#### Abstract

X-ray spectra of $2 l-\mathrm{n} l^{\prime}$ transitions with $3 \leq \mathrm{n} \leq 12$ in the row five transition metals zirconium ( $Z=40$ ), niobium ( $Z=41$ ), molybdenum ( $Z=42$ ) and palladium ( $\mathrm{Z}=46$ ) from charge states around neonlike have been observed from Alcator C-Mod plasmas. Accurate wavelengths ( $\pm .2 \mathrm{~m} \AA$ ) have been determined by comparison with neighboring argon, chlorine and sulphur lines with well known wavelengths. Line identifications have been made by comparison to $a b$ initio atomic structure calculations, using a fully relativistic, parametric potential code. For neonlike ions, calculated wavelengths and oscillator strengths are presented for 2 p -nd transitions with n between 3 and 12. The magnitude of the configuration interaction between the $\left(2 \mathrm{p}^{5}\right)_{\frac{1}{2}} 6 \mathrm{~d}_{\frac{3}{2}} J=1$ level and the $\left(2 \mathrm{p}^{5}\right)_{\frac{3}{2}} 7 \mathrm{~d}_{\frac{5}{2}} J=1$ levels has been measured as a function of energy level spacing for successive atomic number neonlike ions, and the agreement with theory is good. Transitions in the $2 p_{\frac{1}{2}}-$ nd $_{\frac{3}{2}}$ series in neonlike $\mathrm{Mo}^{32+}$ with $\mathrm{n} \geq 13$ are not observed; the upper levels lie above the first ionization potential of the neonlike ion and have a large branching ratio towards autoionization. Measured and calculated wavelengths and oscillator strengths of selected transitions in the aluminum-, magnesium-, sodium-, fluorine- and oxygenlike isosequences are also presented.

## Introduction

Recently there has been considerable interest in x-ray transitions in high Z atoms with charge states around the neonlike isosequence ${ }^{1-10}$. X-ray lasing ${ }^{11,12}$ has been demonstrated in neonlike ions, and a need to understand the kinetics of this system has motivated development of very precise collisional-radiative modelling tools ${ }^{13}$. The identifications of many $x$-ray lines from neonlike ions allow high resolution experimental data to be used for benchmarking multi-electron atomic structure calculations ${ }^{14-18}$. Most of the work which has been done in the past has been limited to 3-3, 2-3 and 2-4 transitions in the Ne-I isosequence and adjacent charge states. The high temperature, optically thin tokamak plasmas enable the measurement of many lines originating in transitions from levels having $n \geq 5$; in fact, all of the transitions in the $2 \mathrm{p}-\mathrm{nd}$ series in $\mathrm{Mo}^{32+}$ lying under the ionization potential have been measured ${ }^{10}$. The availability of a large number of transitions in several adjacent elements provides the opportunity to study the systematics of configuration interaction effects. Also, it has been observed that a systematic uncertainty enters the calculation for the wavelengths of the transitions with a 2 s hole in the upper state through the treatment of QED contributions in the calculation of these level energies when a relativistic parametric potential code (RELAC ${ }^{19,20}$ ) is used. The tendancy to overestimate level energies in multi-electron atoms based on hydrogenic calculations with QED corrections ${ }^{21}$ has been noted in comparisons between precise measurements of the level structure in neonlike ytterbium ${ }^{14}$ and other relativistic codes which use the same procedure as RELAC. Issues relating to the calculation of level energies for states with a 2 s hole have been investigated based on observations of the level structure of neonlike gold ${ }^{15}$.

In this paper are presented measured wavelengths and calculated wavelengths and oscillator strengths for 2 p -nd transitions with n between 3 and 12 in neonlike $\mathrm{Zr}, \mathrm{Nb}$ and $\mathrm{Pd} ; 2 \mathrm{~s}-\mathrm{np}$ transitions with n between 3 and 9 in neonlike $\mathrm{Zr}, \mathrm{Nb}, \mathrm{Mo}$ and Pd ; fluorinelike 2 p -nd transitions with n between 4 and 7 in Zr and Nb and with n between 7 and 10 in Mo; 2p-nd transitions with $n$ between 3 and 7 in sodium- and
magnesiumlike $\mathrm{Zr}, \mathrm{Nb}$ and Pd ; 2p-3d and $2 \mathrm{p}-4 \mathrm{~d}$ transitions in aluminumlike Pd ; and 2p-4d transitions in oxygenlike Mo, obtained from Alcator C-Mod plasmas ${ }^{22}$. The magnitude of the configuration interaction between the $\left(2 \mathrm{p}^{5}\right)_{\frac{1}{2}} 6 \mathrm{~d}_{\frac{3}{2}} J=1$ level and the $\left(2 \mathrm{p}^{5}\right)_{\frac{3}{2}} 7 \mathrm{~d}_{\frac{5}{2}} J=1$ levels has been measured as a function of energy level spacing for successive atomic number neonlike ions, and the agreement with theory is good. Transitions in the $2 \mathrm{p}_{\frac{1}{2}}-\mathrm{nd}_{\frac{3}{2}}$ series in neonlike $\mathrm{Mo}^{32+}$ with $\mathrm{n} \geq 13$ are not observed; the upper levels lie above the first ionization potential of the neonlike ion and have a large branching ratio towards autoionization.

## Experiment Description

The x-ray observations described here were obtained from the Alcator C-Mod ${ }^{22}$ tokamak, a compact high field device with all molybdenum plasma facing components. For these measurements, the plasma parameters were in the range of 7.7 x $10^{13} / \mathrm{cm}^{3} \leq \mathrm{n}_{e 0} \leq 2.0 \times 10^{14} / \mathrm{cm}^{3}$ and $1500 \mathrm{eV} \leq \mathrm{T}_{e 0} \leq 3400 \mathrm{eV}$. A laser blow-off impurity injection system ${ }^{23}$, which has been used to study impurity transport, was used to inject niobium, palladium and zirconium into Alcator C-Mod plasmas.

The spectra presented here were recorded by a five chord, independently spatially scannable, high resolution $x$-ray spectrometer array ${ }^{24}$. In the present paper, high resolution x-ray observations in the wavelength range $2.84 \AA \leq \lambda \leq 4.08 \AA$ are shown. Wavelength calibration ${ }^{2,3}$ has been achieved by determining the instrumental dispersions in reference to H - and He-like argon, chlorine and sulphur lines and previously measured molybdenum ${ }^{10}$ lines. The argon was introduced through a piezo-electric valve and chlorine is an intrinsic impurity from solvents used to clean vacuum components. Presumably sulphur is a trace impurity in the molybdenum. Lines from hydrogen ${ }^{25,26}$ - and heliumlike ${ }^{27-29}$ charge states are taken to have well known wavelengths, either measured or calculated.

## Calculation of Energy Levels and Oscillator Strengths

$A b$ initio atomic structure calculations for the aluminum- through oxygenlike isosequences (ground states $2 p^{6} 3 s^{2} 3 p$ to $2 s^{2} 2 p^{4}$, respectively) have been performed using the RELAC code ${ }^{19,20}$, which solves the Dirac equation by optimizing a parametric potental. Contributions to level energies from the Breit operator and vacuum polarization effects ${ }^{30}$ are also computed. RELAC computes the self-energy of a bound electron due to the emission and re-absorption of a virtual photon, in the case of an s- or p-orbital, by computing an effective-Z and interpolating on the hydrogenic values tabulated in Ref.(21). The effective- Z is found by the requirement that the mean value of the relativistic subshell $\left\langle\mathrm{r}_{n l j}\right\rangle$ agrees with the corresponding hydrogenic value. RELAC has been used to calculate the full multiconfiguration transition wavelengths and oscillator strengths for all lines observed in this paper. In a previous paper discussing the structure of neonlike molybdenum ions ${ }^{10}$, part of the systematically larger difference between observed and calculated $2 \mathrm{~s}-\mathrm{np}$ transition energies, and the more accurately predicted 2 p -nd transition energies was ascribed to RELAC's use of the effective-Z method for QED corrections to the binding energies of $L$-shell electrons. Recent work looking at the energies of $2 \mathrm{p}^{5} 3$ s levels in several neonlike ions ${ }^{17}$ with atomic numbers from 10 to 90 and the energies of $2 \mathrm{~s}-2 \mathrm{p}$ transitions in neonlike uranium ${ }^{18}$ implies that a many-body perturbation calculation of the ionic structure of the neonlike ions in the present work can remove most remaining discrepancies between the predicted and observed level energies. A quantitative discussion of the observed and calculated $2 \mathrm{~s}-2 \mathrm{p}$ neonlike transition energies will be given below.

This paper presents the wavelengths and oscillator strengths for newly identified $2 \mathrm{~s}-\mathrm{np}, 2 \mathrm{p}-\mathrm{nd}$ and $2 \mathrm{p}-\mathrm{ns}$ transitions in highly ionized zirconium, niobium, molybdenum and palladium. The $2 \mathrm{p}-\mathrm{nd}$ transitions considered here are strongly split by the $j$-value (in $j$-coupling) of the 2 p hole in the ionic core. The splitting is very apparent in the neonlike ions, where the resonance transitions with upper states containing a $2 \mathrm{p}_{\frac{1}{2}}$ hole are at much shorter wavelengths than the corresponding transitions with a $2 \mathrm{p}_{\frac{3}{2}}$ hole. This splitting can lead to significant configuration
interaction when a $\left(2 \mathrm{p}^{5}\right)_{\frac{1}{2}}$ nd orbital is close in energy to a $\left(2 \mathrm{p}^{5}\right)_{\frac{3}{2}} \mathrm{n}^{\prime} \mathrm{d}\left(\mathrm{n}^{\prime}>\mathrm{n}\right)$ orbital. Interaction between the orbitals will perturb transition wavelengths and redistribute oscillator strength within a class of transitions ${ }^{31}$. Another by-product of the above mentioned $2 \mathrm{p}_{j}$-splitting in the neonlike series is the possibility of autoionization from the (higher energy) $2 \mathrm{p}_{\frac{1}{2}}-\mathrm{nd}_{\frac{3}{2}}$ transitions' upper states. Indeed, for $\mathrm{n} \geq$ 12 , the upper state of the transition lies above the ground state of the fluorinelike ion, $2 \mathrm{~s}^{2} 2 \mathrm{p}^{5} J=\frac{3}{2}$, and hence, lines in this series can be quenched by autoionization. RELAC is used to compute the autoionization rate coefficents for this class of transitions in the distorted wave approximation ${ }^{32}$. This quenching effect will be discussed in more detail below.

## Experimental Spectra

Shown in Fig. 1 are the time histories of several quantities of interest for a typical Alcator C-Mod 6.4 T , deuterium discharge. There was a palladium injection into this particular discharge at 0.5 seconds, when the plasma current was 0.8 MA, the central electron temperature was 2000 eV and the central electron density was $1.5 \times 10^{14} / \mathrm{cm}^{3}$. The palladium stayed in the plasma for about 100 ms , as shown by the bottom frame of the figure. In Fig. 2 is shown the spectrum taken during an injection which demonstrates the strongest palladium line which falls within the wavelength range of the spectrometer, the $2 \mathrm{p}^{6}-\left(2 \mathrm{p}^{5}\right)_{\frac{3}{2}} 3 \mathrm{~d}_{\frac{5}{2}}$ transition in neonlike $\mathrm{Pd}^{36+}$ at $3904.7 \mathrm{~m} \AA$. Also apparent in this spectrum are some sodiumlike $2 \mathrm{p}-3 \mathrm{~d}$ lines around $3.93 \AA$, a strong $2 \mathrm{p}-3 \mathrm{~d}$ magnesiumlike line at $3948.9 \mathrm{~m} \AA$, several $2 \mathrm{p}-3 \mathrm{~d}$ transitions in aluminumlike palladium around $3.98 \AA$, and a $2 \mathrm{p}-3 \mathrm{~s} \mathrm{Pd}^{36+}$ line at $4001.4 \mathrm{~m} \AA$. A synthetic spectrum, generated using calculated wavelengths, typical instrumental and Doppler line widths, and line amplitudes proportional to the oscillator strengths within a given charge state, is shown at the bottom of the figure. Wavelength calibration was obtained from several nearby $\mathrm{Ar}^{16+}$ lines ${ }^{28,33}$, $S^{14+}$ lines $^{28,29}$ and $\mathrm{S}^{15+}$ lines ${ }^{25}$. The observed palladium lines are within $1 \mathrm{~m} \AA$ of the calculated wavelengths (except for the aluminumlike palladium lines, which are
discussed below).

A strong neonlike $\mathrm{Nb}^{31+}$ line, the $2 \mathrm{p}^{6}-\left(2 \mathrm{p}^{5}\right)_{\frac{3}{2}} 5 \mathrm{~d}_{\frac{5}{2}}$ transition at $3591.2 \mathrm{~m} \AA$, obtained from a niobium injection, is shown in Fig.3. Also prominent in the figure are the $2 \mathrm{~s}-4 \mathrm{p} \mathrm{Nb}^{31+}$ lines at 3640.5 and $3652.6 \mathrm{~m} \AA$. Sodium and magnesiumlike $2 \mathrm{p}-5 \mathrm{~d}$ transitions are apparent, in addition to the $2 \mathrm{p}^{6}-\left(2 \mathrm{p}^{5}\right)_{\frac{1}{2}} 4 \mathrm{~d}_{\frac{3}{2}}$ transition in $\mathrm{Mo}^{32+}$ at $3626.1 \mathrm{~m} \AA^{10}$. The wavelength calibration for this spectrum was obtained from nearby molybdenum ${ }^{10}$ and $\mathrm{Cl}^{15+}$ lines ${ }^{28}$. At the bottom of the figure is a synthetic spectrum. The wavelength agreement is very good, except in the case of transitions with a 2 s hole, as has been discussed elsewhere for molybdenum ${ }^{10}$. Line identifications for several charge states of interest for injected niobium, zirconium and palladium are given in Tables I-VI, where transition upper levels, measured and theoretical wavelengths and calculated oscillator strengths are presented. Complete tables for molybdenum can be found in Ref.(10). Table I summarizes the strongest lines observed, the $2 \mathrm{p}-\mathrm{nd}$ transitions in the neonlike ions $\mathrm{Zr}^{30+}, \mathrm{Nb}^{31+}$ and $\mathrm{Pd}^{36+}$. The 2-3 transitions in these ions may be compared with the observations and calculations in Ref.(4). Theoretical wavelengths are within $1 \mathrm{~m} \AA$, or $.03 \%$ of the observed level energies, and often the calculations are within $0.5 \mathrm{~m} \AA$.

The $2 \mathrm{~s}-\mathrm{np}$ transitions for $\mathrm{Zr}^{30+}, \mathrm{Nb}^{31+}, \mathrm{Mo}^{32+}$ and $\mathrm{Pd}^{36+}$ are given in Table II. Theoretical wavelengths for the $2 \mathrm{~s}-\mathrm{np}$ transitions are generally $\sim 2 \mathrm{~m} \AA$ shorter than the observed wavelengths. In the case of $\mathrm{Pd}^{36+}$, RELAC predicts that the Lamb shift (vacuum polarization energy ${ }^{30}$ and the electron self-energy) to the transition energies will contribute a total of -2.938 and -2.882 eV to the $2 \mathrm{~s}-3 \mathrm{p}_{\frac{1}{2}}$ and $2 \mathrm{~s}-3 \mathrm{p}_{\frac{3}{2}}$ transition energies, respectively; these QED effects increase the calculated transition wavelengths for these two lines by 3.10 and $2.96 \mathrm{~m} \AA$, respectively. (Note, the calculated contribution of the QED effects to the transition energies are less than $0.1 \%$ of the total energies). The calculated transition wavelengths are 2.3 and $2.2 \mathrm{~m} \AA$ shorter, respectively, than the observed $2 \mathrm{~s}-3 \mathrm{p}_{\frac{1}{2}}$ and $2 \mathrm{~s}-3 \mathrm{p}_{\frac{3}{2}}$ transition wavelengths. Hence, if all the difference between the calculated and observed transition wavelengths were due to the effective-Z calculation of the electron self-energy,
then RELAC would be over-estimating the nuclear screening (under-estimating the electron self energy) by $\sim 70 \%$. The work in Ref. (14) with neonlike $\mathrm{Yb}^{60+}$ concludes that the effective-Z approach under-estimates the self-energy contribution (over-estimates nuclear screening effects) to $2 \mathrm{~s}-3$ p transition energies by $\sim 10 \%$. Ytterbium and even heavier neonlike ions ${ }^{15}$, are in a regime where the effect of the finite size of the atomic nucleus is not negligible; the effect of the nuclear size on calculated level energies is almost non-existant in elements near in atomic number to paladium. Even so, a $70 \%$ under-estimate of the electron self energy by RELAC for the ions in this work is unlikely, so other sources of uncertainty in the theoretical wavelengths in Table II, such as relativistic correlation effects, are being investigated. The measured wavelengths presented here are accurate to $\pm .2 \mathrm{~m} \AA$, so these shifts are too large to be instrumental in origin.

For the electron temperature range of Alcator C-Mod, zirconium and niobium can easily reach the fluorinelike state, and several of these transitions are listed in Table III. Many of these observed lines are unresolved blends. (F-like barium 2-3 transitions are presented in Ref.(6).) Sodiumlike and magnesiumlike E1 lines in $\mathrm{Zr}, \mathrm{Nb}$ and Pd are presented in Tables IV and V , respectively, and aluminumlike $\mathrm{Pd}^{33+}$ E1 transitions can be found in Table VI. (2-3 transitions in these three charge states in silver may be found in Ref.(2).) The observed Na-like lines are mostly within $1 \mathrm{~m} \AA$ of the calculated wavelengths, and as in the case of the $F$ like lines, there are many blends between adjacent transitions. The differences between the observed and calculated wavelengths are larger for the magnesiumlike ions than for the preceeding isosequences. The energy of the magnesiumlike $3 \mathrm{~s}^{2}$ $J=0$ ground state is sensitive to numerous small corrections from mixing with $J=0$ levels of other even-parity configurations, up to and including levels in the continuum. Turning off all configuration interaction between $3 s^{2} J=0$ and other $J$ $=0$ levels (particularly the two $3 \mathrm{p}^{2} J=0$ levels) increases the transition wavelengths (decreases the transition energies) for the lines in Table V by approximately $3 \mathrm{~m} \AA$. For the observed Al-like $\mathrm{Pd}^{33+}$ lines, the wavelength difference with the calculations can be as large as $7 \mathrm{~m} \AA$; in contra-distinction to the magnesiumlike case, this is
a result of incomplete accounting of the interaction between doubly excited states with inner-shell vacancies and the innershell-excited upper states listed in Table VI.

For higher $n$ transitions in neonlike systems, the upper levels of certain lines in the $2 p^{6}-\left(2 p^{5}\right)_{\frac{3}{2}} n d_{\frac{5}{2}}$ series and the $2 p^{6}-\left(2 p^{5}\right)_{\frac{1}{2}} n d_{\frac{3}{2}}$ series can have nearly identical energies, giving rise to significant configuration interaction. In particular, the effect is seen in the enhancement of the intensity of the $2 p^{6}-\left(2 p^{5}\right)_{\frac{3}{2}} 7 d_{\frac{5}{2}}$ transition at the expense of the $2 \mathrm{p}^{6}-\left(2 \mathrm{p}^{5}\right)_{\frac{1}{2}} 6 \mathrm{~d}_{\frac{3}{2}}$ transition ${ }^{10}$ in $\mathrm{Mo}^{32+}$, where the difference in the upper state energy levels is 3.5 eV . A spectrum of these two lines is shown in Fig.4a. In the case of neonlike $\mathrm{Nb}^{31+}$, the separation of these two lines is larger ( 7.1 eV ), and the interaction is smaller, as seen in Fig. 4 b . The intensity of the $2 \mathrm{p}^{6}-\left(2 p^{5}\right)_{\frac{1}{2}} 6 \mathrm{~d}_{\frac{3}{2}}$ line has grown relative to the $2 \mathrm{p}^{6}-\left(2 \mathrm{p}^{5}\right)_{\frac{3}{2}} 7 \mathrm{~d}_{\frac{5}{2}}$ line compared to the molybdenum case. For $\mathrm{Zr}^{30+}$, the separation is 11 eV and there is little configuration interaction at all, as shown in Fig.4c. The smooth solid curves in Fig. 4 are the synthetic spectra, and the relative intensities are proportional to the oscillator strengths. (See Table I.) This situation is somewhat muddled by the occurance of the sodiumlike $2 \mathrm{p}-8 \mathrm{~d}$ transitions, shown by dotted lines in the figure. (See Table IV.) These observations are summarized in Fig. 5 where the intensity ratios of the $2 p^{6}-\left(2 p^{5}\right)_{\frac{3}{2}} 7 d_{\frac{5}{2}}$ and $2 p^{6}$ $\left(2 \mathrm{p}^{5}\right)_{\frac{1}{2}} 6 \mathrm{~d}_{\frac{3}{2}}$ lines are plotted as asterisks versus their upper energy level separation. The large error bar on the molybdenum point is due to the contribution from the unresolved sodiumlike line at $3141.4 \mathrm{~m} \AA$. The solid circles are the calculated oscillator strength ratios as a function of calculated energy level separations, and the agreement is quite good. Also included are the calculated points from palladium, technetium, ruthenium and yttrium. In the case of $\mathrm{Pd}, \mathrm{Tc}$ and Ru , the $2 \mathrm{p}^{6}$ $\left(2 p^{5}\right)_{\frac{1}{2}} 6 d_{\frac{3}{2}}$ line is at shorter wavelength and the $2 p^{6}-\left(2 p^{5}\right)_{\frac{3}{2}} 7 d_{\frac{5}{2}}$ line is the weaker of the two.

The spectrum in the vicinity of the $2 \mathrm{p}^{6}-\left(2 \mathrm{p}^{5}\right)_{\frac{3}{2}} n d_{\frac{5}{2}}$ series limit in $\mathrm{Mo}^{32+}$ was shown in Ref.(10), where transitions up to and including $2 \mathrm{p}^{6}-\left(2 \mathrm{p}^{5}\right)_{\frac{3}{2}} 18 \mathrm{~d}_{\frac{5}{2}}$ were resolved, and the wavelength agreement with calculations was excellent. Spectra including the $2 \mathrm{p}^{6}-\left(2 \mathrm{p}^{5}\right)_{\frac{3}{2}} \mathrm{nd}_{\frac{5}{2}}$ series limit at $2914.78 \mathrm{~m} \AA$, and the $2 \mathrm{p}^{6}-\left(2 \mathrm{p}^{5}\right)_{\frac{1}{2}} n d_{\frac{3}{2}}$
series limit at $2841.44 \mathrm{~m} \AA$ in $\mathrm{Mo}^{32+}$ are shown in Fig.6. The wavelength calibration for these spectra was obtained from the high $n$ series of hydrogenlike $\mathrm{Ar}^{17+}$, transitions from $1 \mathrm{~s}-5$ p to $1 \mathrm{~s}-10 \mathrm{p}$, with wavelengths of $2917.50,2881.04,2859.38$, $2845.51,2836.07$ and $2829.36 \mathrm{~m} \AA^{22}$. The calculated $2 \mathrm{p}^{6}-\left(2 \mathrm{p}^{5}\right)_{\frac{1}{2}} \mathrm{nd}_{\frac{3}{2}} \operatorname{series}^{10}$ in $\mathrm{Mo}^{32+}$ with n between 10 and 19 is shown by the thick solid lines, and the $2 \mathrm{~s}-7 \mathrm{p}$ and $2 \mathrm{~s}-8 \mathrm{p}$ transitions are shown as the thin solid lines. This region of the spectrum is complicated by the presence of many $\mathrm{Mo}^{33+}$ transitions, shown as dotted lines. Clearly identified in the spectrum of Fig.6a are the $M o^{32+} 2 p^{6}-\left(2 p^{5}\right)_{\frac{1}{2}} 10 d_{\frac{3}{2}}$ line at $2941.0 \mathrm{~m} \AA$, the $\mathrm{Mo}^{32+} 2 \mathrm{~s}-7 \mathrm{p}$ and $2 \mathrm{~s}-8 \mathrm{p}$ lines at 2902.1 and $2853.0 \mathrm{~m} \AA$, respectively (see Table II), the $\mathrm{Mo}^{33+} 2 \mathrm{p}-7 \mathrm{~d}$ lines at $2935.8 \mathrm{~m} \AA$, and the $\mathrm{Mo}^{33+} 2 \mathrm{p}-9 \mathrm{~d}$ lines at $2930.2 \mathrm{~m} \AA$ and $2849.1 \mathrm{~m} \AA$. Clearly missing from this spectrum are the transitions from the $\mathrm{Mo}^{32+} 2 \mathrm{p}^{6}-\left(2 \mathrm{p}^{5}\right)_{\frac{1}{2}} \mathrm{nd}_{\frac{3}{2}}$ series with $\mathrm{n}=13,14,17,18$ and 19. The $\mathrm{n}=11,12,15$ and 16 lines have nearby transitions from $\mathrm{Mo}^{33+}$, so the line identifications are ambiguous. The spectrum of Fig.6a was from a plasma with an electron temperature of 3.4 keV and an electron density of $7.7 \times 10^{13} / \mathrm{cm}^{3}$. At this temperature, $\mathrm{Mo}^{33+}$ is the dominant ionization state ${ }^{34}$, so the presence of strong fluorinelike lines is expected. In contrast, shown in Fig.6b is a spectrum taken from a plasma with $\mathrm{T}_{e}=2.1 \mathrm{keV}$ and $\mathrm{n}_{e}=8.8 \times 10^{13} / \mathrm{cm}^{3}$, where $\mathrm{Mo}^{32+}$ is the dominant charge state. In this spectrum, all of the $\mathrm{Mo}^{33+}$ lines have dropped in intensity, which suggests that the line at $2883: 7 \mathrm{~m} \AA$ is due to $2 \mathrm{p}-8 \mathrm{~d} \mathrm{Mo}{ }^{33+}$ transitions, and the lines at $2922.8,2910.2$ and $2878.6 \mathrm{~m} \AA$, respectively, are the $2 \mathrm{p}^{6}-\left(2 \mathrm{p}^{5}\right)_{\frac{1}{2}} 11 \mathrm{~d}_{\frac{3}{2}}$, $2 \mathrm{p}^{6}-\left(2 \mathrm{p}^{5}\right)_{\frac{1}{2}} 12 \mathrm{~d}_{\frac{3}{2}}$ and $2 \mathrm{p}^{6}-\left(2 \mathrm{p}^{5}\right)_{\frac{1}{2}} 16 \mathrm{~d}_{\frac{3}{2}}$ transitions.

Identifications of high n fluorinelike $\mathrm{Mo}^{33+}$ transitions are summarized in Table VII, where the upper levels, measured and theoretical wavelengths, and calculated oscillator strengths are given. A table of lower $n \mathrm{Mo}^{33+}$ lines can be found in Ref.(10). The $2 p^{6}-\left(2 p^{5}\right)_{\frac{1}{2}} n d_{\frac{3}{2}}$ transitions with $n \geq 13$ (with the exception of $2 p^{6}$ $\left.\left(2 p^{5}\right)_{\frac{1}{2}} 16 d_{\frac{3}{2}}\right)$ are missing from the spectra of Fig. 6 because the upper states of these transitions lie above the ionization limit of the $2 p^{6}-\left(2 p^{5}\right)_{\frac{3}{2}} n d_{\frac{5}{2}}$ series at 2914.78 $\mathrm{m} \AA$, and the branching ratios towards autoionization is greater than 0.9 in every case. Radiative and autoionization rate coefficients for these levels are shown in

Fig.7. For all levels the autoionization rates are about a factor of 10 higher than the corresponding radiative rates, so it's reasonable that these lines are absent. From Fig. 7 it is expected that the $2 p^{6}-\left(2 p^{5}\right)_{\frac{1}{2}} 12 d_{\frac{3}{2}}$ transition would be supressed, but it is clearly visible in Fig.6. Given the very high accuracy of the energy level calculations for the neonlike and fluorinelike transitions in Tables I and VII (better than 1 part in 4000 ) it is unlikely that the first ionization potential for $\mathrm{Mo}^{32+}$ has been incorrectly calculated, so at present, no explanation is offered for why the $2 \mathrm{p}_{\frac{1}{2}}$ $-12 \mathrm{~d}_{\frac{3}{2}}$ line is so strong. Similarly, the $2 \mathrm{p}^{6}-\left(2 \mathrm{p}^{5}\right)_{\frac{1}{2}} 16 \mathrm{~d}_{\frac{3}{2}}$ transition is quite strong in Fig.6. It's possible that this upper level is selectively populated by charge exchange recombination.

For the higher temperature plasmas, molybdenum can reach the oxygenlike state ${ }^{34}$. The strongest $2 \mathrm{p}-4 \mathrm{~d}$ transitions in $\mathrm{Mo}^{34+}$ are shown in Fig. 8 and listed in Table VIII, dominated by the line at $3483.2 \mathrm{~m} \AA$. Plasma parameters for the discharge for which this spectrum was obtained were $T_{e}=2700 \mathrm{eV}$ and $\mathrm{n}_{e}=9 \mathrm{x}$ $10^{13} / \mathrm{cm}^{3}$. In this spectral region under these conditions, five molybdenum charge states can be viewed simultaneously. O-like 2-3 transitions in barium may be found in Ref.(6).

## Conclusions

X-ray transitions in the magnesiumlike through fluorinelike charge states in zirconium, niobium and palladium have been observed from Alcator C-Mod plasmas. Line identifications have been made by comparison to the results of $a b$ initio calculations and overall wavelength agreement is very good. 2p-3d transitions in aluminumlike $\mathrm{Pd}^{33+}$ and $2 \mathrm{p}-4 \mathrm{~d}$ transitions in oxygenlike $\mathrm{Mo}^{34+}$ have also been identified. The magnitude of the configuration interaction between the $\left(2 \mathrm{p}^{5}\right)_{\frac{1}{2}} 6 \mathrm{~d}_{\frac{3}{2}}$ level and the $\left(2 \mathrm{p}^{5}\right)_{\frac{3}{2}} 7 \mathrm{~d}_{\frac{5}{2}}$ level has been measured as a function of energy level spacing for the successive atomic number neonlike ions $\mathrm{Mo}^{32+}, \mathrm{Nb}^{31+}$ and $\mathrm{Zr}^{30+}$, and the agreement with theory is good. Transitions in the $2 \mathrm{p}_{\frac{1}{2}}-\mathrm{nd}_{\frac{3}{2}}$ series in neonlike $\mathrm{Mo}^{32+}$
with $n \geq 13$ are not observed, since the upper levels are greater than the ionization potential of the $2 \mathrm{p}_{\frac{3}{2}}-\mathrm{nd}_{\frac{5}{2}}$ series, and autoionization to $\mathrm{Mo}^{33+}$ dominates over radiative transitions to the ground state.

## Acknowledgements

The authors would like to thank F. Bombarda for assistance with the spectrometer system, U. Safronova for calculations of high n helium-like wavelengths, J. Irby for electron density measurements, A. Hubbard for electron temperature measurements and the Alcator C-Mod operations group for expert running of the tokamak. KBF would like to thank M.H. Chen for useful conversations and suggestions. Work supported at MIT by DoE Contract No. DE-AC02-78ET51013 and at LLNL by DoE Contract No. W-7405-ENG-48.

## Table Captions

Table I Neonlike 2p-nl E1 transitions in $\mathrm{Zr}^{30+}, \mathrm{Nb}^{31+}$ and $\mathrm{Pd}^{36+}$. The upper level designations in the first column are indicated by three $j j$-coupled orbitals where ' - ' indicates $l-s$ coupling and ' + ' indicates $l+s$ coupling: the first two orbitals show the occupancy of the $2 \mathrm{p}_{\frac{1}{2}}$ and $2 \mathrm{p}_{\frac{3}{2}}$ subshells, respectively, the third orbital is where the 2 p-electron has been promoted. It's the third orbital that makes the transition to fill the inner-shell vacancy. $\lambda_{E}$ and $\lambda_{T}$ are the experimental and theoretical wavelengths, respectively, and the $\mathrm{g}^{*} \mathrm{fs}$ are the calculated oscillator strengths. Also included is the $2 \mathrm{p}-3 \mathrm{~s}$ transition in $\mathrm{Pd}^{36+}$

Table II Neonlike $2 \mathrm{~s}-\mathrm{np} \mathrm{E} 1$ transitions in $\mathrm{Zr}^{30+}, \mathrm{Nb}^{31+}, \mathrm{Mo}^{32+}$ and $\mathrm{Pd}^{36+}$. The upper level designations in the first column are indicated by three $j j$-coupled orbitals where '-' indicates $l-s$ coupling and ' + ' indicates $l+s$ coupling: the first orbital shows the 2 s -subshell vacancy, the second orbital indicates a full (spectator) 2 p-subshell and the third orbital is where the 2 s-electron has been promoted. The third orbital makes the transition to fill the inner-shell vacancy. The $2 s_{+}\left[2 p^{6}\right] 6 p_{-}$ $\mathrm{J}=1$ transition in $\mathrm{Mo}^{32+}$, shown by the asterisk, is at the same wavelength as the strong $2 \mathrm{p}^{6}-\left(2 \mathrm{p}^{5}\right)_{\frac{3}{2}} 12 \mathrm{~d}_{\frac{5}{2}}$ transition in $\mathrm{Mo}^{32+}$ at $2986.4 \mathrm{~m} \AA$.

Table III Fluorinelike E1 transitions in $\mathrm{Zr}^{31+}$ and $\mathrm{Nb}^{32+}$. The upper level designations in the first column are indicated by three $j j$-coupled orbitals where '-' indicates $l-s$ coupling and ' + ' indicates $l+s$ coupling: the first two orbitals show the occupancy of the 2 s and spectator or $2 \mathrm{p}_{\frac{1}{2}}$ and $2 \mathrm{p}_{\frac{3}{2}}$ subshells, respectively, and the third orbital is where the 2 s - or 2 p -electron has been promoted. The third orbital makes the transition to fill the inner-shell vacancy. The transition denoted (a) ends on the second excited state, $2 \mathrm{~s} 2 \mathrm{p}^{6} J=1 / 2$.

Table IV Sodiumlike E1 transitions in $\mathrm{Zr}^{29+}, \mathrm{Nb}^{30+}$ and $\mathrm{Pd}^{35+}$. The upper state of each transition is indicated by three $\ddot{j j}$-coupled orbitals where '-' indicates $l-s$ coupling and ' + ' indicates $l+s$ coupling: the first orbital is the inner shell vacancy (either $2 \mathrm{~s}, 2 \mathrm{p}_{\frac{1}{2}}$ or $2 \mathrm{p}_{\frac{3}{2}}$ ), the second orbital is a spectator electron and
the third is the excited electron which makes the transition to fill the inner shell vacancy. The calculated ( $2 \mathrm{p}_{-}$) [3s $] 3 \mathrm{~d}$ _ $\mathrm{J}=3 / 2$ transition in $\mathrm{Pd}^{35+}$ (asterisk) is close in wavelength to the strong $2 \mathrm{p}-3 \mathrm{~d} \mathrm{Pd}^{36+}$ line at $3731.7 \mathrm{~m} \AA$. The transitions denoted (a) end on the second excited state, $2 \mathrm{p}^{6} 3 \mathrm{p} J=\frac{3}{2}$. The transition denoted (b) ends on the first excited state, $2 \mathrm{p}^{6} 3 \mathrm{p} J=\frac{1}{2}$.

Table V Magnesiumlike 2p-nd E1 transitions in $\mathrm{Zr}^{28+}, \mathrm{Nb}^{29+}$ and $\mathrm{Pd}^{34+}$. The upper state of each transition is indicated by three $j 0$-coupled orbitals where '-' indicates $l-s$ coupling and ' + ' indicates $l+s$ coupling: the first orbital is the inner shell vacancy (either $2 \mathrm{~s}, 2 \mathrm{p}_{\frac{1}{2}}$ or $2 \mathrm{p}_{\frac{3}{2}}$ ), the second orbital lists the spectator electrons and the third is the excited electron which makes the transition to fill the inner shell vacancy. Also included are some $2 \mathrm{~s}-3$ p transitions.

Table VI Aluminumlike $\mathrm{Pd}^{33+}$ E1 transitions. The upper state of each transition is indicated by three $j j$-coupled orbitals where ' '' indicates $l-s$ coupling and ' + ' indicates $l+s$ coupling: the first orbital is the inner shell vacancy (either 2 s , $2 p_{\frac{1}{2}}$ or $2 p_{\frac{3}{2}}$, the second orbital lists the spectator electrons and the third is the excited electron which makes the transition to fill the inner shell vacancy. The transitions denoted (a) end on the true ground state, $2 \mathrm{p}^{6} 3 \mathrm{~s}^{2} 3 \mathrm{p}_{-} J=\frac{1}{2}$ and are enabled only through configuration mixing between the upper state and configurations of the form $\overline{2 p}\left[3 s^{2} 3 \mathrm{p}_{-}\right] 3 \mathrm{~d}_{j} J=\frac{3}{2}$ where $\overline{2 p}$ indicates a hole in the 2 p -subshell. The transition denoted (b) ends on the true ground state, $2 \mathrm{p}^{6} 3 \mathrm{~s}^{2} 3 \mathrm{p}-J=\frac{1}{2}$ and is enabled only through configuration mixing between the upper state and configurations of the form $\overline{2 p}\left[3 s^{2} 3 p_{-}\right] 3 \mathrm{~d}_{j} J=\frac{1}{2}$. The transition denoted (c) ends on the first excited state, $2 \mathrm{p}^{6} 3 \mathrm{~s}^{2} 3 \mathrm{p}_{+} J=\frac{3}{2}$.

Table VII High n fluorinelike $\mathrm{Mo}^{33+}$ E1 transitions. The upper level designations in the first column are indicated by three $j j$-coupled orbitals where '-' indicates $l-s$ coupling and ' + ' indicates $l+s$ coupling: the first two orbitals show the occupancy of the $2 \mathrm{p}_{\frac{1}{2}}$ and $2 \mathrm{p}_{\frac{3}{2}}$ subshells, respectively, the third orbital is where the 2 p-electron has been promoted. The third orbital makes the transition to fill an inner-shell vacancy leaving the ion in the $2 \mathrm{p}^{5} J=\frac{3}{2}$ ground state. The calculated

2 p-8d transitions around $2967.3 \mathrm{~m} \AA$ are nearly degenerate in wavelength with the strong $2 \mathrm{p}^{6}-\left(2 \mathrm{p}^{5}\right)_{\frac{3}{2}} 14 \mathrm{~d}_{\frac{5}{2}}$ and $2 \mathrm{p}^{6}-\left(2 \mathrm{p}^{5}\right)_{\frac{1}{2}} 9 \mathrm{~d}_{\frac{3}{2}}$ transitions in $\mathrm{Mo}^{32+}$. Most of the observed lines are blends of two adjacent transitions.

Table VIII Oxygenlike $\mathrm{Mo}^{34+}$ E1 transitions. Transitions are indicated by both the upper and lower state. The index refers to the positions in the energy heirarchy of the nine levels possible from the $2 s^{2} 2 p^{4}$ ground configuration ( 5 levels) and the $2 \mathrm{~s} 2 \mathrm{p}^{5}$ first excited configuration ( 4 levels). Both lower and upper states are indicated by three $\dddot{j j}$-coupled orbitals where '-' indicates $l-s$ coupling and ' + ' indicates $l+s$ coupling: the first two orbitals show the occupancy of the 2 s or $2 \mathrm{p}_{\frac{1}{2}}$ and $2 \mathrm{p}_{\frac{3}{2}}$ subshells, respectively, the third orbital is where the 2 s - or 2 p -electron has been promoted. The third orbital makes the transition to fill an inner-shell vacancy.

## Figure Captions

Fig. 1 Plasma current, electron temperature, electron density and Pd x -ray (3.9-4.0 $\AA$ ) brightness time histories in a discharge with a palladium injection at .5 sec.

Fig. $2 \quad 2 \mathrm{p}-3 \mathrm{~d}$ transitions in $\mathrm{Pd}^{33+}-\mathrm{Pd}^{36+}$. Theoretical lines for neonlike $\mathrm{Pd}^{36+}$ (solid), $\mathrm{Pd}^{35+}$ (dotted), $\mathrm{Pd}^{34+}$ (dashed) and $\mathrm{Pd}^{33+}$ (dash-dot-dash) are shown at the bottom, where the relative intensities within a given charge state are proportional to the oscillator strengths of each transition.

Fig. $32 \mathrm{p}-5 \mathrm{~d}$ transitions in neonlike $\mathrm{Nb}^{31+}$ (solid), $\mathrm{Nb}^{30+}$ (dotted) and $\mathrm{Nb}^{29+}$ (dashed), and $2 \mathrm{~s}-4 \mathrm{p}$ transitions in $\mathrm{Nb}^{31+}$ (solid). Molybdenum transitions are shown by the thin dash-dot-dot-dot-dash lines.

Fig. $4 \quad 2 \mathrm{p}_{\frac{3}{2}}-7 \mathrm{~d}_{\frac{5}{2}}$ and $2 \mathrm{p}_{\frac{1}{2}}-6 \mathrm{~d}_{\frac{3}{2}}$ transitions in the neonlike ions a.) $\mathrm{Mo}^{32+}$, b.) $\mathrm{Nb}^{31+}$ and c.) $\mathrm{Zr}^{30+}$, and the calculated neonlike (solid) and sodiumlike (dotted) lines.

Fig. 5 Ratios of the intensities of the $2 p_{\frac{3}{2}}-7 d_{\frac{5}{2}}$ transitions to the $2 p_{\frac{1}{2}}-6 d_{\frac{3}{2}}$ transitions as a function of the upper level energy differences are shown as asterisks for the observed lines. The calculated ratios of the oscillator strengths as a function of calculated energy differences are shown as solid dots. The points at -3.6 , -$9.0,-23.5$ and +13.7 eV are for technetium, ruthenium, palladium and yttrium, respectively.

Fig. 6 Transitions in $\mathrm{Mo}^{32+}$ near the $2 \mathrm{p}_{\frac{1}{2}}-\operatorname{nd}_{\frac{3}{2}}$ series limit for a.) $\mathrm{T}_{e}=3400$ eV and b.) $\mathrm{T}_{e}=2100 \mathrm{eV}$. Theoretical lines for $\mathrm{Mo}^{32+}$ (solid) and $\mathrm{Mo}^{33+}$ (dotted) are shown at the bottom, and the vertical dashed lines indicate the series limits. The molybdenum line at $2872.1 \mathrm{~m} \AA$ is unidentified.

Fig. 7 Autoionization and Einstein rate coefficients as a function of $n$ for $2 p_{\frac{1}{2}}$ $\mathrm{nd}_{\frac{3}{2}}$ transitions in $\mathrm{Mo}^{32+}$.

Fig. 8 A spectrum including oxygenlike $\mathrm{Mo}^{34+}$. Five molybdenum charge states are present in this figure, $\mathrm{Mo}^{34+}$ (thick dash-dot-dot-dot-dash lines) and $\mathrm{Mo}^{30+}$ $\mathrm{Mo}^{33+}$ (thin dashed, dotted, solid and dash-dot-dash lines, respectively) ${ }^{10}$.
