Abstract

The aim of this study was to investigate the possible effects of corticosteroids in women with systemic lupus erythematosus (SLE) in two processes of executive function: cognitive flexibility and decision-making. To that end, we evaluated 121 women divided into three groups: 50 healthy women, 38 women with SLE not receiving corticosteroid treatment and 33 women with SLE receiving corticosteroid treatment. Cognitive flexibility was measured with the Trail Making Tests A and B; decision-making was measured with the Iowa Gambling Task. Additionally, demographic (age and education level), clinical (SLEDAI, SDI and disease duration) and psychological characteristics (stress vulnerability, perceived stress and psychopathic symptomatology) were evaluated. The results showed that both SLE groups displayed poorer decision-making than the healthy women ($p = 0.006$) and also that the SLE group receiving corticosteroid treatment showed lower cognitive flexibility than the other two groups ($p = 0.030$). Moreover, they showed the poorest scores on the following SCL-90-R subscales: *somatisation* ($p = 0.005$), *obsessions and compulsions* ($p = 0.045$), *depression* ($p = 0.004$), *hostility* ($p = 0.013$), *phobic anxiety* ($p = 0.005$), *psychoticism* ($p = 0.016$) and *positive symptom total* ($p = 0.001$). Additionally, they were more vulnerable to stress ($p = 0.000$). These findings help to understand the effects of corticosteroid treatment on cognitive flexibility and decision-making, in addition to the disease-specific effects suffered by women with SLE.

Keywords

Corticosteroids, executive function, flexibility, decision-making, systemic lupus erythematosus (SLE)

Introduction

Patients with systemic lupus erythematosus (SLE) show a diverse symptomatology that manifests on both organic and neuropsychiatric levels. Its prevalence is slightly below 1:1000 in women and is tenfold lower in men.¹⁻³

The decision to treat SLE with corticosteroids depends on the symptomatology, activity and severity of the disease. However, while corticosteroid treatment is indispensable for controlling the disease in some cases, it does produce adverse effects, some of which can lead to major organ damage.^{1,4,5}

The adverse effects of corticosteroid treatment and organ damage in SLE patients have been broadly studied and reviewed and reveal major implications.⁵⁻⁷ A few of the most characteristic side effects are adrenal damage (which affects the thyroid), cardiovascular damage (hypertension or myocardial infarction), bone fractures, infections, cataracts, mood swings and sleep disorders.

The possible cognitive effects of corticosteroid use have also been studied. The majority of these studies have found no association between corticosteroid use and

cognitive deficits in SLE patients.⁸⁻¹⁴ To the best of our knowledge, only one study has identified corticosteroid use as a factor associated with cognitive impairment in SLE. This study followed SLE patients for three years, and made evaluations every four months. These evaluations included standard medical history, physical examinations and cognitive testing. The results show that prednisone use was a factor associated with decreased cognitive function in SLE patients, as well as the presence of positive antiphospholipid antibodies, diabetes, increased depression and a lower education level. A few of the processes measured by Automated Neuropsychological Assessment Metrics (ANAM) were working memory, attention, non-verbal memory and visuospatial perception.¹⁵

Possible cognitive impairment in SLE patients has also been studied and associated with other variables linked to the disease itself or to the patients' psychological condition. The majority of these studies did not find any association between cognitive impairment and clinical characteristics such as disease activity, disease duration or neuropsychiatric manifestations.¹⁰ An association was found, however, between psychological characteristics, such as stress, anxiety and depression, and cognitive impairment in SLE patients, namely with total attention accuracy, immediate visual memory, delayed visual memory and visual fluency, where greater stress indicated dysfunction in these processes.^{2,16-18} Moreover, research findings show that SLE patients with cognitive impairment had affected verbal and visuospatial

1
2
3
4
5
6
7
8
9 memory and visuoconstructional abilities associated with neuropsychiatric
10 manifestations. This cognitive impairment was not associated with disease activity,
11 disease duration or corticosteroid use.¹⁰
12
13
14

15
16 Even though cognitive deficits and neuropsychiatric symptoms in SLE have
17 been studied broadly, the possible effects of corticosteroid use on other aspects of
18 executive function in SLE patients, such as flexibility and decision-making, have not.
19 Various studies do show an association, however, between corticosteroid use and
20 impairment in executive function (inhibition, working memory, shifting and
21 planning,)¹⁹ thus showing that corticosteroid use does have negative effects on working
22 memory and the hippocampus, which in some cases leads to cerebral atrophy, regardless
23 of dose and treatment duration or disease activity.^{20,21} Only one study has compared
24 SLE patients receiving corticosteroid treatment with others not receiving corticosteroid
25 treatment and healthy women. They found that the patients receiving corticosteroid
26 treatment have greater cerebral atrophy than healthy women. Furthermore, SLE patients
27 receiving corticosteroid treatment display more severe cerebral atrophy than patients
28 without SLE who receive corticosteroid treatment, regardless of dose or treatment
29 duration.²²

48 In spite of these approximations, the effects of corticosteroid treatment on
49 executive function in SLE patients have not been studied. Therefore, the aim of our
50 research has been to study if corticosteroid use has any effects on cognitive flexibility

9 and decision-making in women with SLE when compared with healthy women. We
10
11 hypothesise that women with SLE who receive corticosteroid treatment will display
12
13 poorer decision-making and cognitive flexibility than women with SLE who do not
14
15 receive corticosteroid treatment and healthy women.
16

17 18 **Material and methods**

19 20 *Patients*

21
22
23
24 One hundred twenty-one women participated in this study. They were divided in three
25
26 groups. Group 1 (HW) was composed of 50 healthy women who were recruited via
27
28 posters and Internet. Group 2 (SLE-CT) consisted of 38 women with SLE receiving
29
30 corticosteroid treatment; group 3 (SLE-noCT) included 33 women with SLE not
31
32 receiving corticosteroid treatment. The inclusion criteria for the women with SLE were
33
34 to meet at least four ACR Classification Criteria for Diagnosis of SLE, to be over 18
35
36 years of age, to be literate and to not present any psychological disorders. Additionally,
37
38 participants from the SLE-noCT group had to have not received corticosteroid treatment
39
40 for at least one year previous to the study. All the participants with SLE were patients
41
42 from the Systemic Autoimmune Disease Unit (Internal Medicine Service) at the
43
44 University Hospital ‘Virgen de las Nieves’ and the Clinical Hospital ‘San Cecilio’ in
45
46 Granada, Spain. The inclusion criteria for the healthy women comprising the control
47
48 group were the same as those for the SLE groups, except that, additionally, they

8 presented no mental or physical illnesses. This information was obtained through a brief
9 semi-structured interview conducted when the women contacted us to participate in the
10 study.
11
12
13
14
15

16 The main socio-demographic, clinical (SLEDAI, SDI and years with SLE) and
17 treatment variables data were collected and recorded from the women with SLE. All the
18 patients could at least read and write, and none of them presented any associated mental
19 illnesses at the time of the study. All these patients and the healthy women gave their
20 signed informed consent to take part in this study, which was approved by the ethics
21 committee at our hospital and carried out in compliance with the Helsinki Declaration.

38 *Trail Making Tests A and B (TMTA, TMTB)*. This is one of five stand-alone tests from
39 the Delis-Kaplan Executive Function System (D-KEFS).²⁴ Trail Making Tests A and B
40 are timed tests of cognitive flexibility and visual motor integration that assess speed in
41 processing information, attention and cognitive flexibility. The score obtained after
42 dividing TMTB by TMTA produces the cognitive flexibility index and is the best
43 execution indicator for the TMT.²⁵⁻²⁸

9 *Iowa Gambling Task (IGT)*. This computerized task has been used to assess decision-
10 making in a wide variety of studies.²⁹ It simulates essential components of decision-
11 making common to everyday life, and the assessment of rewarding and punishing
12 events under conditions of uncertainty and risk. In the task, subjects must choose among
13 four decks of cards. The task is composed of five blocks, each comprising twenty trials.
14 Two decks provide a high and immediate gain but great future losses (long-term loss),
15 while the other two decks provide lower immediate gains but a smaller future loss
16 (long-term gain). The purpose of the task is to try to earn as much money as possible
17 and to incur minimal losses when it is impossible to win. Initially, participants do not
18 know these deck characteristics, but the program provides feedback about the
19 consequences of each choice made by the participants.³⁰

32

33
34 *Stress Vulnerability Inventory (SVI)*. The SVI consists of 22 items and evaluates the
35 individual's predisposition to be affected by perceived stress.³¹ The Spanish adaptation
36 shows a Cronbach's alpha of 0.87.³² As for convergent validity, the results show a
37 significant positive correlation ($p < 0.01$) with the following assessment scales: STAI-R,
38 Beck Depression Inventory, Somatic Symptom Scale and Survey of Recent Life
39 Experiences (SRLE).
40
41
42
43
44
45
46
47

48 *Perceived Stress Scale (PSS)*. The PSS is a self-report scale used to evaluate perceived
49 stress levels and the degree to which people find their lives unpredictable,
50 uncontrollable or overwhelming (aspects that contribute to stress).^{33,34} It consists of 14
51

8
9 items with five response alternatives. The highest score corresponds to the highest
10 perceived stress level. The Spanish version of the PSS (14 items) has adequate
11 reliability (internal consistency=0.81 and test-retest=0.73), concurrent validity and
12 sensitivity. Here, we have considered those scores over 22 (i.e. the mean score for the
13 Spanish population) as reflecting high levels of perceived stress.³⁴
14
15
16
17
18

19
20
21 *SCL-90-R Symptoms Inventory*.³⁵⁻³⁶ We used this instrument to rule out potential
22 psychopathology in the participants. This self-report questionnaire was developed to
23 assess symptoms of psychopathology and it includes 90 items with five response
24 alternatives (0-4) on a Likert scale. Subjects respond according to how they have felt
25 within the past seven days, including the day the inventory is administered. The
26 inventory is scored and interpreted according to nine main dimensions (somatisation,
27 obsessive-compulsive symptoms, interpersonal sensitivity, depression, anxiety,
28 hostility, phobic anxiety, paranoid ideation, and psychoticism) and three global indices
29 of psychological distress (Global Severity Index (GSI), Positive Symptom Total (PS),
30 and Positive Symptom Distress Index (PSDI)). In this study, we have analysed these last
31 three global indices. This instrument is thought to have satisfactory reliability and
32 validity.³⁶

27 28 *Procedure*

29
30
31 All the participants were scheduled individually at the Mind, Brain and Behaviour
32 Research Centre at the University of Granada, Spain. Upon arrival to the laboratory they
33 gave their signed informed consent. Their socio-demographic variables were then
34 collected before carrying out the executive function tasks: the TMT (cognitive
35 flexibility) and the IGT (decision-making). Subsequently, the psychological and stress
36 tests were administered (SVI, SSP and SCL-90-R). Each session lasted approximately
37 one and a half hours.

Results are presented as mean and standard deviation. To begin, ANOVAs were used for examining socio-demographic differences (age and education level) among the three groups (healthy women, SLE patients receiving corticosteroid treatment and SLE patients not receiving corticosteroid treatment). Also, Student's *t*-tests were used for comparing the clinical characteristics of SLEDAI, SDI and disease duration between both SLE groups. In addition, various ANOVAs were carried out for analysing differences in psychological variables (SVI, PSS and SCL-90-R) among all three groups. The independent variables were the three groups, i.e. healthy women, SLE patients receiving corticosteroid treatment and SLE patients not receiving corticosteroid treatment; the dependent variables were the scores on the SVI, PSS, and the SCL-90 subscales.

Finally, one-way ANOVAs were administered with the TMT (for cognitive flexibility) and the IGT (for decision-making) in order to check for any statistically significant differences in executive function between the three groups. Education level and SLEDAI were used as a covariate, as the groups were not evenly weighted in these variables, which can be closely tied to executive function. Differences were considered significant when $p = 0.05$. Additionally, correlation analyses were used to test the relationship between the psychological stress variables and executive function variables in each group, and correlation analyses were used to test the relationship between the SLEDAI and the cognitive performance variables.

Results

Participants' socio-demographic and clinical characteristics

Socio-demographic and clinical data for the participants can be found in Table 1. The results showed statistically significant differences in education level and SLEDAI.

TABLE 1

Psychological characteristics

Table 2 shows psychological characteristics for the three groups. The results showed statistically significant differences in SVI ($p < 0.001$) among the three groups. The SLE-CT group is the most vulnerable to stress (11.33 ± 4.87), followed by SLE-noCT (8.74 ± 5.11) and finally by the healthy women (5.96 ± 3.77).

There were significant differences in the SCL-90 R results for the healthy women when compared with the SLE groups. Both SLE groups scored higher than the healthy women in the following sub-scales: *somatisation* ($p = 0.005$), *obsessions and compulsions* ($p = 0.045$), *depression* ($p = 0.004$), *hostility* ($p = 0.013$). In *phobic anxiety* ($p = 0.005$), *psychoticism* ($p = 0.016$) and *positive symptom total* ($p = 0.001$) the SLE-CT group scored higher than SLE-noCT and healthy women.

TABLE 2

Executive function

The results showed statistically significant results on the IGT (decision-making) between both SLE groups and healthy women ($p = 0.006$). Healthy women (4.08 ± 20.38) scored higher on the decision-making task than SLE-CT (-7.13 ± 18.62) and SLE-noCT (-9.00 ± 23.35) (Figure 1). As the negative value indicates, SLE patients show poorer decision-making regardless of corticosteroid use.

FIGURE 1

Figure 2 shows the decision-making scores from each of the five trials for the three groups.

FIGURE 2

Regarding cognitive flexibility, the results showed statistically significant differences on the TMT B/A (cognitive flexibility) among the three groups ($p = 0.030$). SLE-CT (2.57 ± 0.90) showed poorer scores than SLE-noCT (2.18 ± 0.65) and healthy women (2.06 ± 0.60) (Figure 3).

FIGURE 3

Finally, no significant correlations were found among psychological stress, psychopathology, SLEAI and SDI or the executive function variables.

Discussion

The aim of this research was to investigate if corticosteroid use is associated with impairment in two processes of executive function, i.e. cognitive flexibility and decision-making.

To this end, women with SLE receiving corticosteroid treatment, women with SLE not receiving corticosteroid treatment and healthy women were evaluated by testing cognitive flexibility and decision-making by using the Trail Making Test and the Iowa Gambling Task, respectively, while controlling for other variables such as the socio-demographic, clinical and psychological characteristics as well as disease-specific variables.

The results showed that women with SLE make poorer decisions than healthy women, regardless of corticosteroid use. This conduct, therefore, cannot be attributed to the medication. Notwithstanding, when comparing women with SLE receiving corticosteroid treatment with others who are not and with healthy women, a statistically significant difference does exist, namely that the first group scores the lowest. These results are in line with another study in which SLE patients scored higher than the control group on the TMTA and TMTB, thus displaying worse task execution.¹¹ This also supports various studies reporting that corticosteroid use decreases both declarative and working memory, due to the atrophy it brings about in the hippocampus,^{41,42} and

1
2
3
4
5
6
7
8
9 that this decrease is reversible by lowering the dose or stopping corticosteroid treatment
10 altogether.^{39,40}
11

12
13
14 The results show lower decision-making scores for both SLE groups.
15
16 Consequently, we can infer that it is the disease itself and its effects on the nervous
17 system that may be affecting a poor task execution. On the other hand, factors such as
18 disease activity could also be affecting these results. This parameter, however, did not
19 correlate with decision-making or cognitive flexibility in our study. Therefore, decision-
20 making cannot be attributed to disease activity. In this regard, our data coincide with
21 those of other studies reporting that SLEDAI is not a predictive factor of cognitive
22 deficit in SLE.^{43,44} It is related indirectly, however, as SLEDAI is a marker of lupus
23 activity, which in some instances requires corticosteroids, a treatment component used
24 for decreasing disease activity. Therefore, controversy remains regarding an association
25 between cognitive impairment and markers of disease activity,^{11,45} as some studies find
26 an association,^{11,46} while others, such as ours, do not.^{43,44,47}

31
32
33
34
35
36
37
38
39
40

41 Regarding psychological conditions, there were differences in the majority of the
42 stress and psychopathic symptoms variables between the women with SLE and the
43 healthy women. These results can be expected however, because individuals suffering
44 from a chronic disease experience pain, disability, major side effects from treatment and
45 unpredictable aggravation of the disease, all of which can be extremely stressful and
46 produce anxiety and depression. These results are consistent with other studies that

11
12

13
14 When considering the present study and its findings, there are a few limitations
15 that need to be taken into account. This is the first study to analyse the effects of
16 corticosteroids on executive function in women with SLE. In future studies more
17 executive function parameters should be included with a similar sample, such as
18 behaviour production, working memory, planning and inhibition, in order to assess if
19 there are differences in the remaining executive function processes between women
20 with SLE who receive corticosteroid treatment and others who do not receive
21 corticosteroid treatment. Additionally, our groups did not share the same education
22 levels, however, as this could be important, we did make sure to control for this factor.
23 This variable was included as a co-variable in the TMT and IGT analyses among
24 groups, as we are aware that some studies identify a lower education level as a factor
25 associated with cognitive degeneration in SLE patients.¹⁰ At any rate, it is important to
26 highlight the inherent difficulty in achieving equality in clinical populations.

42

43 In conclusion, the results from our study show that women with SLE display
44 broader psychopathological symptoms, greater vulnerability to stress and poorer
45 decision-making when compared with healthy women. Furthermore, as cognitive
46 flexibility is lower in women with SLE who receive corticosteroid treatment than in
47 healthy women and in women with SLE who do not receive corticosteroid treatment,

7
8
9 the adverse effects of corticosteroid treatment on the cognitive flexibility of the first
10 group should be considered. Whereas most studies have limited their research to the
11 physical effects of corticosteroid treatment, the findings from our study are useful for
12 studying the neuropsychological effects of corticosteroid treatment, as they provide
13 more information regarding side effects, such as poorer decision-making and cognitive
14 flexibility.
15
16
17
18
19
20
21
22

23 Poor decision-making and diminished cognitive flexibility entail a series of
24 clinical implications for patients that concern doctors, as well as patients and their
25 families, such as inadequate adherence to treatment plans or difficulties making the
26 necessary changes to effectively deal with the disease. These findings are important for
27 the specialised medical professionals caring for these patients, because a better
28 understanding of these cognitive deficits can make a substantial advance towards
29 understanding and even solving some of the different problems encountered on a daily
30 basis.
