Accepted 29 January 2015

The synthesis and crystal structure determination (at 293 K) of the title complex, Cs[Fe(C₈H₆BrN₃OS)₂], are reported. The compound is composed of two dianionic O,N,S -tridentate 5-bromosalicylaldehyde thiosemicarbazone(2 $-$) ligands coordinated to an Fe^{III} cation, displaying a distorted octahedral geometry. The ligands are orientated in two perpendicular planes, with the O- and S-donor atoms in *cis* positions and the N-donor atoms in *trans* positions. The complex displays intermolecular N–H···O and N–H···Br hydrogen bonds, creating $R_4^4(18)$ rings, which link the Fe^{III} units in the *a* and *b* directions. The Fe^{III} cation is in the low-spin state at 293 K.

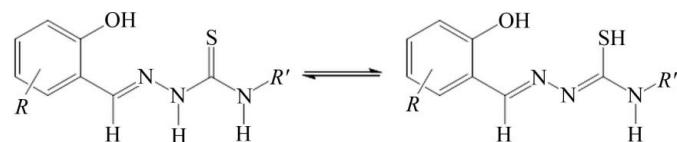

Keywords: spin-crossover behaviour; low-spin state Fe^{III}; crystal structure; caesium salt; salicylaldehyde thiosemicarbazone; Fe^{III} coordination compound.

1. Introduction

It is recognised that octahedral metal complexes with $3d^4$ – $3d^7$ configurations with specific ligands can exhibit spin-crossover behaviour, *i.e.* the magnetic interconversion between low-spin and high-spin states, dependent upon external perturbations of temperature, pressure or light irradiation (Gütlich & Goodwin, 2004). In recent years, particular interest has been focused on Fe^{III} ($3d^5$) complexes of substituted derivatives of *R*-salicylaldehyde 4-*R'*-thiosemicarbazone (Floquet *et al.*, 2003, 2006, 2009; Li *et al.*, 2013; Yemeli Tido *et al.*, 2008; Yemeli Tido, 2010; Powell *et al.*, 2014) for generating Fe^{III} spin-crossover. The spin-crossover properties of this class of Fe^{III} bis(ligand) complexes have been found to be sensitive to the

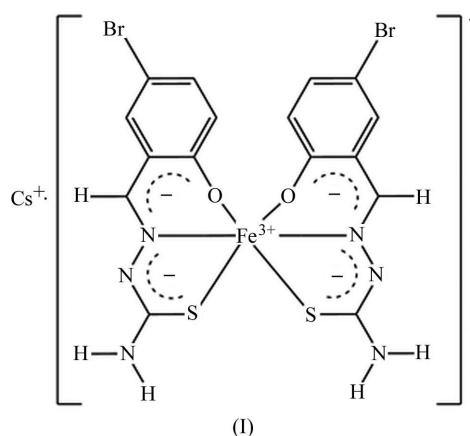

presence of a particular counter-ion, the degree of solvation and the nature of the *R*- and *R'*-substituted ligands (van Koningsbruggen *et al.*, 2004; Yemeli Tido *et al.*, 2008). Furthermore, it has been established that varying the pH during the synthesis of the Fe^{III} bis(ligand) units leads to the formation of Fe^{III} compounds differing in the degree of deprotonation of the ligand, whereby the complex unit can be neutral, monocationic, tricationic or monoanionic (Floquet *et al.*, 2009; Yemeli Tido *et al.*, 2010; Yemeli Tido, 2010).

In Fe^{III} compounds, it is possible for the tridentate *R*-salicylaldehyde 4-*R'*-thiosemicarbazone ligand (H₂L) to exist in tautomeric forms, and the ligand may also be present in its neutral, anionic or dianionic form. Free H₂L in solution exists in two tautomeric forms, *i.e.* the thione (left) and thiol (right) forms illustrated in Scheme 1.

Scheme 1

We recently reported the structure (at 100 K) of Cs[Fe(L1)₂]·CH₃OH, where L1²⁻ = 3-ethoxysalicylaldehyde 4-methylthiosemicarbazone(2 $-$) (Powell *et al.*, 2014). Both of the ligands were found to be twofold deprotonated, as no H atoms were located on the phenolate O or thiolate S atoms. From the values of the geometric parameters, it was established that the Fe^{III} cation is in the low-spin state. Continuing our research, we have varied the *R* and *R'* substituents of the ligand and studied the structural and electronic properties of the resulting Fe^{III} coordination compounds. Herein, we report the room-temperature structure of the title Fe^{III} salt, Cs[Fe(L2)₂], (I), containing two dianionic tridentate 5-bromosalicylaldehyde thiosemicarbazone(2 $-$) (L2²⁻) ligands.

2. Experimental

2.1. Synthesis and crystallization

5-Bromosalicylaldehyde thiosemicarbazone was synthesized according to the procedure described in the literature by Yemeli Tido (2010). 5-Bromosalicylaldehyde (98%, 49 mmol)

was dissolved in ethanol (80 ml) with constant stirring and then added to thiosemicarbazide (99%, 49 mmol) dissolved in ethanol (40 ml). The mixture was refluxed for 120 min. After the mixture had been allowed to cool to room temperature, a yellow solid, *i.e.* 5-bromosalicylaldehyde thiosemicarbazone, was isolated by filtration and dried.

FeCl₃·6H₂O (1.0 mmol, 0.27 g) was dissolved in methanol (10 ml). 5-Bromosalicylaldehyde thiosemicarbazone (2.0 mmol, 0.54 g) was dissolved in methanol (60 ml) with the addition of CsOH·H₂O (4.0 mmol, 0.67 g). To this mixture, the methanolic Fe^{III} salt solution was added with constant stirring. The resulting dark-green solution was stirred and heated to 353 K for approximately 10 min. The solution was then allowed to stand at room temperature until crystals were formed. Dark-green microcrystals of (I) were isolated by filtration and dried.

2.2. Refinement

Crystal data, data collection and structure refinement details are summarized in Table 1. The structure of (I) was solved routinely by direct methods and refined by least squares, with H atoms placed in anticipated positions and non-H atoms given anisotropic displacement parameters. However, the refined parameters did not match the quality of the data set, since the unweighted discrepancy index R_1 of 0.092 was much higher than the R_{int} value of 0.045. Since all 50 of the reflections with the worst discrepancy had $F_{\text{obs}} > F_{\text{calc}}$, twinning was suspected, and the closeness of the unit-cell β angle to 90° suggested a mechanism for pseudo-merohedral twinning. Application of *ROTAX* (Cooper *et al.*, 2002) indi-

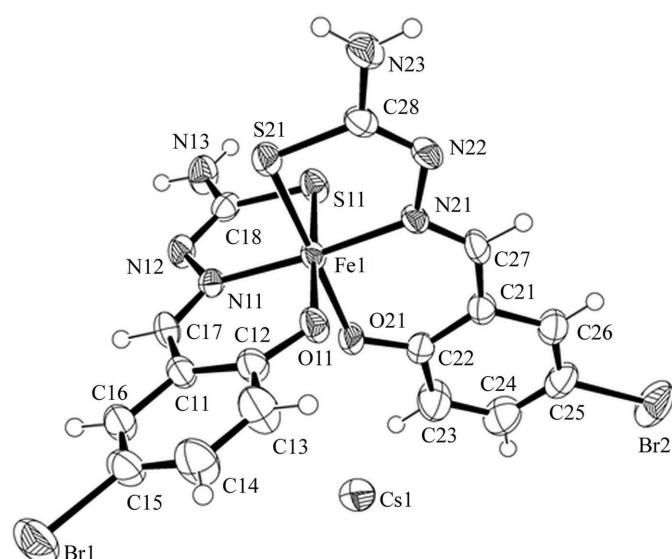

cated 180° rotation about the a axis as the likely twin law. Repeating the refinement with this twin law drastically reduced the discrepancy indices.

Now, all polar H atoms were omitted from the model and sought in a difference Fourier map. The H atoms on the secondary atoms N13 and N23 were located in a difference Fourier map at peak heights between 0.60 and 0.70 e Å⁻³, while no comparable peaks appeared adjacent to N11, N12, N21, N22 or any O or S atom. In subsequent refinements, the amino H atoms thus established were treated as riding, with N—H = 0.86 Å and $U_{\text{iso}}(\text{H}) = 1.2U_{\text{eq}}(\text{N})$. The remaining H atoms were included in the refinement in calculated positions and treated as riding on their parent atoms, with C—H = 0.93 Å and $U_{\text{iso}}(\text{H}) = 1.2U_{\text{eq}}(\text{C})$ for aryl (—CH=) H atoms. After final refinement, R_1 reached 0.033 and wR_2 was equal to 0.086, and a fractional contribution of 0.1306 (8) from the minor twin component was indicated.

3. Results and discussion

The crystal structure of (I) (Fig. 1) was determined at 293 K. Compound (I) crystallizes in the monoclinic system in the space group $P2_1/c$. The asymmetric unit corresponds to the formula unit Cs[Fe($L2$)₂] [$L2^{2-}$ is 5-bromosalicylaldehyde thiosemicarbazone(2-)] with no atom on a special position. The central Fe^{III} cation is hexacoordinated by two dianionic O,N,S-tridentate $L2^{2-}$ ligands, displaying a distorted octahedral Fe^{III} S₂N₂O₂ geometry. Deprotonation occurs for the phenol O and thiol S atoms. Selected geometric parameters are listed in Table 2.

The Fe^{III} S₂N₂O₂ unit is distorted from ideal octahedral geometry, as indicated by the bond angles (Table 2) of the donor atoms and atom Fe1 (see below). The tridentate $L2^{2-}$ ligands are coordinated to the Fe^{III} cation by the O- and S-donor atoms, which are situated in two perpendicular planes in

**Figure 1**

Symmetry codes: (i) $x, y, z - 1$; (ii) $x, -y + \frac{1}{2}, z - \frac{1}{2}$; (iii) $x, -y + \frac{3}{2}, z - \frac{1}{2}$.

the *cis* positions, such that the N-donor atoms are situated in mutually *trans* positions.

X-ray structural data of similar Fe^{III} bis(ligand) compounds containing dianionic thiosemicarbazone(2–) ligands show that the Fe—S, Fe—O and Fe—N bond distances are in the ranges 2.23–2.31, 1.93–1.95 and 1.88–1.96 \AA , respectively, for low-spin Fe^{III} compounds, and 2.40–2.44, 1.96–1.99 and 2.05–2.15 \AA , respectively, for corresponding high-spin Fe^{III} compounds (van Koningsbruggen *et al.*, 2004). Comparison of the bond distances of (I) involving the Fe^{III} atom and the donor atoms (Table 2) suggests that the present compound contains low-spin Fe^{III} at 293 K.

The distortion of the Fe^{III} S₂N₂O₂ unit results from the constraints imposed by the five- and six-membered chelate rings formed. The six-membered chelate ring involves a significantly wider bite angle than the ideal octahedral value of 90° [O11—Fe—N11 = 94.35 (12) $^\circ$ and O21—Fe—N21 = 93.78 (12) $^\circ$], while the bite angle is narrowed in the five-membered chelate ring [S11—Fe—N11 = 86.01 (9) $^\circ$ and S21—Fe—N21 = 86.07 (9) $^\circ$]. There is no major strain relief through puckering: the r.m.s. deviations from the least-squares planes of the atoms comprising the six-membered Fe1/N11/C17/C11/C12/O11 and Fe1/N21/C27/C21/C22/O21 chelate rings are 0.034 and 0.038 \AA , respectively; the corresponding values for the five-membered Fe1/N11/N12/C18/S11 and Fe1/N21/N22/C28/S21 rings are 0.014 and 0.009 \AA , respectively. Compared with the 120° angles in a regular hexagon, the O—Fe—N bite angle is deficient by *ca* 26°, and each of the remaining angles in the six-membered rings is within 2° of 125°. Because the angle at the vertex of a regular pentagon is only 108°, the S—Fe—N bite angles are deficient by only 22°. However, the C—S—Fe

angles are only about 95°, providing an additional deficiency of 13° and a total which could be neatly offset by increasing the other angles to *ca* 120°. (In fact, the N—N—C angles are <120° and the N—C—S angles are >120°.) Such 120° angles are consistent with *sp*² hybridization at the C and N atoms. The stability of the Fe^{III} complex is enhanced by the high degree of electron delocalization throughout the chelated ligands.

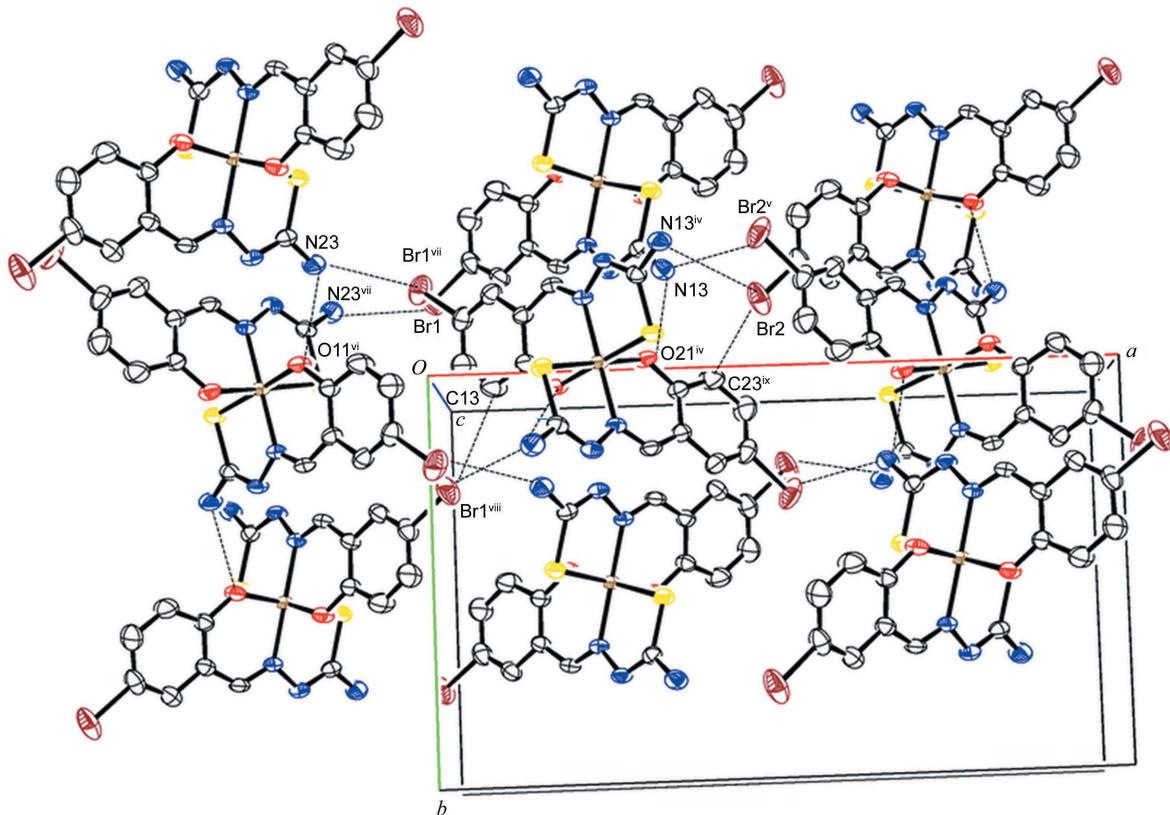

The bond distances of the ligands coordinated to the Fe^{III} cation in (I) can be related to bond order. The C—S, C—N and N—N bonds obtained for (I) show characteristics of a bond order between a single and a double bond. As expected, the C18—S11 bond distance of 1.750 (4) \AA and the C28—S21 bond distance of 1.753 (4) \AA suggest a partial electron delocalization of these bonds. Ryabova, Ponomarev, Zelentsov, Shipilov & Atovmyan (1981) reported the related low-spin compound NH₄[Fe(L2)₂] at 298 K, which crystallizes in the centrosymmetric space group *Pnca* with $Z' = 0.5$. Thus, the ligands coordinated around the Fe^{III} cation are related by symmetry. The C—S bond distances of (I) correspond with the C—S bond distance of 1.750 (9) \AA for NH₄[Fe(L2)₂], suggesting the occurrence of partial electron delocalization in both compounds. Furthermore, the electron delocalization of the ligands is confirmed by a bond order larger than 1 for the C—N bond involving the deprotonated hydrazinic N atom. The bond distances for the C17—N11 and C27—N21 bonds in (I) are 1.281 (5) and 1.296 (5) \AA , respectively, which are similar to the C—N bond distance of 1.292 (10) \AA reported for NH₄[Fe(L2)₂]. In addition, the N—N bond distances of (I) are N11—N12 = 1.394 (4) \AA and N21—N22 = 1.401 (4) \AA , indicating partial electron delocalization.

The Cs⁺ cation of (I) is at the centre of an irregular seven-donor atom polyhedron, the donor atoms of which originate from symmetry-related equivalents of both symmetry-independent ligands. Selected geometric parameters are listed in Table 2.

Several donor atoms coordinated to the Fe^{III} atom of (I) form interactions with the Cs⁺ cation in the second coordination sphere, modulating the electron density of the Fe-donor-atom bonds and hence influencing the electronic state of the Fe^{III} cation.

The phenolate O11 and O21 Fe^{III} donor atoms bind to the Cs⁺ cation within the same Fe^{III} unit. The Cs—O distances are Cs1—O11 = 3.220 (3) \AA and Cs1—O21 = 3.129 (3) \AA , somewhat longer than the mean Cs—O bond length of 3.074 (1) \AA in the hydrated Cs⁺ cation (Mähler & Persson, 2012). The small O11—Cs1—O21 bond angle of 50.34 (7) $^\circ$ is a corollary of the closeness of the two ligands bound to Fe^{III}. The Cs1···Fe separation involving the μ -diphenolate bridge is 4.2703 (6) \AA and the Cs—O—Fe bond angles are Cs1—O11—Fe = 109.12 (11) $^\circ$ and Cs1—O21—Fe = 112.16 (11) $^\circ$.

The thiolate S11ⁱ and S21ⁱ [symmetry code: (i) $x, y, z - 1$] Fe^{III} donor atoms coordinate to the Cs⁺ cation with bond distances of 3.7159 (11) and 3.5564 (11) \AA , respectively. Moreover, the terminal N23ⁱ atom of the same Fe^{III} unit forms a bond with the Cs⁺ cation, with a Cs1—N23ⁱ bond distance of 3.699 (4) \AA . The proximity of atoms N23 and S21 is shown by the small N23ⁱ—Cs1—S21ⁱ bond angle of 42.99 (6) $^\circ$, whereas

**Figure 2**

A projection showing the unit cell of (I). The Cs^+ cation has been omitted for clarity. Displacement ellipsoids are drawn at the 50% probability level. Dashed lines indicate hydrogen bonds. [Symmetry codes: (iv) $x, -y + \frac{1}{2}, z + \frac{1}{2}$; (v) $-x + 1, y - \frac{1}{2}, -z + \frac{3}{2}$; (vi) $x, -y + \frac{3}{2}, z + \frac{1}{2}$; (vii) $-x + 2, y + \frac{1}{2}, -z + \frac{3}{2}$; (viii) $-x + 2, y + \frac{1}{2}, -z + \frac{1}{2}$; (ix) $-x + 1, y - \frac{1}{2}, -z + \frac{1}{2}$]

the small $\text{S}21^{\text{i}}-\text{Cs}1-\text{S}11^{\text{i}}$ bond angle of $53.27(2)$ Å is related to the vicinity of the two ligands bound to Fe^{III} . Furthermore, the thiolate S-donor atoms coordinate to the Cs^+ cation, as well as to the Fe^{III} cation, which gives rise to the $\text{Cs}1\cdots\text{Fe}^{\text{III}}$ separation of $4.7695(6)$ Å [symmetry code: (i) $x, y, z - 1$]. The $\text{Cs}-\text{S}-\text{Fe}$ bond angles involving the μ -dithiolate bridge are $\text{Cs}1-\text{S}11^{\text{i}}-\text{Fe} = 103.80(4)$ ° and $\text{Cs}1-\text{S}21^{\text{i}}-\text{Fe} = 108.55(4)$ °. In addition, atoms $\text{N}12^{\text{ii}}$ and $\text{N}22^{\text{iii}}$ [symmetry codes: (ii) $x, -y + \frac{1}{2}, z - \frac{1}{2}$; (iii) $x, -y + \frac{3}{2}, z - \frac{1}{2}$] next to the imine N-donor atoms in the first coordination sphere of Fe^{III} are also coordinated to the Cs^+ cation (see Table 2).

The $\text{Cs}^+\cdots\text{Cs}^+$ separations of $7.4530(5)$ Å for $\text{Cs}1\cdots\text{Cs}1(x, -y + \frac{3}{2}, z + \frac{1}{2})$ and $7.6404(5)$ Å for $\text{Cs}1\cdots\text{Cs}1(x, -y + \frac{1}{2}, z - \frac{1}{2})$ do correlate with the shortest $\text{Fe}^{\text{III}}\cdots\text{Fe}^{\text{III}}$ separations in (I). These are $7.5369(9)$ Å for $\text{Fe}\cdots\text{Fe}(x, -y + \frac{3}{2}, z + \frac{1}{2})$ and $7.5559(6)$ Å for $\text{Fe}\cdots\text{Fe}(x, -y + \frac{1}{2}, z - \frac{1}{2})$.

The previously reported compound $\text{Cs}[\text{Fe}(\text{L}1)_2]\cdot\text{CH}_3\text{OH}$ [$\text{L}1$ is 3-ethoxysalicylaldehyde 4-methylthiosemicarbazone(2–)] displays $\text{Fe}^{\text{III}}\cdots\text{Fe}^{\text{III}}(x + 1, y, z)$ separations of $8.486(3)$ Å (Powell *et al.*, 2014). The absence of any solvent molecule in (I) allows the Fe^{III} units to be closer to each other in the crystal structure than in the former compound. Furthermore, the R and R' substituents of the ligands coordinated to the Fe^{III} atom, *i.e.* $R = 5\text{-Br}$ and $R' = \text{H}$ in (I), and $R = 3\text{-EtO}$ and $R' = 4\text{-Me}$ in $\text{Cs}[\text{Fe}(\text{L}1)_2]\cdot\text{CH}_3\text{OH}$, might have some effect on how the Fe^{III} units are assembled in the crystal

structure. The sizes and positions of the R and R' substituents are different, as (I) contains a Br substituent on the C15/C25 atom of the salicylaldehyde group, whereas $\text{Cs}[\text{Fe}(\text{L}1)_2]\cdot\text{CH}_3\text{OH}$ contains a relatively bulky ethoxy group on the C13/C23 atom of the salicylaldehyde group, as well as a methyl substituent on the terminal N atom of the thiosemicarbazide group. In addition, the Br substituent of one Fe^{III} unit of (I) provides a hydrogen-bonding interaction with an amino group of a neighbouring Fe^{III} unit (see below). The occurrence of intermolecular hydrogen-bonding interactions between Fe^{III} units in (I) contributes to the arrangement of the Fe^{III} entities in the unit cell.

The hydrogen-bonding interactions of (I) are listed in Table 3 and displayed in Fig. 2. The main features of the molecular packing of (I) are the $\text{N}-\text{H}\cdots\text{O}$ and $\text{N}-\text{H}\cdots\text{Br}$ hydrogen bonds. Although the latter are weak, their grip on the Br atoms is augmented by $\text{C}-\text{H}\cdots\text{Br}$ interactions at similar $\text{H}\cdots\text{Br}$ contact distances. The $\text{N}13-\text{H}13B\cdots\text{Br}2^{\text{v}}$ and $\text{N}13-\text{H}13A\cdots\text{O}21^{\text{iv}}$ (see Table 3 for symmetry codes) contacts form hydrogen bonds to two different ring systems. In turn, atom O21 in the former system and atom Br2 in the latter accept hydrogen bonds from inversion-related atom $\text{N}13(-x + 1, -y, -z + 2)$, giving rise to $R_4^4(18)$ rings (Bernstein *et al.*, 1995). In a similar manner, the $\text{N}23-\text{H}23B\cdots\text{Br}1^{\text{vii}}$ and $\text{N}23-\text{H}23A\cdots\text{O}11^{\text{vi}}$ contacts create $R_4^4(18)$ rings with inversion-related atom $\text{N}23(-x + 2, -y + 2, -z + 2)$. The ring

systems created by the hydrogen bonding between the Fe^{III} units link them in the a and b directions. Furthermore, the Cs^+ cations link the Fe^{III} complex anions into a chain along [010].

Compound (I) does not contain any solvent molecules in the crystal lattice. This feature has also been observed for the following Fe^{III} compounds: $\text{Cs}[\text{Fe}(\text{thsa})_2]$ (H_2thsa is salicylaldehyde thiosemicarbazone; Ryabova, Ponomarev, Zelentsov & Atovmyan, 1981), $\text{NH}_4[\text{Fe}(5\text{-Br-thsa})_2]$ (Ryabova, Ponomarev, Zelentsov, Shipilov & Atovmyan, 1981) and $\text{NH}_4[\text{Fe}(5\text{-Cl-thsa})_2]$ (Ryabova *et al.*, 1978), for which relevant data are compiled in Table 4. This table shows the nonsolvated Fe^{III} bis(ligand) compounds together with the spin state of the Fe^{III} cation at the temperature at which the crystal structure was determined. The crystallographic data of (I) will now be compared with similar Fe^{III} bis(ligand) type compounds (Table 4), all of which are nonsolvated compounds.

The Fe^{III} cation in the compound $\text{Cs}[\text{Fe}(\text{thsa})_2]$ is in a high-spin state at both 103 and 298 K, whereas the Fe^{III} cation in $\text{NH}_4[\text{Fe}(5\text{-Cl-thsa})_2]$ is in a low-spin state at both 135 and 298 K (Table 4). Furthermore, in $\text{NH}_4[\text{Fe}(5\text{-Br-thsa})_2]$, the Fe^{III} cation is in a low-spin state at 298 K, while the Fe^{III} cation in (I) is in a low-spin state at 293 K. A transition from low-spin to high-spin Fe^{III} has been detected for similar materials with increasing temperature (Ryabova *et al.*, 1982), but crystallographic data are not available for these nonsolvated materials. Noting that (I) contains low-spin Fe^{III} at 293 K, perhaps it may exhibit a change in spin state above room temperature.

The generation of any spin transition is governed by the energy difference between the high-spin and low-spin electronic states. This energy gap can be tuned by variation of the ligand field strength. The features of the second coordination sphere, such as the arrangement of Fe^{III} units within a unit cell belonging to a particular crystal system, also influence the

ligand field characteristics. The packing of Fe^{III} units is evidenced by symmetry requirements, which are embedded within the space group in which the material crystallizes. X-ray structural analysis has revealed that the Fe^{III} bis(ligand) type compounds (Table 4) adopt different crystal systems and space groups compared with (I). Compound (I) displays a monoclinic crystal system and crystallizes in the space group $P2_1/c$ with $Z = 4$, or alternatively $Z' = 1$. In contrast, the nonsolvated Fe^{III} bis(ligand) compounds listed in Table 4 all exhibit an orthorhombic crystal system, although in some cases their space groups differ. For example, $\text{Cs}[\text{Fe}(\text{thsa})_2]$ crystallizes in the space group $Pna2_1$ with $Z' = 1$, whereas $\text{NH}_4[\text{Fe}(5\text{-Br-thsa})_2]$ in its tabular form crystallizes in the space group $Pnca$ with $Z' = 0.5$. The compound $\text{NH}_4[\text{Fe}(5\text{-Cl-thsa})_2]$ also crystallizes in the space group $Pnca$, also with $Z' = 0.5$. The Fe^{III} bis(ligand) entities present variances with respect to their symmetry; in some instances, a value for Z' of 0.5 is encountered, which for space group $Pnca$ implies that the ligands coordinated to the Fe^{III} cation are related by twofold rotational symmetry. Interestingly, Ryabova, Ponomarev, Zelentsov, Shipilov & Atovmyan (1981) reported that $\text{NH}_4[\text{Fe}(5\text{-Br-thsa})_2]$ crystallizes in two different forms, one crystallizing as tabular plates and the other as mica-like crystals. It was established that these two different polymorphs exhibit a spin-crossover at different temperatures, *i.e.* the mica-like crystals in the region around 200 K and the tabular plate crystals in the region around 300 K. It appears that the crystallographic data analysed so far for this family of materials do not reveal a relation between Fe^{III} spin state and the crystal system and space group.

It is widely recognized that significant changes in the electronic state of Fe^{III} bis(ligand) compounds may arise from the associated cation in the complex system, the R substituents at the benzene ring of the salicylaldehyde group or the introduction of R' substituents into the thioamide group of the thiosemicarbazide group, and the Fe^{III} $\text{S}_2\text{N}_2\text{O}_2$ geometry. The main difference observed between the compounds (Table 4) compared with (I) is the varying size of the associated cation (either NH_4^+ or Cs^+) in the crystal structure and the variation in the slight distortions of the octahedral Fe^{III} $\text{S}_2\text{N}_2\text{O}_2$ coordination sphere. It appears that the variation of the associated cation in the Fe^{III} bis(ligand) compounds may have an indirect impact on the spin state of Fe^{III} by influencing the crystal packing. In addition to the difference in size between NH_4^+

Table 4
Selected average Fe–donor-atom bond distances for nonsolvated Fe^{III} bis(ligand) complexes of R -salicylaldehyde R' -thiosemicarbazone.

Compound†	Temperature (K)	Space group and Z'	$\text{Fe}-\text{S}$ (\AA)	$\text{Fe}-\text{N}$ (\AA)	$\text{Fe}-\text{O}$ (\AA)	Spin state‡	Reference

$\text{NH}_4[\text{Fe}(5\text{-Cl-thsa})_2]$ §	298	$Pnca, Z' = 0.5$	2.24	1.95	1.93	LS	Ryabova <i>et al.</i> (1978)
	135		2.23	1.96	1.94	LS	Ryabova <i>et al.</i> (1978)

† The ligands are defined as follows: H_2thsa is salicylaldehyde thiosemicarbazone, $\text{H}_2\text{-5-Br-thsa}$ is 5-bromosalicylaldehyde thiosemicarbazone and $\text{H}_2\text{-5-Cl-thsa}$ is 5-chlorosalicylaldehyde thiosemicarbazone. ‡ The spin states are defined as low-spin (LS) and high-spin (HS). § Determined for crystals of tabular form.

and Cs^+ cations, the former may engage in directed interactions through hydrogen bonding, while the latter presents a more uniform electrostatic field without a preferred direction for hydrogen bonds. The R and R' substituents of the ligand may exhibit steric and electronic effects [including being involved in hydrogen bonding, *via* the Br substituents in (I)], but at this stage it is unclear how these features may be harnessed to induce a particular spin state for Fe^{III} .

The $\text{Fe}^{\text{III}} \text{S}_2\text{N}_2\text{O}_2$ coordination spheres of the compounds are slightly distorted from ideal octahedral geometry. It has been acknowledged that there are subtle differences in the Fe^{III} coordination geometry among the members of this particular type of compound. Clearly, the stabilization of Fe^{III} in a particular spin state is governed by a subtle balance of geometric parameters, as is implied by the fact that a single compound, *i.e.* $\text{NH}_4[\text{Fe}(5\text{-Br-thsa})_2]$, exists in slightly different polymorphs, each with its own distinct magnetic behaviour. The latter example shows that it is too early to derive a possible relation between Fe^{III} spin state and $\text{Fe}^{\text{III}} \text{S}_2\text{N}_2\text{O}_2$ geometry and crystal packing (the latter evidenced by crystal system and space group).

The development of a strategy towards the synthesis of Fe^{III} bis(ligand) compounds with a predetermined spin state will require the measurement and analysis of crystallographic data from a larger number of Fe^{III} compounds of this family, including those having different R and/or R' substituents and a variety of associated cations. Other parameters that we are currently considering in our studies are the alteration of the degree of solvation and the tuning of the deprotonation characteristics of the R -salicylaldehyde R' -thiosemicarbazone ligand.

The authors thank the EPSRC UK National Crystallography Service (Coles & Gale, 2012) at the University

of Southampton for the collection of the crystallographic data.

Special details

Geometry. All s.u.'s (except the s.u. in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell s.u.'s are taken into account individually in the estimation of s.u.'s in distances, angles and torsion angles; correlations between s.u.'s in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell s.u.'s is used for estimating s.u.'s involving l.s. planes.

Refinement. Refinement of F^2 against ALL reflections. The weighted R -factor wR and goodness of fit S are based on F^2 , conventional R -factors R are based on F , with F set to zero for negative F^2 . The threshold expression of $F^2 > 2\sigma(F^2)$ is used only for calculating R -factors(gt) etc. and is not relevant to the choice of reflections for refinement. R -factors based on F^2 are statistically about twice as large as those based on F , and R -factors based on ALL data will be even larger.
