Rail Preemption

- Designed to **transfer right-of-way** to the track movement and **clear vehicles** off the track(s) before the train arrives
- Preemption sequence in traffic signal controller:
 - Initiated by a signal from the rail equipment
 - Transfer right-of-way to track movements
 - Service and terminate track movements
 - Must be done before **train arrives!**

Current Design Methodology

- ① Use maximum right-of-way transfer time
- ② Assumes a heavy vehicle stopped on track
- ③ Calculates time to get that vehicle off track
- ④ Track clearance green time set to this value
- ⑤ Request advance preemption time, if needed
- ⑥ Assures vehicle is off track when train arrives

Design Case

Question

- Is this good enough to guarantee safe operations?

No!

Operations

- **Variability** impacts preemption operations
- Variability in **traffic signal operations**
 - Due to unknown controller state at preemption initiation
 - Affects right-of-way transfer time
- Variability in **rail operations**
 - Due to “train handling”
 - Affects warning times

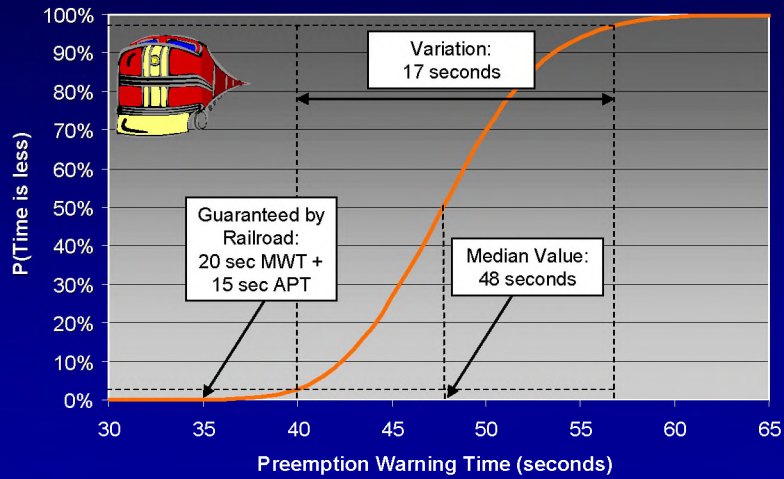

Data Collection

- Train monitoring opportunities at TTI
 - Instrumented rail corridor in College Station, TX
 - Good relationship with City of College Station
- Train data collection
 - Logged signal changes
 - Logged preemptions
 - Logged lights & gates
 - Logged train arrivals

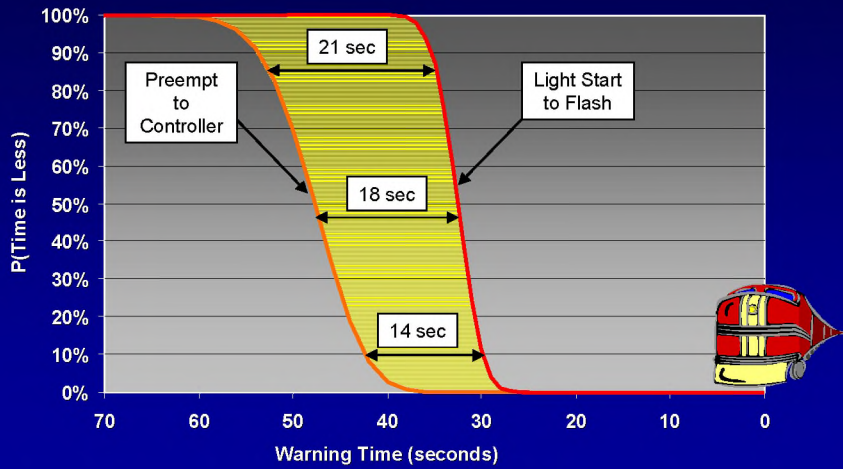

Preemption Warning Time Distribution

Problem

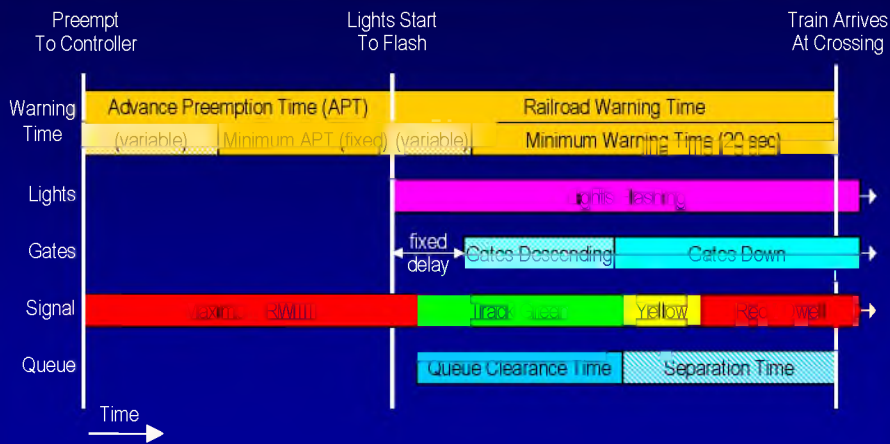

- Exists with **advance preemption**
- Preemption initiation and warning device initiation are **independent** processes

“Uncoupling” of Events

Operations (2)

Operations (3)

“Preempt Trap”

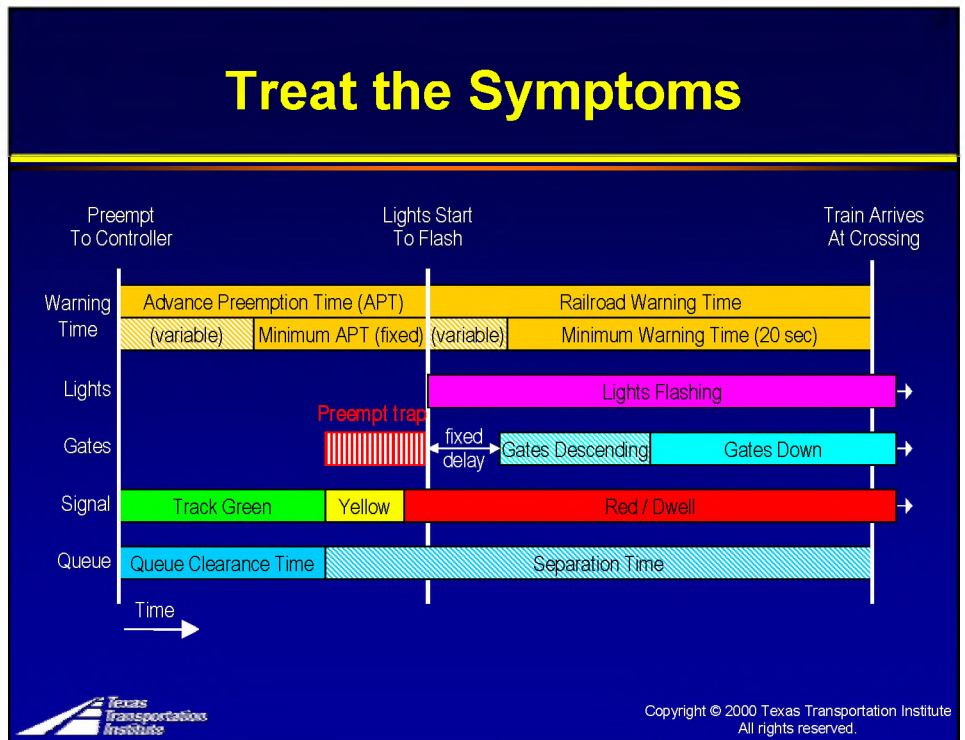

- Track clearance green may end before warning lights start to flash
- Vehicles have no indication of impending train arrival and **may cross tracks**
- **But the track clearance interval has already expired!**

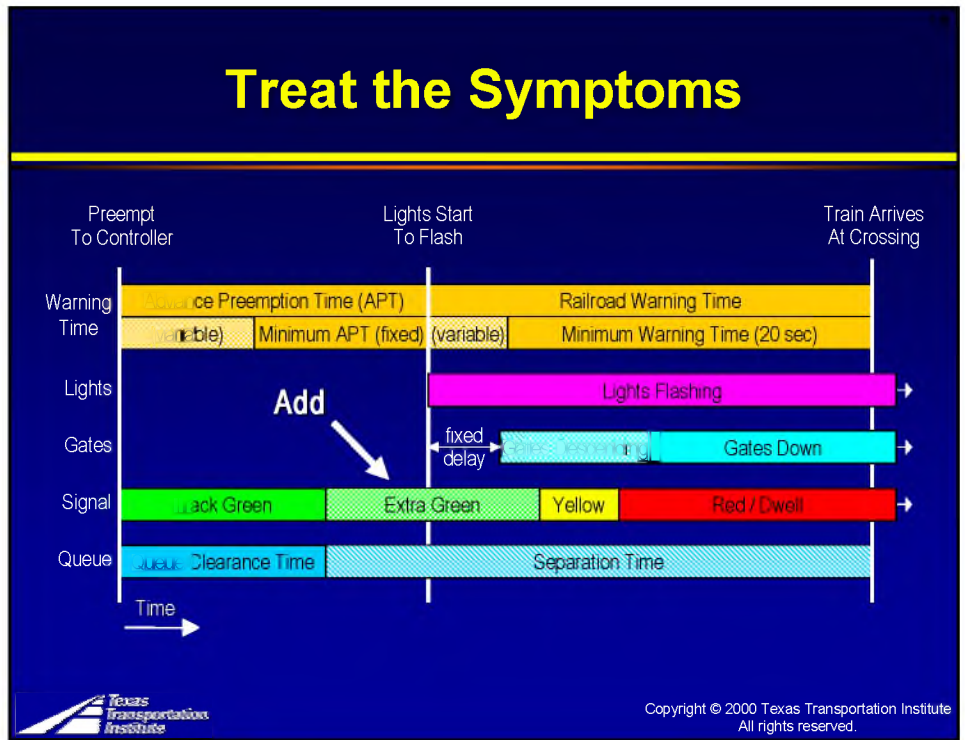

Solutions

Treat the symptoms
and / or
Treat the cause

Treat the Symptoms

Treat the Symptoms

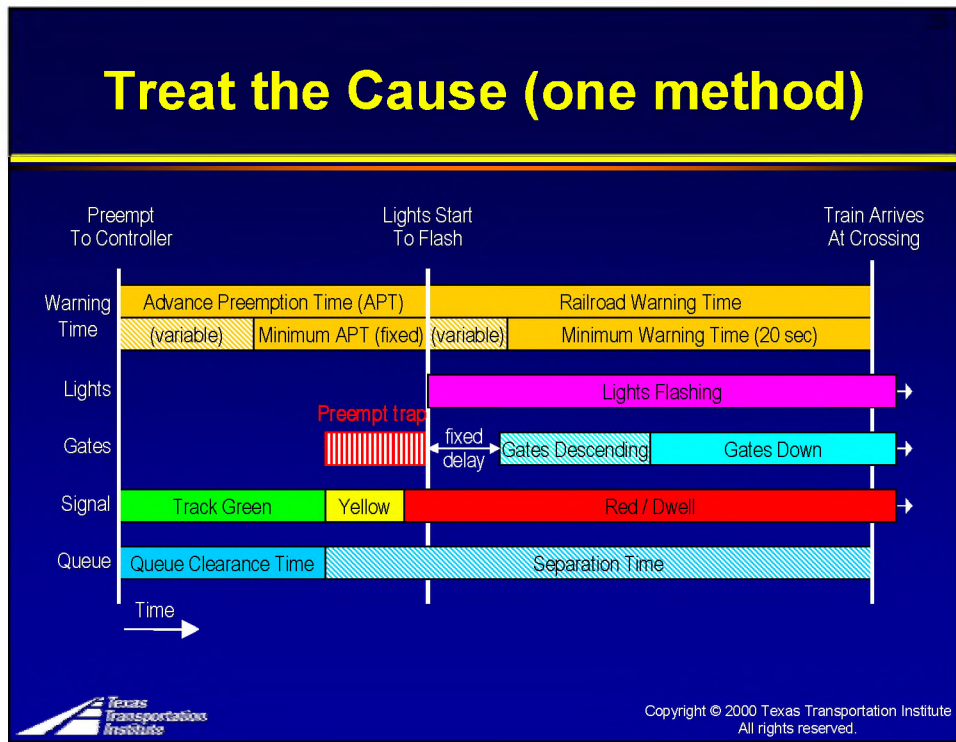

Treat the Symptoms

- Provide **more than the minimum** required track clearance green
- Balance probability of preempt trap with operational efficiency
- For example:
 - Set track green to APT + 15 seconds
 - Design for measured APT times

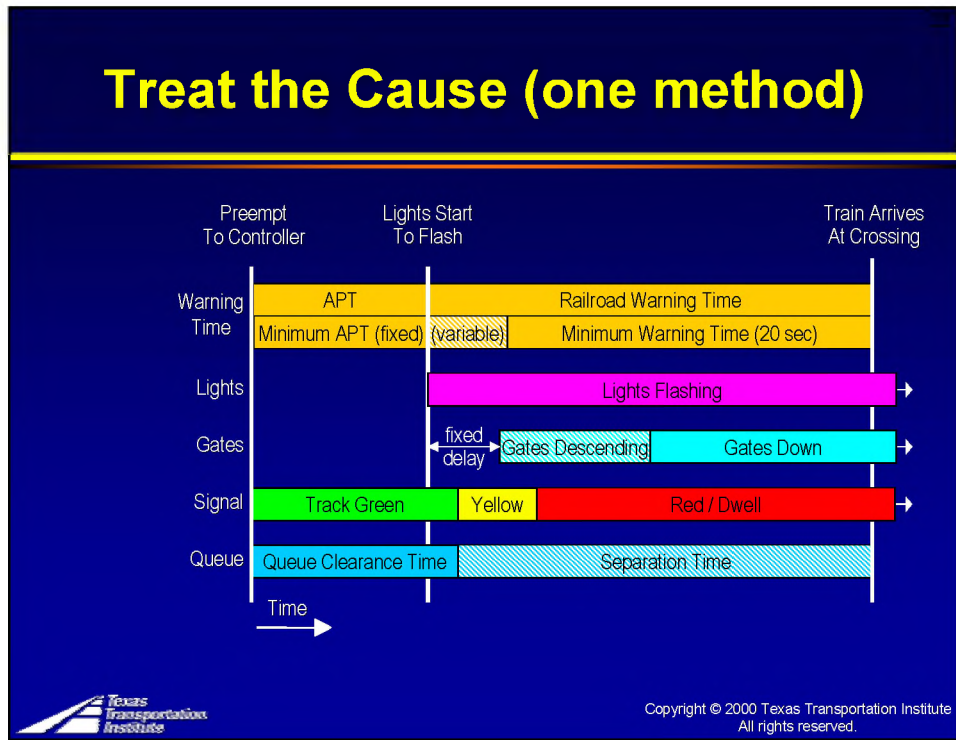

Treat the Cause (one method)

- Reduce variability in rail operations:
 - Reduce variability in advance preemption time
 - Use a “not-to-exceed” timer to **control maximum APT** as per 2000 AREMA Signal Manual

Treat the Cause (one method)

Treat the Cause (one method)

Conclusion

- **Be aware** of the potential problems of advance preemption
- Take the necessary steps to avoid (or at least minimize the probability of) the **preempt trap**
- Consider **design and operational** scenarios
