. She lives with her mother and sister who are both overweight. Her father, 45, has metabolic syndrome. No one in the family attains recommended levels of PA. Emma skips breakfast, eats lunch at a fast-food outlet and a supermarket ‘ready meal’ in the evening. She accumulates six hours per day screen time. Emma expresses dissatisfaction in feeling ‘unfit.’

a core component of the multidisciplinary National Institute for Health and Care Excellence (NICE) lifestyle change management approach for overweight and obese young people, with emphasis on education, nutrition and a supportive environment with family and school engagement.²⁶ Qualified health professionals can advise on PA in a primary or secondary care setting, with attention to physical, psychological and physiological barriers.²⁷

Adolescents with complex obesity should be referred to tier 3 specialist obesity services. Bariatric surgery is reserved for severely morbidly obese adolescents (BMI >50 or >40 with comorbidity). Surgery is associated with significant risks, with a paucity of long-term outcome and safety data. Ethical concerns arise regarding invasive management of lifestyle-related conditions.²⁸

Box 4. Health risks in adolescent obesity.^{24,25}**Increased prevalence of insulin resistance in obese children**

- > Three-fold likelihood of obese adolescents developing type-2 diabetes
- > Higher risk in some ethnic minorities

Increased risk of bone and joint injury

- > Excess load on developing skeleton (eg tibia vara, slipped capital femoral epiphysis)
- > Higher self-reported musculoskeletal pain

Psychological health

- > Higher prevalence of depression and lower self-esteem

50–75% of obese adolescents become obese adults

- > Heightened risk of metabolic disease, cardiovascular and musculoskeletal problems

The initial consultation

- > Document PA as daily MET intensity and time equivalents.
- > Use principles of motivational interviewing (MI).²⁹
- > Exclude contraindications to immediate commencement of PA or the need for screening.
- > Agree a PA action plan and ‘exercise prescription’ including:
 - > initial and incremental steps, using the ‘FITT’ principle
 - > preferred activity options
 - > supportive influences eg named friends, family and pets
 - > short-term goals for the next review appointment
 - > long-term goals.

Eliciting the adolescent’s preference for type of physical activity is vital. Home-based exercise may be preferable initially where self-confidence is low, with peer-supported group exercise introduced progressively. Behaviour change strategies can enhance self-efficacy and an online app is available to provide health professional skills in motivational interviewing.³⁰ Initiating exercise at low intensity is appropriate for the least active and confers the greatest initial benefits.³¹

Weight management

Targeting 0.5–1 kg reduction per week for healthy weight loss should be supported by dietary advice regarding reduced calorific intake, while increasing energy expenditure through PA and breaking up sedentary time.

Physical activity and mental health

Promotion of psychological wellbeing is essential. Further concerns about mental health should be addressed in conjunction with mental health services.

Physical activity and environmental factors

Urban living in communities with multiple deprivations and limited access to safe open spaces has been shown to have detrimental health impact.⁵ Urban residential areas can present a hostile environment to psychological, physical and cognitive wellbeing, engendering chronic stress and isolation.³² There is

a positive correlation between PA levels in young people where park and open-space play areas are available close to home and school, and where recreational infrastructure is improved.

Transport

The majority of school children commute an average two miles to school. Safety concerns, a lack of pavements and poor lighting can present barriers to active transport such as walking or cycling to school. Improved local transport planning is recommended by NICE to facilitate active transport as the number of physically active commuters increases.³³

Walking to school incorporates a ‘dose’ of PA within daily routine, replacing a sedentary commute while increasing social interaction. It provides first steps toward an active lifestyle, from which point progression to moderate and vigorous PA, such as cycling, swimming and team sports, can be made.

Conclusion

PA promotion offers a preventative and therapeutic tool akin to a polypill that reduces morbidity, mortality and economic burden from lifestyle-related non-communicable diseases. Healthcare professionals caring for adolescents are in a unique position to engender lifelong behaviour change. We advocate asking about PA and sedentary behaviour at every patient encounter with appropriate promotion and sign-posting strategies. ■
