# THE REACTIVITY AND TRANSIENT ANALYSIS OF MITR-II

by

Tolga Yarman

Submitted to the Department of Nuclear Engineering on 24 July, 1972, in partial fulfillment of the requirements for the degree of Doctor of Philosophy.

## ABSTRACT

The two-dimensional, time dependent, three-group diffusion equations for the proposed designed core of the MIT reactor are written with an extra source term accounting for the photoneutrons generated in the D<sub>2</sub>O reflector. An analytical expression is developed for this term. Then an approximate flux composed of two spatial shapes chosen beforehand, each having an unknown time coefficient, is inserted into the time dependent multigroup equations and the weighted residual criteria is applied. This yields multimode kinetics equations with generalized definitions for the conventional matrix parameters: generation time, reactivity, delayed neutron (and photoneutron) fractions matrices. Computational methods for these parameters are presented. An accident concerning the withdrawal of the shim rods is examined with the code OZAN written for the purpose of the computations required by the present work. This study suggests that a space-dependent analysis is required to analyse the accident postulated.

Thesis Supervisors: A. F. Henry, Professor of Nuclear Engineering  
D. D. Lanning, Professor of Nuclear Engineering  
J. W. Gosnell, Assistant Professor of Nuclear Engineering

## ACKNOWLEDGEMENTS

The author would like to express his gratitude to Professor A. F. Henry. He provided guidance and made himself available for discussions whenever requested.

To Professor D. D. Lanning. He shared the guidance of this work and several ideas. He provided a Research Assistantship when it was necessary and support for performing computations required by the present work, at the M.I.T. Information Processing Center.

To Professor J. W. Gosnell. He also shared the guidance of this work and several ideas.

To his parents, brothers and sisters, his friends and Pan. With their help and encouragement they made the accomplishment of this work much easier.

The author would like to extend his thanks to the Scientifical and Technical Research Council of Turkey who provided a NATO fellowship for most of the course of the present work.

## BIOGRAPHICAL NOTE

Tolga Yarman was born in 1945, in Istanbul (Turkey). He attended elementary and secondary school at the "Galatasaray Lisesi", in Istanbul. He graduated in June 1963.

He entered the "Institut National des Sciences Appliquées (INSA) de Lyon" in September 1963. In June 1967 he received the "equivalent" of a B.S.-M.S. degree in Chemical Engineering.

In October 1967 he was appointed as a teaching assistant in the Chemical Engineering Department (Physical Chemistry Division) of The Technical University of Istanbul. At the same time he enrolled as a graduate student in the "Institute for Nuclear Energy" of the Technical University of Istanbul. In September 1968 he was graduated with the "equivalent" of an M.S. degree in Nuclear Engineering.

He then entered Massachusetts Institute of Technology as a graduate student in the Department of Chemistry. He transferred to the Department of Nuclear Engineering in February, 1969.

## CHAPTER I

### INTRODUCTION

The reactivity and transient analysis of a reactor consists of predicting the behavior of the neutron flux at a point in the reactor during a transient. This leads ultimately to information about the behavior of the power level of the reactor, during the transient.

#### 1-1 Point Kinetics Method

There are a number of ways of performing the analysis. The point kinetics method is the conventional one. This method assumes that the time and space dependent neutron flux, throughout a transient can be expressed in terms of the product of two functions: the first one a function of time alone, and the second one a function of space alone. Supposing that the space function is known, one can then derive (from the multigroup diffusion equations) the conventional point kinetics equations for the time function - of the time and space dependent flux expression - .

Parameters appearing in the point kinetics equations;

The point kinetics equations involve a number of parameters (reactivity, generation time and delayed neutron fractions) the value of which depend on the manipulations

(weighting, integration, etc.) undertaken to get rid of the space dependency in deriving the point kinetics equations.

Thus the point kinetics method consists of fixing a space function that is supposed to express the space dependency of the time and space dependent flux, and then determining, through appropriate manipulations the conventional parameters of the point kinetics equations.

Case where the space function is the flux shape of the critical reactor;

It is customary to choose as the space function the shape of the critical reactor. In this case (and assuming that the weighting function is the same for all cases) generation time and delayed neutron fractions, are always the same for all changes in the reactor that cause the transient.

Thus the reactivity and transient analysis of a given reactor will consist of determining the reactivity that characterizes the transient in question, and solving the point kinetics equations for the time function of the flux expression. The time and space dependent flux at any point of the reactor is then predicted to be the steady state, critical shape changing in magnitude during the transient in accord with the solution of the point kinetics equations.

Hence, if possible small changes in fission cross section are neglected, the solution of the points kinetics equations characterizes the behavior of the power level of the reactor during a transient.

1-2 Solution Techniques accounting for the space dependency of the time and space dependent flux during a transient

A number of methods that account for changes in the shape of the flux during a transient have been developed and may be used for the transient analysis of a reactor.

These methods can be placed into two broad categories [26,27].

Indirect solution techniques;

The first category involves indirect solution techniques that make some assumptions about the mathematical form of the time and space dependent flux over subregions or over the entire reactor, and perhaps also over various periods of time during the transient. These assumptions are then forced into the final solution.

Direct solution techniques;

The second category involves direct techniques that generally consist of finding the solution of the finite difference approximation to the time dependent multigroup diffusion equations.

Differences between the Indirect and Direct solution techniques;

It is worthwhile to point out that there are two major differences between the indirect techniques and direct techniques, of attacking the space-dependent kinetics equations.

The indirect techniques are reasonably fast in computing the final solution, but lack definitive error bounds. Thus whether or not a set of trial functions (assumptions made about the shape of the time and space dependent flux) will give good results for a particular perturbation, is rather intuitive. The direct finite difference techniques, in contrast, require much more time for computations, but are characterized by definitive error estimates. For this reason they are very useful as numerical standards against which the more approximate methods can be compared.

\*

The very first step that must be taken for the "Reactivity and Transient Analysis of MITR-II" is to choose an appropriate method (among these summarized in the first two sections of the present chapter), or if necessary to construct one ourselves.

1-3 The reactivity and transient analysis of MITR-II; set up of the problem.

MITR-II stands for the redesign of the Massachusetts Institute of Technology research reactor. This reactor [28] (cf. also Appendix G) will be cooled and moderated by light water. The reflector is composed of heavy water. Photoneutron sources are present in the  $D_2O$  reflector because of the interaction of the radiation coming out of the core with

Can the point kinetics method be adequate?

There are complications in applying the point kinetics model to MITR-II. First of all it is not clear how we are going to account for the photoneutrons in the computation of the reactivity characterizing the transient in question. More serious than that, it is not guaranteed in the case of MITR-II, that the time and space dependent flux can be represented using only one shape throughout a transient.

Thus the primary purpose of this thesis is to investigate a more sophisticated method of analysis and to compare the predictions with the ones obtained through a point kinetics type of approach (accounting also for the photoneutrons).

The Basic Model;

As a basic model we assume that the time dependent multi-group diffusion equations can describe the time and space dependent flux in the MITR-II. However the presence of photoneutron sources in  $D_2O$  reflector, will require more elaboration. Thus we write

$$\begin{aligned}
 v^{-1} \frac{\partial \phi(\underline{r}, t)}{\partial t} &= [v \cdot D(\underline{r}, t) \nabla - A(\underline{r}, t) + (1-\beta) v \chi_p \Sigma_F^T(\underline{r}, t)] \phi(\underline{r}, t) \\
 &+ \sum_{j=1}^J \lambda_j \chi_j \eta_j(\underline{r}, t) + S(\underline{r}, t) \quad , \quad (1-1)
 \end{aligned}$$

$$\frac{\partial \eta_j(\underline{r}, t)}{\partial t} = \beta_j \nu \Sigma_F^T(\underline{r}, t) \phi(\underline{r}, t) - \lambda_j \eta_j(\underline{r}, t) ,$$

$$(j = 1, \dots, J), \quad (1-2)$$

where;  $S(\underline{r}, t)$  refers to the photoneutrons generated in the reflector and the familiar diffusion theory, matrix notation (spelled out in the body of the dissertation - cf. Chapter III-) is used.

An analytical solution of Equations (1-1) and (1-2), even when the photoneutron source term  $S(\underline{r}, t)$  is not present, is not known, and the method we are to investigate will consist of obtaining an approximate solution to these simultaneous equations. This requires first constructing an analytical expression for the photoneutron source term,  $S(\underline{r}, t)$ .

#### 1-4 Photoneutron source term

In the analysis of a reactor [25] , similar to MITR-II it is pointed out that the photoneutrons may be significant during a transient. The argument we develop below, supports this assumption.

A simple scheme;

Consider an atom of  $U^{235}$  fissioning in an infinite medium of heavy water. Let  $N_0$  be the total number of delayed photons coming out of the fission products that have sufficient energy to generate photoneutrons. Let  $\bar{\Sigma}$  and  $\bar{\Sigma}_D$  be respectively the average macroscopic attenuation and photoneutron reaction cross sections in  $D_2O$ , for the photons of interest. Thus

$$N_0 \int_{R_1}^{R_2} \frac{1}{4\pi r^2} \bar{\Sigma}_D e^{-\bar{\Sigma}r} 4\pi r^2 dr = N_0 \frac{\bar{\Sigma}_D}{\bar{\Sigma}} (e^{-\bar{\Sigma}R_1} - e^{-\bar{\Sigma}R_2}), \quad (1-3)$$

represents the total number of photoneutrons produced by the photons of interest in the volume between the two spheres of radius  $R_2$  and  $R_1$  centered at the point where the atom of  $U^{235}$  is located in the infinite medium of heavy water (cf. Appendix B).

Next assume that, MITR-II can be represented by a spherical model with  $R_1$  and  $R_2$  being the inner and outer radius of the  $D_2O$  reflector and that the radiation is coming from a point source located at the center of the reactor and embedded in pure  $D_2O$  (cf. Chapter II). We then expect

$$\text{pct} = \frac{N_0 \frac{\bar{\Sigma}_D}{\bar{\Sigma}} (e^{-\bar{\Sigma}R_1} - e^{-\bar{\Sigma}R_2}) \times 100}{N_0 \frac{\bar{\Sigma}_D}{\bar{\Sigma}}} \quad (1-4)$$

percent of the total amount of the delayed photoneutrons pro-

duced by delayed photons from fission products of  $U^{235}$  on  $D_2O$ , to be produced in the  $D_2O$  reflector of MITR-II. Taking  $R_1 = 30$  cm,  $R_2 = 60$  cm and  $\bar{\Sigma} = 0.04$   $cm^{-1}$ , we obtain

$$\text{pct} \approx 21\% \quad (1-5)$$

Thus the ratio of delayed photoneutrons to the total number of neutrons produced due to the fission of  $U^{235}$  in an infinite medium of heavy water being  $\approx 1 \cdot 10^{-3}$ , the MITR-II delayed photoneutrons can reach a fraction of  $\approx 2 \cdot 10^{-4}$ . This may indeed be significant compared to the total delayed neutron fraction ( $\approx 7 \cdot 10^{-3}$ ).

#### Prompt photoneutrons;

Besides the delayed photoneutrons there are also prompt photoneutrons due to prompt gamma rays (fission, capture, inelastic scattering, etc.) generated within the reactor. A quick comparison of prompt photoneutrons produced by prompt photons from the fission of  $U^{235}$  on  $D_2O$ , with delayed photoneutrons produced by delayed photons from the fission products of  $U^{235}$ , on  $D_2O$  (cf. Chapter II) will suggest that the former ones are as important as the latter ones.

These considerations require that we devote attention to the photoneutrons throughout this thesis. Thus the photoneutron source term will be studied, and Chapter II, Appendices A and B are concerned with an appropriate analytical expression for the photoneutron source term in Eq. (1-1).

## 1-5 Proposed method

Among the approximate ways of attacking Equations (1-1) and (1-2) summarized in the first two sections of the present chapter we intend to examine the simplest one that will account for the space dependency of the time and space dependent flux.

## Time synthesis;

This method, called time synthesis, assumes that  $\phi(\underline{r}, t)$  can be expressed approximately as the sum of two fixed shapes, each having an undetermined, time dependent coefficient. We thus intend to examine a trial function of the form

$$\bar{\phi}(\underline{r}, t) = \psi_1(\underline{r}) N_1(t) + \psi_2(\underline{r}) N_2(t), \quad (1-7)$$

in which the flux shapes  $\psi_1(\underline{r})$  and  $\psi_2(\underline{r})$  do not depend on time and can be selected in a number of ways.

## Application of the weighted residual method [27];

By substituting the RHS of Eq. (1-7) into Equations (1-1) and (1-2) we obtain residuals.

Chapter III describes the application of the weighted residual method to find equations for  $N_1(t)$  and  $N_2(t)$  from these residuals. In this chapter, in spite of the complicated expression accounting for the photoneutron source term in Eq. (1-1) we shall still be able to obtain the conventional form for the multi mode kinetics equations, with however dif-

ferent definitions for the various parameters.

Thus the problem will be reduced to solving for  $N(t)$

$$\Lambda \frac{dN(t)}{dt} = [\rho_{\text{new}}(t) - \bar{\beta}_{\text{new}}(t)] N(t) + \sum_{j=1}^H \lambda_j C_j(t) \quad (1-8)$$

$$\frac{dC_j(t)}{dt} = \bar{\beta}_{j_{\text{new}}}(t) N(t) - \lambda_j C_j(t), \quad (j=1, \dots, H), \quad (1-9)$$

and where the summation over the delayed neutron groups also includes delayed photoneutron groups, and  $\Lambda$ ,  $\rho_{\text{new}}(t)$  and  $\bar{\beta}_{j_{\text{new}}}$ 's are [2x2] matrices.

1-6 Computation of the parameters  $\Lambda$ ,  $\rho_{\text{new}}(t)$  and  $\bar{\beta}_{j_{\text{new}}}(t)$ 's; Chapter IV and V

The computation of the matrix parameters that appears in Equations (1-8) and (1-9) turned out to be a difficult problem.

In Chapter V, which is closely related to Chapter IV, methods for computing various parameters appearing in Equations (1-8) and (1-9) in a consistent way are presented.

\*

A computer code OZAN\* (described briefly in Appendix N, and presented in Appendix O) was created to perform computations required by the present work.

—\* OZAN means poet in Turkish.

1-7 Chapter VI, A problem treated by the proposed method

We attempted to use OZAN in the case of the withdrawal of the blade of shim rods and to predict the behavior of the power level. The accident of interest is presented in Chapter VI. The complications that arose - because of the particular character of the problem - are then discussed. Finally a comparison of these predictions with the ones obtained through a point kinetics type of approach is made.

1-8 Chapters VII and VIII, checks and conclusions

Tests that validate OZAN are described in Chapter VII, and conclusions about the present work are drawn in Chapter VIII.

## CHAPTER II

### STUDY OF THE PHOTONEUTRON SOURCE TERM $S_g(\underline{r}, t)$

In this chapter our goal is to develop an analytical expression for  $S_g(\underline{r}, t)$  which will account for the number of photoneutrons generated per  $\text{cm}^3$  per sec. within the  $g^{\text{th}}$  neutron group at a point  $\underline{r}$  and time  $t$  in the  $\text{D}_2\text{O}$  reflector.

If we had a  $\text{D}_2\text{O}$  cooled AND reflected reactor, we could think of using the data (shown in Table 2-1) relevant to the generation of photoneutrons - in an infinite medium of heavy water by photons coming out of the fission of  $\text{U}^{235}$ . With some effectiveness correction due to the leakage out of the reactor of photons giving rise to photoneutrons, this would have covered the production of delayed photoneutrons.

Table 2-1 [1]

**Group Constants for Delayed Photoneutrons  
from U<sup>235</sup> Fission Gammas on D<sub>2</sub>O**

Group index, <i>i</i>	Half-life	$\lambda_j$	$\beta_j(10^{-5})$
1	12.8 d	$6.26 \times 10^{-7}$	0.05
2	53 h	$3.63 \times 10^{-6}$	0.103
3	4.4 h	$4.37 \times 10^{-5}$	0.323
4	1.65 h	$1.17 \times 10^{-4}$	2.34
5	27 m	$4.28 \times 10^{-4}$	2.07
6	7.7 m	$1.50 \times 10^{-3}$	3.36
7	2.4 m	$4.81 \times 10^{-3}$	7.00
8	41 s	$1.69 \times 10^{-2}$	20.4
9	2.5 s	$2.77 \times 10^{-1}$	65.1
			Total 100.75

Average D<sub>2</sub>O photoneutron half-life  $\equiv (\ln_2) \sum(\beta_j/\lambda_j)/\sum\beta_j$   
 $= 16.7$  min (following saturation irradiation)

Instead, in the MITR-II  $D_2O$  is present in the reflector only. In addition we have other gamma rays than the ones coming from  $U^{235}$  and causing the photoneutron reaction. We would also like to have a space dependent photoneutron source term. All this forces us to drop the previous data of Table 2-1 and to try a different approach to the solution of the problem.

To this end we will start with the production of photons within the reactor. We next compute through a shielding type of calculation the photon flux in a given energy range at a point  $\underline{r}$  in the reflector, and finally make use of the photoneutron reaction cross sections.

Let then  $I(\underline{r}, \Lambda, t)$  be the non-directional flux of photons of energy  $\Lambda$  per  $cm^2$  per Mev per second in the reflector at  $\underline{r}$  and time  $t$ .

Let  $\Sigma_D(\underline{r}, \Lambda, t)$  be the macroscopic photoneutron reaction cross section of deuterium in the reflector at  $\underline{r}$  and time  $t$ , for the incident photons of energy  $\Lambda$ .

Let  $P_\Lambda(E)dE$  be the probability for the photoneutron generated by an incident photon of energy  $\Lambda$  to be emitted within the energy  $dE$  around  $E$ . ( $P_\Lambda(E)$  - with some pertinent forms- is described in Appendix C).

Thus the product

$$I(\underline{r}, \Lambda, t) \Sigma_D(\underline{r}, \Lambda, t) P_\Lambda(E) dE d\Lambda, \quad (2-1)$$

gives the number of photoneutrons per  $cm^3$  per sec. generated in the reflector, at  $\underline{r}$  and time  $t$  in the range  $dE$  about  $E$ , by incident photons of energy lying within  $d\Lambda$  around  $\Lambda$ .

This is the first step in obtaining  $S_g(\underline{r}, t)$ , the photoneutron source term. However there are a number of problems hidden in Eq. (2-1). How are we going to determine  $I(\underline{r}, \Lambda, t)$ ? Trying to solve the transport equation for the directional photon flux over the reactor volume [9] is impractical and also ill advised unless we have reason to believe photoneutrons are very important.

It would in fact be a great simplification if we could work only with the uncollided photons. But would this approximation be valid? In other words, can the photoneutrons generated by photons having had collisions, especially by photons having had one and only one collision, be neglected as compared to photoneutrons generated by the uncollided photons?

The answer to the latter question is developed in Appendix A and is yes (within an approximation of a few per cent).

A second problem concerns the accuracy of the data specifying the production and attenuation of photons, and the accuracy of photoneutron reaction cross sections. Are these data consistent? If so, one should be able to generate theoretically the results of Table 2-1 starting with the data for the production of photons coming out of the fission of  $U^{235}$ .

The latter question has been studied in Appendix B, and the data we shall work with, has been found satisfactorily consistent.

Furthermore this checking procedure led us to establish an analytical expression for the decay curves of fission photons having an energy above 2.23 Mev (the threshold energy for the

photoneutron reaction in heavy water) - Fig. B-1 - in terms of - the time wise - group decay constants of photoneutrons shown in Table 2-1. This correlation becomes clear when we recognize that the appearance of a photoneutron of a given half life, implies there must be a photon having that same half life to generate the photoneutron in question.

Our next problem concerns the geometry of the system. Even though we use the uncollided photon flux approximation the expression for  $I(\underline{r}, \Lambda, t)$  is extremely complicated. Again, since we do not expect photoneutrons to be very important, we make a gross approximation.

Thus if  $S_f(\underline{r}, \Lambda, t)$  is the number of photons of "f<sup>th</sup> type" (this terminology will become more clear shortly) emitted per  $\text{cm}^3$  per Mev per second at location  $\underline{r}$  in the reactor, with energy  $\Lambda$  and at time  $t$ , we define

$$S_f(\Lambda, t) = \int_{\underline{r}, \text{reactor}} S_f(\underline{r}, \Lambda, t) d\underline{r} \quad (2-2)$$

We then assume for the purpose of computing  $I(\underline{r}, \Lambda, t)$  in the reflector that the extended source,  $S_f(\underline{r}, \Lambda, t)$ , throughout the reactor may be replaced by the point source,  $S_f(\Lambda, t)$ , located at the center of the reactor, and embedded in pure  $\text{D}_2\text{O}$ .<sup>†</sup>

<sup>†</sup> This simplification has two consequences that tend to cancel each other: the intensity of photons from a source that is moved back, will be decreased at a point  $(r, z)$  in the reflector; but also the attenuation through  $\text{D}_2\text{O}$  instead of the heavier core material, is now easier.

For the purpose of comparing these two consequences we suppose we have reason to adopt the scheme shown on the next page.

In addition assume we deal with photons of energy, approximately, 3 Mev, for which the total macroscopic attenuation cross section in the heavy core material and in the  $D_2O$  is taken to be, respectively, 0.2 and  $0.04 \text{ cm}^{-1}$ .

Then the attenuation coefficient for both of the cases (point source placed at the center of the reactor and embedded in pure  $D_2O$ , and point source placed at a more appropriate location within the core - where the self absorption distance can be figured out through a shielding type of information - ), - assuming that the photons are emitted isotropically - , is

$$\frac{1}{4\pi(900)} e^{-(30 \times 0.04)}$$

and

$$\frac{1}{4\pi(169)} e^{-(3 \times 0.8 + 10 \times 0.04)}$$

Hence supposing that the second description for the attenuation is closer to the reality than the first one, we can see that

- Moving back the point source to the center of the reactor decreases the intensity of photons at a point in the reflector as much as:  $\frac{900}{169} \approx 5$ ;

- But also, the attenuation is now easier as much as

$$\frac{e^{-(30 \times 0.04)}}{e^{-(3 \times 0.8 + 10 \times 0.04)}} \approx 5.$$

We are now ready to work out an expression for  $I(\underline{r}, \Lambda, t)$ . This photon flux has two components, one due to the prompt gamma rays, the other due to delayed gamma rays, that, we believe, deserve equal attention.

To see that consider one atom of  $U^{235}$  fissioning in the middle of an infinite medium of  $D_2O$ . Both prompt and delayed gamma rays will be emitted due to that fission. Thus we intend to compare the number of photoneutrons generated by the uncollided prompt photons, with the number of photoneutrons generated by the uncollided delayed photons, from respectively, the fission, and fission products of  $U^{235}$  on  $D_2O$ .

For the purpose of calculation we recall the results given in Appendix B for the two-group scheme of photons, and the output of the Code POPOP IV (cf. Appendix D) for the prompt fission gamma rays from  $U^{235}$  (that is, 0.163 photons for the higher energy group -  $\Lambda_0 = 7$  Mev - and 0.483 photons for the second group -  $\Lambda_1 = 3.5$  Mev -, per fission). Then it is found:

-  $\approx 2. \times 10^{-3}$  prompt photoneutrons due to uncollided prompt photons, per fission of  $U^{235}$ , and;

-  $\approx 1.4 \times 10^{-3}$  delayed photoneutrons due to uncollided delayed photons (emitted between  $t=1$  sec. and  $t=\infty$  sec.), per fission of  $U^{235}$ .

As will be seen below, there are also other prompt gamma rays than the fission prompt gamma rays. Hence an equal attenuation will be paid to the study of the prompt photoneutron source term as well as the study of the delayed photoneutron source term.

†

2-1 Component of  $I(r,z,\Lambda,t)^*$  due to Prompt gamma rays and the corresponding photoneutron source term

The prompt gamma rays are emitted within  $10^{-7}$  sec. and can be coming from the fission event, inelastic scattering of neutrons, or capture of neutrons.

Let  $\phi(r,z,E,t)$  be the scalar neutron flux at  $(r,z)$  of neutrons having an energy within an interval of energy of 1 Mev around  $E$ , and at time  $t$ .

Let  $\Sigma_f(r,z,E,t)$  be the macroscopic neutron cross section for  $f^{\text{th}}$  type of reaction (either fission or inelastic scattering or capture), at  $(r,z)$ , of neutrons of energy  $E$ , at time  $t$ , and let  $\Gamma_{f,E}^n(\Lambda)d\Lambda$  be the yield of photons of energy within  $d\Lambda$  and  $\Lambda$

\* To be more specific, instead of  $I(\underline{r},\Lambda,t)$  the notation has been changed to  $I(r,Z,\Lambda,t)$  for the  $(r,Z)$  geometry.

resulting from the  $f^{\text{th}}$  type of reaction induced by neutrons of energy  $E$ , in nuclei  $n$  [that takes place at  $(r,z)$ ].

Next we define

$$\phi_g(r,z,t) = \int_{E_g}^{E_{g-1}} \phi(r,z,E,t) dE, \quad (2-3)$$

$$\Sigma_{fg}(r,z,t) = \frac{1}{\phi_g(r,z,t)} \int_{E_g}^{E_{g-1}} \Sigma_f(r,z,E,t) \phi(r,z,E,t) dE, \quad (2-4)$$

$$\Gamma_{fg}^n(\Lambda) = \frac{1}{\Sigma_{fg}(r,z,t) \phi_g(r,z,t)} \int_{E_g}^{E_{g-1}} \Sigma_f(r,z,E,t) \Gamma_{fE}^n(\Lambda) \phi(r,z,E,t) dE, \quad (2-5)$$

where  $E_g$  and  $E_{g-1}$  are the lower and upper limits in this order of  $g^{\text{th}}$  neutron group (cf. Fig. 2-1).

Fig. 2-1 Neutron Energy group limits for  $G$  energy groups

Then with the definitions

$$\Gamma_f^n(\Lambda) = \text{diag} (\Gamma_{f_1}^n(\Lambda) \dots \Gamma_{f_G}^n(\Lambda)), \quad (2-6)$$

$$\Sigma_f(r,z,t) = \text{column} (\Sigma_{f_1}(r,z,t) \dots \Sigma_{f_G}(r,z,t)), \quad (2-7)$$

$$\phi(r, z, t) = \text{column } (\phi_1(r, z, t) \dots \phi_G(r, z, t)), \quad (2-8)$$

We may write

$$S_{P_f}(r, z, E, t) = \frac{1}{4\pi(r^2+z^2)} \int_{\Lambda=2.23 \text{ Mev}}^{\infty} d\Lambda \Sigma_D(r, z, \Lambda, t) P_{\Lambda}(E) e^{-\Sigma(\Lambda, t)\sqrt{r^2+z^2}}$$

$$2\pi \int_{r', \text{ reactor}}^{r' dr'} \int_{z', \text{ reactor}}^{dz'} \Sigma_f^T(r, z, t) \Gamma_f(r, z, \Lambda) \phi(r, z, t) \quad (2-9)$$

for the number of photoneutrons due to photons induced by f<sup>th</sup> type of neutron reaction, generated per unit energy, per cm<sup>3</sup> per sec. at (r, z) and time t.

In Eq. (2-9);  $\Sigma_f^T(r, z, t)$  is the transpose of  $\Sigma_f(r, z, t)$ .

$$2\pi \int_{r', \text{ reactor}}^{r' dr'} \int_{z', \text{ reactor}}^{dz'} \Sigma_f^T(r', z', t) \Gamma_f(r', z', \Lambda) \phi(r', z', t) ,$$

is the previously defined point source  $S_f(\Lambda, t)$  placed in the center of the neutron [cf. Eq. (2-2)]. The quantity  $e^{-\Sigma(\Lambda, t)\sqrt{r^2+z^2}}$  is the attenuation coefficient, with  $\Sigma(\Lambda, t)$  the macroscopic attenuation cross section, for photons of energy  $\Lambda$ , at time t for the heavy water medium.

The term  $\frac{1}{4\pi(r^2+z^2)}$  appears because of the assumption that photons are emitted isotropically from a point source at r=z=0.

\*  $\Gamma_f(r, z, \Lambda) \equiv \Gamma_f^n(\Lambda)$ ; In case there are N(>1) nuclei present at (r, z),  $\sum_{n=1}^N \Sigma_f^{nT}(r, z, t) \Gamma_f^n(\Lambda)$  shall replace  $\Sigma_f^T(r, z, t) \Gamma_f^n(\Lambda)$ .

We define now

39

$$\Sigma_{D_\ell}(r, z, t) = \frac{1}{\Delta\Lambda_\ell} \int_{\Lambda_\ell}^{\Lambda_{\ell-1}} \Sigma_D(r, z, \Lambda, t) d\Lambda, \quad (2-10)$$

where  $\Lambda_\ell$  and  $\Lambda_{\ell-1}$  are the lower and upper limits of  $\ell^{\text{th}}$  photon group (cf. Fig. 2-2).

Fig. 2-2 Photon Energy Group limits for L energy groups

$$\Sigma_D(r, z, t) = \text{column} (\Sigma_{D_1}(r, z, t) \dots \Sigma_{D_L}(r, z, t)), \quad (2-11)$$

$$P_\ell(E) = \frac{1}{\Delta\Lambda_\ell} \int_{\Lambda_\ell}^{\Lambda_{\ell-1}} P_\Lambda(E) d\Lambda, \quad (2-12)$$

$$P(E) = \text{diag.} (P_1(E) \dots P_L(E)), \quad (2-13)$$

$$\Sigma_\ell(t) = \frac{1}{\Delta\Lambda_\ell} \int_{\Lambda_\ell}^{\Lambda_{\ell-1}} \Sigma(\Lambda, t) d\Lambda, \quad (2-14)$$

$$E(r, z, t) = \text{diag.} \left( e^{-\Sigma_1(t)(r^2+z^2)^{\frac{1}{2}}} \dots e^{-\Sigma_L(t)(r^2+z^2)^{\frac{1}{2}}} \right), \quad (2-15)$$

$$\Gamma_{f_\ell}^n = \int_{\Lambda_\ell}^{\Lambda_{\ell-1}} \Gamma_f^n(\Lambda) d\Lambda, \quad (2-16)$$

$$\Gamma_f^n = \text{column} (\Gamma_{f_1}^n \dots \Gamma_{f_L}^n), \quad (2-17)$$

$$P_g = \int_{E_g}^{E_{g-1}} p(E) dE, \quad (2-18) \quad 40$$

$$q_f(r', z', t) = \text{column } (\Sigma_f^T(r', z', t) \prod_{f_1} \dots \Sigma_f^T(r', z', t) \prod_{f_L}(r, z)) \quad (2-19)$$

With integrations over  $\Lambda$  from  $\Lambda_\ell$  to  $\Lambda_{\ell-1}$  ( $\ell$  varying from  $L$  to  $1$ ) and over  $E$  from  $E_g$  to  $E_{g-1}$ , summation over the three types of prompt photon production and the above definitions Eq. (2-9) finally becomes

$$S_{P_g}(r, z, t) = \frac{1}{4\pi(r^2+z^2)} \Sigma_D^T(r, z, t) P_g E(r, z, t) \times \\ 2\pi \int_{r', \text{reactor}} r' dr' \int_{z', \text{reactor}} dz' \sum_{f=1}^3 q_f(r', z', t) \phi(r', z', t), \quad (2-20)$$

which is the component of  $S_g(r, z, t)$  due to prompt photons.

To get more insight into Eq. (2-20) choose two energy groups of photons and define

$$Q(r, z, t) = \frac{1}{2(r^2+z^2)} \int_{r', \text{reactor}} r' dr' \int_{z', \text{reactor}} dz' \sum_{f=1}^3 q_f(r', z', t) \phi(r', z', t) \quad (2-21)$$

Then Eq. (2-20) yields

41

$$S_{P_g}(r,z,t) = \Sigma_{D_1}(r,z,t) P_{1g} E_{\Lambda}(r,z,t) Q_1(r,z,t) \\ + \Sigma_{D_2}(r,z,t) P_{2g} E_2(r,z,t) Q_2(r,z,t) . \quad (2-22)$$

In Eq. (2-22) the first term gives the number of prompt photoneutrons born at  $(r,z)$  and time  $t$  per  $\text{cm}^3$  per sec. within the  $g^{\text{th}}$  group of neutrons, induced by photons belonging to the first energy group of photons. Similarly the second term in Eq. (2-22) gives the number of prompt photoneutrons born at  $(r,z)$  and time  $t$  per  $\text{cm}^3$  per sec. within the  $g^{\text{th}}$  group of neutrons, induced by photons belonging to the second energy group of photons.

The quantities

$$\Sigma_{f_g}(r',z',t) \prod_{f_{\ell g}}(r,z), (\ell=1, \dots, L)$$

appearing in Eq. (2-22) through Eq. (2-21) and Eq. (2-19) are to be determined for all the locations (or materials present in MITRII) and any of the three types of neutron reaction inducing prompt photons. Fortunately there is a code with its own library for doing this.

Thus the code POPOP IV [2] computes

$$SGCS_{\ell g}(r,z,t) = \sum_{f=1}^3 \Sigma_{f_g}(r,z,t) \prod_{f_{\ell g}}(r,z) , \quad (2-23)$$

the secondary gamma ray cross sections for photons of  $\ell^{\text{th}}$  group, induced by neutrons of  $g^{\text{th}}$  group. In Appendix D POPOP IV

is briefly discussed and the relevant numbers are presented.

2-2 Component of  $I(r,z,\Lambda,t)$  due to Delayed gamma rays and the corresponding photoneutron source term

Delayed gamma rays can be due to fission products decay and activation of the material leading to delayed gamma ray emission.

Activation gamma rays of sufficient energy happen not to be significant in MITR II. Hence we need to consider only the decay of fission products.

To this end we turn our attention to the fission product having the decay constant  $\lambda_j$ . The photons that will follow will appear with the same decay constant. Any photoneutrons caused by these photoneutrons will show up with that decay constant too.

We let then,  $L_j(r,z,t)$ , be the concentration per  $\text{cm}^3$ , per sec. of the  $j^{\text{th}}$  delayed photon precursor (the fission product having the decay constant  $\lambda_j$ ) at  $(r,z)$  and  $t$ .

Let  $N_0$  be the total number of delayed photon precursors created per fission that may decay with one of the  $\lambda_j$ 's, and let  $y_j$  be the fraction of these  $N_0$  delayed photon precursors that decay with the decay constant  $\lambda_j$ .

Let  $\Sigma_F(r,z,E,t)$  be the macroscopic fission cross section for neutrons of energy  $E$ , at  $(r,z)$  and  $t$ , and define

$$\Sigma_{F_g}(r, z, t) = \frac{1}{\phi_g(r, z, t)} \int_{E_g}^{E_g-1} \Sigma_F(r, z, E, t) \phi(r, z, E, t) dE, \quad (2-24)$$

$$\Sigma_F^T(r, z, t) = \text{row} (\Sigma_{F_1} \dots \Sigma_{F_G}) \quad (2-25)$$

$L_j(r, z, t)$  can now be obtained from

$$\frac{\partial L_j(r, z, t)}{\partial t} = \Sigma_F^T(r, z, t) \phi(r, z, t) y_j N_0^{-\lambda_j} L_j(r, z, t) \quad (2-26)$$

The total rate at which delayed photons of the  $j^{\text{th}}$  kind are emitted from the core is then

$$S_e^j(t) = 2\pi \int_{r', \text{core}} r' dr' \int_{z', \text{core}} dz' \lambda_j L_j(r', z', t) \quad (2-27)$$

We let  $Y_{j_\ell}$  be the probability that the photons of sufficient energy to produce photoneutron reaction in  $D_2O$ , emitted from the  $j^{\text{th}}$  precursor appear in the  $\ell^{\text{th}}$  photon group and define

$$Y_j = \text{column} (Y_{j_\ell} \dots Y_{j_L}) \quad (2-28)$$

Then as we did with the prompt photons, we assume that all the delayed photons are born at the center of the reactor and are attenuated in reaching to the reflector as if they were travelling through pure  $D_2O$ . As a result, in complete analogy with Eq. (2-2) we obtain the delayed photoneutron source;

$$S_{D_g}^j(r, z, t) = \frac{1}{4\pi(r^2+z^2)} \Sigma_D^T(r, z, t) P_g^E(r, z, t) Y_j \lambda_j \times$$

$$2\pi \int_{r', \text{ core}}^{r'} dr' \int_{z', \text{ core}}^{z'} dz' L_j(r', z', t), \quad (2-29)$$

at which the-energy wise-group-g photoneutrons appear per unit volume and per unit time at point  $(r, z)$  in the reflector and time  $t$  due to the -time wise-group  $j$  delayed photons.

The total rate of delayed photoneutrons emitted in neutron group  $g$  is then

$$S_{D_g}(r, z, t) = \sum_{j=7}^{15} S_{D_g}^j(r, z, t), \quad (2-30)$$

where having reserved  $j$  from 1 to 6 for delayed neutron groups, we use  $j$  from 7 to 15 for 9 groups of delayed photoneutrons.

The form of Eq. (2-29) suggests that we picture the delayed photoneutrons appearing at  $(r, z)$  as coming from fictitious precursors actually present at  $(r, z)$ . Accordingly we define a concentration  $\theta_g^j(r, z, t)$  of "delayed photoneutron precursors" in relation with the delayed photoneutron group  $j$ , and emitting neutrons into neutron group  $g$  at time  $t$ ;

$$\theta_g^j(r, z, t) = \frac{S_{D_g}^j(r, z, t)}{\lambda_j}, \quad (2-31)$$

so that from Eq. (2-30),

$$S_{D_g}(r, z, t) = \sum_{j=7}^{15} \lambda_j \theta_j(r, z, t) \quad (2-32)$$

To find equations for the  $\theta_g^j(r, z, t)$  we integrate Eq. (2-26) over the core volume and multiply it at the left by

$$\frac{1}{4\pi(r^2+z^2)} \Sigma_D^T(r, z, t) P_g E(r, z, t) Y,$$

where we omit the subscript  $j$  on the column vector [cf. Eq. (2-28)] since the experimental data (cf. Appendix B) indicates this approximation is justified.

The first term of Eq. (2-26) then becomes

$$\frac{1}{4\pi(r^2+z^2)} \Sigma_D^T(r, z, t) P_g E(r, z, t) Y \quad \times$$

$$2\pi \int_{r', \text{core}} r' dr' \int_{z', \text{core}} dz' \frac{\partial L_j}{\partial t}(r', z', t) = \frac{\partial \theta_D^j(r, z, t)}{\partial t}$$

$$- \frac{\frac{\partial}{\partial t} (\Sigma_D^T(r, z, t) P_g E(r, z, t)) Y}{\Sigma_D^T(r, z, t) P_g E(r, z, t) Y} \theta_g^j(r, z, t) \quad (2-33)$$

and the last term becomes

$$\frac{1}{4\pi(r^2+z^2)} \Sigma_D^T(r, z, t) P_g E(r, z, t) Y \lambda_j \quad \times$$

$$2\pi \int_{r', \text{core}} r' dr' \int_{z', \text{core}} dz' L_j(r', z', t) = \lambda_j \theta_g^j(r, z, t) \quad (2-34)$$

It appears legitimate to ignore the time dependence of

$\Sigma_D(r, z, t)$  and  $E(r, z, t)$ . In Eq. (2-33), accordingly we drop the last term and obtain

$$\frac{\partial \theta_g^j(r, z, t)}{\partial t} = \frac{1}{4\pi(r^2+z^2)} y_j N_0 \Sigma_D^T(r, z, t) P_g E(r, z, t) Y \times$$

$$2\pi \int_{r', \text{core}}^{r' dr'} \int_{z', \text{core}}^{dz'} \Sigma_F^T(r', z', t) \phi(r', z', t) - \lambda_j \theta_g^j(r, z, t), \quad (2-35)$$

We discuss in Appendix B how values of  $\lambda_j$ ,  $y_j$ ,  $N_0$  and  $Y$  may be obtained from experimental data.

### 2.3 Summary

In order to find an analytical expression for the photoneutron source term in the  $D_2O$  reflector of MITR-II we have first computed the production of prompt and delayed photons and then, by making a very gross approximation have estimated their attenuation through the core.

Eq. (2-20) (prompt photoneutrons) and Eq. (2-32) coupled with Eq. (2-35) (delayed photoneutrons) are the end products of this procedure. We thus have;

$$S_g(r, z, t) = S_{p_g}(r, z, t) + \sum_{j=7}^{15} \lambda_j \theta_g^j(r, z, t) \quad (2-36)$$

### CHAPTER III

#### APPLICATION OF THE WEIGHTED RESIDUAL METHOD

We shall use the weighted residual method to describe the space and time dependent flux in terms of spatial shapes chosen beforehand and unknown time coefficients.

To carry out this procedure, we begin with the time dependent multigroup diffusion equation with our extra photo-neutron source term

$$v^{-1} \frac{\partial \phi(r, z, t)}{\partial t} = [\nabla \cdot D(r, z, t) \nabla - A(r, z, t) + (1 - \beta) v \chi_p \Sigma_F^T(r, z, t)] \phi(r, z, t)$$

$$+ \sum_{j=1}^J \lambda_j \chi_j \eta_j(r, z, t) + \frac{\alpha}{4\pi(r^2 + z^2)} \text{column} \left( \Sigma_D^T(r, z, t) P_g E(r, z, t) \right)$$

$$2\pi \int_{r', \text{reactor}} r' dr' \int_{z', \text{reactor}} dz'$$

$$\sum_{f=1}^3 \text{column} \left[ \Sigma_f^T(r', z', t) \prod_{f_l} (r', z') \right] \phi(r', z', t) \Bigg) + \sum_{j=J+1}^H \lambda_j \theta_j(r, z, t),$$

(3-1)

$$\frac{\partial \eta_j(r, z, t)}{\partial t} = \beta_j v \Sigma_F^T(r, z, t) \phi(r, z, t) - \lambda_j \eta_j(r, z, t), \quad (3-2)$$

$$\frac{\partial \theta_j(r, z, t)}{\partial t} = \frac{\alpha}{4\pi(r^2+z^2)} y_j N_0 \text{ column} \left( \Sigma_D^T(r, z, t) P_g E(r, z, t) Y \right)$$

$$2\pi \int_{r', \text{core}} r' dr' \int_{z', \text{core}} dz' \left( \Sigma_F^T(r', z', t) \theta(r', z', t) \right) - \lambda_j \theta_j(r, z, t) \quad , (3-3)$$

where

$$v^{-1} = \text{diag} \left( \frac{1}{v_1} \dots \frac{1}{v_G} \right) \quad , \quad (3-4)$$

$$D(r, z, t) = \text{diag} (D_1(r, z, t) \dots D_G(r, z, t)) \quad , \quad (3-5)$$

$$A(r, z, t) = \begin{bmatrix} \Sigma_{a_1}(r, z, t) + \sum_{h=1}^G \Sigma_{s_{h1}}(r, z, t) & & & & & \\ & \cdot & & & & \\ & & \cdot & & & \\ & & & \Sigma_{a_G}(r, z, t) + \sum_{h=1}^G \Sigma_{s_{hG}}(r, z, t) & & \\ & & & & & \end{bmatrix}$$

$$- \begin{bmatrix} \Sigma_{l1}^+(r, z, t) & \dots & \Sigma_{lG}^+(r, z, t) \\ \vdots & & \vdots \\ \Sigma_{G1}^+(r, z, t) & \dots & \Sigma_{GG}^+(r, z, t) \end{bmatrix} ; \quad (3-6)$$

$\Sigma_{a_g}(r, z, t)$ : macroscopic absorption cross section of neutrons belonging to  $g^{\text{th}}$  group at  $(r, z)$  and  $t$  ;

$\alpha$ : correction factor (generated or empirical) for overcoming the error introduced by the approximations made for the computation of the photoneutron source term in the reflector;

$\Sigma_{hg}^*(r,z,t)$ : macroscopic scattering cross section of neutrons from group  $g$  into group  $h$  at  $(r,z)$  and  $t$ .

$\beta_j$  : delayed neutron fraction for group  $j$ , ( $j=1, \dots, J$ ),

$$\beta = \sum_{j=1}^J \beta_j \quad . \quad (3-7)$$

There are  $J$  delayed neutron group(s).

$\nu$  : number of neutrons created per fission ,

$$\chi_p = \text{column } (\chi_{p_1} \dots \chi_{p_G}) \quad . \quad (3-8)$$

$\lambda_j$  : delayed neutron precursor decay constant for  $j^{\text{th}}$  group ( $j=1, \dots, J$ ); delayed photoneutron group decay constant for  $j^{\text{th}}$  group [ $j=(J+1), \dots, H$ ].

There are  $(H-J)$  delayed photoneutron group(s).

$\eta_j(r,z,t)$ : delayed neutron precursor concentration for  $j^{\text{th}}$  group at  $(r,z)$  and  $t$ .

$$\chi_j = \text{column } (\chi_{j_1} \dots \chi_{j_G}) \quad . \quad (3-9)$$

$\chi_{p_g}$  and  $\chi_{j_g}$  are the probabilities, respectively for prompt and delayed neutrons of  $j^{\text{th}}$  group, to appear within the  $g^{\text{th}}$  neutron group.

By column  $\left( \quad \right)$  in Eq. (3-1) and Eq. (3-3) is meant the column matrix obtained by varying  $g$  in  $P_g$  of the expression in between the brackets from 1 to  $G$ . In the same way column  $[ \quad ]$  in Eq. (3-1) describes the column matrix obtained by varying  $\ell$  in  $\prod_{f_\ell}$  from 1 to  $L$ .

Finally

50

$$\theta_j(r, z, t) = \text{column} (\theta_1^j(r, z, t) \dots \theta_G^j(r, z, t)) . \quad (3-10)$$

Other symbols appearing in eqs. (3-1), (3-2) and (3-3) have been defined previously.

Since it is impractical to obtain an analytical solution to the system of equations (3-1), (3-2) and (3-3), we shall employ an approximation method based on expressing  $\varnothing(\underline{r}, t)$  by a trial function of the form

$$\varnothing(\underline{r}, t) = \sum_{i=1}^I \psi_i(\underline{r}) N_i(t) , \quad (3-11)$$

where  $\psi_i(\underline{r})$  is the  $i^{\text{th}}$  mode, a column matrix having  $G$  elements ( $\psi_{ig}(\underline{r})$ ,  $g=1, \dots, G$ ) that are spatial functions selected beforehand, and  $N_i(t)$  is an unknown time coefficient. We then have  $I$  unknown time coefficients to be determined.

The idea behind the expression (3-11) consists in choosing  $\psi_i(\underline{r})$ 's that are linearly independent functions (cf. Appendix E) so that various combinations of them will provide a good approximation to the flux shape expected during the transient. [ 3 ] . The accuracy of the solution will naturally depend on the good choice of these spatial shapes.

### 3-1 Formulation of the residuals .

We now rewrite Eq. (3-11) using the matrix notation

$$\bar{\varnothing}(r, z, t) = \psi(r, z) N(t) , \quad (3-12)$$

with

51

$$\psi(r, z) = \begin{bmatrix} \psi_{11}(r, z) & \dots & \psi_{11}(r, z) \\ \vdots & & \vdots \\ \psi_{G1}(r, z) & \dots & \psi_{GI}(r, z) \end{bmatrix}, \quad (3-13)$$

$$N(t) = \text{column } (N_1(t) \dots N_I(t)) \quad (3-14)$$

The bar on top of  $\bar{\psi}(r, z, t)$  is to indicate that this is an approximate solution. Thus when we insert it into Eq. (3-1), Eq. (3-2) and Eq. (3-3) the left hand sides of these equations are no longer exactly equal to their right hand sides. The differences are called residuals;

$$R(r, z, t) = v^{-1} \frac{dN(t)}{dt} \psi(r, z)$$

$$-[\nabla \cdot D(r, z, t) \nabla - A(r, z, t) + (1-\beta) v \chi_p \Sigma_F^T(r, z, t)] \bar{\psi}(r, z) N(t) -$$

$$\sum_{j=1}^J \lambda_j \chi_j \bar{\eta}_j(r, z, t) - \frac{\alpha}{4\pi(r^2+z^2)} \text{column} \left( \Sigma_D^T(r, z, t) P_g^E(r, z, t) \right)$$

$$2\pi \int_{r', \text{reactor}} r' dr' \int_{z', \text{reactor}} dz' \sum_{f=1}^3 \text{column} [\Sigma_f^T(r', z', t) \bar{\Gamma}_{f\ell}(r', z')] \bar{\psi}(r', z') N(t)$$

$$- \sum_{j=J+1}^H \lambda_j \bar{\theta}_j(r, z, t), \quad (3-15)$$

$$R_{P_j}(r, z, t) = \frac{\partial \eta_j(r, z, t)}{\partial t} - \beta_j v \Sigma_F^T(r, z, t) \psi(r, z) N(t) + \lambda_j \eta_j(r, z, t),$$

(j=1, \dots, J),

52  
(3-16)

$$R_{H_j}(r, z, t) = \frac{\partial \theta_j(r, z, t)}{\partial t} - \frac{\alpha}{4\pi(r^2+z^2)} y_j N_0 \text{ column} \left( \Sigma_D^T(r, z, t) P_g E(r, z, t) \right.$$

$$\left. + 2\pi \int_{r', \text{core}} r' dr' \int_{z', \text{core}} dz' \Sigma_F^T(r', z', t) \psi(r', z') N(t) \right) + \lambda_j \theta_j(r, z, t),$$

(j=(J+1), \dots, H) .

(3-17)

In addition to these three residuals we should in general have interface, boundary and initial condition residuals. However we intend to use good trial functions that will not leave interface residuals and that will satisfy boundary and initial conditions; namely

$$\bar{\phi}(R_0, z, t) = \bar{\phi}(r, z_+, t) = \bar{\phi}(r, z_-, t) = 0, \quad (3-18)$$

$$\bar{\phi}(r, z, 0) = \phi(r, z, 0), \quad (3-19)$$

where  $R_0$  is the extrapolated radius of the reactor (the one which is taken for criticality calculations). Similarly  $z_+$  and  $z_-$  are the upper and lower levels where the flux is taken to be zero.

### 3-2 Weighting of the residuals and preparation of the equations for the unknown time coefficients

Because of the inherent inaccuracy of Eq. (3-12) we cannot make the residuals (3-15), (3-16) and (3-17) vanish at all points  $\underline{r}$ . However we can choose the  $N(t)$  so that the residuals vanish in an integral sense. Accordingly we define the GxI matrix of weighting shapes;

$$W(r,z) = \begin{bmatrix} W_{11}(r,z) & \dots & W_{1I}(r,z) \\ \vdots & & \vdots \\ W_{G1}(r,z) & \dots & W_{GI}(r,z) \end{bmatrix}, \quad (3-20)$$

where the  $i^{\text{th}}$  column is the  $i^{\text{th}}$  weighting mode and no two weighting modes can be proportional to one another.  $W_{gi}$  is chosen to be continuous and defined\* throughout the entire reactor.

We then require;

$$0 = 2\pi \int_{r,\text{reactor}} r dr' \int_{z,\text{reactor}} dz W^T(r,z) R(r,z,t), \quad (3-21)$$

\* These conditions will be automatically satisfied since we intend to use the adjoint fluxes as weighting functions.

$$0 = 2\pi \int_{r, \text{reactor}} r dr \int_{z, \text{reactor}} dz w^T(r, z) \chi_j R_{P_j}(r, z, t),$$

$$(j=1, \dots, J), \quad (3-22)$$

$$0 = 2\pi \int_{r, \text{reactor}} r dr \int_{z, \text{reactor}} dz w^T(r, z) R_{H_j}(r, z, t),$$

$$[j=(J+1), \dots, H], \quad (3-23)$$

3-3 Formulation of the system of equations for the time dependent coefficients

In order to abstract the equations for  $N(t)$  implied by equations (3-21), (3-22) and (3-23) we introduce the definitions;

$$\xi_{P_g}(r, z, t) = \frac{1}{4\pi(r^2+z^2)} \Sigma_D^T(r, z, t) P_g^E(r, z, t) 2\pi \int_{r', \text{reactor}} r' dr' \int_{z', \text{reactor}} dz' \sum_{f=1}^3$$

$$\text{column } [\Sigma_F^T(r', z', t) \prod_{f_l} (r', z') \psi(r', z')] \quad (3-24)$$

$$\xi_P(r, z, t) = \text{column } (\xi_{P_1}(r, z, t) \dots \xi_{P_G}(r, z, t)), \quad (3-25)$$

$$\beta_g^j(r, z, t) = \frac{1}{4\pi(r^2+z^2)} \gamma_j N_0 \Sigma_D^T(r, z, t) P_g^E(r, z, t) \gamma 2\pi \int_{r', \text{core}} r' dr' \int_{z', \text{core}} dz'$$

$$\Sigma_F^T(r', z', t) \psi(r', z') \quad (3-26)$$

$$\beta_j(r, z, t) = \text{column } [\beta_1^j(r, z, t) \dots \beta_G^j(r, z, t)] , \quad (3-27)$$

$$\Lambda = 2\pi \int_{r, \text{reactor}} r dr \int_{z, \text{reactor}} dz W^T(r, z) V^{-1} \psi(r, z) , \quad (3-28)$$

$$\begin{aligned} \rho(t) = 2\pi \int_{r, \text{reactor}} r dr \int_{z, \text{reactor}} dz W^T(r, z) [V \cdot D(r, z, t) - A(r, z, t) \\ + (1-\beta) \chi_p v \Sigma_F^T(r, z, t)] \psi(r, z) + \alpha \xi_p(r, z, t) , \end{aligned} \quad (3-29)$$

$$\begin{aligned} \bar{\beta}_j(t) = \beta_j 2\pi \int_{r, \text{core}} r dr \int_{z, \text{core}} dz W^T(r, z) v \Sigma_F^T(r, z, t) \psi(r, z) , \\ (j = 1, \dots, J) , \end{aligned} \quad (3-30)$$

$$\begin{aligned} D_{j_i}(t) = 2\pi \int_{r, \text{core}} r dr \int_{z, \text{core}} dz W_i^T(r, z) \chi_j \eta_j(r, z, t) , \\ (i = 1, \dots, I) , (j = 1, \dots, J) , \end{aligned} \quad (3-31)$$

$$D_j(t) = \text{column } (D_{j_1}(t) \dots D_{j_I}(t)) , (j = 1, \dots, J) , \quad (3-32)$$

$$\begin{aligned} \bar{\beta}_j(t) = 2\pi \int_{r, \text{reflector}} r dr \int_{z, \text{reflector}} dz W^T(r, z) \beta_j(r, z, t) , \\ [j = (J+1), \dots, H] , \end{aligned} \quad (3-33)$$

$$\theta_j(t) = 2\pi \int_{r, \text{reflector}} r dr \int_{z, \text{reflector}} dz W^T(r, z) \theta_j(r, z, t), \quad (3-34) \quad 56$$

With these definitions Eq. (3-21) becomes:

$$\Lambda \frac{dN(t)}{dt} = \rho(t)N(t) + \sum_{j=1}^J \lambda_j D_j(t) + \sum_{j=J+1}^H \lambda_j \theta_j(t). \quad (3-35)$$

Eq. (3-22) becomes

$$\frac{D_j(t)}{dt} = \bar{\beta}_j(t) N(t) - \lambda_j D_j(t), \quad (j=1, \dots, J). \quad (3-36)$$

Finally Eq. (3-23) becomes

$$\frac{d\theta_j(t)}{dt} = \alpha \bar{\beta}_j(t) N(t) - \lambda_j \theta_j(t), \quad (j = (J+1), \dots, H). \quad (3-37)$$

In order to simplify further we define

$$\bar{\beta}_{j_{\text{new}}}(t) \equiv \bar{\beta}_j(t), \quad (j = 1, \dots, J), \quad (3-38)$$

$$\bar{\beta}_{j_{\text{new}}}(t) = \alpha \bar{\beta}_j(t), \quad (j = (J+1), \dots, H), \quad (3-39)$$

$$\bar{\beta}_{\text{new}}(t) = \sum_{j=1}^H \bar{\beta}_{j_{\text{new}}}(t), \quad (3-40)$$

$$\rho_{\text{new}}(t) = \rho(t) + \bar{\beta}_{\text{new}}(t), \quad (3-41)$$

so that  $\rho_{\text{new}}(t)$  has four components;

1. The prompt neutron reactivity:

$$2\pi \int_{r, \text{core}} r dr \int_{z, \text{core}} dz W^T(r, z) [\nabla \cdot D(r, z, t) \nabla - A(r, z, t)$$

$$+ (1 - \beta) v \chi_p \Sigma_F^T(r, z, t)] \psi(r, z);$$

2. The prompt photoneutron reactivity:

$$2\pi \int_{r, \text{reflector}} r dr \int_{z, \text{reflector}} dz W^T(r, z) \xi_p(r, z, t);$$

3. The delayed neutron reactivity:

$$\sum_{j=1}^J \bar{\beta}_j(t) = \sum_{j=1}^J \beta_j 2\pi \int_{r, \text{core}} r dr \int_{z, \text{core}} dz W^T(r, z) v \chi_j \Sigma_F^T(r, z, t) \psi(r, z);$$

4. The delayed photoneutron reactivity:

$$\sum_{j=J+1}^H \alpha \bar{\beta}_j(t) = \sum_{j=J+1}^H 2\pi \int_{r, \text{reflector}} r dr \int_{z, \text{reflector}} dz W^T(r, z) \beta_j(r, z, t);$$

Both prompt and delayed photoneutron reactivities are produced in the reflector.

We finally define

$$C_j(t) \equiv D_j(t) \quad , \quad (j = 1, \dots, J) \quad , \quad (3-42)$$

$$C_j(t) \equiv \theta_j(t) \quad , \quad (j = (J+1), \dots, H) \quad , \quad (3-43)$$

With the new definitions we obtain from Eq. (3-35), Eq. (3-36) and Eq. (3-37) a system of equations for the unknown time coefficients that has the familiar point kinetics form;

$$\Lambda \frac{dN(t)}{dt} = [\rho_{\text{new}}(t) - \bar{\beta}_{\text{new}}(t)] N(t) + \sum_{j=1}^H \lambda_j C_j(t) , \quad (3-44)$$

$$\frac{dC_j(t)}{dt} = \bar{\beta}_{j_{\text{new}}}(t) N(t) - \lambda_j C_j(t) , \quad (j=1, \dots, H) . \quad (3-45)$$

By analogy with the point kinetics equations  $\Lambda(I \times I)$  will be called the generation time matrix;  $\rho_{\text{new}}(t) (I \times I)$ , the reactivity matrix;  $\bar{\beta}_{j_{\text{new}}}(t) (I \times I)$ , the delayed neutron fraction matrix for the  $j^{\text{th}}$  group and  $C_j(t) (I \times 1)$ , the precursor amplitude function matrix for the  $j^{\text{th}}$  group.

It is worthwhile to point out that the form obtained for the above equations does not depend on the formulation of the energy and time dependent photon flux or the choice of the geometry in the course of the calculation of the photoneutron source term in the reflector. In a different case the same form would be found with however different expressions for the parameters  $\Lambda$ ,  $\rho(t)$  and  $\beta_j(t)$ 's.

Equations (3-44) and (3-45) represent a set of  $I (H+1)$  equations for  $I$  time coefficients and  $I \times H$  precursor amplitude functions.

There are several ways of solving these equations [4]. That topic is outside of the scope of the present work. One of these ways based on the weighted residual method with sub-domain weighting has been adopted since it was the only method implemented by an available computer program, when we first needed a solution. This method is briefly described in Appendix F.

### 3-4 Summary

In order to find a solution for the space and time dependent flux we have used an expression in prechosen spatial shapes and unknown time dependent coefficients. The insertion of this approximate flux into the equations gave us residuals. Then we have chosen as many weighting modes as the number of unknown time coefficients, weighted the residuals and integrated over the reactor volume. That procedure furnished us equations of the point kinetics type for the unknown time coefficients.

We must describe now a method of computing the very complicated integral expressions for  $\Lambda$ ,  $\rho_{\text{new}}(t)$  and  $\bar{\beta}_{j_{\text{new}}}(t)$ 's (subject to Chapter V). This however shall require that we know the way the spatial shapes have been selected, that is done next.

## CHAPTER IV

### SELECTION OF OUR SPATIAL FUNCTIONS

To describe in the simplest way the time and space dependent flux during a transient in MITR-II, we shall choose two trial modes and two weighting modes. Each of the modes is a G-element column vector of spatial functions (G being the number of neutron groups).

Thus

$$\bar{\phi}(r,t) = \psi_1(\underline{r}) N_1(t) + \psi_2(\underline{r}) N_2(t), \quad (4-1)$$

where  $N_1(t)$  and  $N_2(t)$  will be determined through the manipulations involving  $W_1(\underline{r})$  and  $W_2(\underline{r})$ , described in the previous chapter.

Following former criticality calculations done for MITR-II, a three-group model in (r,z) geometry (cf. Appendix G) with no upscattering and down scattering to the closest lower group only, is adopted. That model has 40 mesh points in the r direction and 48 mesh points in the z direction. The boundaries for neutron energy groups are given in Table 4-1.

Group boundaries for three-group scheme

Group	Group boundaries in Mev
Fast	$3 \times 10^{-3}$ - $\infty$
Epithermal	$4 \times 10^{-7}$ - $3 \times 10^{-3}$
Thermal	$2.5 \times 10^{-10}$ - $4 \times 10^{-7}$

The code Exterminator II[5] was used to obtain the spatial functions.

#### 4-1. The Selection of the First Trial and Weighting Modes

The first trial mode is taken to be the solution of

$$\{\nabla \cdot D_1(\underline{r}) \nabla - A_1(\underline{r}) + [(1-\beta)\chi_p + \sum_{j=1}^J \beta_j \chi_j] \nu \Sigma_{F_1}^T(\underline{r})\} \psi_1(\underline{r}) = 0, \quad (4-2)$$

where  $D_1(\underline{r}) = D(\underline{r}, 0)$ ,  $A_1(\underline{r}) = A(\underline{r}, 0)$ ,  $\Sigma_{F_1}(\underline{r}) = \Sigma_F(\underline{r}, 0)$  and  $D(\underline{r}, t)$ ,  $A(\underline{r}, t)$ ,  $\Sigma_F(\underline{r}, t)$  have been defined previously.

That is physically, (ignoring the photoneutrons)  $\psi_1(\underline{r})$  is the flux shape of MITR-II in a steady state critical condition.

Both prompt and delayed neutrons appear in the fast group of the three-group scheme shown in Table 4-1. Therefore

$$X = X_p = X_j = \begin{pmatrix} 1 \\ 0 \\ 0 \end{pmatrix} \quad (4-3)$$

Thus Eq. (4-2) will be written as

$$[\nabla \cdot D_1(\underline{r}) \nabla - A_1(\underline{r}) + v\chi \Sigma_{F_1}^T(\underline{r})] \psi_1(\underline{r}) = 0. \quad (4-4)$$

\*

$W_1(\underline{r})$  is chosen to be  $\psi_1^*(\underline{r})$ ; the solution of the equation adjoint to Eq. (4-4), namely

$$H_1^+(\underline{r}) \psi_1^*(\underline{r}) = 0, \quad (4-5)$$

with

$$\langle \psi_1(\underline{r}) | H_1^+(\underline{r}) | \psi_1^*(\underline{r}) \rangle = \langle \psi_1^*(\underline{r}) | H_1(\underline{r}) | \psi_1(\underline{r}) \rangle, \quad (4-6)$$

and

$$H_1(\underline{r}) = \nabla \cdot D_1(\underline{r}) \nabla - A_1(\underline{r}) + v\chi \Sigma_{F_1}^T(\underline{r}) \quad (4-7)$$

#### 4-2 The Selection of the second trial and weighting modes

The selection of the second trial and weighting modes will be undertaken in the case of a particular transient where a control rod has been withdrawn. We intend to study the transient up to time  $t=T$ ; by then the reactor is presumed to be on a prompt critical period.

Thus the rod being in its withdrawn position at time  $t=T$ , we select as the second expansion mode a vector such that in the vicinity of time  $t=T$ ;

$$\phi(\underline{r}, t) = \psi_2(\underline{r}) e^{\omega t}, \quad (4-8)$$

with

63

$$\begin{aligned} \nabla^{-1} \frac{\partial \phi(\underline{r}, t)}{\partial t} = & [\nabla \cdot D(\underline{r}, t) \nabla - A(\underline{r}, t) + (1-\beta) \chi_p \nabla \Sigma_F^T(\underline{r}, t)] \phi(\underline{r}, t) \\ & + \sum_{j=1}^J \lambda_j \chi_j \eta_j(\underline{r}, t), \end{aligned} \quad (4-9)$$

$$\frac{\partial \eta_j(\underline{r}, t)}{\partial t} = \beta_j \nabla \Sigma_F^T \phi(\underline{r}, t) - \lambda_j \eta_j(\underline{r}, t), \quad (j=1, \dots, J), \quad (4-10)$$

and

$$\eta_j(\underline{r}, t) = M_j(\underline{r}) e^{\omega t} \quad (4-11)$$

Eq. (4-10) with Equations (4-9) and (4-11) then gives;

$$M_j(\underline{r}) = \frac{\beta_j \nabla \Sigma_F^T(\underline{r}, t) \psi_2(\underline{r})}{\omega + \lambda_j} \quad (4-12)$$

and Eq. (4-9) with Equations (4-8), (4-12) and (4-3) becomes

$$\{ \nabla \cdot D(\underline{r}, t) \nabla - A(\underline{r}, t) - \nabla^{-1} \omega + \chi_p \nabla \left( 1 - \sum_{j=1}^J \frac{\omega \beta_j}{\omega + \lambda_j} \right) \Sigma_F^T(\underline{r}, t) \} \psi_2(\underline{r}) = 0 \quad (4-13)$$

In the case of a prompt run away we expect to find  $\omega \gg \lambda_j$  so that, at  $t=T$ ,

$$\{ \nabla \cdot D_2(\underline{r}) \nabla - [A_2(\underline{r}) + \omega V^{-1}] + (1-\beta) \chi_p \Sigma_{F_2}^T(\underline{r}) \} \psi_2(\underline{r}) = 0, \quad (4-14)$$

where  $D_2(\underline{r}) = D(\underline{r}, t)$ ,  $A_2(\underline{r}) = A(\underline{r}, T)$  and  $\Sigma_{F_2}(\underline{r}) = \Sigma_F(\underline{r}, T)$ .

An eigenvalue  $\omega$  can be found such that Eq.(4-14) is satisfied at every point.

The numerical procedure for finding a value of  $\omega$  that satisfies Eq.(4-14) is called a poison search, one introducing a  $(\frac{1}{v})$  - poison (i.e. an effective neutron absorber whose cross section varies inversely with the incident neutron velocity) which is spread uniformly throughout the supercritical reactor until criticality calculation for the reactor yields an eigenvalue of  $\frac{1}{1-\beta}$ .

Thus our second trial mode is determined through a poison search procedure.

\*

$W_2(\underline{r})$  is chosen to be  $\psi_2^*(\underline{r})$ ; the solution of the equation adjoint to Eq.(4-14). Thus as with Equations(4-5),(4-6) and(4-7) we have;

$$H_2^+(\underline{r}) \psi_2^*(\underline{r}) = 0 \quad , \quad (4-15)$$

$$\langle \psi_2(\underline{r}) | H_2^+(\underline{r}) | \psi_2^*(\underline{r}) \rangle = \langle \psi_2^*(\underline{r}) | H_2(\underline{r}) | \psi_2(\underline{r}) \rangle \quad , \quad (4-16)$$

$$H_2(\underline{r}) = \nabla \cdot D_2(\underline{r}) \nabla - A_2(\underline{r}) - \omega v^{-1} + (1-\beta) v \chi \Sigma_{F_2}^T(\underline{r}) \quad . \quad (4-17)$$

4-3 Recomputation, in an integral sense, of the eigenvalue relative to the trial mode

In Section 4-1 we have tacitly assumed that the reactor is critical; also both in sections 4-1 and 4-2 a well converged solution was supposed to be available so that Equations (4-4) and (4-14) are valid at every point of the reactor.

The fact that the reactor may not be critical could be dismissed by merely assuming that the eigenvalue of the reactor is already within  $v\chi \cdot \Sigma_{F_1}^T(\underline{r})$ , the same way  $\frac{1}{1-\beta}$  divides  $v\chi \cdot \Sigma_{F_2}^T(\underline{r})$  in the case of Eq. (4-14). More serious than that is the fact that we may not have a converged solution. Then the eigenvalue [assumed to be unity in case of Eq. (4-4) and  $\frac{1}{1-\beta}$  in case of Eq. (4-14)] coming from a criticality calculation does not anymore insure the balance - in Equations (4-4) and (4-14) - at every point of the reactor.

In addition, the fact that we drop some of the figures of the fluxes coming out of Exterminator-II run or we might use a slightly different scheme of calculation as compared to the one used in Exterminator-II, may also disturb the balance in Equations (4-4) and (4-14). That is if  $\psi_1(\underline{r})$ , for example, as it is punched out on cards from an Exterminator-II run, is inserted in Eq. (4-4) and the latter being weighted by  $\psi_1^*(\underline{r})$ , is integrated over the reactor volume, a finite value results rather than exactly zero.

This is an undesirable situation for we intend to make use further (cf. Chapter V section 5-2), of the balance equations (4-4) and (4-14).

Thus it was necessary to recompute

$$k_k = \frac{\int_{\underline{r}, \text{reactor}} W_1^T(\underline{r}) F_k(\underline{r}) \psi_k(\underline{r}) d\underline{r}}{\int_{\underline{r}, \text{reactor}} W_1^T(\underline{r}) [A'_k(\underline{r}) - \nabla \cdot D_k(\underline{r}) \nabla] \psi_k(\underline{r}) d\underline{r}}, \quad (4-18)$$

where for  $k=1$ ;  $F_k(\underline{r}) = v \chi \Sigma_{F_1}^T(\underline{r})$ ,  $A'_k(\underline{r}) = A_1(\underline{r})$ ; for  $k=2$ ;

$F_k(\underline{r}) = v \Sigma_{F_2}^T(\underline{r})$  and  $A'_k(\underline{r}) = A_2(\underline{r}) + \omega V^{-1}$ , so that we assume

we could write;

$$[\nabla \cdot D_k(\underline{r}) - A'_k(\underline{r}) + \frac{1}{k_k} v \chi \Sigma_{F_k}^T(\underline{r})] \psi_k(\underline{r}) = 0, \quad k=1, 2. \quad (4-19)$$

#### 4-4 Summary

We intend to use two trial modes for the expression of the time and space dependent flux. The first one is composed of the flux shape at the beginning of the transient and the second one, the flux shape at the end of the transient (the end of the time during which we wanted to study the transient). Thus along the bracketing idea, the flux shape will run from the steady state shape onto the shape at the end of the transient.

Both of the modes and the corresponding weighting modes for MITR-II will be computed for a 40x48 mesh point-cylindrical model and three-group scheme, from a steady state type of equations.

The computation of the second mode and its adjoint in the particular case of withdrawal of a control rod, required a poison search.

The computations will be performed with the code Exterminator-II. Thereafter it was necessary to recompute in an integral sense, the eigenvalue relative to the trial mode, to overcome the disturbance of the balance in equations giving  $\psi_1(\underline{r})$  and  $\psi_2(\underline{r})$ , due to numerical disagreements.

## CHAPTER V

### METHODS FOR COMPUTING THE PARAMETERS APPEARING IN THE FINAL EQUATIONS FOR THE UNDETERMINED TIME COEFFICIENTS

The aim in this chapter is to formulate a way for computing  $\Lambda$ ,  $\rho(t)$  and  $\bar{\beta}_{j_{\text{new}}}(t)$ 's in

$$\Lambda \frac{dN(t)}{dt} = \left[ \rho(t) - \bar{\beta}(t) \right] N(t) + \sum_{j=1}^H \lambda_j C_j(t), \quad (5-1)$$

$$\frac{dC_j(t)}{dt} = \bar{\beta}_{j_{\text{new}}}(t) N(t) - \lambda_j C_j(t), \quad (j=1, \dots, H), \quad (5-2)$$

where

$$\bar{\beta}(t) = \sum_{j=1}^H \bar{\beta}_{j_{\text{new}}}(t). \quad (5-3)$$

The expressions giving the coefficients  $\Lambda$ ,  $\rho(t)$ ,  $\bar{\beta}_{j_{\text{new}}}(t)$ 's involve two main forms:

1. 
$$2\pi \int_{r, \text{reactor}} r dr \int_{z, \text{reactor}} dz W^T(r, z) \underline{F}(r, z, t) = \underline{C}_1(t), \quad (5-4)$$

where  $\underline{F}(r, z, t)$  is a known function of  $r$ ,  $z$ , and  $t$ ;  
and

Fig. 5-1 Mesh Scheme in  $(r, z)$  Geometry

$$2. \quad 2\pi \int_{r, \text{reactor}} r dr \int_{z, \text{reactor}} dz \quad W^T(r, z) (\nabla \cdot D(r, z, t) \nabla \psi(r, z)) = \underline{C}_2(t).$$

For the purpose of calculating  $\underline{C}_1(t)$  and  $\underline{C}_2(t)$  consider the Fig. 5-1 [6], where in two dimensions an equivalent mesh volume,  $V_{eq}$  composed of four submesh volumes:  $V_1$ ,  $V_2$ ,  $V_3$ , and  $V_4$ , is shown around the mesh point  $(v, u)$ .

As is customary, we define for each mesh volume a constant neutron cross section for any event (fission, absorption, etc), hence a constant diffusion coefficient, for each neutron group. Also, a constant value for  $\psi_{g1}(r, z)^*$  and  $W_{g1}(r, z)$  is fixed within the equivalent mesh volume around the mesh point  $(v, u)$  (cf. Fig. 5-2).

As shown in Fig. 5-2, there are  $U \times V$  mesh points and  $(U-1) \times (V-1)$  mesh volumes.

### 5-1 Calculation of $\underline{C}_1(t)$

In terms of the coordinate system described above  $\underline{C}_1(t)$  can be written as

$$\underline{C}_1(t) = 2\pi \sum_{v=2}^{V-1} \sum_{u=1}^{U-1} W_{v,u}^T \int_{V_{eq}} r dr \int_{V_{eq}} dz \underline{F}(r, z, t), \quad (5-6)$$

where the integration is performed over the equivalent mesh volume  $V_{eq}$  around the mesh point  $(v, u)$  and the summation

---

\* The  $g^{\text{th}}$  element of the  $i^{\text{th}}$  mode, as it is computed by the Code Exterminator II.

Fig. 5-2 Set Up of the Mesh Scheme

is carried up to  $U-1$  and  $V-1$  only, since  $W_{v,u}^T$  vanishes at  $u = U$  for all values of  $v$ , and at  $v = 1$  and  $v = V$  for all values of  $u$ .

In accord with Eq. (5-6) we then have

$$\underline{C}_1(t) \quad (5-7)$$

$$= \sum_{v=2}^{V-1} \sum_{u=1}^{U-1} W_{v,u}^T \left( \underline{F}_{-v-1,u-1}(t)V_1 + \underline{F}_{-v-1,u}(t)V_2 + \underline{F}_{-v,u-1}(t)V_3 + \underline{F}_{-v,u}(t)V_4 \right)$$

where  $\underline{F}_{-v,u}(t)$  is the constant quantity involving cross sections within the  $(v,u)^{th}$  mesh volume at time  $t$ ; and

$$V_1 = \Delta\theta \frac{h_{v-1}}{2} \cdot \frac{h_{u-1}}{2} \left( r - \frac{h_{u-1}}{4} \right), \quad (5-8)$$

$$\text{with } r = \sum_{u=1}^{U-1} h_u,$$

$$V_2 = \Delta\theta \frac{h_{v-1}}{2} \cdot \frac{h_u}{2} \left( r + \frac{h_u}{4} \right), \quad (5-9)$$

$$V_3 = \Delta\theta \frac{h_v}{2} \cdot \frac{h_{u-1}}{2} \left( r - \frac{h_{u-1}}{4} \right), \quad (5-10)$$

$$V_4 = \Delta\theta \frac{h_v}{2} \cdot \frac{h_u}{2} \left( r + \frac{h_u}{4} \right). \quad (5-11)$$

In addition, the cross sections at the left-hand side of the center line are taken to be zero.

Integrating Eq. (5-7) over the angle ( $\theta$  from 0 to  $2\pi$ ) and using the expressions (5-9), (5-10), and (5-11), we arrive at

$$\underline{C}_1(t) = \frac{\pi}{2} \sum_{v=2}^{V-1} \sum_{u=1}^{U-1} W_{v,u}^T \left\{ \left( \underline{F}_{v-1,u-1}(t) h_{v-1} h_{u-1} + \underline{F}_{v,u-1}(t) h_v h_{u-1} \right) \left[ r - \frac{h_{u-1}}{4} \right] + \left( \underline{F}_{v-1,u}(t) h_{v-1} h_u + \underline{F}_{v,u}(t) h_v h_u \right) \left[ r + \frac{h_u}{4} \right] \right\}. \quad (5-12)$$

#### 5-2 Calculation of $\underline{C}_2(t)$

$\underline{C}_2(t)$  is an  $I \times I$  matrix ( $I$  being the number of expansion modes) composed of elements:

$$\underline{C}_{2,ik}(t) = 2\pi \int_{r, \text{reactor}} r dr \int_{z, \text{reactor}} dz W_1^T(r, z) \left[ \nabla \cdot D(r, z, t) \nabla \psi_k(r, z) \right], \quad (5-13)$$

$$i = 1, 2, \quad k = 1, 2.$$

We know from the previous chapter (Eq. (4-19)) that the two  $\psi_k(r, z)$ 's are the solutions of

$$\left[ \nabla \cdot D_k(r, z) \nabla - A'_k(r, z) + \frac{F_k(r, z)}{k_k} \right] \psi_k(r, z) = 0, \quad k = 1, 2 \quad (5-14)$$

Because of the assumed spatial independence of  $D(r, z, t)$  in the  $b^{\text{th}}$  submesh volume around the mesh point  $(v, u)$ , we

can write

$$\nabla \cdot D(r, z, t) \nabla \psi_k(r, z) = D_{b_{v,u}}(t) \nabla \cdot \nabla \psi_k(r, z), \quad (5-15)$$

but also from Eq. (5-14),

$$D_{k_{b_{v,u}}} \nabla \cdot \nabla \psi_k(r, z) = \left[ A'_{k_{b_{v,u}}} - \frac{F_{k_{b_{v,u}}}}{k_k} \right] \psi_k(r, z). \quad (5-16)$$

Thus, combining Equations (5-15) and (5-16), we have in the  $b^{\text{th}}$  submesh volume around the mesh point  $(v, u)$

$$\nabla \cdot D(r, z, t) \nabla \psi_k(r, z) = D_{b_{v,u}}(t) D_{k_{b_{v,u}}}^{-1} \left[ A'_{k_{b_{v,u}}} - \frac{1}{k_k} F_{k_{b_{v,u}}} \right] \psi_k(r, z), \quad (5-17)$$

such that, through Eq. (5-12),

$$C_2(t) = \frac{\pi}{2} \sum_{v=2}^{V-1} \sum_{u=1}^{U-1} W_{v,u}^T \quad \text{row} \left\{ \right. \quad (5-18)$$

$$\left[ \left( D_{v-1,u-1}(t) M_{k_{v-1,u-1}} h_{v-1} + D_{v,u-1}(t) M_{k_{v,u-1}} h_v \right) h_{u-1} \left( r - \frac{h_{u-1}}{4} \right) + \left( D_{v-1,u}(t) M_{k_{v-1,u}} h_{v-1} + D_{v,u}(t) M_{k_{v,u}} h_v \right) h_u \left( r + \frac{h_u}{4} \right) \right] \psi_{k_{v,u}}$$

where  $\text{row} \{ \}$  denotes the row matrix whose  $k^{\text{th}}$  ( $k=1, \dots, K$ ) element stands in between  $\{ \}$ . (Note that this element is

a  $G \times 1$  matrix), and

$$M_{k_{b_{v,u}}} = D_{k_{b_{v,u}}}^{-1} \left( A_{k_{b_{v,u}}} - \frac{F_{k_{b_{v,u}}}}{k_k} \right). \quad (5-19)$$

The column vector  $D_{b_{v,u}}(t) M_{k_{b_{v,u}}} \psi_{k_{v,u}}$  encountered

in Eq. (5-18) when written explicitly is

(5-20)

$$D_{b_{v,u}}(t) M_{k_{b_{v,u}}} \psi_{k_{v,u}} = \left[ \begin{array}{l} \left[ \left[ \Sigma_{a1k_{b_{v,u}}} + \Sigma_{21k_{b_{v,u}}}^* - \frac{v\Sigma_{F1k_{b_{v,u}}}}{k_k} \right] \psi_{1k_{v,u}} - \frac{v\Sigma_{F2k_{b_{v,u}}}}{k_k} \psi_{2k_{v,u}} \right. \\ \left. - \frac{v\Sigma_{F3k_{b_{v,u}}}}{k_k} \psi_{3k_{v,u}} \right] \frac{D_{1b_{v,u}}(t)}{D_{1k_{b_{v,u}}}} \\ \left[ - \Sigma_{21k_{b_{v,u}}}^* \psi_{1k_{v,u}} + \left[ \Sigma_{a2k_{b_{v,u}}} + \Sigma_{32k_{b_{v,u}}}^* \right] \psi_{2k_{v,u}} \right] \frac{D_{1b_{v,u}}(t)}{D_{1k_{b_{v,u}}}} \\ \left[ - \Sigma_{32k_{b_{v,u}}}^* \psi_{2k_{v,u}} + \Sigma_{a3k_{b_{v,u}}} \psi_{3k_{v,u}} \right] \frac{D_{3b_{v,u}}(t)}{D_{3k_{b_{v,u}}}} \end{array} \right]$$

The  $\underline{C}_{2_{ik}}(t)$  can be presented as

(5-21)

$$\underline{C}_{2_{ik}}(t) \equiv \text{LAP}_{ik}(t) = \frac{\pi}{2} \sum_{v=2}^{V-1} \sum_{u=1}^{U-1} \left[ W_{i1_{v,u}} X_{1k_{v,u}}(t) + W_{i2_{v,u}} X_{2k_{v,u}}(t) + W_{i3_{v,u}} X_{3k_{v,u}}(t) \right],$$

where the notation  $\text{LAP}_{ik}(t)$  (cf. laplacian) is introduced with

(5-22)

$$\begin{aligned} & X_{1k_{v,u}}(t) \\ &= \left\{ \left[ \left( \Sigma_{a_{1k_{v-1,u-1}}} + \Sigma_{\xi_{2_{1k_{v-1,u-1}}} - \frac{v\Sigma_{F_{1k_{v-1,u-1}}}}{k_k} \right) \text{COEF}_{1k_{v-1,u-1}}(t) h_{v-1} \right. \right. \\ &+ \left. \left[ \left( \Sigma_{a_{1k_{v,u-1}}} + \Sigma_{\xi_{2_{1k_{v,u-1}}} - \frac{v\Sigma_{F_{1k_{v,u-1}}}}{k_k} \right) \text{COEF}_{1k_{v,u-1}}(t) h_v \right] h_{u-1} \left( r - \frac{h_{u-1}}{4} \right) \right. \\ &+ \left. \left[ \left( \Sigma_{a_{1k_{v-1,u}}} + \Sigma_{\xi_{2_{1k_{v-1,u}}} - \frac{v\Sigma_{F_{1k_{v-1,u}}}}{k_k} \right) \text{COEF}_{1k_{v-1,u}}(t) h_{v-1} \right. \right. \\ &+ \left. \left[ \left( \Sigma_{a_{1k_{v,u}}} + \Sigma_{\xi_{2_{1k_{v,u}}} - \frac{v\Sigma_{F_{1k_{v,u}}}}{k_k} \right) \text{COEF}_{1k_{v,u}}(t) h_v \right] h_u \left( r + \frac{h_u}{4} \right) \right] \left. \right\} \psi_{1k_{v,u}} \\ &- \left[ \left( v\Sigma_{F_{2k_{v-1,u-1}}} \text{COEF}_{1k_{v-1,u-1}}(t) h_{v-1} + v\Sigma_{F_{2k_{v,u-1}}} \text{COEF}_{1k_{v,u-1}}(t) h_v \right) \right. \\ &h_{u-1} \left( r - \frac{h_{u-1}}{4} \right) + \end{aligned}$$

(equation continued on next page)

$$+ \left[ v \Sigma_{F2} \text{COEF}_{1k_{v-1,u}}^{(t)h_{v-1}} + v \Sigma_{F2} \text{COEF}_{1k_{v,u}}^{(t)h_v} \right] h_u \left( r + \frac{h_u}{4} \right)$$

$$\frac{1}{k_k} \psi_{2k_{v,u}}$$

$$- \left[ \left( v \Sigma_{F3} \text{COEF}_{1k_{v-1,u-1}}^{(t)h_{v-1}} + v \Sigma_{F3} \text{COEF}_{1k_{v,u-1}}^{(t)h_v} \right) \right]$$

$$h_{u-1} \left( r - \frac{h_{u-1}}{4} \right)$$

$$+ \left[ v \Sigma_{F3} \text{COEF}_{1k_{v-1,u}}^{(t)h_{v-1}} + v \Sigma_{F3} \text{COEF}_{1k_{v,u}}^{(t)h_v} \right] h_u \left( r + \frac{h_u}{4} \right)$$

$$\frac{1}{k_k} \psi_{3k_{v,u}}$$

where

$$\text{COEF}_{1k_{b_{v,u}}}(t) = \frac{D_{1b_{v,u}}(t)}{D_{1k_{b_{v,u}}}}, \quad (5-23)$$

$$\begin{aligned}
 & X_{2k_{v,u}}(t) \\
 &= - \left[ \left( \Sigma_{21k_{v-1,u-1}}^* \text{COEF}_{2k_{v-1,u-1}}(t)h_{v-1} + \Sigma_{21k_{v,u-1}}^* \text{COEF}_{2k_{v,u-1}}(t)h_v \right) \right. \\
 & \quad \left. h_{u-1} \left( r - \frac{h_{u-1}}{4} \right) + \left( \Sigma_{21k_{v-1,u}}^* \text{COEF}_{2k_{v-1,u}}(t)h_{v-1} + \Sigma_{21k_{v,u}}^* \text{COEF}_{2k_{v,u}}(t)h_v \right) \right. \\
 & \quad \left. h_u \left( r + \frac{h_u}{4} \right) \right] \psi_{1k_{v,u}} + \left\{ \left[ \left( \Sigma_{a_{2k_{v-1,u-1}}} + \Sigma_{32k_{v-1,u-1}}^* \right) \text{COEF}_{2k_{v-1,u-1}}(t)h_{v-1} \right. \right. \\
 & \quad \left. \left. + \left( \Sigma_{a_{2k_{v,u-1}}} + \Sigma_{32k_{v,u-1}}^* \right) \text{COEF}_{2k_{v-1,u-1}}(t)h_v \right] h_{u-1} \left( r - \frac{h_{u-1}}{4} \right) \right. \\
 & \quad \left. + \left[ \left( \Sigma_{a_{2k_{v-1,u}}} + \Sigma_{32k_{v-1,u}}^* \right) \text{COEF}_{2k_{v-1,u}}(t)h_{v-1} \right. \right. \\
 & \quad \left. \left. + \left( \Sigma_{a_{2k_{v,u}}} + \Sigma_{32k_{v,u}}^* \right) \text{COEF}_{2k_{v,u}}(t)h_v \right] h_u \left( r + \frac{h_u}{4} \right) \right\} \psi_{2k_{v,u}},
 \end{aligned}$$

and,

$$\begin{aligned}
 & X_{3k_{v,u}}(t) \\
 &= - \left[ \left( \Sigma_{32k_{v-1,u-1}}^{\dagger} \text{COEF}_{3k_{v-1,u-1}}(t)h_{v-1} + \Sigma_{32k_{v,u-1}}^{\dagger} \text{COEF}_{3k_{v,u-1}}(t)h_v \right) \right. \\
 & \quad \left. h_{u-1} \left( r - \frac{h_{u-1}}{4} \right) + \left( \Sigma_{32k_{v-1,u}}^{\dagger} \text{COEF}_{3k_{v-1,u}}(t)h_{v-1} + \Sigma_{32k_{v,u}}^{\dagger} \text{COEF}_{3k_{v,u}}(t)h_v \right) \right. \\
 & \quad \left. h_u \left( r + \frac{h_u}{4} \right) \right] \psi_{2k_{v,u}} + \left[ \left( \Sigma_{a3k_{v-1,u-1}} \text{COEF}_{3k_{v-1,u-1}}(t)h_{v-1} \right. \right. \\
 & \quad \left. \left. + \Sigma_{a3k_{v,u-1}} \text{COEF}_{3k_{v,u-1}}(t)h_v \right) h_{u-1} \left( r - \frac{h_{u-1}}{4} \right) \right. \\
 & \quad \left. + \left( \Sigma_{a3k_{v-1,u}} \text{COEF}_{3k_{v-1,u}}(t)h_{v-1} + \Sigma_{a3k_{v,u}} \text{COEF}_{3k_{v,u}}(t)h_v \right) h_u \left( r + \frac{h_u}{4} \right) \right] \psi_{3k_{v,u}}
 \end{aligned}$$

5-3 A different approach to the leakage integral for a special case

The indirect method just described avoids the use of the finite difference technique to determine the laplacian part of  $C_{2,1k}(t)$ . However, a direct approach to the leakage

integral is necessary when we want to compute  $k_k$ , the eigenvalue of the balance equation for  $\psi_k$  (cf. Eq. (4-18)). That quantity was assumed to be known in the course of the previous section.

Thus we want to compute

$$\underline{L}_k = \int_{V_1, \text{reactor}} dr \quad W_1^T(\underline{r}) \nabla \cdot D_k(\underline{r}) \psi_k(\underline{r}). \quad (5-26)$$

With the help of Fig. 5-1, Eq. (5-26) can be written as

$$\begin{aligned} \underline{L}_k &= \sum_{v=2}^{V-1} \sum_{u=1}^{U-1} W_{1,v,u}^T \left[ D_{k_{v-1,u-1}} 2\pi \int_{V_1} r dr \int_{V_1} dz \nabla \cdot \nabla \psi_k(r,z) \right. \\ &+ D_{k_{v-1,u}} 2\pi \int_{V_2} r dr \int_{V_2} dz \nabla \cdot \nabla \psi_k(r,z) \\ &+ D_{k_{v,u-1}} 2\pi \int_{V_3} r dr \int_{V_3} dz \nabla \cdot \nabla \psi_k(r,z) \\ &\left. + D_{k_{v,u}} 2\pi \int_{V_4} r dr \int_{V_4} dz \nabla \cdot \nabla \psi_k(r,z) \right]. \end{aligned} \quad (5-27)$$

By the divergence theorem the integrals in Eq. (5-27) can be reduced to surface integrals of  $\frac{\partial \psi_k}{\partial n}(r,z)$  (the derivative of  $\psi_k(r,z)$  in the direction of outward normal

to the surface) over the six surfaces which enclose the equivalent mesh volume.

Making this transformation on, for instance, the second integral in Eq. (5-27) yields

$$\begin{aligned}
 & 2\pi \int_{V_2} r dr \int_{V_2} dz \nabla \cdot \nabla \psi(r, z) \quad (5-28) \\
 &= \int_{S_1} \frac{\partial \psi(r, z)}{\partial n} dS + \int_{S_2} \frac{\partial \psi(r, z)}{\partial n} dS + \int_{S_9} \frac{\partial \psi(r, z)}{\partial n} dS \\
 &+ \int_{S_{10}} \frac{\partial \psi(r, z)}{\partial n} dS.
 \end{aligned}$$

Since the neutron current,  $D_{gk}(r, z) \frac{\partial \psi_{gk}(r, z)}{\partial n}$  is assumed to be continuous across interfaces, the surface integrals over the common surfaces to the submesh volumes cancel when the four expressions similar to Eq. (5-28) are added. Then Eq. (5-27) becomes,

$$\begin{aligned}
 \underline{L}_k &= \sum_{v=2}^{V-1} \sum_{u=1}^{U-1} W_{1v,u}^T \left[ D_{kv-1,u} \sum_{b=1}^2 \int_{S_b} \frac{\partial \psi_k(r, z)}{\partial n} dS \right. \\
 &+ D_{kv-1,u-1} \sum_{b=3}^4 \int_{S_b} \frac{\partial \psi_k(r, z)}{\partial n} dS + D_{kv,u-1} \sum_{b=5}^6 \int_{S_b} \frac{\partial \psi_k(r, z)}{\partial n} dS \left. \right] \quad (5-29)
 \end{aligned}$$

(equation continued on next page)

$$+ D_{k_{v,u}} \sum_{b=7}^8 \int_{S_b} \frac{\partial \psi_k(r,z)}{\partial n} dS .$$

(5-29)  
cont.

Next we let  $I_{p_k}$  stand for  $\int_{S_p} \frac{\partial \psi_k(r,z)}{\partial n} dS$  and note that

$$I_{1k} = \frac{\psi_{k_{v,u+1}} - \psi_{k_{v,u}}}{h_u} \Delta\theta \frac{h_{v-1}}{2} \left( r + \frac{h_u}{2} \right), \quad (k=1,2), \quad (5-30)$$

$$I_{2k} = \frac{\psi_{k_{v-1,u}} - \psi_{k_{v,u}}}{h_{v-1}} \Delta\theta \frac{h_u}{2} \left( r + \frac{h_u}{4} \right), \quad (k=1,2), \quad (5-31)$$

$$I_{3k} = \frac{\psi_{k_{v-1,u}} - \psi_{k_{v,u}}}{h_{v-1}} \Delta\theta \frac{h_{u-1}}{2} \left( r - \frac{h_{u-1}}{4} \right), \quad (k=1,2), \quad (5-32)$$

$$I_{4k} = \frac{\psi_{k_{v,u-1}} - \psi_{k_{v,u}}}{h_{u-1}} \Delta\theta \frac{h_{v-1}}{2} \left( r - \frac{h_{u-1}}{2} \right), \quad (k=1,2), \quad (5-33)$$

$$I_{5k} = \frac{\psi_{k_{v,u-1}} - \psi_{k_{v,u}}}{h_{u-1}} \Delta\theta \frac{h_v}{2} \left( r - \frac{h_{u-1}}{2} \right), \quad (k=1,2), \quad (5-34)$$

$$I_{6k} = \frac{\psi_{k_{v+1,u}} - \psi_{k_{v,u}}}{h_v} \Delta\theta \frac{h_{u-1}}{2} \left( r - \frac{h_{u-1}}{4} \right), \quad (k=1,2), \quad (5-35)$$

$$I_{7k} = \frac{\psi_{k_{v+1,u}} - \psi_{k_{v,u}}}{h_v} \Delta\theta \frac{h_u}{2} \left( r + \frac{h_u}{4} \right), \quad (k=1,2), \quad (5-36)$$

$$\underline{I}_8_k = \frac{\psi_{k_{v,u+1}} - \psi_{k_{v,u}}}{h_u} \frac{h_v}{2} \left[ r + \frac{h_u}{2} \right], \quad (k=1,2). \quad (5-37)$$

Inserting Equations (5-30) up to (5-37) into Eq. (5-27) and integrating over the angle ( $\theta$  from 0 to  $2\pi$ ) one gets

(5-38)

$$\begin{aligned} \underline{L}_k = & \sum_{v=2}^{V-1} \sum_{u=1}^{U-1} W_{1,v,u}^T \left\{ \frac{\psi_{k_{v,u+1}}}{h_u} \left[ D_{k_{v-1,u}} h_{v-1} + D_{k_{v,u}} h_v \right] \left[ r + \frac{h_u}{2} \right] \right. \\ & + \frac{\psi_{k_{v-1,u}}}{h_{v-1}} \left[ D_{k_{v-1,u}} h_u \left[ r + \frac{h_u}{4} \right] + D_{k_{v-1,u-1}} h_{u-1} \left[ r - \frac{h_{u-1}}{4} \right] \right] \\ & + \frac{\psi_{k_{v,u-1}}}{h_{u-1}} \left[ D_{k_{v-1,u-1}} h_{v-1} + D_{k_{v,u-1}} h_v \right] \left[ r - \frac{h_{u-1}}{2} \right] \\ & + \frac{\psi_{k_{v+1,u}}}{h_v} \left[ D_{k_{v,u-1}} h_{u-1} \left[ r - \frac{h_{u-1}}{4} \right] + D_{k_{v,u}} h_v \left[ r + \frac{h_u}{4} \right] \right] \\ & - \psi_{k_{v,u}} \left[ \left[ D_{k_{v-1,u}} h_{v-1} + D_{k_{v,u}} h_v \right] \frac{1}{h_u} \left[ r + \frac{h_u}{2} \right] + \left[ D_{k_{v-1,u}} h_v \left[ r + \frac{h_u}{4} \right] \right. \right. \\ & \left. \left. + D_{k_{v-1,u-1}} h_{u-1} \left[ r - \frac{h_{u-1}}{4} \right] \right] \frac{1}{h_{v-1}} + \left[ D_{k_{v-1,u-1}} h_{v-1} + D_{k_{v,u-1}} h_v \right] \right\} \times \end{aligned}$$

(equation continued on next page)

$$\times \frac{1}{h_{u-1}} \left( r - \frac{h_{u-1}}{2} \right) \left\{ D_{k_{v,u-1}} h_{u-1} \left( r - \frac{h_{u-1}}{4} \right) + D_{k_{v,u}} h_u \left( r + \frac{h_u}{4} \right) \right\} \frac{1}{h_v} \Bigg\} .$$

This method of evaluating the leakage integral has not been used to calculate  $C_2(t)$  because we cannot insure that it is valid to write relationships such as

$$D_{g_k}^L (r, z, t) \frac{\partial \psi_{gk}(r, z)}{\partial n} = D_{g_k}^R (r, z, t) \frac{\partial \psi_{gk}}{\partial n} \tag{5-39}$$

with L and R indicating the left and right hand sides of an interface, respectively, and n being either r or z.

Whereas with a diffusion coefficient belonging to the space function in question, an equation like Eq. (5-39) is true, it will not in general hold for any other diffusion coefficient. Hence we had to work out the method described in the previous section.

5-4 Computation of  $k_k$

The calculation of  $C_2(t)$  cannot be completed unless  $k_k$  is known. For this purpose, besides the leakage integral [Eq. (5-38)] we need the fission and absorption integrals. These quantities are given by

$$\begin{aligned}
\underline{F}_k &= \frac{\pi}{2} \sum_v \sum_u \quad W_{11v,u} \quad v \left( \left( \left( \begin{array}{c} \Sigma_{F1k_{v-1,u-1}} h_{v-1} + \Sigma_{F1k_{v,u-1}} h_v \\ 85 \end{array} \right) \right. \right. \\
&\quad \text{over the core} \\
&h_u \left( r - \frac{h_{u-1}}{4} \right) + \left( \Sigma_{F1k_{v-1,u}} h_{v-1} + \Sigma_{F1k_{v,u}} h_v \right) h_u \left( r + \frac{h_u}{4} \right) \left. \right) \psi_{1k_{v,u}} \\
&+ \left( \left( \Sigma_{F2k_{v-1,u-1}} h_{v-1} + \Sigma_{F2k_{v,u-1}} h_v \right) h_u \left( r - \frac{h_{u-1}}{4} \right) \right. \\
&+ \left. \left( \Sigma_{F2k_{v-1,u}} h_{v-1} + \Sigma_{F2k_{v,u}} h_v \right) h_u \left( r + \frac{h_u}{4} \right) \right) \psi_{2k_{v,u}} \\
&+ \left( \left( \Sigma_{F3k_{v-1,u-1}} h_{v-1} + \Sigma_{F3k_{v,u-1}} h_v \right) h_u \left( r - \frac{h_{u-1}}{4} \right) \right. \\
&+ \left. \left( \Sigma_{F3k_{v-1,u}} h_{v-1} + \Sigma_{F3k_{v,u}} h_v \right) h_u \left( r + \frac{h_u}{4} \right) \right) \psi_{3k_{v,u}} \left. \right), \quad (5-40)
\end{aligned}$$

(5-41)

$$\underline{A} = \frac{\pi}{2} \sum_{v=2}^{V-1} \sum_{u=2}^{U-1} \left( W_{11v,u} Z_{1k_{v,u}} W_{12v,u} Z_{2k_{v,u}} W_{13v,u} Z_{3k_{v,u}} \right)$$

where  $Z_{1k_{v,u}}$ ,  $Z_{2k_{v,u}}$ , and  $Z_{3k_{v,u}}$  can be found from

Equations (5-23), (5-24), and (5-25) by taking out the terms involving the fission cross sections, omitting

COEF  $\beta_{k_b}$ 's and changing the signs.

Finally we have

$$k_k = \frac{F_{-k}}{A_{-k} - L_{-k}} \quad (5-42)$$

5-5 Final expressions for the parameters  $\Lambda$ ,

$$\rho_{\text{new}}(t), \bar{\beta}_{j_{\text{new}}}(t)$$

Using the final integral expressions found for  $\Lambda$ ,  $\rho_{\text{new}}(t)$ , and  $\bar{\beta}_{j_{\text{new}}}(t)$ 's in Chapter III, and Equations (5-12)

and (5-21), one obtains

(5-43)

$$\Lambda_{ik} = \frac{\pi}{2} \sum_{v=2}^{V-1} \sum_{u=1}^{U-1} \left( \sum_{g=1}^G W_{ig_{v,u}} \psi_{kg_{v,u}}^{v-1} \right) \left[ \left( h_{v-1} + h_v \right) h_{u-1} \left( r - \frac{h_{u-1}}{4} \right) + \left( h_{v-1} + h_v \right) h_u \left( r + \frac{h_u}{4} \right) \right],$$

$$\rho_{\text{new}_{ik}}(t) = \text{PPR}_{ik}(t) + \text{LAP}_{ik}(t) + \text{FMA}_{ik}(t) + \text{DPR}_{ik}(t), \quad (5-44)$$

where the prompt photoneutron reactivity matrix is defined by its  $i^{\text{th}}$  row,  $k^{\text{th}}$  column element;

$$\begin{aligned}
 & \text{PPR}_{ik}(t) \tag{5-45} \\
 &= \frac{\pi}{2} \sum_{re=1}^{\text{RE}} \text{ATT}_{re} \sum_{\substack{v \\ \text{over the reflector}}} \sum_u W_{il_{v,u}} \left\{ \sum_{\ell=1}^L \right. \\
 & \left[ \left( \Sigma_{D_{\ell_{v-1,u-1}}} (t) h_{v-1} + \Sigma_{D_{\ell_{v,u-1}}} (t) h_v \right) h_{u-1} \left( r - \frac{h_{u-1}}{4} \right) \right. \\
 & \left. + \left( \Sigma_{D_{\ell_{v-1,u}}} (t) h_{v-1} + \Sigma_{D_{\ell_{v,u}}} (t) h_v \right) h_u \left( r + \frac{h_u}{4} \right) \right] \\
 & \times \frac{\pi}{2} \sum_{v=2}^{V-1} \sum_{u=1}^{U-1} \sum_{g=1}^G \left[ \left[ \left[ \text{SGCS}_{g_{\ell_{v-1,u-1}}} (t) h_{v-1} \right. \right. \right. \\
 & \left. \left. + \text{SGCS}_{g_{\ell_{v,u-1}}} (t) h_v \right] h_{u-1} \left( r - \frac{h_{u-1}}{4} \right) + \left[ \text{SGCS}_{g_{\ell_{v-1,u}}} (t) h_{v-1} \right. \right. \right. \\
 & \left. \left. + \text{SGCS}_{g_{\ell_{v,u}}} (t) h_v \right] h_u \left( r + \frac{h_u}{4} \right) \right] \left. \right\} \psi_{gk_{v,u}}
 \end{aligned}$$

RE being the number of regions in the reflector, each coupled with a constant attenuation factor for photons to simplify the computation. That is,  $ATT_{re}$  replaces

$$\frac{1}{4\pi(r^2+z^2)} e^{-\Sigma_{\ell}(r^2+z^2)^{\frac{1}{2}}} \quad \text{within the } re^{th} \text{ region (cf. Appendix H); and}$$

$$SGCS_{g\ell_{v,u}}(t) = \sum_{f=1}^3 \Sigma_f \left( \prod_{\ell}^n g_{v,u} \right); \quad (5-46)$$

where  $n$  stands for the nuclei  $n$  present at  $(v,u)$ . The computation of  $LAP_{ik}(t)$  is described in Section 5-2 above; and  $FMA_{ik}(t)$  can be found from the expression for  $LAP_{ik}(t)$  by omitting  $COEF_{g_{kb}}$ 's and the dependency

of the cross sections on  $k$ , making the cross sections time-dependent and changing all the signs.

The delayed photoneutron reactivity matrix is defined by its  $i^{th}$  row,  $k^{th}$  column element;

$$DPR_{ik}(t) = \sum_{j=J+1}^H \bar{\beta}_{j_{new_{ik}}}(t), \quad (5-47)$$

with

$$\begin{aligned}
\bar{\beta}_{j_{\text{new}_{1k}}}(t) &= \frac{\pi}{2} y_j N_0 \sum_{re=1}^{\text{RE}} \text{ATT}_{re} \sum_{\mathbf{v}} \sum_{\mathbf{u}} W_{11_{\mathbf{v},\mathbf{u}}} \left\{ \sum_{\ell=1}^L Y_{\ell} \right. \\
&\quad \left. \left[ \left( \Sigma_{D_{\mathbf{v}-1,\mathbf{u}-1}}(t) h_{\mathbf{v}-1} + \Sigma_{D_{\mathbf{v},\mathbf{u}-1}}(t) h_{\mathbf{v}} \right) h_{\mathbf{u}-1} \left( r - \frac{h_{\mathbf{u}-1}}{4} \right) \right. \right. \\
&\quad \left. \left. + \left( \Sigma_{D_{\mathbf{v}-1,\mathbf{u}}}(t) h_{\mathbf{v}-1} + \Sigma_{D_{\mathbf{v},\mathbf{u}}}(t) h_{\mathbf{v}} \right) h_{\mathbf{u}} \left( r + \frac{h_{\mathbf{u}}}{4} \right) \right] \right. \\
&\quad \times \frac{\pi}{2} \sum_{\mathbf{v}} \sum_{\mathbf{u}} \left[ \sum_{g=1}^G \nu \left[ \left( \Sigma_{F_{\mathbf{g}\mathbf{v}-1,\mathbf{u}-1}}(t) h_{\mathbf{v}-1} \right. \right. \right. \\
&\quad \left. \left. + \Sigma_{F_{\mathbf{g}\mathbf{v},\mathbf{u}-1}}(t) h_{\mathbf{v}} \right) h_{\mathbf{u}-1} \left( r - \frac{h_{\mathbf{u}-1}}{4} \right) + \left( \Sigma_{F_{\mathbf{g}\mathbf{v}-1,\mathbf{u}}} \right. \right. \\
&\quad \left. \left. + \Sigma_{F_{\mathbf{g}\mathbf{v},\mathbf{u}}} \right) h_{\mathbf{u}} \left( r + \frac{h_{\mathbf{u}}}{4} \right) \right] \right] \psi_{gk_{\mathbf{v},\mathbf{u}}}, \quad (j = (g+1), \dots, H).
\end{aligned}$$

We finally have,

(5-49)

$$\bar{\beta}_{j_{\text{new}_{1k}}}(t) = \bar{\beta}_j \frac{\pi}{2} \sum_{\mathbf{v}} \sum_{\mathbf{u}} W_{11_{\mathbf{v},\mathbf{u}}} \nu \left[ \left[ \left( \Sigma_{F_{1_{\mathbf{v}-1,\mathbf{u}-1}}}(t) h_{\mathbf{v}-1} \right. \right. \right.$$

(equation continued on next page)

$$\begin{aligned}
& + \Sigma_{F_{1v,u-1}}^{(t)h_v} h_{u-1} \left( r - \frac{h_{u-1}}{4} \right) + \left( \Sigma_{F_{1v-1,u}}^{(t)h_{v-1}} \right. \\
& + \Sigma_{F_{1v,u}}^{(t)h_v} h_u \left( r + \frac{h_u}{4} \right) \left. \right) \psi_{1k_{v,u}} + \left( \left( \Sigma_{F_{2v-1,u-1}}^{(t)h_{v-1}} \right. \right. \\
& + \Sigma_{F_{2v,u-1}}^{(t)h_v} h_{u-1} \left( r - \frac{h_{u-1}}{4} \right) + \left( \Sigma_{F_{2v-1,u}}^{(t)h_{v-1}} \right. \\
& + \Sigma_{F_{2v,u}}^{(t)h_v} h_u \left( r + \frac{h_u}{4} \right) \left. \right) \psi_{2k_{v,u}} + \left( \left( \Sigma_{F_{3v-1,u-1}}^{(t)h_{v-1}} \right. \right. \\
& + \Sigma_{F_{3v,u-1}}^{(t)h_v} h_{u-1} \left( r - \frac{h_{u-1}}{4} \right) + \left( \Sigma_{F_{3v-1,u}}^{(t)h_{v-1}} \right. \\
& + \Sigma_{F_{3v,u}}^{(t)h_v} h_u \left( r + \frac{h_u}{4} \right) \left. \right) \psi_{3k} \left. \right), \quad (j = 1, \dots, J).
\end{aligned}$$

5-6 Computation of  $k_{OZAN}^*$  for  $\rho_{new_{11}}(0)$

For clarity assume we have only one expansion mode (point kinetics case) that is composed of the steady state shape of the reactor and the reactor is critical. Had then  $\rho_{new_{11}}$  [Eq.(5-44)] failed to vanish, the time-dependent

---

\* OZAN is the name of the computer code written to perform calculations required by the present work.

equations will predict a change in the power level that must remain constant. To remedy this erroneous behavior we shall compute a quantity  $k_{OZAN}$  that divides the fission integral in Eq. (5-44), and insures that  $\rho_{new_{11}}(0) = 0$ . Thus if the reactor is critical at the beginning of the transient we define

$$k_{OZAN} = \frac{F_{11}(0)}{A_{11}(0) - [LAP_{11}(0) + PPR_{11}(0) + DPR_{11}(0)]} \quad (5-50)$$

with

$$F_{11}(t) - A_{11}(t) = FMA_{11}(t). \quad (5-51)$$

Note that in case the photoneutrons are neglected  $k_{OZAN} \equiv k_1$  [cf. Eq. (4-18)].

We point out that while  $k$  ( $k = 1, 2$ ) was introduced to make use of the balance equation furnishing  $\psi_k(\underline{r})$  in order to compute  $LAP_{ik}(t)$  [Eq. (5-21)],  $k_{OZAN}$  is physically the eigenvalue of the reactor (at  $t = 0$ ), computed in an integral sense. Hence the fission cross sections of the critical reactor are supposed to be equal to

$$\frac{\Sigma_{F_1}(\underline{r})}{k_{OZAN}}.$$

5-7 Representation of the time dependency of the parameters  $\rho_{\text{new}}(t)$  and  $\bar{\beta}_{j_{\text{new}}}(t)$ 's

The solution to the system of equations for the time coefficients will require analytical representations for the parameters  $\rho_{\text{new}}(t)$  and  $\bar{\beta}_{j_{\text{new}}}(t)$ 's. For this purpose we shall assume that throughout the transient

$$\rho_{\text{new}}(t) = \rho_{\text{new}}(0) + \rho_1 t, \quad (5-52)$$

$$\bar{\beta}_{j_{\text{new}}}(t) = \bar{\beta}_{j_{\text{new}}}(0) + \bar{\beta}_{j_1} t, \quad (j = 1, \dots, H), \quad (5-53)$$

where  $\rho_{\text{new}}(0)$  and  $\bar{\beta}_{j_{\text{new}}}(0)$  are the initial values of  $\rho_{\text{new}}(t)$  and  $\bar{\beta}_{j_{\text{new}}}(t)$ , and

$$\rho_1 = \frac{\rho_{\text{new}}(T) - \rho_{\text{new}}(0)}{T}, \quad (5-54)$$

$$\bar{\beta}_{j_1} = \frac{\bar{\beta}_{j_{\text{new}}}(T) - \bar{\beta}_{j_{\text{new}}}(0)}{T}, \quad (5-55)$$

where  $T$  in seconds is the duration of the transient beginning at  $t = 0$ .

## 5-8 Summary

In this chapter we have developed a method for computing various parameters appearing in the equations for the unknown time coefficients. For this purpose a finite difference technique is used in keeping with the way the spatial functions are computed.

The leakage part of the reactivity matrix requires a special treatment since the time-dependent diffusion coefficient in the desired integral is not the one associated with the expansion modes and the continuity condition across interfaces fails. This procedure, however, requires knowing the eigenvalue that balances the equation from which the trial mode is generated. In calculating this eigenvalue we were able to use a direct way of attacking the leakage integral.

If the reactor was critical at the beginning of the transient and the photoneutrons were felt to be significant, it was then necessary to introduce an eigenvalue  $k_{OZAN}$  so that the initial value of the first element of the reactivity matrix vanishes. Thus  $k_{OZAN}$  is the eigenvalue of the reactor (at  $t = 0$ ).

## CHAPTER VI

### A PROBLEM HANDLED BY THE PROPOSED METHOD

To compare the proposed synthesis method (use of two spatial modes in the expansion of the space and time dependent flux) with the point kinetics type of approach (use of only one spatial mode for the same expansion), we have considered the following problem:

The MITR-II operator loses control on the shim rods during the start up of the reactor. It is assumed that all six shim blades begin moving out at once rather than the usual operation of a single blade at a time. - It is worthwhile to mention that this is a very improbable accident, involving a simultaneous short circuit of six contacts. - That is the bank of shim rods starts from its shutdown position - corresponding to a  $-0.12$  of reactivity (we will further clarify what we mean by the word "reactivity") - going up with a constant insertion rate,  $0.003$  in reactivity per sec. (that notion of ramp insertion of reactivity will also be further clarified).

The bank continues going up until the reactor reaches the power level of  $6$  MW (assuming even further that the high rate-of-rise shut down system does not operate). Once the powermeter reads  $6$  MW, the shim rods receive automatically the order to scram. However there is a delay of

0.1 sec. due to the instrumentation. That is from 6 MW on the power level will continue to increase for 0.1 second more. The question is: What will be the maximum power level of the reactor during this incident?

#### 6-1 Further Theoretical Preparations

There are a number of hidden difficulties, that we must overcome to be able to attack the problem by our proposed method. All of these difficulties, except one, are due to the fact that the reactor is subcritical at the beginning of the transient.

The first difficulty involves the fact that we need an external source to start up the reactor. Yet nowhere in the course of the development of the proposed method have we taken into account an external source.

##### 6-1-1 Overcoming the Difficulty Due to the Presence of an External Source

Adding an external source term to the diffusion equation (3-1) and carrying out the calculations from there is impractical. Instead we found it easier to describe the source by the activity of a fictitious delayed neutron precursor that has a relatively long half life. The strength of this activity can be computed in the following way:

Consider the point kinetics equations with the familiar notation:

$$\frac{dN_{PK}(t)}{dt} = \frac{\rho_{PK}(t) - \beta_{PK}}{\Lambda_{PK}} N_{PK}(t) + \sum_{j=1}^H \lambda_j C_{PK_j}(t) + S_{PK}, \quad (6-1)$$

$$\frac{dC_{PK_j}(t)}{dt} = \frac{\beta_{PK_j}}{\Lambda_{PK}} N_{PK}(t) - \lambda_j C_{PK_j}(t), \quad (j = 1, \dots, H), \quad (6-2)$$

where the subscript PK stands for point kinetics, and everything is a scalar. At this stage the initial reactivity and the constant reactivity insertion we have pointed out above, should be understood merely as two quantities used to determine  $\rho_{PK}(t)$  - in case of a ramp change. (We will later consider the way they are obtained.)

We take the time origin at the time the reactor becomes critical with the given motion of the rods (i.e.,  $-t_s = 40$  sec. after the transient has started; the initial reactivity being  $-0.12$  and the insertion rate  $0.003$  per sec.). In addition we assume the reactor is at 1 milliwatt power level at the beginning of the transient. That is, 5 MW being the power level of the critical reactor working under normal circumstances, at the start up the power level is,

$$N_{PK}(t_s) = \frac{1 \times 10^{-3}}{5 \times 10^{-6}} = 2 \times 10^{-10}, \quad (6-3)$$

times smaller than the normal power level (5 MW) of the reactor.

Thus assuming that the reactor is at a steady state with the external source in, prior to the change, we obtain from Eq. (6-2)

$$\frac{\beta_{PKj}}{\Lambda_{PK}} N_{PK}(t_s) = \lambda_j C_{PKj}(t_s), \quad (j = 1, \dots, H) \quad (6-4)$$

$$\text{Next with } \left. \frac{dN_{PK}(t)}{dt} \right|_{t_s} = 0, \quad \text{Equations (6-4) and}$$

(6-1) yield (for the source,  $S_{PK}$ , represented as a fictitious precursor concentration,  $C_{PK(H+1)}(t_s)$ , decaying with a time constant,  $\lambda_{H+1}$ )

$$S_{PK} \equiv \lambda_{H+1} C_{PK(H+1)}(t_s) = \frac{-\rho_{PK}(t_s)}{\Lambda_{PK}} N_{PK}(t_s) \quad (6-5)$$

with

$$\beta_{PK(H+1)} = 0 \quad (6-6)$$

We can pick  $\lambda_{H+1}$  as small as we want so that

$$C_{PK(H+1)}(t) = C_{PK(H+1)}(t_s) e^{\lambda_{H+1}(t-t_s)}, \quad (6-7)$$

stays constant throughout the transient. Thus we choose arbitrarily  $\lambda_{H+1} = 1 \times 10^{-13} \text{ sec}^{-1}$ .

$\Lambda_{PK}$  is taken ( $1 \times 10^{-4}$ ), - as it will be justified later - to be the first row, first column element of the generation time matrix [cf. Eq. (3-44)].

Hence we can compute  $C_{PK(H+1)}(t_s)$  (to be

$\frac{0.12 \times 2 \times 10^{-10}}{1 \times 10^{-4} \times 1 \times 10^{-13}} = 2.4 \times 10^6$ ) and express  $S_{PK}$  in terms of the  $(H+1)^{\text{th}}$  fictitious precursor concentration.

### 6-1-2 Selection of the First Spatial Mode

A second difficulty arises when we come to choose a spatial shape to describe the flux at the beginning of the transient. The period of time while the reactor is still subcritical - during the transient - is not of interest. Also the computations may be unnecessarily time consuming if we took a look at the transient with the two-shape method starting subcritical. Thus we choose as the first trial mode the flux shape of the critical reactor, and start

studying the transient with the two-shape method at the time when the reactor becomes - momentarily - critical under the given accident. That, however, brings up a major difficulty:

Since the reactor is not at a steady state when it becomes critical, how do we compute the precursor concentrations at time  $t = 0$  ( $-t_s$  seconds after the transient took off)? This is answered in the next two sections.

#### 6-1-3 Calculation of the Initial Value of the First Precursor Amplitude Function

We need to compute  $C_j(0)$ 's,  $j = 1, \dots, (H+1)$ , of Eq. (3-45).  $C_j(t)$  is a column matrix having two elements in the case of two trial modes. The calculation of the first element will be done in this section whereas we save the calculation of the second element for the next section.

Over the period of time  $t_s \leq t \leq 0$ , only one trial mode (the flux shape of the critical reactor) is used to describe the flux. Then at  $t = 0$  we can write

$$C_{j_1}(0) = \Lambda_{PK} C_{PK_j}(0), [j = 1, \dots, (H+1)], \quad (6-8)$$

where  $C_j(t)$  is the solution of Eq. (3-45),  $C_{PK_j}$  the solution of Eq. (6-2), and the subscript 1 stands for the first element of the column matrix  $C_j(0)$ .

Thus with Equations (6-3), (6-5), (6-6), (6-8) and  $\rho_{PK}(t) = -0.12 + 3 \times 10^{-3}(t-t_s)$ ,  $\Lambda_{PK}(\equiv \Lambda_{11}) \approx 1. \times 10^{-4}$ , the Equations (6-1) and (6-2) will furnish  $C_{j_1}(0)$ 's. For the purpose of the calculation we have run a points kinetics computer code [18] to find  $N_{PK}(0) \equiv N_1(0)$ , the factor that multiplies the power level when the reactor becomes - momentarily - critical under the given accident.

We emphasize that while writing the Equation (6-8), we have tacitly assumed that the reactivity  $\rho_{PK}(t)$  is the same as  $\rho_{new_{11}}(t)$  of Eq. (3-44) for  $t_s \leq t \leq 0$ . That is, for instance, if we computed the reactivity corresponding to "bank of shim rods completely inserted", through Equations (3-41) and (3-29) we assume we would find -0.12 (the number taken above as the negative reactivity of the shutdown reactor). However this is not necessarily true for that reactivity may be determined through other procedures (weighting by unity instead of a weighting function, taking the relative difference of the eigenvalues of the reactor at the shutdown and critical positions - thus abandoning the perturbation type of calculation where the flux shape of the critical reactor is used alone -, etc.).

Now we turn our attention to the second element of the column matrix  $C_j(0)$ .

6-1-4 Calculation of the Initial Value of the  
Second Precursor Amplitude Function

To compute  $C_{j_2}(0)$ ,  $j = 1, \dots, (H+1)$ , we recall through Equations (3-42), (3-43), (3-31) and (3-34)

$$C_{j_i}(t) \equiv D_{j_i} = 2\pi \int_{r, \text{core}} r dr \int_{z, \text{core}} dz W_i^T(r, z) \chi_j \eta_j(r, z, t),$$

$$(i = 1, 2), (j = 1, \dots, J), \quad (6-9)$$

$$C_{j_i}(t) \equiv \theta_{j_i}(t) = 2\pi \int_{r, \text{reflector}} r dr \int_{z, \text{reflector}} dz W_i^T(r, z)$$

$$\theta_j(r, z, t), (i = 1, 2), [j = (J+1), \dots, H],$$

$$(6-10)$$

$$C_{(H+1)_i}(t) = s 2\pi \int_{r, \text{reactor}} r dr \int_{z, \text{reactor}} dz W_i^T(r, z) \chi, (i = 1, 2),$$

$$(6-11)$$

where  $s$  is the constant source spread out uniformly throughout the reactor such that

$$\lambda_{H+1} \frac{C_{(H+1)}}{\Lambda_{11}}(t_s) = S_{PK}, \quad (6-12)$$

first mentioned in Eq. (6-1), and  $\chi$  is defined through Eq. (4-3).

The initial conditions for the undetermined time

coefficients being  $N(t) = \begin{pmatrix} 2 \times 10^{-10} \\ 0 \end{pmatrix}$ , we find it legitimate to assume;

- At times very close to  $t = 0$  ( $t > 0$ ), the second shape contributes practically nothing, and, with one shape and one undetermined time coefficient, it is appropriate to write

$$\eta_j(r, z, t) = M_j(r, z) e^{\omega t}, \quad (j = 1, \dots, J), \quad (6-13)$$

and

$$\theta_j(r, z, t) = T_j(r, z) e^{\omega t}, \quad [j = (J+1), \dots, H], \quad (6-14)$$

-  $\omega$  at times close to  $t = 0$  can be considered independent of  $t$ .

Then one can through Equations (3-45), (6-9), (6-10), (6-13) and (6-14), arrive at

$$C_{j_i}(t) = C_{j_i}(0) e^{\omega t}, \quad (i = 1, 2), \quad (j = 1, \dots, H), \quad (6-15)$$

where

$$C_{j_i}(0) = 2\pi \int_{r, \text{core}} r \, dr \int_{z, \text{core}} dz \, W_i^T(r, z) \chi_j M_j(r, z), \quad (i = 1, 2), \quad (j = 1, \dots, J), \quad (6-16)$$

$$C_{j_i}(0) = 2\pi \int_{r, \text{reflector}} r \, dr \int_{z, \text{reflector}} dz W_i^T(r, z) \times T_j(r, z), \quad (i = 1, 2), \quad [j = (J+1), \dots, H], \quad (6-17)$$

and

$$(\omega + \lambda_j) C_{j_i}(t) = \left( \bar{\beta}_{j_{\text{new}}} (t) N(t) \right)_i, \quad (i = 1, 2), \quad (j = 1, \dots, H), \quad (6-18)$$

where  $C_{j_i}(t)$ ,  $(i = 1, 2)$  and  $\bar{\beta}_{j_{\text{new}}}(t)$ 's,  $(i = 1, 2)$ , were

defined in Chapter III.

Thus taking the ratio of the equation obtained with  $i = 1$ , in Eq. (6-18), to the equation obtained with  $i = 2$ , in Eq. (6-18), we finally have, near time  $t = 0$

$$\frac{C_{j_1}(t)}{C_{j_2}(t)} = \frac{\bar{\beta}_{j_{\text{new}11}}(t)}{\bar{\beta}_{j_{\text{new}21}}(t)}, \quad (j = 1, \dots, H). \quad (6-19)$$

Knowing  $C_{j_1}(0)$ ,  $(j = 1, \dots, H)$ , we then can compute from Eq. (6-19)

$$C_{j_2}^{(0)} = C_{j_1}^{(0)} \frac{\bar{\beta}_{j_{\text{new}21}}^{(0)}}{\bar{\beta}_{j_{\text{new}11}}^{(0)}} \quad (6-20)$$

The calculation of  $C_{(H+1)_2}^{(0)}$  is straightforward

from Eq. (6-11). Taking  $\chi = \begin{pmatrix} 1 \\ 0 \\ 0 \end{pmatrix}$ , we have

$$C_{(H+1)_2}^{(0)} = C_{(H+1)_1}^{(0)} \frac{2\pi \int_{r,\text{reactor}} r dr \int_{z,\text{reactor}} dz W_{12}(r,z)}{2\pi \int_{r,\text{reactor}} dr \int_{z,\text{reactor}} dz W_{11}(r,z)} \quad (6-21)$$

#### 6-1-5 Determination of the Position of the Bank of Shim Rods at the Time the Signal for Scram is Received.

The last difficulty to overcome is how to determine the position of the bank of shim rods at the time the signal for scram is received. We must estimate this position in order to choose the second trial mode for the expansion of the flux (poison search, cf. Chapter IV, section 4-2).

This last question is resolved by using the point kinetics approach. A point kinetics code [18] is applied

in order to determine the time at which  $N_{PK}(t)$  [cf. Eqs. (6-1) and (6-2)] is 1.2, that is the time at which the power level reaches a 6 MW ( $5 \times 1.2$ ) level. We then add 0.1 second to find the time,  $T$ , at which the bank of shim rod will scram. To determine the bank position at that time  $T$ , we write

$$\rho_{PK}(T) = \rho_{PK}(0) + \rho_{1PK} T, \quad (6-22)$$

with  $\rho_{PK}(0) = 0$ . and  $\rho_{1PK} = 3 \times 10^{-3}$  [The terms in Eq. (6-22) are equal to the corresponding first row, first column elements of the matrix equation (5-52).]. Now we consider Fig. 6-1 [19] where for MITR-II the reactivity versus the position of the shim rods bank is shown. Knowing  $\rho_{PK}(T)$  permits us to use this figure to determine the approximate position of the shim bank at time  $T$ . (One should however keep in mind that, the reactivity appearing in Fig. 6-1 does not exactly correspond to that defined previously. The reactivity of Fig. 6-1 was calculated by computing the eigenvalue of the reactor with the bank of shim rods at different positions; then taking the relative difference  $\Delta k/k$  for that position.)

The ramp change slope of the reactivity matrix,  $\rho_1$  [cf. Eq. (5-52)], can be calculated by computing first

Fig. 6-1 The Bank of Shim Rods Worth Curve for MITR-II [19]

$\rho_{\text{new}}(0)$ , the reactivity matrix at time  $t = 0$  (the time the reactor becomes momentarily critical and we begin studying the transient with the two-trial mode method); next by determining the reactivity matrix at time  $T$ , through the integral expression for reactivity formulated in Chapter III, and finally by writing

$$\rho_1 = \frac{\rho_{\text{new}}(T) - \rho_{\text{new}}(0)}{T} . \quad (6-23)$$

We note that within our scheme of attacking the transient if only one trial mode is chosen to describe the spatial shape of the flux we will use for the ramp change slope of the reactivity, the first row, first column element of the matrix  $\rho_1$  [cf. Eq. (6-23)]. That will not necessarily equal  $\rho_{1PK}$  ( $3 \times 10^{-3}$ ) of Eq. (6-22) because of the difference in the definitions of our reactivity and the reactivity of Fig. 6-1.

\*

Now that we have overcome the difficulties encountered because of the special nature of the problem, we can proceed with it by our proposed method. The code OZAN (cf. Appendices N and O) has been created to perform the computations required by the present work. It has been used along with the code Exterminator-II [5] and the point

kinetics code [18]. The relevant results are presented in the next section.

\*

### 6-2 Results

The point kinetics code [18] is run first to furnish the precursor concentrations [hence through Eq. (6-8), the first element of the column matrix  $C_j(0)$ ,  $j = 1, \dots, (H+1)$ ] and the time  $T$  at which the bank of shim rods receive the signal to scram. (The transient will be studied by the two-trial mode method throughout the period of time  $0 \leq t \leq T$ .) The relevant input and output are presented below.

#### 6-2-1 Input to the Point Kinetics Code [18]

Table 6-1-1 Input (1) to the Point Kinetics Code [18]

Generation time: $\Lambda_{PK}$	$1.2980 \times 10^{-4}$ sec.
Initial Reactivity: $\rho_{PK}(t_s)$	-0.12
Ramp change slope of Reactivity: $\frac{d\rho_{PK}(t)}{dt}$	$3 \times 10^{-3}$ sec. <sup>-1</sup>

6-2-2 Comments on the Input to the Point Kinetics Code, Correction Factor for the Delayed Neutron Fractions

In Table 6-1-1  $\Lambda_{PK}$  appears to be  $1.298 \times 10^{-4}$  (rather than  $1.0107 \times 10^{-4}$  as computed by OZAN for the first row, first column element of the matrix  $\Lambda$ ). The reason is that  $\Lambda_{PK}$  was obtained by a previous run where, as the weighting function, the flux, instead of the adjoint flux, was used. For the same reason the delayed photoneutron fractions shown in Table 6-1-2 ( $j = 7, \dots, 14$ ) differ from those given subsequently in this chapter. These differences are not very important since the run with the point kinetics code was made only to estimate the quantities -  $C_{PK_j}(0)$ 's,  $N(0)$ , and  $T$  - and not to determine them precisely. In addition, because of the nature of the transient, the delayed neutrons (chiefly the delayed photoneutrons) are not very significant. Thus, the fact that the numbers for the delayed photoneutron fractions, shown in Table 6-1-2, differ from the ones presented subsequently (obtained by using the adjoint flux as the weighting function), is even more tolerable.

$\alpha$  (the correction factor introduced in Chapter III for overcoming the error due to approximations made in calculating the photoneutron source term - see Chapter II) was taken equal to 10 (approximately).

### Correction Factor for the Delayed Neutron Fractions

The delayed neutron fractions shown in Table 6-1-2 ( $j = 1, \dots, 6$ ) are not exactly the ones given by the nuclear data [20]. The reason for that is as follows: At emission, the energy of a delayed neutron is generally less than the energy of a prompt neutron. Therefore during the thermalization, a delayed neutron has less chance to leak out of the reactor, than a prompt neutron. That is, in causing fission, a delayed neutron is more effective than a prompt neutron. However, in the three-group scheme that we have adopted, both delayed and prompt neutrons are born in the same - fast - group. The fact that the delayed neutrons are worth more is, then, not taken into account automatically.

An adequate way to correct for this condition would be to multiply the  $\beta_j$  by the factor

$$\frac{\int_{\underline{r}, \text{core}} d\underline{r} \psi_1^*(\underline{r}) \sum_F^T(\underline{r}, 0) \chi_j \psi_1(\underline{r})}{\int_{\underline{r}, \text{core}} d\underline{r} \psi_1^*(\underline{r}) \sum_F^T(\underline{r}, 0) \chi_p \psi_1(\underline{r})}, \quad (j = 1, \dots, 6),$$

(6-24)

where a multigroup scheme is considered so that  $\chi_j \neq \chi_p$ . (In expression (6-24) the familiar notation is being used; i.e., the subscript 1 refers to the steady state of the reactor).

This method of computing the correction factor for the delayed neutrons was not undertaken because applying it for a fifteen-group scheme would be very expensive. Also on a theoretical ground we had reason to believe that one could estimate the correction factor by applying a neutron balance argument to the already available fifteen-group Exterminator-II output for MITR-II.

Therefore, rather than choosing the expensive, straightforward way of solving the problem, we developed a method (described briefly in Appendix K) based on the multigroup output of Exterminator-II obtained for MITR-II. The computer code embodying this method is shown in Appendix L. (It is worthwhile to mention that this code worked for less than a fiftieth of the cost estimated for the more exact calculation.)

Unfortunately a serious difficulty was encountered: When the eigenvalue of the reactor was recomputed through the numbers obtained by the proposed method, a discrepancy (of about 8%) was found as compared to the eigenvalue given by the original output of Exterminator-II.

This is thought to be due to the fact that the convergence of the flux in the output was rather poor (relative convergence of the flux =  $4.48 \times 10^{-1}$ ). As a result, the neutron current across interfaces was not continuous. Indeed when we computed the total leakage out of the core by means of the numbers (given in the fifteen-group output of Exterminator-II) relevant to the core and by means of the numbers relevant to the regions outside of the core we found a difference of about 10%. This fact increases confidence in our method and code, but does not change our doubts about the result;

$$CF_j = 1.2467, \quad j = 1, \dots, 5,$$

$$CF_6 = 1.4312, \quad (6-25)$$

where CF stands for correction factor ( $CF_6$  is greater than  $CF_j$ ,  $j = 1, \dots, 5$ , since the 6<sup>th</sup> group delayed neutrons, at the emission, are less energetic than the delayed neutrons of other groups).

With some account taken of Eq. (6-25) and in view of estimates appearing in reference [21],  $CF_j$ , ( $j = 1, \dots, 5$ ), was chosen to be 1.20 and accordingly  $CF_6$ , 1.38.

### 6-2-3 Output from the Point Kinetics Code

$N_{PK}(0)$  was found to be  $4.242331 \times 10^{-9}$ , and corresponding  $C_{PK_j}(0)$ 's are shown in Table 6-2. The behavior of the power level beyond 6 MW is sketched in Fig. 6-2. The time  $T$ , when the shim rods receive the signal to scram, is seen to be 3.77 sec. At the end of this time the point kinetics code predicts a power level of 81.80 MW.

### 6-2-4 The Accident Analyzed

Further Preparations for the Code OZAN;

Knowing  $T$  we compute  $\rho_{PK}(T) = 1.131 \times 10^{-2}$

through Eq. (6-22). Applying the procedure discussed in section 6-1-5 above, we found from Fig. 6-1 that at time  $t=T$  the rods would be about an inch higher from their initial position. Accordingly a poison search was made through Exterminator-II. The value  $\omega$  [cf. Eq. (4-18)] was found to be 17.262131 (the eigenvalue of the reactor was required to converge to  $\frac{1}{1-\beta} = 1.007896$  and turned out to be - after 90 iterations - 1.0078964). Thus the absorption cross sections throughout the reactor were increased by  $\omega v^{-1}$  (the average values shown in Table 6-3 were used for  $v^{-1}$ ) and a second shape and its adjoint were computed.

Fig. 6-2 Behavior of the Power Level Beyond 6MW under the Fictitious Accident in Question

Table 6-2 The Precursor Concentrations at Time  $t = 0$   
Under the Accident in Question, as Computed  
by the Point Kinetics Code

y E n stands for  $y 10^n$

The output from the point kinetics code will be a portion  
of the input to OZAN.

The value for  $V_g$  ( $g = 1$  to  $3$ );

An average for  $V_g$  was computed through

$$V_g^{-1} = \frac{\int_{\underline{r}, \text{reactor}} d\underline{r} \int_{E_g}^{E_{g-1}} dE \phi(\underline{r}, E, 0) V^{-1}(E)}{\int_{\underline{r}, \text{reactor}} d\underline{r} \int_{E_g}^{E_{g-1}} dE \phi(\underline{r}, E, 0)} \quad (6-26)$$

For the purpose of the calculation the fifteen-group output of Exterminator-II for MITR-II was used with  $V(E)$ 's (for fifteen-group scheme) taken from reference [22]. We thus computed

$$V_g^{-1} = \frac{\sum_m^M \sum_{h=h_{g-1}}^{h_g} \phi_{mh}(0) V_h^{-1}}{\sum_m^M \sum_{h=h_{g-1}}^{h_g} \phi_{mh}(0)} \quad (6-27)$$

where  $M$  is the number of compositions,  $\phi_{mh}(0)$  is the flux given in the output in question, for the  $h^{\text{th}}$  group and in the  $m^{\text{th}}$  material,  $V_h$  is the  $h^{\text{th}}$  group velocity as given in reference [22] and  $h_{g-1}$  and  $h_g$  are respectively the initial

and final groups in the fifteen-group scheme that are framing the  $g^{\text{th}}$  group of the three-group scheme.

The computer code that was written in order to perform the computation for Eq. (6-27) is presented in Appendix M. The results are shown in Table 6-3.

Table 6-3 Average Group Velocities for MITR-II

g	$v^{-1}$ (sec/cm)	V (cm/sec)
1	$1.9903 \times 10^{-9}$	$5.0244 \times 10^8$
2	$2.3170 \times 10^{-7}$	$4.3159 \times 10^6$
3	$4.5454 \times 10^{-6}$	$2.200 \times 10^5$

Further input data to OZAN;

In addition to data already discussed, it is necessary to input to OZAN, the mesh volume dimensions, various cross sections at the beginning and the end of the transient, the delayed neutron fractions, etc. A complete set up of the input is discussed in Appendix N and shown in Appendix O.

6-2-5 Output from OZAN (NMODES\* = 2)

The output relevant to the final step before the solution of the time dependent equations is as follows;

The generation time matrix:

$$\Lambda = \begin{pmatrix} 0.10107 \text{ E-3} & 0.97859 \text{ E-4} \\ 0.98072 \text{ E-4} & 0.95077 \text{ E-4} \end{pmatrix} ; \quad (6-28)$$

The reactivity matrix at  $t = 0$ :

$$\rho_{\text{new}}(0) = \begin{pmatrix} -0.40165523 \text{ E-5} & 0.14627143 \text{ E-2} \\ 0.19336105 \text{ E-4} & -0.52609537 \text{ E-1} \end{pmatrix} ; \quad (6-29)$$

The ramp change slope of the reactivity matrix:

$$\rho_1 = \begin{pmatrix} 0.20038732 \text{ E-2} & 0.22407090 \text{ E-2} \\ 0.15396409 \text{ E-1} & 0.16423021 \text{ E-1} \end{pmatrix} ; \quad (6-30)$$

The delayed neutron (and photoneutron) fraction matrices;

$$\begin{matrix} & 1 & & & 2 \\ \begin{pmatrix} 0.30100 \text{ E-3} & 0.29948 \text{ E-3} \\ 0.28180 \text{ E-3} & 0.28045 \text{ E-3} \end{pmatrix} & , & \begin{pmatrix} 0.17090 \text{ E-2} & 0.17003 \text{ E-2} \\ 0.16000 \text{ E-2} & 0.15923 \text{ E-2} \end{pmatrix} \end{matrix}$$

---

\* NMODES: the number of trial modes used in expanding the flux.

$$\begin{array}{cc} 3 & 4 \\ \left( \begin{array}{cc} 0.15290 \text{ E-2} & 0.15213 \text{ E-2} \\ 0.14315 \text{ E-2} & 0.14246 \text{ E-2} \end{array} \right) & , \left( \begin{array}{cc} 0.30820 \text{ E-2} & 0.30664 \text{ E-2} \\ 0.28855 \text{ E-2} & 0.28716 \text{ E-2} \end{array} \right) \end{array}$$

15

$$\begin{pmatrix} 0.0 & 0.0 \\ 0.0 & 0.0 \end{pmatrix}, \quad (6-31)$$

where for the delayed photoneutron fractions, a correction factor  $\alpha = 10$  is used and the 15<sup>th</sup> matrix elements are set to zero since the fictitious 15<sup>th</sup> group delayed precursor amplitude functions are used merely to represent the external source.

Note that the first row, first column element of the matrix  $\rho_1$  is different than  $3 \times 10^{-3}$  - initially input to the point kinetics code as the ramp change slope of the reactivity - because of the difference between the definition of reactivity of Fig. 6-1 and the one adopted throughout the present dissertation (cf. Chapter III).

To attack the time dependent equations, we finally have to add to Equations (6-28) up to (6-31) the  $N_{PK}(0)$  and  $C_j(0)$ 's computed through the point kinetics code and the manipulations described in the previous sections. It was mentioned (cf. section 6-2-2) that we did not use the best values for,  $\Lambda_{PK}$  and  $\beta_{jPK}$ 's in determining  $N_{PK}(0)$  and the  $C_{PK_j}(0)$ 's earlier. For the present run (OZAN, NMODES = 2) we had a chance to recompute the initial

Table (6-4) Initial Precursor Amplitude Functions

j	$C_{j_1}(0)$	$C_{j_2}(0)$
1	0.1010 E-10	0.94559 E-11
2	0.38500 E-10	0.36045 E-10
3	0.20100 E-10	0.18818 E-10
4	0.23900 E-10	0.22376 E-10
5	0.27000 E-11	0.25278 E-11
6	0.42100 E-12	0.39415 E-12
7	0.98000 E-12	0.95666 E-12
8	0.10900 E-11	0.10640 E-11
9	0.77400 E-12	0.75557 E-12
10	0.93600 E-12	0.91371 E-12
11	0.18300 E-11	0.17864 E-11
12	0.73200 E-11	0.71457 E-11
13	0.26900 E-11	0.26259 E-11

15	0.23600 E+03	0.22763 E+03

y E n stands for  $y \times 10^n$

values  $N_{PK}(0)$  and  $C_{PK_j}$ 's through the point kinetics code, using this time,  $\Lambda_{11}$  (for  $\Lambda_{PK}$ ), and  $\beta_{j_{new}}(0)$ 's (for  $\beta_{PK_j}$ 's) obtained from a previous OZAN run.  $\Lambda_{PK}$  as a result became  $1.0149 \times 10^{-4}$  and  $\beta_{PK} (= \sum_{j=1}^{15} \beta_{PK_j})$ ,  $8.03316 \times 10^{-3}$  (instead of  $7.89737 \times 10^{-3}$  used for the previous point kinetics run).

The corresponding  $N_{PK}(0)$  is  $4.149860 \times 10^{-3}$  and the final  $C_{j_1}(0)$  [cf. Eq. (6-8), with  $H = 14$ ] is presented along with  $C_{j_2}(0)$  [cf. Equations (6-20) and (6-21)] in Table (6-4).

$C_{1_1}(0)$  computed from  $C_{PK_1}(0)$  of Table 6-2 becomes for instance,  $0.78880 \text{ E-7} \times 1.298 \text{ E-4} \approx 0.1020 \text{ E-10}$ . The difference between that number and the one given for  $C_{1_1}(0)$  in Table 6-4 ( $0.1010 \text{ E-10}$ ) is 1%. The difference between  $N_{PK}(0)$  just computed and  $N_{PK}(0)$  computed through the previous run is also about the same. Thus these differences are not very significant, as it was anticipated in section 6-2-2.

\*

The solution of the time dependent equations is presented in Table (6-5).

Table 6-5 The Two Time Coefficients  
With Respect to the Time

t(sec.)	$N_1(t)$	$N_2(t)$
0	0.41499 E-08	0.
1	0.61103 E-08	0.20874 E-08
2	0.99747 E-08	0.10478 E-08
3	0.61673 E-07	0.22693 E-06
4	-0.54800 E-01	0.92655 E 00
5	-0.12375 E+19	0.47876 E+19

We note that while at the beginning of the transient  $N_1(t)$  is dominant and  $N_2(t)$  is small (one can show that for the initial conditions imposed  $\left. \frac{dN_2(t)}{dt} \right|_{t=0} = 0$ ), as the rods get closer to the position 2.54 cm higher than their initial level, the second shape gradually takes over.

As will be explained in the next chapter, one can obtain an equivalent time function  $N_{eq}(t)$  out of  $N_1(t)$  and  $N_2(t)$  with appropriate manipulations. Thus the power

level follows 
$$N_{eq}(t) = N_1(t) + \frac{\Lambda_{12}}{\Lambda_{11}} N_2(t).$$

$N_{eq}(t)$  for the present run is shown in Fig. 6-3.

OZAN NMODES = 2

$$N_{eq}(t) = N_1(t) + \frac{\Lambda_{12}}{\Lambda_{11}} N_2(t)$$

Start critical, source of 1 mW in

Fig. 6-3 Behavior of  $N_{eq}(t)$  under the Accident in Question, Studied by the Proposed Method

In this figure we see that 6 MW level is reached at around 4 sec., and 0.1 second later the power level reaches about 90 MW.

We note that around  $t = T$ , the inverse period,  $\omega$ , of the reactor is about the one predicted by the poison search made for the second trial mode ( $\omega = \frac{1}{N_{eq}} \frac{dN_{eq}}{dt} \approx 17.2$  around 3.7 sec.).

The derivation of an equivalent scalar reactivity and generation time and their variation with respect to the time, is presented in the next chapter.

#### 6-2-6 Output from OZAN (NMODES = 1)

The same study is repeated with however only one trial function. Thus the problem is reduced to a point kinetics case. Then the solution  $N_1(t)$  is searched with  $\Lambda_{PK} = \Lambda_{11}$ ,  $\rho_{PK}(0) = \rho_{new_{11}}(0)$ ,  $\rho_{1_{PK}} = \rho_{1_{11}}$ , and  $\beta_{PK_j} = \bar{\beta}_{j_{new_{11}}}(0)$ , [ $j = 1, \dots, (H+1)$ ], defined through respectively equations (6-28), (6-29), (6-30) and (6-31).

The behavior of  $N_1(t)$  is shown in Fig. (6-4), where we see that 6 MW level is reached at around 5.06 sec. 0.1 sec. more from there on brings the reactor onto about 60 MW power level.

Fig. 6-4 OZAN Studying the Accident in Question with one Trial Mode Only

We note that (although  $\omega \approx 23$  around 5.1 sec. in the last case)  $N_1(t)$  of Fig. (6-4) is much slower than  $N_{eq}(t)$  of Fig. (6-3). A comparison of these two quantities with respect to the time is shown in Table 6-6.

Table 6-6 Behavior of the Power Level Predicted by  
OZAN-NMODES = 2-and -NMODES = 1-

t(sec.)	$N_{eq}(t)$ (NMODES=2)	$N_1(t)$ (NMODES=1)
1	0.813 E-08	0.742 E-08
2	0.201 E-07	0.140 E-07
3	0.282 E-06	0.438 E-07
4	0.850	0.991 E-06
5	0.340 E+19	0.332

We emphasize that in both studies (cf. Table 6-6) everything was the same except for the number of trial modes used in the expansion of the flux.

In the next chapter we shall discuss in detail the validity of the numbers shown in Table 6-6. If these results are correct, there is certainly a large difference between the two predictions shown in Table 6-6.

### 6-3 Summary

In this chapter we aimed to study a fictitious accident with the proposed method and compare the results (NMODES = 2) with those obtained through a point kinetics approach (NMODES = 1). We also wanted to answer the question: For the given accident, how far beyond 6 MW does the power level continue to climb in 0.1 more sec.?

The problem was of a special nature [startup sub-critical and requiring that we have an estimate of the answer (position of the rods when they receive the signal to scram) before beginning space-dependent analysis].

We decided to use a single critical shape until the rods were at a critical position and then use the two-shape method for the rest of the transient.

We then required more theoretical preparations. An external source was expressed in terms of an extra delayed neutron precursor concentration. The initial values (at  $t = 0$ ) for the first precursor amplitude functions and the first time coefficient, as well as the duration of the transient ( $T$ ) - input to OZAN - were estimated through a point kinetics code. The initial values for the second precursor amplitude functions were found in a consistent way [Equations (6-20) and (6-21)].

The position of the rods at  $t = T$  was then deter-

mined. Then a poison search was made and the second shape and its adjoint were computed.

Finally a study of the problem with OZAN (NMODES = 2 and NMODES = 1) was undertaken. The end results are summarized in Table 6-7.

Table 6-7  
Summary of the Results

	the first point kinetics run	OZAN NMODES=2	OZAN NMODES=1
time t (sec.) at which the 6 MW level is reached	3.67	≈ 4.	5.06
the power level (MW) reached 0.1 sec. after time t	81.8	≈ 90	60

In conclusion it is important to recall that this is a fictitious case, not only has the assumption been made that the safety controls and instrumentation failed but also the inherent safety features of negative void and tempera-

ture coefficients have been neglected. If the negative reactivity feed back from the void formation is included, the shape of the transient would be significantly altered.

Rather than an explicit representation of the power history for the proposed problem, the results of these calculations should be viewed as study of the importance of special effects in fast transient calculations. The fact that the OZAN result with NMODES = 2 is significantly higher than the result with NMODES = 1, indicates that care must be taken if one is trying to make conservative conclusions based only on a point kinetics calculations.

## CHAPTER VII

### CROSS CHECKING OF THE RESULTS

The main question that arises from the previous chapter is: Do we believe in the numbers we have obtained? In fact this question has two parts:

1. Do we believe in the computer code (OZAN) written to perform the computations required by the proposed method?
2. Assuming that the answer to the first question is yes, do we believe in the prediction made by the proposed method?

Unfortunately the second question will be answered only superficially (and that will be done in the next chapter). Much more would have to be done to answer this question definitively.

In this chapter, we shall consider the validity of the computer code (OZAN) written to perform computations required by the proposed method. For this purpose five distinct tests were applied.

7-1 Some of the results computed through OZAN checked against the same quantities computed by Exterminator-II

The eigenvalues relative to the spatial shapes and the first row first column element of the generation time matrix

are computed in both OZAN and Exterminator-II. In addition an Exterminator-II poison search predicted a value for  $\omega$  (the inverse period that the reactor supposedly assumes near the time the rods receive the signal for scram).  $\omega$  can also be estimated through the time behavior of the expansion coefficients predicted by OZAN (NMODES = 2) - cf. Fig. 6-3.

The results are summarized in Table 7-1, where  $k_k$  ( $k=1,2$ ) is given by Eq. (4-18) [Note that in the case of Exterminator-II the weighting function is unity. Thus, in computing  $k_k$  ( $k=1,2$ ) - assuming that the current across interfaces is continuous - , the leakage integral involved in the denominator of Eq. (4-18) was reduced to a surface integral over the outer surface of the reactor].  $\Lambda_{11}$  is the one obtained from Eq. (3-28) through the normalization

$$\Lambda_{11} = \frac{2\pi \int_{r, \text{reactor}} r dr \int_{z, \text{reactor}} dz \psi_1^{*T}(r,z) V^{-1} \psi_1(r,z)}{\frac{1}{k^{(*)}} 2\pi \int_{r, \text{core}} r dr \int_{z, \text{core}} dz \psi_1^{*T}(r,z) v \chi \Sigma_F^T(r,z,0) \psi_1(r,z)}, \quad (7-1)$$

where the integrals are evaluated by the methods shown in Chapter V.

We point out that the relative convergence for the first shape, given by Exterminator-II was  $3.452 \times 10^{-4}$  and for the second shape,  $6.199 \times 10^{-5}$ ; for the first weighting mode,

(\*) In OZAN, instead of  $k_1$ ,  $k_{\text{OZAN}}$  (1.01795673) is used. However this is a minor difference

Table 7-1

Comparison of some of the results computed through OZAN with the same quantities computed through Exterminator-II

	OZAN (NMODES=2)	Exterminator-II
$k_1$ (Eigenvalue of the first trial mode)	1.01737499	0.99973398
$k_2$ (Eigenvalue of the second trial mode)	1.02579212	1.007946
$\Lambda_{11}$ (first row, first column element of the generation time matrix)	$1.0107050 \times 10^{-4}$	$1.043922 \times 10^{-4}$
$\omega$ (inverse period at around time $t=T=3.77$ sec.)	$\sim 17.2$ ( $t=3.7$ sec.)	17.262131

$8.180 \times 10^{-1}$  and for the second weighting mode,  $8.528 \times 10^{-1}$   
 (Note the poor degree of convergence for the weighting mode as compared to the degree of convergence for the spatial shape ; the same number of iterations were used in computing both.).

Thus the agreement of the eigenvalues (shown in Table 7-1) computed by OZAN with the ones computed by Exterminator-II is within less than 1.75%. The discrepancy between the generation time computed by one code and the generation time computed by the other code is less than 3.2%.

We conjecture that the difference between the eigenvalue computed by one code and the eigenvalue computed by the other may be due to the differences between the methods of computations used in both codes; namely differences in the evaluation of the leakage integral, use of - a rather poor - weighting function in OZAN, in comparison to use of unity as weighting function in Exterminator-II, etc. It is nevertheless possible that programming or input errors in OZAN may be responsible for the discrepancies observed between the two codes. We note however that  $k_1$  and  $k_2$  computed by OZAN are consistent with respect to  $k_1$  and  $k_2$  computed by Exterminator-II in that  $(k_2 - k_1)_{\text{OZAN}} = 8.41713 \times 10^{-3}$  while  $(k_2 - k_1)_{\text{Ext. II}} = 8.212 \times 10^{-3}$ .

7-2 Cross checking of the elements of the matrix  $\rho_1$   
 [The ramp change slope of the reactivity matrix - Eq. (6-30)], against the same quantities computed by a perturbation type of approach handled by an independent code written for this purpose

We recall that  $\rho_1$  is computed through Eq. (5.54) in OZAN. That is specifically, we have (in terms of the notation adopted throughout the dissertation);

$$\begin{aligned}
 T\rho_1 &= (2\pi \int_{r, \text{reactor}} r \, dr \int_{z, \text{reactor}} dz \, W^T(r, z) \{ [\nabla \cdot D(r, z, T) - A(r, z, T) \\
 &+ \chi_p \nu \Sigma_F^T(r, z, T) ] \} \psi(r, z) + \alpha \xi_p(r, z, T) + \sum_{j=J+1}^H \bar{\beta}_j^{\text{new}}(T)) \\
 &- (2\pi \int_{r, \text{reactor}} r \, dr \int_{z, \text{reactor}} dz \, W^T(r, z) \{ [\nabla \cdot D(r, z, 0) - A(r, z, 0) \\
 &+ \chi_p \nu \Sigma_F^T(r, z, 0) ] \} \psi(r, z) + \alpha \xi_p(r, z, 0) + \sum_{j=J+1}^H \bar{\beta}_j^{\text{new}}(0)) \quad (7-2)
 \end{aligned}$$

Actually OZAN will test each component ( $D, A, \Sigma_F, \xi_p$  and  $\bar{\beta}_{\text{new}}$ ) and will then form the differences.

$$\begin{aligned}
 &\{ 2\pi \int_{r, \text{reactor}} r, dr \int_{z, \text{reactor}} dz \, W^T(r, z) [\text{COMP}(r, z, T)] \psi(r, z) \} \\
 &- \{ 2\pi \int_{r, \text{reactor}} r \, dr \int_{z, \text{reactor}} dz \, W^T(r, z) [\text{COMP}(r, z, 0)] \psi(r, z) \} , \quad (7-3)
 \end{aligned}$$

(where COMP stands for  $D, A, \Sigma_F$  etc.) only if the component in

question is subject to a change during the transient.

Thus, since only D and A vary during the accident (withdrawal of the control rods) we have studied, OZAN has computed as  $T\rho_1$  the quantity

$$T\rho_1 = \left\{ 2\pi \int_{r, \text{reactor}} r \, dr \int_{z, \text{reactor}} dz \, W^T(r, z) [\nabla \cdot D(r, z, T) - A(r, z, T)] \right. \\ \left. \psi(r, z) \right\} - \left\{ 2\pi \int_{r, \text{reactor}} r \, dr \int_{z, \text{reactor}} dz \, W^T(r, z) [\nabla \cdot D(r, z, 0) - A(r, z, 0)] \right. \\ \left. \psi(r, z) \right\} \quad (7-4)$$

That is, OZAN does not consider the particular-perturbation-nature of the problem, according to which Eq. (7-4) can be written

$$T\rho_1 = 2\pi \int_{r, \text{perturbed area}} r \, dr \int_{z, \text{perturbed area}} dz \, W^T(r, z) [\nabla \cdot \delta D(r, z) \\ - \delta A(r, z)] \psi(r, z) \quad , \quad (7-5)$$

where  $\delta D(r, z) = D(r, z, T) - D(r, z, 0)$ ,  $\delta A(r, z) = A(r, z, T) - A(r, z, 0)$ , and the "perturbed area" refers to the location of the reactor being perturbed by the withdrawal of the rods. Thus instead of computing the integrals shown in Eq. (7-5) over only one mesh volume (for the problem studied the perturbation

takes place in one mesh volume), OZAN deals with the problem as though it were general and computes  $T\rho_1$  from Eq. (7-4) with the integrals performed over the entire reactor volume.

Thus we can check the results obtained by OZAN through Eq. (7-4), against results obtained by applying Eq. (7-5). For the purpose of this calculation a separate code was written (shown in Appendix 0, next to the code OZAN). Results are compared in Table 7-2.

Table 7-2

The matrix  $\rho_1$  computed by OZAN and by a perturbation type of approach

	OZAN	Perturbation type of approach
$\rho_{1A}$	$\begin{pmatrix} 0.20929807E29 & 0.12860273E30 \\ 0.12197004E30 & 0.90442634E30 \end{pmatrix}$	$\begin{pmatrix} 0.20932522E29 & 0.12861792E30 \\ 0.12199029E30 & 0.90486858E30 \end{pmatrix}$
$\rho_{1D}$	$\begin{pmatrix} 0.88040249E29 & -0.67456125E28 \\ 0.71528204E30 & -0.11339531E29 \end{pmatrix}$	$\begin{pmatrix} 0.88058761E29 & -0.67489701E28 \\ 0.71562643E30 & -0.11343823E29 \end{pmatrix}$

$$yEx \equiv yx10^x$$

In Table 7-2  $\rho_{1A}$  and  $\rho_{1D}$  refer to the components of  $\rho_1$  due to absorption and leakage so that

$$\rho_1 = \rho_{1A} + \rho_{1D} \quad ; \quad (7-6)$$

In order to normalize, these quantities must be divided by the denominator of Eq. (7-1).

We note that the two sets of numbers shown in Table 7-2 agree with each other very closely. This is, we believe, strong evidence that, the matrix elements (-at least-of  $\rho_1$ ) are correctly computed in OZAN.

7-3 The matrix  $\rho_1$  calculated algebraically in terms of quantities output from OZAN; comments on  $\rho_{\text{new}}(0)$ : the initial value of the reactivity matrix

Our third way of cross-checking consists of calculating  $\rho_1$  through an algebraic relationship that involves quantities output from OZAN. We first develop that relationship.

#### 7-3-1 Algebraic relationship

For this purpose define

$$H_1(\underline{r}) = \nabla \cdot D_1(\underline{r}) \nabla - A_1(\underline{r}) + \frac{F_1(\underline{r})}{k_1} \quad , \quad (7-7)$$

and

$$H_2(\underline{r}) = \nabla \cdot D_2(\underline{r}) \nabla - A_2(\underline{r}) + \frac{F_2(\underline{r})}{k_2} - \omega v^{-1} \quad , \quad (7-7)$$

with the notation used in Chapter IV.

$H_1(\underline{r})$  and  $H_2(\underline{r})$  are the operators used in computing  $\psi_1(\underline{r})$  and  $\psi_2(\underline{r})$ .

We next subtract Eq. (7-7) from Eq. (7-8) to obtain

$$H_2(\underline{r}) - H_1(\underline{r}) = \nabla \delta D(\underline{r}) \nabla - \delta A(\underline{r}) + F_1(\underline{r}) \left( \frac{1}{k_2} - \frac{1}{k_1} \right) - \omega v^{-1}, \quad (7-9)$$

where  $\delta D(\underline{r}) = D_2(\underline{r}) - D_1(\underline{r})$ ;  $\delta A(\underline{r}) = A_2(\underline{r}) - A_1(\underline{r})$ , and we have used the fact that  $F_1(\underline{r}) = F_2(\underline{r})$ .

Further define

$$\delta(\underline{r}) = \nabla \delta D(\underline{r}) \nabla - \delta A(\underline{r}) \quad , \quad (7-10)$$

and

$$H_B(\underline{r}) = \frac{F_1(\underline{r})}{k_{\text{OZAN}}} \text{BET} \quad (7-11)$$

(where  $\text{BET} = \sum_{j=1}^6 \bar{\beta}_j \text{new}_{11} (0)$ )

Then with convenient manipulations we arrive at

$$\delta(\underline{r}) = H_2(\underline{r}) - H_1(\underline{r}) + H_B(\underline{r}) \frac{k_2 - k_1}{k_2 k_1 \text{BET}} k_{\text{OZAN}} + \omega v^{-1} \quad . \quad (7-12)$$

The matrix  $\rho_1$  can now be written as

$$\rho_1 = \frac{\langle \psi^{*T}(\underline{r}) | \delta(\underline{r}) | \psi(\underline{r}) \rangle}{T} \quad . \quad (7-13)$$

Thus we are able to express  $\rho_1$  in terms of

$$\langle \psi^{*T}(\underline{r}) | H_2(\underline{r}) | \psi(\underline{r}) \rangle \quad , \quad (7-14)$$

$$\langle \psi^{*T}(\underline{r}) | H_1(\underline{r}) | \psi(\underline{r}) \rangle \quad , \quad (7-15)$$

$$\langle \psi^{*T}(\underline{r}) | H_B(\underline{r}) | \psi(\underline{r}) \rangle \quad , \quad (7-16)$$

$$\langle \psi^{*T}(\underline{r}) | \omega v^{-1} | \psi(\underline{r}) \rangle (\equiv \Lambda) \quad , \quad (7-17)$$

and  $k_1$ ,  $k_2$ ,  $k_{OZAN}$  and  $\bar{\beta}_{new_{11}}(0)$ . These quantities are output from OZAN except for some of the matrix elements of expressions (7-14) and (7-15) that are the subject of the next subsection.

### 7-3-2 Review of elements of the matrices (7-14) and (7-15)

This review will be done in five stages;

1. The first-row, first-column element of the matrix (7-14) cannot be evaluated:

Apparently there is no possibility of evaluating the element,  $\langle \psi_1^{*T}(\underline{r}) | H_2(\underline{r}) | \psi_1(\underline{r}) \rangle$  under the circumstances we are working with.

2. Two elements are zero by definition:

The elements  $\langle \psi_1^{*T}(\underline{r}) | H_1(\underline{r}) | \psi_1(\underline{r}) \rangle$  and  $\langle \psi_1^{*T}(\underline{r}) | H_2(\underline{r}) | \psi_2(\underline{r}) \rangle$  vanish because of Eq. (4-19) [cf. the definition of  $k_k$  ( $k = 1, 2$ )].

3. Two elements should vanish in view of the definition for  $k_k$  ( $k = 1, 2$ ):

If  $\psi_1(\underline{r})$  and  $\psi_2(\underline{r})$  were well converged, we could write (at all points in the reactor)

$$H_1(\underline{r}) |\psi_1(\underline{r})\rangle = 0 \quad , \quad (7-18)$$

and

$$H_2(\underline{r}) |\psi_2(\underline{r})\rangle = 0 \quad , \quad (7-19)$$

through the definitions

$$\langle \psi_1^{*T}(\underline{r}) | H_1(\underline{r}) | \psi_1(\underline{r}) \rangle = 0 \quad , \quad (7-20)$$

and

$$\langle \psi_1^{*T}(\underline{r}) | H_2(\underline{r}) | \psi_2(\underline{r}) \rangle = 0 \quad , \quad (7-21)$$

Equations (7-18) and (7-19) would then imply respectively

$$\langle \psi_2^{*T}(\underline{r}) | H_1(\underline{r}) | \psi_1(\underline{r}) \rangle = 0 \quad , \quad (7-22)$$

and

$$\langle \psi_2^{*T}(\underline{r}) | H_2(\underline{r}) | \psi_2(\underline{r}) \rangle = 0 \quad . \quad (7-23)$$

4. Two elements should vanish in view of the definition of the adjoint mode:

Provided proper continuity properties exist, the elements  $\langle \psi_2^{*T}(\underline{r}) | H_2(\underline{r}) | \psi_1(\underline{r}) \rangle$  and  $\langle \psi_1^{*T}(\underline{r}) | H_1(\underline{r}) | \psi_2(\underline{r}) \rangle$  can be written respectively

$$\langle \psi_1^T(\underline{r}) | H_2^+(\underline{r}) | \psi_2^*(\underline{r}) \rangle \quad , \quad (7-24)$$

and

$$\langle \psi_2^T(\underline{r}) | H_1^+(\underline{r}) | \psi_1^*(\underline{r}) \rangle \quad , \quad (7-25)$$

with  $H_1^+(\underline{r})$  and  $H_2^+(\underline{r})$  defined in Chapter IV.

If  $\psi_2^*(\underline{r})$  and  $\psi_1^*(\underline{r})$  were well converged we would have

$$H_2^+(\underline{r}) |\psi_2^*(\underline{r})\rangle = 0 \quad , \quad (7-26)$$

and

$$H_1^+(\underline{r}) |\psi_1^*(\underline{r})\rangle = 0 \quad , \quad (7-27)$$

at all the points of the reactor. Thus expressions (7-24) and (7-25) would vanish.

$$5. \quad \langle \psi_2^{*T}(\underline{r}) | H_1(\underline{r}) | \psi_2(\underline{r}) \rangle :$$

To calculate this element we consider

$$H_{\text{OZAN}}(\underline{r}) = \nabla \cdot D_1(\underline{r}) \nabla - A_1(\underline{r}) + \frac{F_1(\underline{r})}{k_{\text{OZAN}}} + H_{\text{PPN}}(\underline{r}) + H_{\text{DPN}}(\underline{r}) \quad , \quad (7-28)$$

where  $H_{\text{PPN}}(\underline{r})$  and  $H_{\text{DPN}}(\underline{r})$  are respectively the prompt and the delayed photoneutron operators defined through

$$\langle \psi^{*T}(\underline{r}) | H_{\text{PPN}}(\underline{r}) | \psi(\underline{r}) \rangle \quad , \quad (7-29)$$

and

$$\langle \psi^{*T}(\underline{r}) | H_{\text{DPN}}(\underline{r}) | \psi(\underline{r}) \rangle \quad , \quad (7-30)$$

that is, the prompt and the delayed photoneutron reactivity matrices introduced in Chapter III. Both matrices (7-29) and (7-30) are output from OZAN.

With appropriate manipulations we obtain

$$H_1(\underline{r}) = H_{OZAN}(\underline{r}) + H_B(\underline{r}) \left( \frac{1}{k_1} - \frac{1}{k_{OZAN}} \right) \frac{k_{OZAN}}{BET} - H_{PPN}(\underline{r}) - H_{DPN}(\underline{r}), \quad (7-31)$$

such that

$$\langle \psi^{*T} | H_{OZAN}(\underline{r}) | \psi(\underline{r}) \rangle = \rho_{new}(0); \quad (7-32)$$

the initial value of the reactivity matrix (comments about  $\rho(0)$  are saved for the subsection 7-3-4).

Thus using Eq. (7-31), Eq. (7-12) can be written as

$$\delta(\underline{r}) = H_2(\underline{r}) - H_{OZAN}(\underline{r}) + \frac{H_B(\underline{r})}{BET} \left( 1 - \frac{k_{OZAN}}{k_2} \right) + H_{PPN}(\underline{r}) + H_{DPN}(\underline{r}) + \omega v^{-1}. \quad (7-33)$$

\*

Hence  $\rho_1$  will be calculated through Eq. (7-13) by making use of Eq. (7-12) (for the first row, second column, and second row, first column; elements) and Eq. (7-33) (for the second row, second column element) in conjunction with the comments made for the matrices (7-14) and (7-15). Further information is given in Table 7-3.

In numbers (appearing in Table 7-3) relevant to the photoneutrons a correction factor  $\alpha = 10$  is present.

Table 7-3 Further information for the purpose  
of the algebraic calculation

$k_{\text{OZAN}}$	1.01795673
$\bar{\beta}_{\text{new}_{11}}(0)$	0.78469925E-2
The delayed neutron fraction matrix [that corresponds to $H_B(\underline{r})$ ]	$\begin{pmatrix} 0.78469925\text{E-}2 & 0.78072660\text{E-}2 \\ 0.73465705\text{E-}2 & 0.73112361\text{E-}2 \end{pmatrix}$
The prompt photoneutron production matrix [that corresponds to $H_{\text{PPN}}(\underline{r})$ ]	$\begin{pmatrix} 0.21412867\text{E}29 & 0.24675711\text{E}29 \\ 0.20902955\text{E}29 & 0.24088097\text{E}29 \end{pmatrix}$
The delayed photoneutron fraction matrix [that corresponds to $H_{\text{DPN}}(\underline{r})$ ]	$\begin{pmatrix} 0.17435974\text{E-}3 & 0.17421108\text{E-}3 \\ 0.17020771\text{E-}3 & 0.1700626\text{E-}4 \end{pmatrix}$

$$y \text{ E } x \equiv y \times 10^x$$

For purposes of normalization the numbers for the prompt photoneutron should be divided by  $0.54379688 \times 10^{32}$ .

Results are regrouped in Table 7-4.

Table 7-4 Elements of the matrix  $\rho_1$  calculated algebraically (by hand) compared with the same elements computed through OZAN

	Algebra	OZAN
Second row first column (21) element	0.254 E-2	0.15396 E-1
First row second column (12) element	0.2241 E-2	0.22409 E-2
Second row second column (22) element	0.1643 E-1	0.16423 E-1

$$y \text{ E } x \equiv y \times 10^x$$

We note that the agreement between the last two elements of Table 7-4 is very good. However the first element computed through OZAN is badly off as compared to the result given by the algebra for the same element. This, we believe, is due to the incorrectness of the assumption that expression (7-24) vanishes -this expression is computed nowhere in OZAN. Similarly, if indeed we assume, throughout the calculation of the (12) element that  $\langle \psi_1^* (\underline{r}) | H_1 (\underline{r}) | \psi_2 (\underline{r}) \rangle$  (which can be calculated

based on the output from OZAN, to be  $1.404 \times 10^{-3}$ ) vanishes [cf. Eq. (7-20)], then we find - through the algebra for the (12) element-  $0.2610 \times 10^{-2}$  instead of  $0.2241 \times 10^{-2}$ .

The error in assumptions such as Eq. (7-20) implies that the fluxes determined by Exterminator-II are not well converged. The degree of convergence for the two adjoint modes are shown in Table 7-5.  $\psi_1^*(\underline{r})$  was computed in 60 iterations and  $\psi_2^*(\underline{r})$ , 50 iterations. For a comparison the degree of convergence for  $\psi_1^*(\underline{r})$  after 50 iterations, is also shown.

Table 7-5 Degree of convergence of the adjoint modes

Fluxes	Iteration number	Relative convergence	Absolute convergence
$\psi_1^*(\underline{r})$	60	8.1799 E-1	-9.5230 E-1
$\psi_2^*(\underline{r})$	50	8.5283 E-1	-9.9201 E-1
$\psi_1^*(\underline{r})$	50	8.5275 E-1	-9.9206 E-1

We note the worse convergence for  $\psi_2^*(\underline{r})$ . We also note that if  $\psi_1^*(\underline{r})$  were computed out of 50 iterations (instead of 60), then its convergence would be as bad as the one for  $\psi_2^*(\underline{r})$ . These facts may be responsible for the greater divergence from zero of  $\langle \psi_2^*(\underline{r}) | H_2(\underline{r}) | \psi_1(\underline{r}) \rangle$  [this can be

computed - see Eq. (7-34) - making use of Eq. (7-12) to be  $\approx 0.048$ ] than the divergence from zero of  $\langle \psi_1^{*T}(\underline{r}) | H_1(\underline{r}) | \psi_2(\underline{r}) \rangle$  ( $\approx 0.0014$ ).

We have calculated  $\langle \psi_2^{*T}(\underline{r}) | H_2(\underline{r}) | \psi_2(\underline{r}) \rangle$  from

$$\begin{aligned} \langle \psi_2^{*T}(\underline{r}) | H_2(\underline{r}) | \psi_1(\underline{r}) \rangle &= \langle \psi_2^{*T}(\underline{r}) | \delta(\underline{r}) | \psi_1(\underline{r}) \rangle \\ &+ \langle \psi_2^{*T}(\underline{r}) | H_1(\underline{r}) - H_B(\underline{r}) \frac{k_2 - k_1}{k_2 k_1 \bar{\beta}_{\text{new}11}(0)} k_{\text{OZAN}} | \psi_1(\underline{r}) \rangle - \Lambda_{22} \end{aligned}$$

(7-34)

[cf. Eq. (7-12)], where  $\langle \psi_2^{*T}(\underline{r}) | \delta(\underline{r}) | \psi_1(\underline{r}) \rangle$  is taken to be the (21) element of the matrix  $\rho_1$  as computed by OZAN.

\*

We shall defer discussion of some suggestions based on the results just derived until the next chapter.

However, because it is closely related to the algebra developed within the present section, we take the opportunity in the following section to comment on  $\rho_{\text{new}}(0)$ , the initial value of the reactivity matrix.

7-3-4 Comments on  $\rho_{\text{new}}(0)$ , the initial value of the reactivity matrix

The matrix  $\rho_{\text{new}}(0)$  [cf. Eq. (7-32)] deserves special attention. Starting to apply the time dependent

Equations (3-44) and (3-45) with some residual reactivity - although this may be small - , while the reactor is critical, is undesirable numerically. Thus to avoid an erroneous prediction,  $k_{\text{OZAN}}$  was introduced in Chapter V, so that, if the reactor is critical at the beginning of the transient, we have  $\rho_{\text{new}_{11}}(0) = 0$ . The purpose of  $k_{\text{OZAN}}$  is then to compensate for the extra reactivity due to the presence of photoneutrons (the balance for the equilibrium trial mode,  $\psi_1(\underline{r})$ , being maintained by dividing the fission cross sections by  $k_1$  - eigenvalue of the first trial mode computed through OZAN).

If  $k_{\text{OZAN}}$  were the eigenvalue of a well converged first trial mode coming out of Exterminator II, we would have  $\rho_{\text{new}_{11}}(0) = \rho_{\text{new}_{21}}(0) = \rho_{\text{new}_{12}}(0) = 0$  [cf. respectively Equations (7-20), (7-22) and (7-25)], since  $H_{\text{OZAN}}(\underline{r})$  [cf. Eq. (7-27)] would then be identical to  $H_1(\underline{r})$  [cf. Eq. (7-31)]. Failing that, we have numbers presented in Eq. (6-29).

Comments about the (11), (21) and (12) elements of  $\rho_{\text{new}}(0)$ .

On the RHS of Eq. (6-29) note that by definition the (11) element is zero (within the accuracy that the machine can insure on single precision).

We would like the (21) element to be as close to zero as the (11) element in view of Eq. (7-18) - written for  $H_{\text{OZAN}}(\underline{r})$  instead of  $H_1(\underline{r})$  - . However not only the fact that the eigenvalue computed for  $\psi_1(\underline{r})$  through OZAN diverges from the one given by Exterminator-II (for  $\lambda \approx 1.75\%$ ) but also the

presence of the photoneutrons makes  $k_{\text{OZAN}}$  a rather artificial eigenvalue computed just to insure  $[\rho_{\text{new}_{11}}(0) = 0]$ . Thus un-

fortunately a relationship such as Eq. (7-18) does not hold for  $H_{\text{OZAN}}(\underline{r})$ . Hence the value of the LHS of Eq. (7-22) is closely bound to the character of the weighting function.

We also note that the second adjoint, having the worse degree of convergence (cf. Table 7-5), makes the divergence from zero, of the (21) element about five times worse than the divergence from zero of the (11) element.

Fortunately the (21) element is still satisfactorily close to zero.

Finally note that we would not expect the (12) element to vanish even if  $H_{\text{OZAN}}(\underline{r})$  and  $H_1(\underline{r})$  were identical since it was pointed out - in subsection 7-3-3 - that presumably, because of the bad convergence of  $\psi_1^*(\underline{r})$ ,  $\langle \psi_1^*(\underline{r}) | H_1(\underline{r}) | \psi_1(\underline{r}) \rangle$  is equal to  $1.404 \times 10^{-3}$  [rather than zero, cf. Eq. (7-25)].

#### Steady State Predictions;

It is important to determine whether or not the expansion coefficients  $N_1(t)$  and  $N_2(t)$  will stay steady if the reactor remains in its critical state, that is if we solve Equations (3-44) and (3-45) for expansion coefficients with

$$[\rho_{\text{new}}(t) = \rho_{\text{new}}(0)]^* .$$

\* The answer to this question more properly belongs to the next chapter (since it rather deals with the second question we have introduced at the beginning of the present chapter). However we find it easier to give the answer here.

To answer this question the solution of Equations (3-44) and (3-45) with  $\rho_{\text{new}}(t) = \rho_{\text{new}}(0)$ , the  $\Lambda$  and  $\bar{\beta}_{j_{\text{new}}}$ 's of Equations (6-28) and (6-31) and the precursor amplitude functions found from  $\frac{dC_j(t)}{dt} = 0$ , ( $j=1, \dots, H$ ), was determined [by applying the subroutine [24] that takes care of the solution of the time dependent Equations (3-44) and (3-45), in OZAN]. The time coefficients  $N_1(t)$  and  $N_2(t)$  were found to be satisfactorily steady for the period of interest.

#### Further comments;

It is recognized that in the previous test,  $N_2(0) = 0$ . Thus the (12) element has no effect on the result. Hence during the normal run - when  $N_2(t)$  becomes greater - the divergence from zero of this element may be of importance. We save the discussion of this point for the next chapter (section 8-3).

#### 7-4 Cross checking the subroutine that solves the time dependent equations

The code [24] that solves the time dependent Equations (3-44) and (3-45) was installed in OZAN after necessary modifications were made. This code has been checked against an other code in the work cited in reference [4] that also solves the multimode kinetics equations. Good agreement was found in the special case of one group of delayed neutrons.

In case only one trial mode is used the multimode kinetics equations reduce to the conventional point kinetics equations.

Thus the prediction made through OZAN (NMODES=1) with 15 groups of delayed neutrons should agree with the one obtained through a point kinetics code if the same parameters are supplied. We were able to obtain good agreement between the point kinetics code [18] and OZAN (NMODES=1).

7-5 The point kinetics model equivalent to the multimode synthesis scheme; cross checking the behavior of the power level predicted by OZAN.

In this section we shall first show that one is able to compute a scalar generation time, reactivity, delayed neutron fractions and a time coefficient equivalent to respectively; generation time matrix,  $\Lambda$ , reactivity matrix  $\rho_{\text{new}}(t)$ , delayed neutron fraction matrices,  $\bar{\beta}_{j_{\text{new}}}(t)$ , [ $j=1, \dots, (H+1)$ ] and time coefficient matrix  $N(t)$ . Thus the point kinetics model described by  $\Lambda_{\text{eq}}$ ,  $\rho_{\text{eq}}(t)$  and  $\beta_{\text{eq}_j}(t)$ 's should predict a change in power level from  $N_{\text{eq}}(t)$  equivalent to that defined by  $N_1(t)$  and  $N_2(t)$ .

$N_{\text{eq}}(t)$  will thus be checked against the behavior of the power level computed through the point kinetics code run with  $\Lambda_{\text{eq}}$ ,  $\rho_{\text{eq}}(t)$  and  $\beta_{\text{eq}_j}(t)$ 's.

## 7-5-1 The equivalent point kinetics model

For the purpose of developing the equivalent point kinetics model we express the neutron flux as

$$\bar{\phi}(r,z,t) = \psi_{eq}(r,z,t) N_{eq}(t) [\equiv \psi_1(r,z)N_1(t) + \psi_2(r,z)N_2(t)],$$

(7-35)

where now the shape,  $\psi_{eq}(r,z,t)$  is a function of time, since we use only one time coefficient  $N_{eq}(t)$  to represent

$$[\psi_1(r,z)N_1(t) + \psi_2(r,z)N_2(t)].$$

Derivation;

Replacing  $\phi(r,z,t)$  in Equations (3-1), (3-2) and (3-3) by  $\psi_{eq}(r,z,t) N_{eq}(t)$  - this expression being identical to  $\psi_1(r,z)N_1(t) + \psi_2(r,z)N_2(t)$  - leads us to the residuals defined through Equations (3-15), (3-16) and (3-17), where  $\psi(r,z)N(t)$  should now be read:  $\psi_{eq}(r,z,t)N_{eq}(t)$ . Thus the first term of the right hand side of Eq. (3-15) becomes

$V^{-1} \frac{\partial [\psi_{eq}(r,z,t)N_{eq}(t)]}{\partial t}$ . We weight the residuals [Eq. (3-15), (3-16) and (3-19)] with the first weighting mode. Thus the first term of the RHS of Eq. (3-15) becomes

$$N_{eq}(t) \int_{\underline{r}, reactor} d\underline{r} W_1^T(\underline{r}) V^{-1} \frac{\partial \psi_{eq}(\underline{r}, t)}{\partial t} +$$

$$\frac{dN_{eq}(t)}{dt} \int_{\underline{r}, reactor} d\underline{r} W_1^T(\underline{r}) V^{-1} \psi_{eq}(\underline{r}, t) . \quad (7-36)$$

For the amplitude function,  $N_{eq}(t)$ , to contain most of the time dependence,  $\psi_{eq}(\underline{r}, t)$  should embody only slowly varying time functions for all  $\underline{r}$  and  $t$ . One way of insuring this is to impose the constraint condition [23]. That is

$$\int_{\underline{r}, reactor} d\underline{r} W_1^T(\underline{r}) V^{-1} \frac{\partial \psi_{eq}(\underline{r}, t)}{\partial t} = 0 \quad . \quad (7-37)$$

That means

$$\int_{\underline{r}, reactor} d\underline{r} W_1^T(\underline{r}) V^{-1} \psi_{eq}(\underline{r}, t) = cste \quad , \quad (7-38)$$

where cste stands for a constante number that is determined by merely setting  $t$  to zero - in Eq. (7-38) - . Thus

$$cste = \int_{\underline{r}, reactor} d\underline{r} W_1^T(\underline{r}) V^{-1} \psi_{eq}(\underline{r}, 0)$$

$$\equiv \int_{\underline{r}, reactor} d\underline{r} W_1^T(\underline{r}) V^{-1} \psi_1(\underline{r}) \equiv \Lambda_{11} \quad . \quad (7-39)$$

Then multiply both sides of Eq. (7-38) by  $N_{eq}(t)$  to obtain

$$\int_{\underline{r}, \text{reactor}} d\underline{r} \quad W_1^T(\underline{r}) \quad V^{-1} \quad \bar{\phi}(\underline{r}, t) \equiv N_1(t) \quad \int_{\underline{r}, \text{reactor}} d\underline{r} \quad W_1^T(\underline{r}) \quad V^{-1} \psi_1(\underline{r})$$

$$+ N_2(t) \int_{\underline{r}, \text{reactor}} d\underline{r} \quad W_1^T(\underline{r}) V^{-1} \psi_2(\underline{r}) \equiv N_1(t) \Lambda_{11} + N_2(t) \Lambda_{12}(t) = \Lambda_{11} N_{\text{eq}}(t).$$

(7-40)

Thus  $N_{\text{eq}}(t)$  is defined as

$$N_{\text{eq}}(t) = N_1(t) + \frac{\Lambda_{12}}{\Lambda_{11}} N_2(t) \quad , \quad (7-41)$$

and can be calculated at various times based on the output from OZAN.

Next multiply both sides of Eq. (7-41) by  $\Lambda_{11}$  and take the derivative of both sides with respect the time. The result is

$$\Lambda_{\text{eq}} \frac{dN_{\text{eq}}(t)}{dt} = \Lambda_{11} \frac{dN_1(t)}{dt} + \Lambda_{12} \frac{dN_2(t)}{dt} \quad , \quad (7-42)$$

with

$$\Lambda_{\text{eq}} \equiv \Lambda_{11} \quad . \quad (7-43)$$

Furthermore we note that the procedure of weighting the residuals analogous to those given by Equations (3-15), (3-16) and (3-19) [the only difference being that  $\psi_{\text{eq}}(\underline{r}, t) N_{\text{eq}}(t)$  replaces  $\psi(\underline{r}) N(t)$ ] by  $W_1^T(\underline{r})$ , leads us to equations for  $N_{\text{eq}}(t)$

that are identical to the first scalar equations of the matrix equations (3-44) and (3-45); namely the equations

$$\Lambda_{11} \frac{dN_1(t)}{dt} + \Lambda_{12} \frac{dN_2(t)}{dt} = [\rho_{\text{new}_{11}}(t) - \bar{\beta}_{\text{new}_{11}}(t)]N_1(t) +$$

$$[\rho_{\text{new}_{12}}(t) - \bar{\beta}_{\text{new}_{12}}(t)]N_2(t) + \sum_{j=1}^{H+1} \lambda_j C_{j1}(t) \quad , \quad (7-44)$$

$$\frac{dC_{j1}(t)}{dt} = \bar{\beta}_{j\text{new}_{11}}(t)N_1(t) + \bar{\beta}_{j\text{new}_{12}}(t)N_2(t) - \lambda_j C_{j1}(t) \quad ,$$

$$(j = 1, \dots, (H+1)) \quad , \quad (7-45)$$

where in accord with the comment made (in the previous chapter) about the external source expressed in terms of an extra delayed neutron precursor amplitude function,  $j$ 's are extended to  $(H+1)$ .

Next we define

$$\beta_{\text{eq}_j}(t) = \frac{\beta_{j\text{new}_{11}}(t)N_1(t) + \bar{\beta}_{j\text{new}_{12}}(t)N_2(t)}{N_{\text{eq}}(t)} \quad , [j=1, \dots, H] \quad ,$$

(Note that  $\bar{\beta}_{(H+1)_{\text{new}11}} = \bar{\beta}_{(H+1)_{\text{new}12}} = 0$ ),

$$\beta_{\text{eq}}(t) = \sum_{j=1}^H \beta_{\text{eq}j}(t) \quad , \quad (7-47)$$

and

$$\rho_{\text{eq}}(t) = \frac{\rho_{\text{new}11}(t) N_1(t) + \rho_{\text{new}12}(t) N_2(t)}{N_{\text{eq}}(t)} \quad (7-48)$$

Thus the equations (7-44) and (7-45) [identical to those we would obtain by finding  $N_{\text{eq}}(t)$ , through weighting by  $W_1^T(\underline{r})$  the residuals given by Equations (3-15), (3-16) and (3-17) with  $\psi(\underline{r})N(t)$  replaced by  $\psi_{\text{eq}}(\underline{r}, t)N_{\text{eq}}(t)$ ], can now be written through Equations (7-43), (7-46), (7-47) and (7-48) as

$$\Lambda_{\text{eq}} \frac{dN_{\text{eq}}(t)}{dt} = [\rho_{\text{eq}}(t) - \beta_{\text{eq}}(t)] N_{\text{eq}}(t) + \sum_{j=1}^{H+1} \lambda_j C_{\text{eq}j}(t) \quad , \quad (7-49)$$

$$\frac{dC_{\text{eq}j}(t)}{dt} = \beta_{\text{eq}j}(t) N_{\text{eq}}(t) - \lambda_j C_{\text{eq}j}(t) \quad , \quad [j=1, \dots, (H+1)] \quad , \quad (7-50)$$

where  $C_{\text{eq}j}(t)$  stands for  $C_{j1}(t)$ .

Thus we have been able to derive a point kinetics model equivalent to the multimode synthesis scheme.

Normalization;

Note that  $\Lambda_{eq}$ ,  $\rho_{eq}(t)$  and  $\beta_{eq_j}(t)$ 's as they appear in equations (7-49) and (7-50) have not been normalized. [cf. Equations (7-43), (7-46) and (7-48)]. However that does not affect the preceding derivation since we know the normalization consists merely in dividing all the matrix elements of  $\Lambda$ ,  $\rho_{new}(t)$ , and  $\beta_{j_{new}}(t)$ 's by the same number: denominator of the RHS of Eq. (7-1) - where  $k_1$  should be read as  $k_{OZAN}$  - . Thus dividing both sides of Equations (7-43), (7-46) and (7-48) we obtain  $\Lambda_{eq}$ ,  $\rho_{eq}(t)$ , and  $\beta_{eq_j}(t)$  - ( $j=1, \dots, H$ ) - now normalized in terms of the normalized  $\Lambda_{11}$ , [ $\rho_{new_{11}}(t)$ , and  $\rho_{new_{12}}(t)$ ], and [ $\beta_{j_{new_{11}}}(t)$ , and  $\beta_{j_{new_{12}}}(t)$  - ( $j = 1, \dots, H$ ) - ] .

Naturally  $N_{eq}(t)$  predicted through Equations (7-49) and (7-50) where  $\Lambda_{eq}$ ,  $\rho_{eq}(t)$ , and  $\beta_{eq_j}(t)$ 's are normalized is the same as  $N_{eq}(t)$  predicted through the same equations with  $\Lambda_{eq}$ ,  $\rho_{eq}(t)$  and  $\beta_{eq_j}(t)$ 's not normalized. This can be seen from Eq. (7-41). Dividing the numerator and the denominator of  $(\Lambda_{12}/\Lambda_{11})$  by the same quantity, will not affect the left hand side of Eq. (7-41), that is,  $N_{eq}(t)$ .

Choice of the weighting function;

Note that to arrive at Equations (7-49) and (7-50) the second adjoint mode  $\psi_2^*(\underline{r})$  (or any other function) could have been chosen as the weighting function. Equations (7-49) and (7-50), now with

$$\Lambda_{eq} \equiv \Lambda_{21} \quad , \quad (7-51)$$

$$\beta_{eq_j}(t) = \frac{\bar{\beta}_{j \text{ new}_{21}}(t)N_1(t) + \bar{\beta}_{j \text{ new}_{22}}(t)N_2(t)}{N_{eq}(t)} \quad , \quad (j=1, \dots, H) \quad , \quad (7-52)$$

$$\beta_{eq}(t) = \sum_{j=1}^H \beta_{eq_j}(t) \quad , \quad (7-53)$$

and

$$\rho_{eq}(t) = \frac{\rho_{\text{new}_{21}}(t)N_1(t) + \rho_{\text{new}_{22}}(t)N_2(t)}{N_{eq}(t)} \quad , \quad (7-54)$$

would predict

$$N_{eq}(t) = N_1(t) + \frac{\Lambda_{22}}{\Lambda_{21}} N_2(t) \quad . \quad (7-55)$$

Note that  $N_{eq}(t)$  defined through Eq. (7-41) is different from the one defined through Eq. (7-55). However the definition of  $\psi_{eq}(\underline{r}, t)$  [through Eq. (7-38) where now  $W_1^T(\underline{r})$  is replaced by  $\psi_2^{*T}(\underline{r})$ ] is also not the same as the one given through Eq. (7-38).

Thus denoting  $\psi_{eq_1}(\underline{r}, t)$ ;  $\psi_{eq}(\underline{r}, t)$  defined through Eq. (7-38) by using  $\psi_1^{*T}(\underline{r})$  as the weighting function, and  $\psi_{eq_2}(\underline{r}, t)$ ;  $\psi_{eq}(\underline{r}, t)$  defined through Eq. (7-38) by using  $\psi_2^{*T}(\underline{r})$  as the weighting function and with

$$N_{eq_1}(t) \equiv N_{eq}(t) \quad \text{Eq. (7-41)} \quad , \quad (7-56)$$

and

$$N_{eq_2}(t) \equiv N_{eq}(t) \quad \text{Eq. (7-55)} \quad (7-57)$$

We expect to have, through Eq. (7-35),

$$\bar{\theta}(\underline{r}, t) \equiv \psi_{eq_1}(\underline{r}, t) N_{eq_1}(t) = \psi_{eq_2}(\underline{r}, t) N_{eq_2}(t) \quad (7-58)$$

Hence using a different weighting function in obtaining the equivalent point kinetics equations parameters, leads to a different shape function  $[\psi_{eq}(\underline{r}, t)]$ , and a different time coefficient  $[N_{eq}(t)]$ . However since  $|\Lambda| = 1.282 \times 10^{-3}$ , we have

$$\frac{\Lambda_{22}}{\Lambda_{21}} \sim \frac{\Lambda_{12}}{\Lambda_{11}} \quad , \quad (7-59)$$

and

$$N_{eq_1}(t) \sim N_{eq_2}(t) \quad , \quad (7-60)$$

Thus

$$\psi_{eq_1}(\underline{r}, t) \quad \psi_{eq_2}(\underline{r}, t) \quad . \quad (7-61)$$

Utility of the equivalent point kinetics Model;

Since the evaluation of  $\Lambda_{eq}$ ,  $\rho_{eq}(t)$  and  $\beta_{eq_j}(t)$ 's require the solution of Equations (3-44) and (3-45), the utility of the equivalence between Equations (3-44), (3-45) and Equations (7-49), (7-50) lies in reducing the complicated matrix scheme to more familiar scalar equations.

The comparison of Equations (7-49) and (7-50) (description of the transient equivalent to OZAN, NMODES = 2) with Equations (3-44) and (3-45) when just one trial mode is used [-the matrix  $N(t)$  being reduced to a scalar  $N_1(t)$ , thus - OZAN, NMODES=1], will be presented in the next chapter.

7-5-2 Cross checking  $N_{eq}(t)$  calculated through Eq. (7-41) against  $N_{eq}(t)$  computed through a point kinetics code

The last cross checking undertaken for OZAN consisted of determining  $\Lambda_{eq}$ ,  $\rho_{eq}(t)$ , and  $\beta_{eq_j}(t)$ 's from respectively the identity (7-43), and Equations (7-48) and (7-46), computing  $N_{eq}(t)$  with these quantities through a point kinetics code, and comparing  $N_{eq}(t)$  to the result calculated from Eq. (7-41).

Actually  $\beta_{eq_j}(t)$ 's can be considered to be constant throughout the transient and, since  $\Lambda_{11}$  is close to  $\Lambda_{12}$ ,  $N_{eq}(t) = N_1(t) + N_2(t)$ ; moreover  $\bar{\beta}_{j_{new_{11}}}$  [j=1, ..., (H+1)] is

almost equal to  $\bar{\beta}_{j \text{ new}_{12}}$ ; thus  $\beta_{\text{eq}_j}(t) \approx \bar{\beta}_{j \text{ new}_{11}}$ . In addition

$\Lambda_{\text{eq}}$  need not be calculated. Thus we are concerned with only the calculation of  $\rho_{\text{eq}}(t)$  in order to be prepared for the point kinetics code.  $\rho_{\text{eq}}(t)$  is shown in Table 7-6.

Table 7-6 The equivalent scalar reactivity

time (sec.)	$\rho_{\text{eq}}(t) \times 10^3$
1	2.445
2	5.10
3	7.80
4	10.85
5	14.04

Approximating the reactivity  $\rho_{\text{eq}}(t)$  by a series of ramp changes and with  $\Lambda_{11}$ ,  $\rho_{\text{eq}}(t)$ ,  $\bar{\beta}_{j \text{ new}_{11}}$  and also  $C_{\text{PK}_j}(0)$ 's from Table 6-2 used as input,  $N_{\text{eq}}(t)$  was computed through the point kinetics code. For a comparison few numbers are shown in Table 7-7.

Table 7-7 Comparison of  $N_{eq}(t)$  calculated through Eq. (7-39) with  $N_{eq}(t)$  computed through the point kinetics code

t(sec.)	$N_{eq}(t)$ (from the point	$N_{eq}(t)$ (OZAN)
0.8	0.71210 E-8	0.713 E-8
0.9	0.75586 E-8	0.748 E-8
1.0	0.80455 E-8	0.813 E-8

$$y E x \equiv y \times 10^x$$

We note that numbers for  $N_{eq}(t)$  calculated from Eq. (7-41) based on the output from OZAN, agree satisfactorily with numbers for  $N_{eq}(t)$  computed through OZAN (within an error of less than 1.15%).

#### 7-6 Summary

In this chapter we have taken a look at five different ways of checking the results given by OZAN to answer the question: Do we believe in the computer code (OZAN) written to perform computations required by the proposed method? At some stages we have presented results that made a positive answer difficult (discrepancy in the eigenvalues and generation

time,) the (21) element of the matrix  $\rho_1$ , etc.). We pointed out however, that discrepancies encountered in section (7-1) are, we believe, due to both the bad convergence of the fluxes determined by Exterminator-II and to the difference in the methods used for computations in both OZAN and Exterminator-II. The worse convergence of the second adjoint mode was found to be responsible for the anomolous divergence of  $\rho_{1_{21}}$  (algebra) from  $\rho_{1_{21}}$  (OZAN).

On the other hand sections 7-2, 7-4 and 7-5 as well as  $\rho_{1_{12}}$  (OZAN) and  $\rho_{1_{22}}$  (OZAN) that checked well against  $\rho_{1_{12}}$  (algebra) and  $\rho_{1_{22}}$  (algebra) very much favor a positive answer to the question of validity of the code OZAN.

Thus we are inclined to say, we believe in OZAN.

## CHAPTER VIII

### THE VALIDITY OF THE PROPOSED METHOD AND CONCLUSIONS

This chapter includes a discussion of the photoneutrons, a word about the reactivity concept, a tentative to answer questions concerning the validity of the two-shape method, a summary of the conclusions and recommendations for further work.

#### 8-1 Photoneutrons

Much effort has been devoted throughout this thesis research to analyse quantitatively the generation of both prompt and delayed photoneutrons in MITR-II.

##### 8-1-1 Prompt photoneutrons

For  $\alpha$  (the correction factor introduced to account for the error due to various approximations made in calculating the photon intensity at a point in the reflector region) = 1 we found

$$PPR_{11}(0) \approx 3.94 \times 10^{-5} \quad , \quad (8-1)$$

where  $PPR_{11}(0)$  denotes the (11) element of the prompt photoneutron production matrix at  $t = 0$ .

This result implies that, if (assuming that  $\alpha$  can be taken equal to 1) the prompt photoneutrons are neglected, an error of less than  $4 \times 10^{-5}$  is made in computing the (initial) reactivity\* of the reactor.

### 8-1-2 Delayed Photoneutrons

In order to see the importance of the delayed photoneutrons in determining the reactor inverse period, for various reactivity insertions we computed [28]

$$\text{RHO} = \omega \left( \Lambda + \sum_{j=1}^H \frac{\text{BETAT}_j}{\omega + \lambda_j} \right) \quad , \quad (8-2)$$

where RHO is a reactivity that corresponds to  $\omega$ , and  $\Lambda$ , the neutron generation time of the reactor.  $\Lambda$  has been taken ( $1.043922 \times 10^{-4}$ ) as given by the Exterminator-II output for the inverse velocities presented in Chapter VI. For easy reference  $\text{BETAT}_j$ 's and  $\lambda_j$ 's are presented in Table 8-1.

The computation of RHO for various values of  $\omega$  was repeated changing the correction factor  $\alpha$  for the delayed photoneutron fractions ( $j = 7, \dots, 14$ ). The results are presented in Table 8-2.

---

\* i.e.  $\rho_{\text{new}}(0)$  defined in Chapter III.

Delayed neutron fractions and the corresponding  
decay constants

j	BETAT <sub>j</sub>	$\lambda_j$ (sec <sup>-1</sup> )
1	0.3010 E-3	0.1240 E-1
2	0.1709 E-2	0.3050 E-1
3	0.1529 E-2	0.111

14	0.1757 E-7	0.363 E-5

$$y \text{ E } x \equiv y \times 10^x$$

Fig. 8-1 Inverse Period versus Reactivity ( $\alpha = 1$ )

Table 8-2 Effect of delayed photoneutrons in determining the inverse period, for various connection factors. Numbers presented are reactivities multiplied by a hundred.

$\alpha$ \ $\omega(\text{sec}^{-1})$	0.02	0.04	0.06	0.08	0.1
0	0.13078	0.20049	0.24888	0.28612	0.31640
1	0.13128	0.20113	0.24961	0.28692	0.31726
3	0.13229	0.20240	0.25106	0.28851	0.31897
5	0.13329	0.20368	0.25252	0.29011	0.32069

As expected we see from Table 8-2 that the delayed photoneutrons become more important for small insertions of reactivity.

$\omega(\text{sec}^{-1})$  is plotted versus RHO for  $\alpha=1$  (as shown in Chapter II) in Fig. 8-1.

### 8-2 The Equivalent Reactivity

In Chapter VII (section 7-5) we have shown that an equivalent generation time, set of delayed neutron fractions and reactivity can be defined so that with these parameters the P

equation predicts the same solution as the one given through the multimode kinetics equations (synthesis method).

The equivalent reactivity makes it easy to visualize the difference between various predictions;

Comparing the parameters ( $\Lambda_{eq}$ ,  $\beta_{eq}(t)$  and  $\rho_{eq}(t)$ ) of the point kinetics model equivalent to OZAN (NMODES=2), to those ( $\Lambda_{11}$ ,  $\bar{\beta}_{new_{11}}(t)$ ,  $\rho_{new_{11}}(t)$ ) determined for the point kinetics type of approach; (OZAN, NMODES=1) we see that the only one that is significantly different is

$$\rho_{eq}(t) \text{ [for } \beta_{eq}(t) = \frac{\bar{\beta}_{new_{11}}(t)N_1(t) + \bar{\beta}_{new_{12}}(t)N_2(t)}{N_{eq}(t)} ;$$

$$N_{eq}(t) = N_1(t) + \frac{\Lambda_{12}}{\Lambda_{11}} N_2(t); \quad \frac{\Lambda_{12}}{\Lambda_{11}} \approx 1, \text{ thus } N_{eq}(t) \approx N_1(t) + N_2(t);$$

$$\bar{\beta}_{new_{11}}(t) \approx \bar{\beta}_{new_{12}}(t) \approx \bar{\beta}_{new_{11}}(0); \text{ thus } \beta_{eq}(t) \approx \bar{\beta}_{new_{11}}(0); \text{ and}$$

$$\Lambda_{eq} = \Lambda_{11} .$$

Thus the three different approaches (the point kinetics Code [18], OZAN; NMODES=1, and OZAN; NMODES=2) undertaken in Chapter VI for analysing the effects of withdrawal of the bank of shim rods, are equivalent to solving equations of type

$$\frac{dN_{eq}(t)}{dt} = \frac{(\rho_{eq}(t) - \beta_{eq}(t))}{\Lambda_{eq}} N_{eq}(t) + \sum_{j=1}^{H+1} \lambda_j C_j(t), \quad (8-3)$$

$$\frac{dC_j(t)}{dt} = \frac{\beta_{eqj}}{\Lambda_{eq}} N_{eq}(t) - \lambda_j C_j(t), \quad (j=1, \dots, H) \quad (8-4)$$

where  $\Lambda_{eq} \equiv \Lambda_{PK}$  (cf. Chapter VI)  $\equiv \Lambda_{11}$  (cf. OZAN, NMODES = 1),

and  $\beta_{eqj}(t) \hat{\equiv} \beta_{PKj}$  (cf. Chapter VI)  $\equiv \bar{\beta}_{j_{new_{11}}}(0)$  (cf. OZAN,

NMODES=1), for respectively  $\rho_{eq}(t) = \rho_{PK}(t)$  (cf. Chapter VI),

$\rho_{eq}(t) = \rho_{new_{11}}(t)$  (cf. OZAN, NMODES=1), and

$$\rho_{eq}(t) = \frac{\rho_{new_{11}}(t)N_1(t) + \rho_{new_{12}}(t)N_2(t)}{N_{eq}(t)} \quad [\text{cf. Eq. (7-41), OZAN,}$$

NMODES = 2].

#### Comparison of various reactivities;

The comparison of these various reactivities, that have been defined for the same transient (withdrawal of the control rods, cf. Chapter VI) is shown in Table 8-3. This table also includes values of two other definitions of reactivity obtained by making the first weighting function unity throughout the entire reactor, first in OZAN (NMODES=1) and then in OZAN (NMODES=2). (We will later come back to the latter study to point out the importance of the weighting function in the weighted residual technique.)

Table 8-3 Comparison of various reactivities defined for the same transient (cf. Chapter VI) through different approaches

t(sec.)	PK	OZAN (NMODES =1)	OZAN (NMODES =2)	OZAN (NMODES =1) $W_1$ ( $\underline{r}$ )=1.	OZAN (NMODES =2) $W_1$ ( $\underline{r}$ )=1.
0.	0.	0.	0.	0.	0.
1	$0.3 \times 10^{-2}$	$0.2 \times 10^{-2}$	$0.2445 \times 10^{-2}$	$0.627 \times 10^{-2}$	$0.585 \times 10^{-2}$
2	$0.6 \times 10^{-2}$	$0.4 \times 10^{-2}$	$0.510 \times 10^{-2}$	$1.253 \times 10^{-2}$	$0.855 \times 10^{-2}$
3	$0.9 \times 10^{-2}$	$0.6 \times 10^{-2}$	$0.788 \times 10^{-2}$	$1.88 \times 10^{-2}$	-
4	$1.2 \times 10^{-2}$	$0.8 \times 10^{-2}$	$1.085 \times 10^{-2}$	$2.51 \times 10^{-2}$	-
5	$1.5 \times 10^{-2}$	$1.0 \times 10^{-2}$	$1.404 \times 10^{-2}$	$3.14 \times 10^{-2}$	-

$P_K$  stands for the reactivity determined by the first approach undertaken in Chapter VI in the course of the study of the withdrawal of the rods by the point kinetics code [18].

Numbers presented in the last two columns of Table 8-3;

The numbers presented in the last two columns of Table 8-3 were obtained in the following way;

A calculation has been made with the first weighting function unity throughout the reactor (and everything else being the same) for the problem (withdrawal of control rods) subject to

Chapter VI. The relevant initial value and the ramp change shape of the reactivity matrices,  $\rho_{\text{new}}(0)$  and  $\rho_1$  were taken from the output OZAN (NMODES=2). A normalization factor (cf. Chapter VIII, section 7-5)

$$\int_{\underline{r}, \text{core}} d\underline{r} (1)^T \nu \chi \Sigma_F^T(\underline{r}, 0) \psi_1(\underline{r}) [(1)^T \text{ denoting the transpose}$$

of the column matrix composed of G (number of neutron groups) elements that are unity] is already present in these matrix elements. On the other hand a normalization factor

$$\int_{\underline{r}, \text{core}} d\underline{r} \psi_1^{*T}(\underline{r}) \nu \chi \Sigma_F^T(\underline{r}, 0) \psi_1(\underline{r}) \text{ is present in the numbers}$$

shown in second, third and fourth columns of the Table 8-3.

Thus for the purpose of the comparison an adjustment of the  $\rho_{\text{new}}(0)$  and  $\rho_1$  relevant to the study;  $W_1(\underline{r}) = 1$ , OZAN (NMODES=2) is made such that the (11) element of the generation time matrix relevant to this study becomes equal to the (11) element of the generation time matrix obtained through the study where  $\psi_1^*(\underline{r})$  is used (as the weighting function).

Then the fifth column numbers of Table 8-3 were obtained by writing, with the adjusted (11) elements of  $\rho_{\text{new}}(0)$  and  $\rho_1$  relevant to the study;  $W_1(\underline{r}) = 1$ , OZAN (NMODES=2);

$$\rho_{\text{eq}}(t) = \rho_{\text{new}_{11}}(0) + t \rho_{1_{11}} ;$$

and the last column numbers of Table 8-3 were obtained by using the Eq. (7-48) along  $\rho_{\text{new}_{11}}(0)$ ,  $\rho_{\text{new}_{12}}(0)$ ,  $\rho_{1_{11}}$ , and  $\rho_{1_{12}}$

relevant to the same study.

\*

We recognize that different sets of numbers for reactivity versus time, shown in Table 8-3 are responsible for different predictions about the transient studied. Thus the interpretation of a prediction in terms of the equivalent parameters (and mainly equivalent reactivity) makes us better understand, how this prediction is different from others.

### 8-3 The Validity of the two-shape calculations

In the previous chapter we examined the correctness of the code OZAN and defined the question of the validity of the proposed method. Specifically one has to examine what conditions must be fulfilled in order to make an accurate prediction for a transient through the weighted residual method and whether or not we fulfilled those conditions for the present study. Are two shapes sufficient for the purpose of analyzing the accident mentioned in Chapter VI? Even further, in Chapter VII it is pointed out that we used the two-shape method to observe the transient only after the reactor had become critical. If the two shape method had been used for the entire transient would the result be significantly different from those given in Chapter VI ?

Unfortunately we will not be able to give a definitive answer to these questions without further study.

We intend, however to discuss two points that relate to the character of the weighted residual method and are for consideration to resolve some of the obscurities.

a) It was pointed out earlier (cf. Chapters IV and V) that in order to compute the leakage integral  $\int_{\underline{r}, \text{reactor}} d\underline{r} W^T(\underline{r})$

$\nabla \cdot D(\underline{r}, t) \nabla \psi(\underline{r})$  (in matrix notation) we needed the balance equations through which  $\psi_1(\underline{r})$  and  $\psi_2(\underline{r})$  [column vectors, components of  $\psi(\underline{r})$ ] are generated. Thus the eigenvalues  $k_1$  and  $k_2$  for the balance equations in question were computed through OZAN, in an integral sense. For the eigenvalues relative to  $\psi_1(\underline{r})$  and  $\psi_2(\underline{r})$  computed through the code (Exterminator-II) would not insure these balance equations (due to the poor convergence of the fluxes and differences in computations used in both codes, etc.) when applied to OZAN.

In addition  $k_{\text{OZAN}}$  was introduced to compensate the photo-neutrons and insure that at time the reactor becomes critical the (11) element of the reactivity matrix,  $\rho_{\text{new}_{11}}(0)$  vanishes so that we do not go to the time dependent equations with a residual reactivity at that time. Otherwise an erroneous prediction would result.

The examination of possible errors arising from these (somewhat artificial) manipulations is made below throughout the subsection 8-3-1.

b) A second point of this validity consideration is a study of the effect of the weighting on the prediction through the weighted residual method. This is done in the subsection 8-3-2.

### 8-3-1 Eigenvalues computed in an integral sense

For the purpose of studying the possible errors arising from the introduction of the eigenvalues  $k_1$ ,  $k_2$  and  $k_{\text{OZAN}}$ , computed in an integral sense (to satisfy the required balances) we develop arguments about  $k_{\text{OZAN}}$  and  $k_2$ . We then try to show that we do not have to fear the artificialities introduced by the definition of these quantities.

#### 1. $k_{\text{OZAN}}$ :

The purpose of defining a quantity  $k_{\text{OZAN}}$  was to compensate for the presence of the photoneutrons (Neither of the operators that generated the trial shapes through Exterminator-II included the photoneutrons) by forcing  $\rho_{\text{new}_{11}}(0)$  to vanish. However since  $k_{\text{OZAN}}(\underline{r})$  then differs from  $H_1(\underline{r})$  (a correction factor  $\alpha = 10$  has been used for photoneutrons throughout the OZAN studies), a relationship such as  $H_1(\underline{r})|\psi_1(\underline{r})\rangle = 0$  does not hold for  $H_{\text{OZAN}}(\underline{r})$ . Thus we expect  $\langle \psi_2^{*T}(\underline{r}) | H_{\text{OZAN}}(\underline{r}) | \psi_1(\underline{r}) \rangle$  [the (21) element of the initial value of the reactivity matrix] to differ from zero. This quantity turned out to be  $1.93 \times 10^{-5}$ , which is still satisfactorily close to zero. Thus we feel the error in the (21) element introduced by this approximation is negligible.

The (12) element of the initial value of the reactivity matrix;  $\psi_1^{*T}(\underline{r}) | H_{OZAN}(\underline{r}) | \psi_2(\underline{r}) >$  is  $\approx 1.463 \times 10^{-3}$ . If there were no photoneutrons it would be  $\langle \psi_1^{*T}(\underline{r}) | H_1(\underline{r}) | \psi_2(\underline{r}) >$  which should vanish if  $\psi_1^*(\underline{r})$  were well converged. Numerically for the un-converged values used, the (12) element without photoneutrons is  $1.404 \times 10^{-3}$ . The difference between  $\langle \psi_1^{*T}(\underline{r}) | H_{OZAN}(\underline{r}) | \psi_2(\underline{r}) >$  and  $\langle \psi_1^{*T}(\underline{r}) | H_1(\underline{r}) | \psi_2(\underline{r}) >$  is then of a minor importance in view of the (12) element of the ramp change slope of the reactivity matrix:  $2.241 \times 10^{-3}$ .

\*

Thus the introduction of  $k_{OZAN}$  is a small correction and apparently gives its expected result.

2. It does not matter if the reactor has not been poisoned to compute  $k_2$  through OZAN:

The second trial mode was generated through Exterminator-II) by increasing the absorption cross sections by the quantity  $\omega v^{-1}$  throughout the reactor (cf. Chapter IV). To be rigorous we should do the same thing when we come to compute  $k_2$  through OZAN. Failure to do so the eigenvalue  $k_2$  (computed in an integral sense through OZAN) will be different (greater) than the one obtained if the reactor was poisoned.  $k_{2_{NP}}$  (NP standing

for "nonpoisoned") will then be rather artificial (for it is

computed so that the balance - cf. Chapter IV - is insured for a flux through some cross sections that does not belong to this flux).

A sensitivity study was made to see the effect on the matrix elements of not poisoning the reactor in computing the eigenvalue  $k_2$  through OZAN. A comparison is presented in Table 8-4-1.

Table 8-4-1 Comparison of reactivity matrix elements in cases the reactor has been poisoned for the computation of  $k_2$  through OZAN, and the reactor has not been poisoned for the same computation

	P	NP
$k_2$	1.02579212	1.02754307
$\rho_{\text{new}}^{(0)}$	$\begin{pmatrix} \times & 0.14621585 \text{ E-2} \\ \times & -0.52545846 \text{ E-1} \end{pmatrix}$	$\begin{pmatrix} \times & 0.14627143 \text{ E-2} \\ \times & -0.52609537 \text{ E-1} \end{pmatrix}$
$\rho_1$	$\begin{pmatrix} \times & 0.22408564 \text{ E-2} \\ \times & 0.16423166 \text{ E-1} \end{pmatrix}$	$\begin{pmatrix} \times & 0.22407090 \text{ E-2} \\ \times & 0.16423021 \text{ E-1} \end{pmatrix}$

$$y \text{ E } x \equiv y \times 10^x$$

P stands for the case the reactor was poisoned for OZAN to compute  $k_2$ , NP for the case the reactor was not poisoned for the same computation.

The crosses in Table 8-4-1 refer to the (11) and (21) elements of the matrices in question that are not affected at all (since these elements do not involve the second trial mode).

The numbers shown in Table 8-4-1 affirm that the differences due to computing  $k_2$  by poisoning the reactor and not poisoning it, are minor. This can also be seen from Table 8-4-2 where we give numbers for  $N_1(t)$  and  $N_2(t)$  for both cases.

Table 8-4-2 The time coefficients  $N_1(t)$  and  $N_2(t)$  for both cases: the reactor has been poisoned to compute  $k_2$  through OZAN, and it has not been poisoned for the same computation

t(sec.)	P	NP	
1	0.61083 E-8	0.611027 E-8	$N_1(t)$
	0.20901 E-8	0.20874 E-8	$N_2(t)$
2	0.99663 E-8	0.99747 E-8	$N_1(t)$
	0.10495 E-7	0.10478 E-7	$N_2(t)$
3	0.61598 E-7	0.61673 E-7	$N_1(t)$
	0.22798 E-6	0.22693 E-6	$N_2(t)$

P, NP and y E x that stand in Table 8-4-2 were defined for Table 8-4-1.

\*

The results presented throughout both parts of this subsection suggest that we do not have to fear artificialities introduced during the course of the proposed method, due to the definitions in an integral sense of  $k_1$ ,  $k_2$  and  $k_{OZAN}$ . An undesirable perturbation (photoneutrons, small variations in the cross sections, etc.) is then successfully absorbed in the definition of the eigenvalue of interest, to reassure the required balance equation. For the study undertaken in part 2 of this subsection this can be clearly seen from the algebraic relationship obtained in Chapter VII (section 7-3) for the elements of the ramp change slope of the reactivity matrix [cf. Eq. (7-33)],

$$\delta(\underline{r}) = H_2(\underline{r}) + \frac{H_B(\underline{r})}{BET} \times \frac{k_2 - k_{OZAN}}{k_2} - H_{OZAN}(\underline{r}) + H_{PPN}(\underline{r}) + H_{DPN}(\underline{r}) + \omega v^{-1} . \quad (8-5)$$

$$\text{(We recall that } \rho_1 = \frac{\langle \psi^{*T}(\underline{r}) | \delta(\underline{r}) | \psi(\underline{r}) \rangle}{T} \text{ )}$$

In case the reactor has not been poisoned to compute  $\rho_1$  the last term in the RHS of Eq. (8-5) will be omitted, but

since  $k_{2_{NP}}$  is now greater than  $k_{2_P}$  (P standing for the case the reactor is poisoned to compute  $k_2$  through OZAN),  $(\rho_{1_{12}})_{NP}$

and  $(\rho_{1_{22}})_{NP}$  are still approximately equal to respectively

$(\rho_{1_{12}})_P$  and  $(\rho_{1_{22}})_P$  (cf. Table 8-4-1). This implies that a

relationship such as

$$\omega v^{-1} = \frac{1}{k_{2_P}} - \frac{1}{k_{2_{NP}}} H_B(\underline{r}) \frac{k_{OZAN}}{\beta_{new_{11}}(0)}, \quad (8-6)$$

is approximately true; that gives (through the values for

$k_{2_P}$ ,  $k_{2_{NP}}$ ,  $k_{OZAN}$ , BET, and  $\omega$  given earlier);

$$\Lambda \approx 1.305 \langle \psi^{*T}(\underline{r}) | H_B(\underline{r}) | \psi(\underline{r}) \rangle \quad (8-7)$$

which happens to be indeed right (cf. Table 8-5).

Table 8-5 Comparison of the elements of the generation time matrix with the ones obtained through the approximate Relationship (8-7)

$\Lambda$	$\Lambda_{Eq. (8-7)}$
$\begin{pmatrix} 0.1011 \text{ E-3} & 0.9786 \text{ E-4} \\ 0.9807 \text{ E-4} & 0.9508 \text{ E-4} \end{pmatrix}$	$\begin{pmatrix} 0.1023 \text{ E-3} & 0.1020 \text{ E-3} \\ 0.960 \text{ E-4} & 0.955 \text{ E-4} \end{pmatrix}$

Throughout this subsection we will try to emphasize the importance of the weighting functions in the weighted residual method. This is done in three parts.

1. The (12) element of the initial value of the reactivity matrix is not small enough;

It was pointed out earlier that (cf. Chapter VII section 7-3-4) the (12) element of the initial value of the reactivity matrix is not close enough to zero due to the bad convergence of  $\psi_1^*(\underline{r})$  ( $\langle \psi_1^*(\underline{r}) | H_1(\underline{r}) | \psi_2(\underline{r}) \rangle \approx 1.4 \times 10^{-3}$ , and the photo-neutrons are shown - cf. part 1. of the previous subsection - not to play a major role in this divergence from zero), and may be a source of trouble. Through Eq. (7-48) one can indeed see that, because the (12) element of the initial value of the reactivity matrix is not negligible as compared to  $\rho_{12}$  (for the period of time of interest), there is a certain contribution of  $\rho_{new_{12}}(0)$  in the computation of the equivalent reactivity,  $\rho_{eq}(t)$ . Equivalent reactivity  $\rho_{eq}(t)$  is calculated assuming that  $\rho_{new_{12}}(0)$  vanishes, and compared in Table 8-6, to the numbers obtained by taking the finite value - for  $\rho_{new_{12}}(0)$  - computed through OZAN.

Thus apparently the prediction about the transient would not be as severe if the first adjoint mode were well converged so that  $\langle \psi_1^*(\underline{r}) | H_1(\underline{r}) | \psi_1(\underline{r}) \rangle$  vanishes and  $\rho_{new_{12}}(0)$  is close

Table 8-6 Comparison of  $\rho_{eq}(t)$  of Table 7-6 with  $\rho_{eq}(t)$  calculated by making  $\rho_{new_{12}}(0)$ , zero.

t(sec.)	$\rho_{eq}(t)$ [with $\rho_{new_{12}}(0) \approx 0.1463E-2$ ]	$\rho_{eq}(t)$ [with $\rho_{new_{12}}(0)=0$ ]
1	2.445 E-3	2.075 E-3
2	5.100 E-3	4.33 E-3
3	7.880 E-3	6.70 E-3
4	10.850 E-3	9.25 E-3
5	14.04 E-3	12.15 E-3

$$y \text{ Ex} \equiv j \times 10^x$$

enough to zero.

We note that in any case;

- A space-dependent analysis (for the transient we have studied) results in a different (and hopefully more accurate) prediction than a point kinetic analysis (cf. numbers presented in Table 8-6 compared to the numbers presented in the third column of Table 8-3);

- The reactivity  $\rho_{eq}(t)$  versus time is initially lower than  $\rho_{PK}(t)$  (cf. the second column of Table 8-3) for sometime and finally intercepts it [at around 5 sec. in case we have numbers presented in the second column of Table 8-6 and later

in case we have numbers presented in the third column of the same table].

2. A comment about the (21) element of the ramp change slope of the reactivity matrix that was found badly off as compared to the prediction made by the algebra (cf. Chapter VII, section 7-3);

It may be thought that we can overcome the divergence of  $\rho_{121}$  computed through OZAN (NMODES=2), from the value given by the algebraic relationship (developed in Chapter VII, section 7-3), by simply setting  $\rho_{121}$  to this algebraic result. This is not as simple for the reasons we give below;

The divergence in question was found due to the bad convergence of the second adjoint mode [specifically  $\langle \psi_2^{*T}(\underline{r}) | H_2(\underline{r}) | \psi_1(\underline{r}) \rangle$  was found to be  $\approx 5. \times 10^{-2}$ , whereas it is expected to vanish].

On the other hand in section 7-2 (Chapter VII) it was shown that the elements of the matrix  $\rho_1$  can be merely computed by taking into account the perturbed area only (that is four points and the relevant fluxes and cross sections). That means, since setting  $\rho_{121}$  to the value found by the algebra implies  $\langle \psi_2^{*T}(\underline{r}) | H_2(\underline{r}) | \psi_1(\underline{r}) \rangle = 0$ , convenient values for  $\psi_2^*(\underline{r})$  over the four points (of the perturbed area) in question, are then tacitly assumed (so that the relationship of interest is now satisfied). This in return implies all the matrix

elements that involve  $\psi_2^*(\underline{r})$  must be accordingly adjusted, or an erroneous prediction will result.

We may think from a different point of view that the nature of the weighted residual method does not require relationships such as  $\langle \psi_2^{*T}(\underline{r}) | H_2(\underline{r}) | \psi_1(\underline{r}) \rangle = 0$ , so that a bad converged adjoint function can be allowed as a weighting function. This is shown to be incorrect throughout the final part of this subsection.

### 3. Effect of Changing the weighting function

Changing the weighting function makes a large difference. We have examined a case where  $W_1(\underline{r})$  is chosen to be unity for all the points of the reactor, for the same accident presented in Chapter VI. The equivalent reactivity,  $\rho_{eq}(t)$  for this case is already presented in the last column of Table 8-3.

We will be content here by giving the final predictions as compared to the ones obtained through the run where  $W_1(\underline{r})$  was  $\psi_1^*(\underline{r})$  (cf. Table 8-7).

Table 8-7 Comparison of the results obtained by making

$$W_1(\underline{r}) = 1$$
 with those obtained by making

$$W_1(\underline{r}) = \psi_1^*(\underline{r})$$

t(sec.)	OZAN (NMODES=2) $W_1(\underline{r}) = 1$	OZAN (NMODES=2) $W_1(\underline{r}) = \psi_1^*(\underline{r})$	
1	0.554 E9	0.611 E-8	$N_1(t)$
	0.128 E8	0.209 E-8	$N_2(t)$
2	0.257 E27	0.997 E-8	$N_1(t)$
	0.116 E27	0.105 E-7	$N_2(t)$

The prediction with  $W_1(\underline{r}) = 1$  is erroneous. The reason is that the reactivity insertion  $\rho_{eq}(t)$ , estimated for the accident is much higher with  $W_1(\underline{r}) = 1$ . (cf. Table 8-3).

\*

Apparently it is inappropriate to use just any weighting function in the weighted residual method. As suggested by the perturbation theory or variational method, the adjoint modes that correspond to the spatial shapes are more properly used as weighting functions. Moreover it is important to have reasonably well converged adjoint functions (as well converged as the spatial shapes) in order to make an accurate prediction.

We find it interesting to note that  $\rho_{eq}(t)$ ,  $W_1(\underline{r}) = 1.$ , NMODES=2 behaves better than  $\rho_{eq}(t)$ ,  $W_1(\underline{r}) = 1$ , NMODES=1 (cf. the last two columns of Table 8-3). It seems then that the two-shape method (NMODES=2) improves the results as compared to a point kinetics type of approach (NMODES=1). However the prediction is still far beyond being realistic.

\*\*

We conclude in this section thus, that the answer of the question: Do we believe in the proposed method?, lies in answering the question: Did we use well converged weighting functions?, everything else, we believe, working correctly. A positive answer to the latter question is not available due to lack of funds, and it seems, better results would be obtained if we had more converged weighting functions, that remains however to be shown.

\*\*\*

In any case one unfortunately cannot tell whether or not he made a good prediction through the weighted residual method until he compares his results with the exact solution, although the method was proven to give successful results (for a much simpler case however) [27], if care is taken to insure "good" working conditions.

It is believed that for some cases, obtaining the exact solution may be even easier. For the generation of well converged trial shapes and weighting functions along the application of the weighted residual criteria, may be as time consuming as 90 minutes of computation (case of the present study) on an IBM 360/65 computer. Even if the exact solution is thought to be "little" more costly than that, we believe it may be worth spending the computation time to obtain a reassuring prediction.

#### 8-4 SUMMARY

It was shown that equivalent point kinetics parameters can be defined so that the same prediction made through the multi-mode kinetics equations about a transient, can be made through a point kinetics equations. It was emphasized that the equivalent reactivity is the predominant parameter in the kind of accident undertaken. Thus it was pointed out that the equivalent reactivity concept makes it easier to visualize the differences in the procedures used by various methods.

We were concerned that erroneous prediction may be caused by the definitions of the eigenvalues  $k_1$ ,  $k_2$  and  $k_{OZAN}$  in an integral sense. The artificialities introduced through the definitions (in an integral sense) of  $k_1$ ,  $k_2$  and  $k_{OZAN}$  are proven to be of a minor importance.

Finally a study about the importance of the weighting functions used in the weighted residual method is presented. It is shown that not just any function can be used as a weighting function, and the adjoint functions are the most appropriate ones for this purpose. Furthermore the weighting functions are required to be as converged as the trial shapes. Otherwise an erroneous prediction may result.

#### 8-5 Recommendations for further work

The concern about the proposed technique has always been the fact that it lacks definitive error bounds.

We recognize that for a good set of fluxes (trial shapes and their adjoint modes) the algebraic relationships presented in Chapter VII (section 7-3) would be satisfied and we would feel much more comfortable about the predictions under these circumstances.

We suggest a study should be done to see the effect of the convergence of the fluxes on the predictions (however in a much simpler case than the one we have undertaken for the

present work). Then we thought a line may be drawn between the divergence of the predictions from the exact solution and the degree at which the algebraic relationships are satisfied.

It may, then, also be possible without having to generate more converged fluxes, to adjust in a consistent way the "bad" matrix elements so that a better prediction can be made quickly. The proposed method would be more fruitful and more satisfactory under these circumstances.

The effect, on the prediction, of more trial shapes and more neutron groups remains to be seen. However the limitations of the available facilities (computer core storage, use of input output devices, etc.) may impede the combination of such studies.

A comparison between the multimode method with OZAN and an exact solution for a simplified transient problem would give valuable information about the validity and usefulness of the proposed method.

## APPENDIX A

### PHOTONEUTRONS GENERATED BY PHOTONS HAVING HAD ONE AND ONLY ONE COLLISION, FROM $U^{235}$ ON $D_2O$

The purpose in this Appendix is to investigate whether the photoneutrons generated in  $D_2O$  by photons from  $U^{235}$ , having had one and only one collision, could be neglected as compared to photoneutrons produced by uncollided photons under the same circumstances.

To this end we seek an estimate of photoneutrons generated by photons having had one and only one collision, from  $U^{235}$  on  $D_2O$ .

Assume then that we know the directional flux of uncollided photons of energy  $\Lambda'$ , per  $cm^2$ , per Mev, per steradian, per sec., from an atom of  $U^{235}$  at a central location, in an infinite medium of  $D_2O$ , at  $r'$ , in the direction  $\underline{\Omega}'$  and at time  $t'$ :  $\xi'(r', \Lambda', \Omega', t')$  photons per  $cm^2 \times Mev \times steradian \times sec.$

Thus

$$\psi'(r', \Lambda', \Omega', t) = \int_0^t \xi'(r', \Lambda', \Omega', t') dt', \quad (A-1)$$

gives the total number of uncollided photons of energy

within a unit interval of energy around  $\Lambda'$ , crossing a unit area at  $r'$  perpendicular to the direction  $\underline{\Omega}'$ , within a unit solid angle around  $\underline{\Omega}'$ , between  $t' = 0$  and  $t' = t$ , from an atom of  $U^{235}$  placed in a central location in an infinite medium of  $D_2O$ .

Define now the microscopic Compton scattering cross section

$$d^2_e \sigma(\Lambda' \rightarrow \Lambda) = \frac{r_0^2}{2} \left( \frac{\Lambda}{\Lambda'} \right)^2 \left( \frac{\Lambda'}{\Lambda} + \frac{\Lambda}{\Lambda'} - \sin^2 \theta \right) d\mu \sin \theta d\theta, \quad (A-2)$$

where  $r_0$  is the classical radius of the electron,  $\Lambda'$  and  $\Lambda$  are the energies of the photon respectively before and after the scattering; in addition, various angles ( $\theta, \mu, \Omega, \Omega'$ ) are shown in Fig. A-1.

Let  $N_{D_2O}$  be the number of  $D_2O$  molecules per  $cm^3$  and  $Z$  be the number of electrons present in one molecule of  $D_2O$ , ( $Z = 10$ ); such that,

(A-3)

$$\phi'(r', \Lambda' \rightarrow \Lambda, \Omega', t) d\underline{r}' = \psi'(r', \Lambda', \Omega', t) d\underline{r}' d^2_e \sigma(\Lambda' \rightarrow \Lambda) N_{D_2O} Z,$$

is the number of photons among those described by the Eq. (A-1), scattered in the elementary volume  $d\underline{r}'$ , into the solid angle  $d\Omega = d\mu \sin \theta d\theta$ .

Furthermore through the study of Compton collision,

$$\frac{1}{\Lambda'} - \frac{1}{\Lambda} = \frac{1 - \cos \theta}{E_0}, \quad (\text{A-4})$$

where  $E_0 = 0.51$  Mev, and considering  $\Lambda'$  to be constant,

$$E_0 \frac{d\Lambda}{\Lambda^2} = \sin \theta d\theta, \quad (\text{A-5})$$

so that the energy of the scattered photon stays within  $d\Lambda$  around  $\Lambda$ ; once the solid angle  $d\Omega$  is chosen,  $\Lambda$  being determined through Eq. (A-4) and  $d\Lambda$  through Eq. (A-5).

Fig. A-1 The Scattering of the Photon, at  $r'$   
from  $d\Omega'$  into  $d\Omega = d\mu \sin \theta d\theta$

The photon flux due to photons described in Eq. (A-3) is  $\phi'(r', \Lambda' \rightarrow \Lambda, \Omega', t) dr'$  divided by  $ds$ , the surface area seen by  $d\Omega$ , at  $r$  and,

$$ds = d\Omega |\underline{r} - \underline{r}'|^2 \quad (\text{A-6})$$

Define now,  $\Sigma_D(\Lambda)$  and  $\Sigma(\Lambda)$  to be respectively the photoneutron reaction and the attenuation cross section for photons of energy  $\Lambda$  in  $D_2O$ .

We can, then, write the total number of photoneutrons generated by photons having had one and only one collision, from an atom of  $U^{235}$  on an infinite medium of  $D_2O$  to be

$$S_1 = \int_{r', r, \Lambda', \Omega', \Omega} d\underline{r}' d\underline{r} d\Lambda' d\Omega' \psi'(r', \Lambda', \Omega', \infty) d^2 \sigma(\Lambda' \rightarrow \Lambda) N_{D_2O}^Z \times \frac{1}{ds} e^{-\Sigma(\Lambda) |\underline{r} - \underline{r}'|} \Sigma_D(\Lambda), \quad (\text{A-7})$$

where  $\int_{r', r, \Lambda', \Omega', \Omega}$  denotes the integrations over the variables  $r', r, \Lambda', \Omega'$  and  $\Omega$ , and  $\infty$  in  $\psi'(r', \Lambda, \Omega', \infty)$  stands for  $t = \infty$ ; that is, the atom of  $U^{235}$  being

fissioned, we wait for all the gamma rays to come out of the fission products.

#### A-1 Calculation of $S_1$

To perform the calculation of  $S_1$  we consider the Fig. B-2 (of Appendix B) where we have  $a(\Lambda', t)$ , the number of photons of energy  $\Lambda'$  emitted per sec., per Mev,  $t$  second(s) after the fission of an atom of  $U^{235}$  took place.

Then,

$$\psi'(r', \Lambda', \Omega', t) = \left\{ \int_0^t a(\Lambda', t') dt' \right\} \frac{1}{4\pi} \times \frac{1}{ds'} e^{-\Sigma(\Lambda')r'}, \quad (\text{A-8})$$

where

$$ds' = d\Omega' r'^2, \quad (\text{A-9})$$

and

$$d\underline{r}' = r'^2 \sin \theta' d\theta' d\mu' dr' \quad (\text{A-10})$$

in the spherical coordinate system relative to  $O(U^{235})$ .

Next notice,

$$d\underline{r} = dsd|\underline{r}-\underline{r}'|. \quad (\text{A-11})$$

Eq. (A-7), through Equations (A-8) up to (A-11), thus becomes,

(A-12)

$$S_1 = \int_{r'=0}^{\infty} \int_{|\underline{r}-\underline{r}'|=0}^{\infty} \int_{\theta'=0}^{\pi} \int_{\theta=0}^{\pi} \int_{\mu'=0}^{\pi} \int_{\mu=0}^{\pi} \int_{\Lambda'=E_{th}}^{\infty} \left\{ \int_0^{\infty} a(\Lambda', t') dt' \right\} \frac{1}{4\pi} \sin \theta' d\theta' d\mu' dr' e^{-\Sigma(\Lambda')r'} d\Lambda'$$

$$d^2_e \sigma(\Lambda' \rightarrow \Lambda)_{\underline{D}_2\text{O}}^{Z\Sigma_D(\Lambda)} d|\underline{r}-\underline{r}'| e^{-\Sigma(\Lambda)|\underline{r}-\underline{r}'|}$$

where  $E_{th}$  is for the threshold energy for photoneutron reaction in  $\underline{D}_2\text{O}$  (2.23 Mev).

Note that  $r'$ ,  $\theta'$ ,  $\mu'$  and  $|\underline{r}-\underline{r}'|$  are independent variables and that  $\mu$  comes into play within  $d^2_e(\Lambda' \rightarrow \Lambda)$  only; thus define

$$d_e \sigma = \int_{\mu=0}^{2\pi} d^2_e \sigma. \quad (\text{A-13})$$

Further define

$$A(\Lambda') = \int_0^{\infty} a(\Lambda', t) dt \quad (\text{A-14})$$

Next consider  $L$  photon groups (Fig. A-2) such that  $\Delta_\ell = \Lambda_{\ell-1} - \Lambda_\ell$  ( $\ell = 1, \dots, L$ ) is small enough to replace  $d\Lambda$ .

Fig. A-2 Photon energy groups

Then the scattering can be assumed to remove the photon into a lower energy group. Also the scattering cross section for photons of energy within such group, into a lower energy group, can be taken as constant and equal to  $d^2_e \sigma(\bar{\Lambda}_\ell' \rightarrow \bar{\Lambda}_\ell)$ ,  $\bar{\Lambda}_\ell'$  and  $\bar{\Lambda}_\ell$  being the representative energies of the photon energy groups to which

the photon belongs respectively before and after the scattering.

We define

$$A_{\ell} = \frac{1}{\Delta\Lambda_{\ell}} \int_{\Lambda_{\ell}}^{\Lambda_{\ell-1}} A(\Lambda) d\Lambda, \quad (\text{A-15})$$

$$\Sigma_{D_{\ell}} = \frac{1}{\Delta\Lambda_{\ell}} \int_{\Lambda_{\ell}}^{\Lambda_{\ell-1}} \Sigma_D(\Lambda) d\Lambda \quad (\text{A-16})$$

$$\Sigma_{\ell} = \frac{1}{\Delta\Lambda_{\ell}} \int_{\Lambda_{\ell}}^{\Lambda_{\ell-1}} \Sigma(\Lambda) d\Lambda \quad (\text{A-17})$$

With the above remarks and definitions Eq. (A-12) can then be written as

$$S_1 = N_{D_2} O^Z \sum_{\ell'=1}^L A_{\ell', \Delta\Lambda_{\ell'}} \frac{1}{\Sigma_{\ell'}} \sum_{\ell=\ell'+1}^L d_e \sigma(\ell' \rightarrow \ell) \Sigma_{D_{\ell}} \times \frac{1}{\Sigma_{\ell}},$$

where

$$d_e \sigma(\ell' \rightarrow \ell) \equiv \int_{\mu=0}^{2\pi} d^2_e \sigma(\bar{\Lambda}_{\ell'} \rightarrow \bar{\Lambda}_{\ell}) \text{ or precisely} \quad (\text{A-19})$$

$$d_e \sigma(\ell' \rightarrow \ell) = \pi r_0^2 \left( \frac{\bar{\Lambda}_{\ell}}{\bar{\Lambda}_{\ell'}} \right)^2 \left( \frac{\bar{\Lambda}_{\ell'}}{\bar{\Lambda}_{\ell}} + \frac{\bar{\Lambda}_{\ell}}{\bar{\Lambda}_{\ell'}} - \sin^2 \theta \right) \sin \theta d\theta,$$

with

$$\frac{1}{\bar{\Lambda}_{\ell'}} - \frac{1}{\bar{\Lambda}_{\ell}} = \frac{1 - \cos \theta}{E_0}, \quad (\text{A-20})$$

$$\sin \theta d\theta = E_0 \frac{\Delta \Lambda_{\ell}}{\bar{\Lambda}_{\ell}^2}. \quad (\text{A-21})$$

Combining Equations (A-18) through (A-21) we finally have

$$S_1 = \pi N_{D_2O} Zr_0^2 \sum_{\ell'=1}^{L-1} \frac{A_{\ell'}}{\Sigma_{\ell'}} \frac{1}{\Sigma_{\ell'+1}} \left( \frac{\bar{\Lambda}_{\ell}}{\bar{\Lambda}_{\ell'}} \right)^2 \left( \frac{\bar{\Lambda}_{\ell'}}{\bar{\Lambda}_{\ell}} + \frac{\bar{\Lambda}_{\ell}}{\bar{\Lambda}_{\ell'}} \right) \quad (\text{A-22})$$

$$- 1 + E_0^2 \left( \frac{1}{E_0} + \frac{1}{\bar{\Lambda}_{\ell}} - \frac{1}{\bar{\Lambda}_{\ell'}} \right)^2 \left. E_0 \frac{\Delta \Lambda_{\ell}}{\bar{\Lambda}_{\ell}^2} \Sigma_{D_{\ell}} \times \frac{1}{\Sigma_{\ell}} \right\}$$

where

$$\underline{A}_{\ell'} = A_{\ell'} \Delta \Lambda_{\ell}'. \quad (\text{A-23})$$

## A-2 Scheme for numerical application

The scheme presented in Table A-1 was the one

adopted for numerical calculations and the

Table A-1  
Photon Energy Groups to Compute  $S_1$

$\ell$	$\Lambda_{\ell-1}$ (Mev)	$\bar{\Lambda}_{\ell}$ (Mev)
1	6.00	5.000
2	4.00	3.500
3	3.00	2.875
4	2.75	2.625
5	2.50	2.365

$\Lambda_{\ell}$ : lower limit of energy group  $\ell$

$\bar{\Lambda}_{\ell}$ : representative energy of group  $\ell$

determination of the relevant data ( $\underline{A}_{\ell}$ ,  $\Sigma_{D_{\ell}}$ ,  $\Sigma_{\ell}$ ,  $\ell=1, \dots, 5$ ) is discussed in the Appendix B.

Results are grouped in Table A-2.

Table A-2  
Data to Compute  $S_1$

$\ell$	$\underline{A}_{\ell}$	$\sigma_{D_{\ell}} \times 10^{27}$ ( $\text{cm}^2$ )	$\Sigma_{\ell}$ ( $\text{cm}^2$ )
1	0.0692	----	---
2	0.141	2.25	0.0366
3	0.0518	1.70	0.0405
4	0.0804	1.20	0.0424
5	---	0.60	0.0448

Note that the number for  $A_q$ 's\* given in Table A-2 has been calculated for the time interval  $2 \text{ sec.} \leq t \leq 10^3 \text{ sec.}$  To speak rigorously a correction ought to be made for those photoneutrons generated (by photons having had collisions) within 2 sec. and after  $10^3 \text{ sec.}$  the fission event took place. Nevertheless we show in this Appendix that photoneutrons generated by photons having had collisions can be neglected. Thus the time correction in question is omitted.

---

\* The value,  $A_1$ , of Table A-2 is 0.0692 whereas it would be 0.0650 as calculated from the last column of Table B-4. The difference is due to the fact that the latter number accounts for photons of the first energy group with an upper limit of only 6 Mev. Yet there are photons of energy beyond 6 Mev. An effort is made to include those photons in the first group. Thus an estimate of the number of photons, emitted from the fission products of an atom of  $U^{235}$ , of energy beyond 6 Mev is made through the energy dependence formula for photons of interest (cf. Appendix B, Fig. B-6):

$6.22 e^{-1.1\Lambda}$  ( $\Lambda > 4 \text{ Mev}$ ). The number

$$\int_0^{\infty} 6.22 e^{-1.1\Lambda} d\Lambda = 0.421 \times 10^2, \text{ is then added to } 0.0650$$

to obtain 0.0692. Note that  $\frac{\sigma_D(\Lambda)}{\Sigma(\Lambda)}$  beyond 6 Mev is approximately constant.

In addition  $r_0$  is taken to be  $2.818 \times 10^{-13}$   
and  $N_{D_2O}$ ,  $3.32 \times 10^{22}$ .

### A-3 Result and conclusion

The calculation for Equation (A-20) was carried out with a computer program shown in Appendix J. The result is

$$S_1 = 0.93 \times 10^{-4} \text{ photoneutrons/fission of } U^{235} \quad (\text{A-24})$$

On the other hand we learn from the Table B-1 of Appendix B that the total number of photoneutrons produced by photons from  $U^{235}$  fission products interacting with  $D_2O$  is  $2.44 \times 10^{-3}$ . We assume that the difference  $(2.44 \times 10^{-3} - 0.093 \times 10^{-3})$  is due to those photoneutrons produced by the uncollided photons (that is an approximation of about 12% according to section B-2 of Appendix B). Thus, with an error of a few percent, —we note that this will be even less for a finite system as in the case of MITR-II, because of the leakage of a considerable number of photons out of the reactor (about 20% only of the fission photons are absorbed in the  $D_2O$  reflector of the Franco-German reactor ALIZE III )—, the photoneutrons due to photons having had collisions can be neglected.

## APPENDIX B

### CORRELATION BETWEEN THE DATA RELEVANT TO THE DELAYED PHOTONS FROM $U^{235}$ FISSION PRODUCTS AND THE DATA RELEVANT TO THE DELAYED PHOTONEUTRONS GENERATED BY THOSE PHOTONS, IN $D_2O$

The purpose of this Appendix is to determine whether the data relevant to the generation of delayed photons from  $U^{235}$  fission products (Fig. B-1 and Fig. B-2) is consistent with the attenuation and photoneutron reaction cross sections of photons in  $D_2O$  (Fig. B-3 and Fig. B-4). If this is the case, then through those data one should be able to obtain the data relevant to the production of delayed photoneutrons by photons from  $U^{235}$  fission products in  $D_2O$  (cf. Table B-1).

To this end we consider the fission of one atom of  $U^{235}$  in an infinite medium of  $D_2O$ .

Let then  $A_\ell$  be the total number of photons within  $\ell^{\text{th}}$  group of photons coming from the fission products of one atom of  $U^{235}$ , between 2 and  $10^3$  sec. after the fission event took place. For these photons let  $\Sigma_\ell$  and  $\Sigma_{D_\ell}$  be the attenuation and photoneutron reaction cross sections in  $D_2O$ .

Thus, taking into account only uncollided photons,

$$S_0 = \sum_{\ell=1}^L \frac{A_\ell \Sigma_{D_\ell}}{\Sigma_\ell} \int_0^\infty \frac{1}{4\pi r^2} e^{-\Sigma_\ell r} 4\pi r^2 dr = \sum_{\ell=1}^L \frac{A_\ell \Sigma_{D_\ell}}{\Sigma_\ell} \quad , (B-1)$$

is the number of photoneutrons generated by photons coming from

Fig. B-1 Time dependence of the emission of gamma rays that can give rise to the photoneutron reaction in  $D_2O$ , for long times after fission [12].

Table B-1 [16]

Fig. B-4 Photoneutron production cross section for deuterium [15]

the fission products of one atom of  $U^{235}$ , placed in an infinite medium of  $D_2O$ , in the interval 2 sec. to  $10^3$  sec. after the fission event took place. ( $L$  is the number of photon groups.).

#### B-1 Calculation of $\underline{A}_\ell$

For the calculation of  $\underline{A}_\ell$  we aim to obtain, starting with Fig. B-2, curves similar to the ones of Fig. B-1, but for more than two groups of photons.  $\underline{A}_\ell$  will be then, the area under the  $\ell^{\text{th}}$  curve ( $2 \text{ sec.} \leq t \leq 10^3 \text{ sec.}$ ) multiplied by the width of the  $\ell^{\text{th}}$  group of photons.

Actually we shall end by adopting the two-group scheme (cf. Fig. B-1). However at this stage of the development we do not know whether or not the photoneutrons produced in  $D_2O$  by photons of energy beyond 5 Mev (upper energy limit of photons sketched in Fig. B-1) can be neglected as compared to the photoneutrons produced by the less energetic photons. In addition we must prepare the material to be used in Appendix A (study of the photoneutrons produced by photons having had collisions), and that will require a scheme with more than two-group of photons. Also for a consistency check of the data we try to avoid possible errors due to the calculation of average cross sections for a few-group scheme.

$\underline{A}_\ell$  is accordingly first calculated in the following way for fifteen-groups of photons;

- Make up Table B-2 out of Fig. B-2, with  $P_\ell(t)$  being the number of photons/Mev x fission x sec., belonging to the  $\ell^{\text{th}}$  group of photons, versus time after fission;

- Then similarly to Fig. B-1, draw Fig. B-5, where we have for each of fifteen groups of photons, the decay of the fission products photons.

- Finally integrate graphically each of the curves of Fig. B-5 between  $t=2$  sec. and  $t=10^3$  sec. (cf. Table B-3) to make up Table B-4, where the product of this procedure,  $A_\ell$ 's ( $\ell=1, \dots, 15$  - the most energetic group bearing the number 15 - ) are given, so that

$$\underline{A}_\ell = \Delta\Lambda_\ell A_\ell = \Delta\Lambda_\ell \int_2^{1000} P_\ell(t) dt, \quad \ell=1, \dots, 15, \quad (\text{B-2})$$

where  $\Delta\Lambda_\ell$  is the width of the  $\ell^{\text{th}}$  group of photons.

15	5.825	0.25	0.0090

$\Delta\bar{\pi}_\ell$ ; width of  $\ell^{\text{th}}$  group

We point out that later in the library of the code POPOP IV (cf. Appendix D) we found numbers for  $\underline{A}_\ell$ 's (photons from the fission of  $U^{235}$ ,  $t \geq 1$  sec.) presented below;

$\ell$	$\Lambda_\ell$ (Mev)	$\underline{A}_\ell$
1	2.2	3.40500 E-1
2	2.6	2.27500 E-1
3	3.0	1.27860 E-1
4	3.5	9.41499 E-2
5	4.0	6.93300 E-2
6	4.5	3.36500 E-2
7	5.0	1.61900 E-2
8	5.5	7.77000 E-3
9	6.0	0.

where  $\Lambda_\ell$  refers to the upper energy limit of the  $\ell^{\text{th}}$  group, and  $yE-n$  stands for  $y \times 10^{-n}$ .

We note that (although slightly higher) these numbers check against our results (11.917 E-2 and 39.264 E-2 against 9.9 E-2 and 34.8 E-2 of Table B-7 - presented further -. In addition according to those numbers of the library of the code POPOP IV we have: 12.694 E-2 for the energy interval 3.5 Mev - 10 Mev, and 43.246 E-2 for the energy interval 2.23 Mev - 3.5 Mev.).

$$\text{B-2 Calculation of } S_0 = \sum_{\ell=1}^L A_{\ell} \frac{\Sigma_{D\ell}}{\Sigma_{\ell}}$$

One can then with the help of Fig. B-3 , Fig. B-6 and Table B-4 , make up the Table B-5 , where the last column multiplied by  $\Delta\Lambda_{\ell}$  and summed over  $\ell$  furnishes the result of Eq. (B-1) .

Table B-5 Calculation of  $A_{\ell} \sigma_{D\ell} / \Sigma_{\ell}$

Energy group $\ell$	$\Sigma_{\ell} \times 10^2$ ( $\text{cm}^{-1}$ )	$\sigma_{D\ell}$ (mb)	$A_{\ell} \frac{\sigma_{D\ell} \text{ (mb)}}{\Sigma_{\ell} \text{ (cm}^{-1}\text{)}}$
1	4.48	0.60	5.24
2	4.24	1.20	9.10
3	4.05	1.70	8.72
4	3.88	2.10	8.11
5	3.73	2.20	10.15
6	3.58	2.30	9.66
7	3.45	2.37	6.21
8	3.33	2.40	5.93
9	3.23	2.44	3.92
10	3.13	2.42	2.87
11	3.05	2.41	1.965
12	2.96	2.40	1.770
13	2.90	2.37	1.720
14	2.83	2.30	1.00
15	2.77	2.26	0.735

$$\text{That is, } S_0 = \left( \sum_{\ell=1}^{15} A_{\ell} \frac{\sigma_{D_{\ell}} \Delta \Lambda_{\ell}}{\Sigma_{\ell}} \right) \times 2 \times N_{D_2O} = 19.42 \times 2 \times 3.32 \times 10^{-5}$$

$$= 1.29 \times 10^{-3} \text{ photoneutrons/fission of } U^{235}, \text{ } 2 \text{ sec.} \leq t \leq 10^3 \text{ sec.}$$

This answer is to be compared to the summation of the number presented in the last column of Table B-1, that is  $2.44 \times 10^{-3}$  photoneutrons/fission of  $U^{235}$ . However one should notice that in the course of the calculation of the number  $S_0$  above, we have dealt with photons of energy up to 6 Mev only, whereas some of the photoneutrons will be produced by photons of energy beyond 6 Mev. In addition we have taken into account photons generated between  $t = 2$  sec. and  $t = 10^3$  sec. only, whereas delayed photons appearing within 2 sec. or  $10^3$  sec. after the fission, will also give rise to photoneutrons. Thus the number for  $S_0$ , found above should be corrected accordingly before being compared to  $2.44 \times 10^{-3}$ , result of Table B-1.

B-2-1 Estimation of photoneutrons produced by photons of energy beyond 6 Mev.

In order to estimate the number of photoneutrons produced by photons of energy beyond 6 Mev, coming from the fission products of  $U^{235}$ , in an infinite medium of  $D_2O$  between  $t=2$  sec. and  $t=10^3$  sec. after fission, we draw the last column of Table B-5 versus the second column of Table B-4 for  $\bar{\Lambda}_{\ell} \geq 4$  Mev, that is Fig. B-6 (where, the last column of Table B-4 versus the second column of Table B-4 is also plotted-bottom curves- for  $\bar{\Lambda}_{\ell} \geq$  Mev., for use in Appendix A, section A-2). We then approximate the photoneutrons produced by photons of energy beyond

Fig. B-6 For extrapolation beyond 6 MW, the total number of photons from fission products of  $U^{235}$  versus energy ( $\geq 4$  MeV) - bottom curve and the total number of photoneutrons produced by those photons - upper curve are approximated by straight lines

6 Mev by  $\int_6^{\infty} 4.9 \times 10^2 e^{-1.1\Lambda} d\Lambda \approx 0.62$ , that is to be added to 19.42. With this  $S_0$  becomes  $1.34 \times 10^{-3}$  photoneutrons/fission of  $U^{235}$ , 2 sec.  $\leq t \leq 10^3$  sec.

B-2-2 Time correction brought to the total number of photoneutrons produced per fission of  $U^{235}$ .

In order to compare the result of Table B-1, that is the number  $2.44 \times 10^{-3}$ , to the number  $S_0$  we obtained, we have to remove from the former, the number of photoneutrons produced within 2 sec. and after  $10^3$  sec. the fission of  $U^{235}$  took place; since  $N$  has been calculated for the interval of time 2 sec.  $\leq t \leq 10^3$  sec.

We assume that, a photoneutron decaying with one of the half lifes shown in Table B-1, implies there must be a photon appearing with that same half life, that creates the photoneutron in question. Thus we let  $N_{0j} (1 - e^{-\lambda_j t})$  be the total number of  $j^{\text{th}}$  -time wise- group of photons emitted until  $t$ . Then, assuming that there is only one energy-group of photons with  $\bar{\Sigma}$  and  $\bar{\Sigma}_D$  being the average attenuation and photoneutron reaction cross sections of photons in  $D_2O$ , to achieve the "time correction" the number  $2.44 \times 10^{-3}$  should be multiplied

by

$$C = \frac{\bar{\Sigma}_D \sum_j \left[ N_{0j} (1 - e^{-\lambda_j \times 10^3}) - N_{0j} (1 - e^{-\lambda_j \times 2}) \right]}{\bar{\Sigma} \sum_j N_{0j}} \quad (B-3)$$

Defining  $y_j$  to be the yield of a photon of  $j^{\text{th}}$  time group,

and noting

$$N_{0j} = N_0 y_j \quad , \quad (B-4)$$

where

$$N_0 = \sum_j N_{0j} \quad , \quad (B-5)$$

and  $\sum_j y_j = 1$ , we find that C becomes

$$C = \sum_j y_j (e^{-\lambda_j \times 2} - e^{-\lambda_j \times 10^3}) \quad . \quad (B-6)$$

$y_j$ 's are presented in Table B-6, being calculated from the information of Table B-1.

Table B-6 Yield of a photoneutron of -time wise-group j

j	$\lambda_j$	$y_j$
1	$2.77 \times 10^{-1}$	0.647
2	$1.69 \times 10^{-2}$	0.2025
3	$4.81 \times 10^{-3}$	$6.97 \times 10^{-2}$
4	$1.50 \times 10^{-3}$	$3.34 \times 10^{-2}$
5	$4.28 \times 10^{-4}$	$2.05 \times 10^{-2}$
6	$1.17 \times 10^{-4}$	$2.31 \times 10^{-2}$
7	$4.37 \times 10^{-5}$	$3.19 \times 10^{-3}$
8	$3.63 \times 10^{-6}$	$1.008 \times 10^{-3}$
9	$6.26 \times 10^{-7}$	$0.496 \times 10^{-3}$

The calculation of C from Eq. (B-6) then gives  $C \approx 0.67$ .

We should also include with the number  $S_0$  the number of photoneutrons produced by photons having had one and only one collision (calculated in Appendix A), that is  $S \approx 1.345 \times 10^{-3} + 0.93 \times 10^{-4} = 1.44 \times 10^{-3}$  photoneutrons/fission of  $U^{235}$ . This is now to be compared to the number  $2.44 \times 10^{-3} \times 0.673 \approx 1.64 \times 10^{-3}$  photoneutrons/fission of  $U^{235}$ . The agreement is satisfactory (for a difference of about 12%, which is we think, partially due to the procedure of calculation, graphical integrations etc.).

Hence we conclude the data relevant to the generation of photons from  $U^{235}$  fission products and the attenuation and photoneutron reaction cross sections of those photons in  $D_2O$ , are consistent.

### B-3 The two group scheme of Fig. B-1

The upper curve of Fig. B-6 suggests that the photoneutrons produced by photons of energy beyond 5 Mev (that is

$$\int_5^{\infty} 4.9 \times 10^2 e^{-1.1\Lambda} d\Lambda$$

can be neglected (within an error of

about 8%). We also have shown we do not have to carry photoneutron generated by photons having had collisions (cf. Appendix A) that required a multigroup scheme. Henceforth we can adopt instead of the complicated fifteen-group scheme derived from Fig. B-2, the two-group scheme already presented in Fig. B-1 ( $2.3 \text{ Mev} \leq \Lambda \leq 5 \text{ Mev}$ ,  $1 \text{ sec.} \leq t \leq 10^3 \text{ sec}$ ).

The relevant numbers are shown in Table B-7.

Table B-7 The two-group photon scheme

$\ell$	$\Lambda_{\ell-1}$ (Mev)	$\Delta\Lambda_{\ell}$ (Mev)	$\underline{A}_{\ell} \times 10^2$	$\Sigma_{\ell} (\text{cm}^{-1}) \times 10^2$	$\sigma_{D_{\ell}}$ (mb)
1	7	1.5	9.9	3.28	2.39
2	3.5	1.2	34.8	4.00	1.56

$$\Lambda_2 = 2.3 \text{ Mev}$$

In Table B-7

$$\underline{A}_{\ell} = A_{\ell} \Delta\Lambda_{\ell}, \quad \ell = 1, 2, \quad (\text{B-7})$$

and  $A_{\ell}$  is obtained by integration of the curves of Fig. B-1 between  $t = 1$  sec. and  $t = 10^3$  sec. For this purpose we approximated the two curves of Fig. B-1, by two equations each; specifically we found for the upper curve of Fig. B-1;

$$a_1(t) = 6 \times 10^{-3} t^{-0.816}, \quad \text{sec} \leq t \leq 10^2 \text{ sec}, \quad (\text{B-8})$$

$$a_1(t) = 3.83 t^{-2.084}, \quad 10^2 \text{ sec.} \leq t \leq 10^3 \text{ sec}, \quad (\text{B-9})$$

and for the lower curve of Fig. B-1 ;

$$a_2(t) = 3.0 \times 10^{-2} t^{-0.85}, \quad 1 \text{ sec.} \leq t \leq 10^2 \text{ sec.}, \quad (\text{B-10})$$

$$a_2(t) = 3.75 \times 10^{-1} t^{-1.398}, \quad 10^2 \text{ sec.} \leq t \leq 10^3 \text{ sec.} \quad (\text{B-11})$$

In addition  $\Sigma_{\ell}$  and  $\sigma_{D_{\ell}}$  ( $\ell = 1, 2$ ) were collapsed from the fifteen-group data. We neglect the photoneutrons generated by photons of energy beyond 5 Mev. and also the photoneutrons

generated by photons having had collisions. We then estimate through the two-group scheme of Table B-7 the number of the photoneutrons produced by the delayed photons from the fission products of an atom of  $U^{235}$  placed in the middle of an infinite medium of  $D_2O$ . The result agrees with the data:  $2.44 \times 10^{-3}$  of Table B-1, within 30% of error.

[It is worthwhile to mention that using  $A_{\ell}$ 's computed through the numbers (presented above) of the library of the code POPOP IV ( $A_1 = 12.694 \times 10^{-2}$ ,  $A_2 = 43.246 \times 10^{-2}$ ), the data shown in Table B-7, and the result of Appendix A, the agreement with the data:  $2.44 \times 10^{-3}$  of Table B-1 falls within 5% of error.]

B-4 Representation of Fig. B-1 in terms of the data of Table B-1.

We were able to reproduce the data of Table B-1, having started with the data relevant to Fig. B-2 or Fig. B-1. This suggests that we can describe the emission of the gamma rays from  $U^{235}$  fission products, of sufficient energy to produce photoneutron reaction in  $D_2O$ , by

$$a_{\ell}(t) = \frac{1}{\Delta\lambda_{\ell}} Y_{\ell} \sum_{j=1}^J \lambda_j y_j N_0 e^{-\lambda_j t}, \quad (B-12)$$

with  $\Delta\lambda_{\ell}$ , the width of the  $\ell^{\text{th}}$  photon group.  $Y_{\ell}$  is the probability that a fission product photon of sufficient energy to produce photoneutron reaction in  $D_2O$ , appears within the  $\ell^{\text{th}}$  group (assuming that this probability is not a function

of time).  $\lambda_j$  is the decay constant of the  $j^{\text{th}}$  ( $j=1, \dots, j$ ) group shown in Table B-1.  $y_j$ 's are presented in Table B-6 and  $N_0$  is defined through Eq. (B-5).  $Y_\ell$  is represented by [17];

$$Y_\ell = \frac{\int_{\Lambda_\ell}^{\Lambda_\ell - 1} 1.1 e^{-1.1\Lambda} d\Lambda}{\int_{2.23}^{\infty} 1.1 e^{-1.1\Lambda} d\Lambda} \tag{B-13}$$

(cf. also the lower curve of Fig. B-6). That is for the two-group scheme we make up the Table B-8.

Table B-8  $Y_\ell, \ell = 1, 2$

$\ell$	$Y_\ell$
1	0.24
2	0.76

$N_0$  remains to be determined so that we can make use of Eq. B-12. Thus from Eq. B-12

$$\underline{A}_\ell = \Delta\Lambda_\ell \int_0^\infty a_\ell(t) dt = Y_\ell N_0. \tag{B-14}$$

Next insert the RHS of Eq.(B-14) in Eq.(B-1). Then with the numbers of Tables B-7 and B-8 we obtain

$$N_0 \approx 0.8 \tag{B-15}$$

Finally based on Equations (B-12),(B-15)and the Tables B-1, B-6, B-7 and B-8, we can make up the Table B-1 and Fig. B-7 where a comparison of the theoretical and experimental behavior of

$$a(t) = \sum_{\ell=1}^2 a_{\ell}(t) \Delta \Lambda_{\ell} \quad (\text{B-16})$$

is shown

Table B-9 Comparison of the theoretical and experimental values of  $a(t)$

t(sec)	$\sum_{j=1}^8 \lambda_j N_{0j} e^{-\lambda_j t}$ theoretical	a(t) experimental
1	$1.1 \times 10^{-1}$	$4.8 \times 10^{-2}$
10	$1.2 \times 10^{-2}$	$7.5 \times 10^{-3}$
$10^2$	$1.2 \times 10^{-3}$	$9.5 \times 10^{-4}$
$10^3$	$1.8 \times 10^{-5}$	$3.4 \times 10^{-5}$

Fig. B-7 Comparison of the Theoretical and Experimental  $\log_{10}(t)$  Behavior of  $a(t)$

## B-5 Conclusion

In this Appendix we have shown that the data relevant to the production of photons -from the fission products of  $U^{235}$  -and the data relevant to the attenuation of photons and photoneutron reaction (cross sections) in heavy water are consistent (within  $\approx 10\%$  of accuracy). Thus for the purpose of our calculations, we can make use of the attenuation and photoneutron reaction cross sections in  $D_2O$ , satisfactorily (at least for the photons of interest:

$$\Lambda \geq 2.23 \text{ MeV}).$$

Moreover, this checking of one data against the other led us, neglecting the photoneutrons produced by photons having had collisions, to derive an analytical representation for the curves of Fig. B-1 as the summation of nine exponential functions:  $e^{-\lambda_j t}$ ,  $\lambda_j$  ( $j = 1, \dots, 9$ ) being the decay constant of the  $j^{\text{th}}$  -time wise- delayed photoneutron group (cf. Table 2-1).

Thus for the purpose of our calculations, Eq. (B-12) coupled with Eq. (B-15) will be used to express the production of delayed photons from  $U^{235}$  fission products\*.

---

\* It is worthwhile to mention that this enables us further to drive our equations for the unknown time coefficients (cf. Chapter III) into the familiar point kinetics form, thus

---

making the solution much easier to find.

APPENDIX C

THE PROBABILITY  $P_{\Lambda}(E_{\Lambda})$ , THAT A PHOTONEUTRON INDUCED IN  $D_2O$  BY PHOTONS OF ENERGY  $\Lambda$ , WILL BE BORN WITH AN ENERGY  $E_{\Lambda}$

A formula relating the energy  $E_{\Lambda}$  of a photoneutron induced by photons of energy  $\Lambda$  can be found in Reference [10] to be

$$E_{\Lambda} = \frac{1}{2} \left( \Lambda - 2.23 - \frac{\Lambda^2}{1862} \right) + \Lambda \left( \frac{\Lambda - 2.23}{931} \right)^{\frac{1}{2}}, \quad (C-1)$$

where  $\Lambda$  and  $E_{\Lambda}$  are in MeV.

The Table C-1 and Fig. C-1 illustrate Eq. (C-1).

Table C-1

Energy  $E_{\Lambda}$  of a Photoneutron Induced by  
Photons of Energy  $\Lambda$ , in  $D_2O$

$\Lambda$ (MeV)	2.5	3	4	5
$E_{\Lambda}$ (MeV)	0.195	0.488	1.08	1.67

According to Eq. (C-1) an appropriate analytical representation of  $P_{\Lambda}(E_{\Lambda})$  would be,

$$P_{\Lambda}(E) = \delta(E - E_{\Lambda}) \quad (C-2)$$

Fig. C-1 Energy of a Photoneutron as a Function of the Energy of the Incident Photon, in  $D_2O$

Furthermore, from Fig. C-1 we can see that the minimum energy that photoneutrons born in a heavy water medium carry, is 43 keV. The lower limit of the fast energy group of our three group scheme being 3keV, all the photoneutrons, therefore, will be born in the fast group.

On the other hand, through Eqs. (2-18), (2-13), (2-12) and (C-2), we have,

$$P_g = \text{diag} \left[ \frac{1}{\Delta\Lambda_1} \int_{\Lambda_1}^{\Lambda_0} d\Lambda \int_{E_g}^{E_{g-1}} \delta(E-E_\Lambda) dE \dots \frac{1}{\Delta\Lambda_L} \int_{\Lambda_L}^{\Lambda_{L-1}} d\Lambda \int_{E_g}^{E_{g-1}} \delta(E-E_\Lambda) dE \right]. \quad (C-3)$$

Hence,

$$P_g = \begin{pmatrix} 1 \\ 1 \end{pmatrix}, g = 1, \quad P_g = \begin{pmatrix} 0 \\ 0 \end{pmatrix}, g \neq 1 \quad (C-4)$$

where only two groups of photons have been considered.

## APPENDIX D

### THE SECONDARY GAMMA RAY CROSS SECTIONS FROM THE CODE POPOP IV

In the expression for the prompt photoneutron source term we have quantities such as,  $\Sigma_{f_g}(r,z,t) \prod_{f_{lg}}(r,z)$ , which is the cross section for photons, induced by  $j^{\text{th}}$  type of neutron reaction (either fission or prompt capture or inelastic scattering) due to neutrons of energy group  $g$ , to appear in the photon group  $l$ , at  $(r,z)$  and  $t$ .

Thus we need to evaluate

$$SGCS_{lg}(r,z,t) = N(r,z,t) \sum_{f=1}^3 \sigma_{f_g}(r,z) \prod_{f_{lg}}(r,z) \quad (D-1)$$

where  $N(r,z,t)$  is the atom density at  $(r,z)$  and  $t$ , and  $\sigma_{f_g}(r,z)$ , the microscopic cross section corresponding to  $\Sigma_{f_g}(r,z,t)$ .

The various quantities,  $\sum_{f=1}^3 \sigma_{f_g}^n \prod_{f_{lg}}^n$

[ where  $n$  replacing  $(r,z)$ , denotes the nuclide  $n$  present at  $(r,z)$  ], were computed by the code POPOP IV [2].

## D-1 Input to the Code POPOP IV

Input to the code POPOP IV consists of the boundaries of the neutron and photon energy groups, the nuclei of interest, and the reaction of interest. It is also necessary to input the neutron cross sections  $\sigma_{fg}^n$ 's. The code computes  $\prod_{f,lg}^n$  out of its own library, performs the multiplication  $\sigma_{fg}^n \times \prod_{f,lg}^n$  and eventually sums it over f if there is more than one reaction that the nuclei n can undergo.

## D-1-1 Cross sections input to the Code

The few groups fission and capture\* cross sections were ready for MITR-II (cf. Appendix I), whereas we had to determine the inelastic scattering cross sections.

There are only two elements present in MITR-II that can cause inelastic scattering gamma rays having an energy above the threshold energy for photoneutron reaction in  $D_2O$  (2.23 Mev). These are carbon and oxygen. The inelastic scattering cross sections for these two elements were estimated in the following way;

\*—

Capture cross section is identical to absorption cross section in case of a non fissile material. It is equal to the difference of absorption and fission cross sections in case of a fissile material.

$$\sigma_{j_{in_g}} = \frac{\int_{E_g}^{E_{g-1}} f(E) \sigma_{j_{in}}(E) dE}{\int_{E_g}^{E_{g-1}} f(E) dE}, \quad (D-2)$$

where  $f(E)$  [7] is the fission spectrum for  $U^{235}$  and  $\sigma_{j_{in}}(E)$  [8], the inelastic scattering cross section for the  $j^{\text{th}}$  nuclide at energy  $E$ .

Only fast neutrons (belonging to the fast group;  $E > 3\text{Kev}$ ) can cause inelastic scattering.

Hence, assuming  $\int_{3\text{Kev}}^{\infty} f(E) dE = 1$ , Eq. (D-2) becomes,

$$\sigma_{j_{in_1}} = \int_{E_{j_{\text{threshold}}}}^{\infty} f(E) \sigma_{j_{in}}(E) dE. \quad (D-3)$$

Equation (D-3) can then be written as,

$$\sigma_{j_{in_1}} = \sum_{n=1}^N \sigma_{j_{in_1}} F_n, \quad (D-4)$$

where

$$F_n = \int_{E_n}^{E_{n-1}} f(E) dE. \quad (D-5)$$

The calculations based on this formula are presented in Table D-1.

Table D-1 Calculation of the inelastic scattering cross section of  ${}^6\text{C}^{12}$  and  ${}^8\text{O}^{16}$  for the fast group of our scheme

Element	$E_{\text{threshold}}$ (MeV)	n	$E_n$ (MeV)	$F_n \times 10^2$	$\sigma_{\text{in}_n}$ (barn)	$\sigma_{\text{in}_n} F_n \times 10^3$
${}^6\text{C}^{12}$	4.8	1	6	3.489	0.1	3.489
		2	7	1.301	0.3	3.903
		3	8	0.615	0.3	1.845
		4	9	0.286	0.4	1.144
		5	10	0.131	0.3	0.393
						$\sum_{n=1}^5 \sigma_{\text{in}_n} F_n =$ 10.774 mb
${}^8\text{O}^{16}$	6.55	1	7	0.650	0.04	0.260
		2	8	0.615	0.20	1.230
		3	9	0.286	0.30	0.858
		4	10	0.131	0.35	0.458
						$\sum_{n=1}^4 \sigma_{\text{in}_n} F_n =$ 2.806 mb

Thus for the inelastic microscopic scattering cross sections we input to the Code POPOP IV, the numbers in millibarn, (10.8, 0,0) for carbon and (2.8, 0,0) for oxygen.

D-1-2 Neutron and Photon energy group boundaries  
input to the Code POPOP IV

The neutron and photon energy group boundaries are given in Tables D-2 and D-3.

Table D-2 Upper energy limits of the neutron  
energy groups

energy groups

l	$E_{l-1}$ (Mev)
1	7.0
2	3.5

D-2 Output from the Code POPOP IV; the microscopic secondary gamma ray cross sections

In Table D-4 are given, in barn, the final microscopic secondary gamma ray cross sections for the two-photon and three-neutron energy group, for various material present in MITR-II. The second column gives the nuclide numbers that refer to the material in question (cf. Appendix I).

The reason that two  $D_2O$ 's appear in Table D-4 is that the few group microscopic cross sections have been obtained through a flux weighted collapsing procedure from a multigroup scheme. We may then have two different cross sections for the same material at different locations.

In Table D-4  $yE-x$  stands for  $yx10^{-x}$ .

We point out that the gamma rays born in  $H_2O$  are due to the inelastic scattering of neutrons with the oxygen nuclei only.

D-3 Macroscopic secondary gamma ray cross sections for materials present in MITR-II.

In order to get  $SGCS_{lg}(r,z,t)$  we have to multiply the numbers given in Table D-4 by the atom densities given in Appendix I. Table D-5 shows the macroscopic secondary gamma ray cross sections, in  $cm^{-1}$ , for the two photon and three neutron energy group, for various compositions (cf. Appendix G) in MITR-II at the steady state.

The Composition numbers 4,5,6,11,12,13,14,15,20,21 do not appear in Table D-5, the sets of Compositions (1,5,6,14), (2,15), (3,4,13), (10,11,12) and (18,20,21) being identical.

## APPENDIX E

### LINEAR DEPENDENCE OF THE SPATIAL FUNCTIONS

Obtaining the time dependent coefficients through the system of equations,

$$\Lambda \frac{dN(t)}{dt} = [\rho_{\text{new}}(t) - \bar{\beta}_{\text{new}}(t)] N(t) + \sum_{j=1}^H \lambda_j C_j(t), \quad (\text{E-1})$$

$$\frac{dC_j(t)}{dt} = \bar{\beta}_{j_{\text{new}}}(t) - \lambda_j C_j(t), \quad (\text{E-2})$$

will require inverting the generation time matrix  $\Lambda$ . This is possible if the determinant of the matrix  $\Lambda$  is not singular. Moreover, numerically an "almost" singular determinant for the matrix  $\Lambda$  is to be avoided. Thus the normalized determinant (Grahm determinant)

$$\det(G) = 1 - \frac{\Lambda_{12} \Lambda_{21}}{\Lambda_{11} \Lambda_{22}}, \quad (\text{E-3})$$

$$\Lambda_{ik} = \langle W_i^T(\underline{r}) \mid v^{-1} \mid \psi_k(\underline{r}) \rangle, \quad i = 1, 2, k = 1, 2, \quad (\text{E-4})$$

should be greater than an imposed criterium.

If we fear an "almost" linear dependence, we can use the difference of the second and first trial modes as the

second trial mode (if only two trial modes are used), that is

$$\psi_2'(\underline{r}) = \delta\psi(\underline{r}) = \psi_2(\underline{r}) - \psi_1(\underline{r}). \quad (\text{E-5})$$

However, here one must be careful in computing the leakage integral subject to section 5-2 of Chapter V, since Eqs. (4-19) or (5-14) do not hold for  $\psi_2'(\underline{r})$ . For the integral  $\langle W_i^T(\underline{r}) \mid \nabla \cdot D_2(\underline{r}, t) \nabla \mid \delta\psi(\underline{r}) \rangle$ ,  $i = 1, 2$  (with the familiar notation used throughout the dissertation) over the reactor volume, an appropriate expression may be found in the following way; write from Eq. (4-18),

$$\langle W_i^T(\underline{r}) \mid \nabla \cdot D_2(\underline{r}) \nabla \mid \psi_2(\underline{r}) \rangle = \langle W_i^T(\underline{r}) \mid A_2'(\underline{r}) - \frac{F_2(\underline{r})}{k_2} \mid \psi_2(\underline{r}) \rangle, \quad i = 1, 2. \quad (\text{E-6})$$

Nothing changes if we add at the right hand side of Eq. (E-6) the quantity  $\langle W_i^T(\underline{r}) \mid \nabla \cdot D_1(\underline{r}) \nabla - A_1(\underline{r}) + \frac{F_1(\underline{r})}{k_1} \mid \psi_1(\underline{r}) \rangle$ ,  $i = 1, 2$ , that is equal to zero by definition.

Next subtract from both sides of Eq. (E-6) the quantity

$$\langle W_i^T(\underline{r}) \mid \nabla \cdot D_2(\underline{r}) \nabla \mid \psi_1(\underline{r}) \rangle, \quad i = 1, 2. \quad \text{Also add and sub-}$$

tract at the same time, to and from the right hand side of

Eq. (E-6), the quantities  $\langle W_i^T(\underline{r}) \mid A_2'(\underline{r}) \mid \psi_1(\underline{r}) \rangle$  and

$\langle W_i^T(\underline{r}) \mid \frac{F_2(\underline{r})}{k_2} \mid \psi_1(\underline{r}) \rangle$ ,  $i = 1, 2$ , to obtain

$$\langle W_i^T(\underline{r}) \mid \nabla \cdot D_2(\underline{r}) \nabla \mid \delta\psi(\underline{r}) \rangle = \langle W_i^T(\underline{r}) \mid A_2'(\underline{r}) - \frac{F_2(\underline{r})}{k_2}$$

$$\mid \delta\psi(\underline{r}) \rangle + \langle W_i^T(\underline{r}) \mid - [\nabla \cdot D_2(\underline{r}) \nabla - \nabla \cdot D_1(\underline{r}) \nabla] + A_2(\underline{r})$$

$$- A_1(\underline{r}) - \left[ \frac{F_2(\underline{r})}{k_2} - \frac{F_1(\underline{r})}{k_1} \right] \mid \psi_1(\underline{r}) \rangle, \quad i = 1, 2. \quad (E-7)$$

Hence, if we wish to use the difference of the second and first trial modes as the second trial mode - to avoid an undesirable "almost" singular generation time matrix  $\Lambda$ , - we should compute the leakage integral associated with that second trial mode according to Eq. (E-7).

## APPENDIX F

### THE SOLUTION OF THE POINT KINETICS-TYPE OF EQUATIONS BY THE WEIGHTED RESIDUAL METHOD

We wanted to solve the system of equations

$$\Lambda \frac{dN(t)}{dt} = [\rho_{\text{new}}(t) - \bar{\beta}_{\text{new}}(t)] N(t) + \sum_{j=1}^H \lambda_j C_j(t), \quad (\text{F-1})$$

$$\frac{dC_j(t)}{dt} = \bar{\beta}_{j_{\text{new}}}(t) N(t) - \lambda_j C_j. \quad (\text{F-2})$$

The solution we have adopted [11] proceeds as follows: Choose a trial function,

$$\bar{N}(t) = \sum_{k=0}^K A_k (t-t_i)^k, \quad (\text{F-3})$$

for the time step:  $t_i \leq t \leq t_i + 1$ , with unknown parameters;  $A_k$ 's ( $k = 1, \dots, K$ ),  $A_0$  being  $N(t_i)$ . The bar on top of  $N(t)$  indicates an approximate expression.

Inserting Eq. (F-3) into Eq. (F-1) and Eq. (F-2) will give rise to time dependent residuals. We perform as many weighted integrals with those residuals as there are unknown parameters. One way of doing this is called subdomain weighting. We integrate the time dependent residuals

first over the entire time step, then over half of the time step, and so forth as many times as the number of unknown parameters.

This way we will get a system of equations in  $K$  unknowns that will determine  $\bar{N}(t)$  over  $t_i \leq t \leq t_i + 1$ . We then can carry out the same attack for the next time step.

The method proposed involves a way to select the time step (halving procedure) so that the convergence of the time coefficients is ensured.

APPENDIX G

THE (R,Z) CYLINDRICAL MODEL ADOPTED

**THE MODEL**

The (r,z) cylindrical model, that we have adopted for the Reactivity and Transient Analysis of MITR-II is shown above. In this model 23 Compositions are shown (note that the composition number 22 does not appear, thus the numbering goes up to 24). Each composition is made of nuclei which are numbered from 1 up to 55 as they were input to the code Exterminator-II. Below is shown the composition numbers before the nuclei numbers they are made of. Below each nuclei number, is presented the nucleus that bears this number.

## APPENDIX H

### APPROXIMATE ATTENUATION COEFFICIENTS, $ATT_{re}$ 's, FOR PRECHOSEN REGIONS OF THE $D_2O$ REFLECTOR

To save computer time, we do not calculate the attenuation coefficient

$$\frac{1}{4\pi(r^2 + z^2)} e^{-\Sigma_{\ell}(r^2 + z^2)^{\frac{1}{2}}}$$

( $\ell = 1, \dots, L$ ) at every point  $(r, z)$ . Instead we divide the reflector into regions within which a constant, approximate attenuation coefficient will be used.

To proceed, we make use of Fig. H-1 to create the final Table H-1.

The macroscopic attenuation cross section is taken to be equal to  $0.04 \text{ cm}^{-1}$ , the value appropriate for photons emitted with an energy of 3 MeV.

The regions in question are rectangular and defined by four mesh point numbers; two in the  $r$  direction:  $INUI_{re}$ ,  $INUF_{re}$ , and two in the  $z$  direction:  $INVI_{re}$ ,  $INVF_{re}$ , as shown in Fig. H-2 (cf. Appendix G for the presentation of the mesh volume structure for MITR-II).

(See following page for Fig. H-2.)

Fig. H-1 The Attenuation Factor as a Function of the Distance  $r$  of a Point in  $D_2O$  Medium, to a Central Point. The Attenuation Cross Section  $\Sigma$ , is Taken to be Equal to  $0.04 \text{ cm}^{-1}$ .

## APPENDIX K

### APPROXIMATE CORRECTION FACTORS FOR THE DELAYED NEUTRON FRACTIONS

We intended to approximate the Eq. (6-24) by applying a neutron balance argument to the already available fifteen-group Exterminator-II output for MITR-II.

The central idea of this method is to compute the ratio of the probability of causing fission of a delayed neutron to the probability of causing fission of a prompt neutron.

For this purpose neutrons born in the first six groups of a fifteen-group scheme are considered. These neutrons may cause fission, or ~~may~~ be absorbed, or may leak out of the core, or may scatter to a lower group. The probability for these events can be computed by a balance argument. The probability of causing fission of a neutron of group  $y$  in the core is for instance the number of fissions per sec. caused in the core by the neutrons of group  $g$  over the number of neutrons gained (or lost -if the reactor is at a steady state critical condition-) per sec. in the core in group  $g$ .

The neutrons born in group  $g$  are followed throughout their story until they become thermalized and the number of fissions caused by these neutrons is counted. The ratio of the final number of fissions caused by the neutrons born in group  $g$  - during the thermalization process - to the number of

neutrons born in group  $g$  give the global probability of causing fission of a neutron born in group  $g$  throughout its entire lifetime.

This probability  $\text{PFISS}(g)$ ,  $g=1, \dots, 6$ , is computed for all the six groups of neutrons and averaged over the prompt neutron spectrum. This yields,  $\text{PRTHP}$ , the global probability of causing fission of a prompt fission neutron over a lifetime period.

Assuming that the delayed neutrons are born in the fifth and sixth energy group of the fifteen-group scheme, the correction factor that we seek is then

$$C_{F_j} = \frac{\text{PFISS}(5)}{\text{PRTHP}}, \quad j = 1, \dots, 5, \quad (\text{K-1})$$

$$C_{F_6} = \frac{\text{PFISS}(6)}{\text{PRTHP}}, \quad (\text{K-2})$$

where  $j$  refers to the  $j^{\text{th}}$  delayed group.

The details of the calculations can be followed from the code written for this purpose (cf. Appendix L).

$\text{PFISS}(g)$ ,  $g = 1, \dots, 6$ , is shown in Table K-1.

Table K-1 PFISS(g), g=1,...,6

g	PFISS(g)
1	0.30629
2	0.40506
3	0.50895
4	0.57297
5	0.65779
6	0.70902

PRTHP is found to be 0.45959

To cross check this result the eigenvalue of the reactor may be computed by simply multiplying PRTHP by  $\nu$ , the average number of neutrons generated through the fission. If this is done a discrepancy of about 8% is found as compared to the eigenvalue given in the relevant Exterminator-II output. It is believed, this is due to the bad convergence of the fluxes.

Nevertheless it is anticipated that an error of the same order of magnitude may be introduced in each of the probabilities PFISS(g)'s. In this case  $C_{F_j}$ 's would not be affected by the fact that we had to work with badly converged fluxes.

C
C THIS PROGRAM COMPUTES THE RATIO OF THE PROBABILITY OF A DELAYED NEUTRON (BORN
C WITHIN THE 5TH OR 6TH GROUP OF THE 15-GROUP SCHEME) TO CAUSE FISSION, TO THE
C PROBABILITY OF A FISSION NEUTRON TO CAUSE FISSION. THIS RATIO WILL BE USED AS A
C CORRECTION FACTOR FOR THE DELAYED NEUTRON FRACTIONS IN FEW GROUP SCHEME WHERE
C PROMPT AND DELAYED NEUTRONS ARE BORN WITHIN THE SAME -FAST- GROUP

## APPENDIX N

### BRIEF DESCRIPTION OF THE INPUT TO OZAN

All the input is in NAMELIST format. That is the class name is introduced by an ampersand sign in the column 2 and the class is terminated by a card bearing &END in columns 2 to 5.

A complete listing of the input is shown in Appendix O.

The input consists of (in this order)

Card type 1, class name INNM;

NMODES: number of trial shapes;

NOEKIN may be input 1 if the cross sections are ready on tapes to be used by OZAN. A zero indicates that the cross sections will be prepared on tapes throughout the run;

KSREX: 1 for this variable indicates that the eigenvalue(s) for the trial shape(s) will be computed in an integral sense by OZAN. If 0 is input the eigenvalue(s) must be supplied in card INSKEF (see below);

KSROZ: 1 for this variable indicates that an eigenvalue for the first trial shape will be computed to compensate the photoneutrons and make the (11) element of the initial value of the reactivity matrix vanish if the reactor is critical at the beginning of the transient. If 0 is input the eigenvalue of the critical reactor must be supplied in card INSKOZ (see below);

COEFIC: The correction factor for the photoneutrons. If this number is input 0, the photoneutrons will be ignored;

LFINAL: Denotes the number of the time zone(s);

INPC: 1 for this variable indicates that the initial value(s) of the first precursor amplitude function(s) will be input to the code (generally when the reactor is not at a steady state at the beginning of the transient). 0 indicates that the initial value(s) of the precursor amplitude function(s) will be computed in the code;

LPSN: 1 for this variable indicates that the absorption cross sections will be increased by  $\text{OMEG} \times \text{V1}(\text{MG})$  (Input in the next type of card, MG being the neutron group,  $\text{MG} = 1, 2, 3$ ) for the computation in an integral sense of the eigenvalue of the second shape; otherwise 0 should be input;

LBYD: 1 for this parameter indicates that we intend to continue computations beyond the end of the time zone (TMAX; see below) established to study the transient with the proposed method;

Card type 2, class name INV1;

V1: Neutron inverse velocities, the first one belonging to the fast group;

OMEG:  $\omega$ , the estimated inverse period that the reactor will assume by the end of the transient;

Card type 3, class name INHU;

HU: the mesh intervals in the r direction;

Card type 4, class name INHV;

HV: the mesh intervals in the z direction;

Card type 5, class name INYL;

YIEL: Relative yields of photons of interest, the first one belonging to the most energetic group of photons;

Card type 6, class name INYJ;

YIEJ: Probabilities of photoneutrons to show up in various - time wise - groups;

NZRO: Total number of photons of interest generated per fission of  $U^{235}$ ;

Card type 7, class name INBA;

BETA: the delayed neutron

NBETA1: number of delayed neutron group fraction(s);

NBETA2: number of delayed photoneutron group(s);

Card type 8, class name INF;

FIJ: the initial conditions for the time coefficients;

FAMLAM: Decay constant(s) for the delayed neutron(s) [and photoneutron(s)];

Card type 9, class name INATT1;

ATT1: The attenuation coefficients for the various attenuation zones

Card type 10, class name INMVU;

An edit of the time dependent flux will be made for the region framed by the mesh points MV1, MVV in the z direction and, MU1, MUU in the r direction;

Card types 11,12,13,14, class names INUI, INUF, INVI, INVF;

MRUI (1), MRUF(1), MRVI(1), MRVF(1) are the mesh points framing the first attenuation zone (the first two numbers in the r direction and the last two ones in the z direction);

Card type 15, class name INGLK;

MGLK: Number of groups for  $D$ ,  $\Sigma_a$ ,  $\nu\Sigma_F$ ,  $\Sigma_F$ ,  $SGCS_1$  (first group of photons),  $SGCS_2$  (second group of photons),  $\Sigma_s$ , and  $\Sigma_D$ ;

Card type 16, Class name INDV;

MDVIC: Input output device numbers for in this order,  $D(0)$ ,  $\Sigma_a(0)$ ,  $\nu\Sigma_F(0)$ ,  $\Sigma_F(0)$ ,  $SGCS_1(0)$ ,  $SGCS_2(0)$ ,  $\Sigma_s(0)$ ,

$\Sigma_D(0)$ ,  $D(T)$ ,  $\Sigma_a(T)$ ,  $\nu\Sigma_F(T)$ ,  $\Sigma_F(T)$ ,  $SGCS_1(T)$ ,

$SGCS_2(T)$ ,  $\Sigma_s(T)$ ,  $\Sigma_D(T)$ ,  $D_2$ ,  $\Sigma_{a_2}$ ,  $\nu\Sigma_{F_2}$ ,

(Here enter three any numbers to fill a blank in the array ),

$\Sigma_{s_2}$ , ( another any number to fill a blank in the array ),

$D_1$ ,  $\Sigma_{a_1}$ ,  $\nu\Sigma_{F_1}$ , (any three numbers),  $\Sigma_{s_1}$ , (any number), where

0 stands for the beginning of the transient, T the end of the transient, 1 for the first trial shape and 2 for the second trial shape.

Card type 17, class name INT;

TMIN: time at which the transient starts;

IJUMP: After Every IJUMP times GONCA (the subroutine solving the multimode kinetics Equations) is called, the time

dependent solutions will be printed out;

**TUP:** is built up out of times at which a complete edit will be made;

**NINT:** Number of times a complete edit will be made;  
**TUP (NINT)** is the end of the time zone established for studying the transient with the proposed method;

**NCM1:** Degree of the polynomial expansion used in determining the time coefficients (cf. Appendix F);

**EPS2:** Criteria insuring the convergence of the time coefficients (1. E-1 is good enough for this purpose);

Card type 18, class name IN1;

**X1:** Macroscopic diffusion coefficients and cross sections in various materials. Input three (-group-) diffusion coefficients for all the materials. Do the same thing for  $\Sigma_a$ ,  $\nu\Sigma_F$ ,  $\Sigma_F$ ,  $SGCS_1$  and  $SGCS_2$ .

Card type 19, class name IN2;

**X2:** Macroscopic scattering cross sections in various materials. Input first the scattering cross section from group one to group 2 [ $\Sigma_g(1 \rightarrow 1)$ ], then the scattering cross section from group 2 to group 3 [ $\Sigma_g(2 \rightarrow 3)$ ] for the first material. Do the same thing for the other materials.

Card type 20, class name IN3;

**X3:** Macroscopic photoneutron reaction cross sections for various materials;

Card type 21, class name INCS;

NCS: If the first, or the second, or the third, or the seventh element of this array is 2,  $D_2$ , or  $\Sigma_{a_2}$ , or  $v\Sigma_{F_2}$  or  $\Sigma_{s_2}$  (in this order) - relative to the second trial shape - is the same as compared to  $D_1$ , or  $\Sigma_{a_1}$ , or  $v\Sigma_{F_1}$  or  $\Sigma_{s_1}$  (in this order) - relative to the first trial shape. If 1 is input for any of these elements the corresponding cross sections relative to the second trial shape are not equal to those relative to the first trial shape.

Card type 22, class name INNCS;

ND=1, NSSGA=1, NUNSF=2, NSCRT=1,  
 = 1  
 Correspond to NCS (1) = 1, NCS(2) = 1, NCS(3) = 2,  
 NCS(7) = 1 (see above Card type 21);

Card type 23, 24, 25, 26, class names INNRK1, INNRK2, INNRK3, INNRK7;

NRK1: Number of regions in which  $D_2$  is different as compared to  $D_1$ .

NRUI1(1), NRUF1(1), NRV11(1), NRVF1(1) frame the first region (the first two numbers in the r direction, and the last two ones in the z direction) where  $D_2$  is different as compared to  $D_1$ . NRCC1(1) = 1 is the material number in this region;

XT1(1): the new diffusion coefficients relative to the trial shape in this region;

The same thing is repeated for INNRK2, INNRK3 and INNRK7 relative respectively to  $\Sigma_{a_2}$ ,  $v\Sigma_{F_2}$  and  $\Sigma_{s_2}$ . If any of  $D_2$ ,

$\Sigma_{a2}$ ,  $\nu\Sigma_{F2}$  and  $\Sigma_{S2}$  do not differ from those relative to the first trial shape, the corresponding cards can be dismissed;

Card type 27, class name INSKEF;

SKEF: The eigenvalue(s) of the trial shapes computed in an integral sense. This card is read in only if KSREX is 1 (cf. first type of cards);

Card type 28, class name INSKOZ;

SKOZN: Eigenvalue of the critical reactor, computed in an integral sense;

Card type 29, class name INCDNC;

CSC: This array has eight elements that correspond respectively to  $D$ ,  $\Sigma_a$ ,  $\nu\Sigma_F$ ,  $\Sigma_F$ ,  $SGCS_1$ ,  $SGCS_2$ ,  $\Sigma_S$  and  $\Sigma_D$ . If during the transient any of these cross section sets receive a ramp change 1 will be input in the place of the element of interest. Otherwise 2 will be input;

Card type 30, class name INDDNC;

DC, SIGAC, UNSFC, SIGFC, SGCS, SCATC, SPNRC

These variables are treated the same way the elements of the CSC array (see above Card type 23) are treated. DC=1 will then mean that the diffusion coefficient-set receives a ramp change during the transient;

Card type 31, 32, 33, 34, 35, 36, 37, 38, class names INMRK1, INMRK2, INMRK3, INMRK4, INMRK5, INMRK6, INMRK7, INMRK8  
( $D$ ,  $\Sigma_a$ ,  $\nu\Sigma_F$ ,  $\Sigma_F$ ,  $SGCS_1$ ,  $SGCS_2$ ,  $\Sigma_S$ ,  $\Sigma_D$ );

Confer Card type 21 with the only difference that the

values at the end of the transient,  $t = TUP(NINT)$ , for those cross sections that vary during the transient will now be input.

Cards, for those cross sections that do not receive any change during the transient, can be dismissed;

Card types 39, 40, 41, 42, 43, 44, 45, 46, 47, 48, class names INSPC, INSTP, INMSK1, INMSK2, INMSK3, INMSK4, INMSK5, INMSK6, INMSK7, INMSK8;

The test that is made for a ramp change through card types 29 up to 38 is now made for a step change.

\*  
If LBYD is greater than 1, then the class INT is repeated to characterize the output beyond the time  $TUP(NINT)$  input through the first INT (see above, card type A).
