Freshwater Biology

Algal richness and life-history strategies are influenced by hydrology and phosphorus in two major subtropical wetlands

Journal:	<i>Freshwater Biology</i>
Manuscript ID	FWB-P-Jun-16-0277.R3
Manuscript Type:	Standard Paper
Date Submitted by the Author:	11-Oct-2016

3 24 **Summary**
4
5

6 25 1. We explored controls of algal taxon richness (hereafter richness) in complex and
7
8 26 hydrologically dynamic flood-pulsed wetlands by comparing results from independent
9
10 27 studies in two globally important subtropical wetlands: the Okavango Delta (Botswana) and
11
12 28 the Florida Everglades (USA). In both wetlands, the flood pulse hydrology is regulated by
13
14 29 distinct wet and dry seasons, and creates floodplain landscapes with heterogeneous habitats;
15
16 30 algal growth is limited by phosphorus (P); and water uses threaten ecosystem function. To
17
18 31 inform future comparisons of algal richness and distribution patterns, we assessed the role of
19
20 32 hydrology and P as key controls of richness, and identified indicator taxa of desiccation
21
22 33 disturbance and P scarcity in these wetlands under increasing hydrological, nutrient and
23
24 34 habitat changes.
25
26
27

28 35 2. We used the intermediate disturbance hypothesis, and the species-energy theory to explain
29
30 36 algal richness patterns, and the competitive, stress-tolerant, ruderal (CSR) framework to
31
32 37 classify indicator taxa. We collected algal samples, environmental data and information
33
34 38 expected to influence community structure (water depth, relative depth change, P
35
36 39 concentrations, hydroperiod, and habitat type) over several years at sites representing a broad
37
38 40 range of environmental characteristics. To account for sample size differences, we estimated
39
40 41 algal richness by determining the asymptote of taxon accumulation curves. Using multiple
41
42 42 regression analysis, we assessed if and how water depth, depth change, P, hydroperiod, and
43
44 43 habitat type influence richness within each wetland. We then compared the strength of the
45
46 44 relationships between these controlling features and richness between wetlands. Using
47
48 45 indicator species analysis on relative abundance data, we classified C, S and R indicator taxa
49
50 46 with shorter/longer hydroperiod, and lower/higher P concentrations.
51
52
53

54 47 3. In either wetland, we did not observe the negative unimodal relationship between site-
55
56 48 specific richness and water depth change that was expected following the intermediate
57
58
59
60

1
2
3 49 disturbance hypothesis. It is possible that this relationship exists at more highly resolved
4
5 50 temporal scales than the semi-annual to annual scales hypothesized here. However, as
6
7 51 nutrient flows and algal habitats depend on these wetlands' flood pulse, maintaining the
8
9 52 Okavango's natural pulse, and increasing freshwater flow in the Everglades would help
10
11 53 protect these wetlands' algal diversity. Chlorophyta richness (Okavango), and total,
12
13 54 Bacillariophyta, Chlorophyta and cyanobacteria richness (Everglades) increased with higher
14
15 55 P concentrations, as per species-energy theory. In the Okavango, we classified 6 C and 49 R
16
17 56 indicator taxa (e.g. many planktonic Chlorophyta), and, in the Everglades, 15 C, 1 S, and 9 R
18
19 57 taxa (e.g. benthic Bacillariophyta and planktonic/benthic Chlorophyta), and 1 stress- and
20
21 58 disturbance-tolerant cyanobacterium species.

22
23
24
25 59 4. Our results offer baseline information for future comparisons of richness, and abundance
26
27 60 of C, S, and R indicator taxa in subtropical wetlands; this can be used to quantify how algal
28
29 61 communities may respond to potential changes in hydrology and P due to water diversion,
30
31 62 anthropogenic nutrient loads, and climate change. Examining microhabitat heterogeneity,
32
33 63 nitrogen and light availability, and grazing pressure in such wetlands would illuminate patch-
34
35 64 scale controls of richness and life-history strategy distribution in algal communities.

74 Introduction

75 Higher biological diversity is thought to increase ecosystem functions (Cardinale *et al.*,
76 2011); for example, different species may use resources complementarily in space or time, or
77 facilitate each other, thus increasing biomass production efficiency (Cardinale *et al.*, 2009).
78 As the loss of biodiversity threatens ecosystem functioning (Ptacnik *et al.*, 2008; Cardinale *et*
79 *al.*, 2011), fundamental research is needed to identify factors that increase and/or maintain the
80 diversity of biological communities. Freshwater ecosystems, especially wetlands, are facing a
81 severe and global loss of species (Strayer & Dudgeon, 2010), and are among the most
82 vulnerable ecosystems to climate change, due to their sensitivity to alterations of the
83 hydrologic cycle (Erwin, 2009). Subtropical, including many flood-pulsed, wetlands are
84 increasingly threatened reservoirs of freshwater biodiversity (Junk *et al.*, 2002), thus
85 understanding major controls of richness and diversity of primary producers at the base of
86 their food webs is a key task for freshwater ecologists (de Tezanos Pinto *et al.*, 2015).

87 In flood-pulsed wetlands, the alternation of wet and dry seasons determines nutrient
88 release upon rewetting, and generates a dynamic mosaic of aquatic and terrestrial
89 environments with high habitat heterogeneity (Junk, Bayley & Sparks, 1989). Hydrology,
90 nutrients, and habitat type in turn influence the richness of algae, effective ecological
91 indicators of water quantity/quality, and nutrient loads (McCormick & Cairns, 1994; Gaiser
92 *et al.*, 2011; Mackay *et al.*, 2012; Lee *et al.*, 2013; de Tezanos Pinto *et al.*, 2015). In the
93 Okavango, algae live in open waters, or are attached to plant substrates and silica-rich
94 sediments (Cronberg *et al.*, 1996); in the Everglades, abundant periphyton mats dominated by
95 benthic algae form in the limestone-rich sediments (Ding *et al.*, 2014). To test the effects of
96 hydrological variability (Reynolds, Padisák & Sommer, 1993; Paidere *et al.*, 2007), and
97 available energy (e.g. nutrients and light; Passy, 2008) on algal richness in the Okavango and
98 Everglades, we bring together the intermediate disturbance hypothesis (Connell, 1978), and

1
2
3 99 the species-energy theory (Wright, 1983; Hubbell, 2001). Moreover, we explore the potential
4
5 100 importance of habitat complexity on richness. We recognize that other factors influence algal
6
7 101 richness, such as water ionic content (Potapova & Charles, 2003), abundance of macrophytes
8
9
10 102 (Borics *et al.*, 2003), and degree of grazing (Liess *et al.*, 2009). To test key hypotheses, we
11
12 103 study the effects of hydrology, phosphorus (P), a growth-limiting nutrient in both wetlands,
13
14 104 on algal richness, and on how hydrology and P influence algal life-history strategies.

15
16 105 The intermediate disturbance hypothesis states that highest species richness is reached
17
18 106 with intermediate frequency/size of, or time since, disturbances, such as flooding, hurricanes
19
20 107 and fire (Connell, 1978; Reynolds *et al.*, 1993). Here we focus on site-specific hydrological
21
22 108 disturbance, defined as: i) mean water depth change in recent years (2006-2010 in the
23
24 109 Okavango, and 2005-2011 in the Everglades); ii) mean hydroperiod, whereby shorter
25
26 110 hydroperiod causes higher desiccation disturbance for algae. The species-energy theory
27
28 111 (Wright, 1983; Hubbell, 2001) posits that energy supply, i.e. resource quantity, controls and
29
30 112 limits species richness. In the Okavango, P limits algal growth, especially during high floods
31
32 113 (Ramberg *et al.*, 2010), or is co-limiting with nitrogen (N; Mackay *et al.*, 2011); in the
33
34 114 Everglades, natural P supply is extremely low, and so N concentrations are rarely regulatory
35
36 115 (Noe, Childers & Jones, 2001). Thus, here we focus exclusively on P, and we expect richness
37
38 116 to increase with higher P, as observed in previous research in the Everglades (Gaiser *et al.*,
39
40 117 2011), and other subtropical wetlands (e.g. Rodrigues & Bicudo, 2001b in Rodrigues &
41
42 118 Bicudo, 2001a; Izaguirre *et al.*, 2004). Moreover, shallower habitats tend to have higher algal
43
44 119 richness due to abundant macrophytes providing substrata for attachment in floodplain
45
46 120 landscapes (Borics *et al.*, 2003; Rodrigues & Bicudo, 2004 in Murakami, Bicudo &
47
48 121 Rodrigues, 2009). Thus, we expect higher richness in shallower habitats.

49
50 122 Algae are often classified in morphological (Kruk *et al.*, 2010), and functional groups (e.g.
51
52 123 diatom guilds; Passy, 2007). Thus, to provide comprehensive ecological interpretations of
53
54
55
56
57
58
59
60

1
2
3 124 community structure beyond richness, we analyse the distribution of algae with different life-
4
5 125 history strategies in relation to desiccation disturbance, and P scarcity. To this end, we use the
6
7 126 well established competitive/opportunistic colonist (C), stress-tolerant (S), and ruderal or
8
9 127 disturbance-tolerant (R) framework on life-history strategies (CSR; Grime, 1977) applied to
10
11 128 algae (Biggs, Stevenson & Lowe, 1998; Reynolds, 2006; Salmaso, Naselli-Flores & Padisák,
12
13 129 2015). The CSR framework has the potential to contribute to biodiversity and ecosystem
14
15 130 functioning research via linking the distribution of traits and ecosystem function (Fry, Power
16
17 131 & Manning, 2014).

18
19
20 132 The aims of this paper are to identify and compare: i) the roles of hydrological disturbance
21
22 133 (mean water depth change, and desiccation risk in shorter hydroperiod sites), resources (P),
23
24 134 and habitat type as controls of mean site-specific algal richness in the Okavango and
25
26 135 Everglades; ii) indicator taxa of shorter/longer hydroperiod, and lower/higher P
27
28 136 concentrations in each wetland. To address these aims, we hypothesise that:

- 29
30
31 137 a) estimated algal richness is highest in regions with intermediate water depth changes
32
33 138 over recent years, as predicted by the intermediate disturbance hypothesis;
34
35 139 b) estimated algal richness increases with higher limiting resource (P) provision, as
36
37 140 predicted by the species-energy theory;
38
39 141 c) estimated algal richness increases in shallower habitats due to the often observed
40
41 142 higher spatial complexity of benthic habitats;
42
43 143 d) more R taxa are classified in the Okavango due to shorter mean hydroperiods, and
44
45 144 benthic C algae are larger, while planktonic C algae are smaller than S, and R taxa in
46
47 145 both wetlands.

2
3 149 **Methods**

4
5 150 Study regions

6
7 151 The Okavango Delta (hereafter Okavango), and the Everglades are subtropical, flood-pulse
8
9 152 wetlands with a low-gradient topography, and mean flood pulse amplitude of 1.85 m and 0.5-
10
11 153 1 m, respectively (Junk *et al.*, 2006). Both are World Heritage Sites, and so recognized as
12
13 154 globally important ecosystems. Whereas the Okavango is a vast inland wetland bound by
14
15 155 geological faults, and fed by alluvial deposits carried by the Okavango River (McCarthy *et*
16
17 156 *al.*, 2003), the Everglades is a rainfall-dependent 'river of grass' (Douglas, 1947) flowing
18
19 157 from Lake Okeechobee to the Gulf of Mexico and Florida Bay (Lodge, 2010). The Okavango
20
21 158 is a largely pristine wetland with minimal technological alteration of water flow (Ramberg *et*
22
23 159 *al.*, 2006). The Everglades however, is a highly regulated system due to agricultural and
24
25 160 urban development, but is undergoing a vast restoration program to enhance its water flow
26
27 161 and quality (www.evergladesrestoration.gov). In common with other large, flood-pulse
28
29 162 systems, their ecosystem functioning faces many challenges, now and into the future, from
30
31 163 both changing climate and management of environmental flows (Milzow *et al.*, 2009;
32
33 164 Estenoz & Bush, 2015). These potential threats are likely to impact their biological
34
35 165 communities, including algae (Lee, Gaiser & Trexler, 2013), leading to uncertainties in future
36
37 166 ecosystem functioning. In biofilms, algae, together with bacteria, fungi and protozoa, enhance
38
39 167 ecosystem functions, such as the retention of nutrients and water (Battin *et al.*, 2003; Gaiser
40
41 168 *et al.*, 2011). Thus, comparing the controls of algal richness between wetlands with similar
42
43 169 natural features, but different anthropogenic impact histories, can inform management
44
45 170 strategies to enhance their ecosystem resilience (Folke *et al.*, 2004; Rojo *et al.*, 2012).

51 171

52 172

53 173

1
2
3 174 Field and sampling protocols
4

5 175 Okavango Delta
6

7 176 To determine spatial patterns of algal richness in the Okavango, we collected 130 algal
8
9 177 samples from 46 sites in five regions spanning most of the 28,000 km² total area of the Delta
10
11 178 (Upper Panhandle, UPH; Lower Panhandle, LPH; Xakanaxa, XAK; Boro, BOR;
12
13 179 Santantadibe, SAN; see Table 1 and Fig. 1a). The sampling sites represent the hydrological
14
15 180 (permanently, seasonally, and occasionally flooded sites), and nutrient gradients from
16
17 181 upstream to downstream areas, and habitats with different water depths (see Marazzi, 2014).
18
19 182 The methods were different between Campaign 1 (Mackay *et al.*, 2011, 2012), and Campaign
20
21 183 2 (Siziba *et al.*, 2011, 2012). In Campaign 1, we collected 61 samples in 38 sites using 1.5 L
22
23 184 PVC bottles filled at ~ 30 cm below surface in September 2006 (flood recession), April/May
24
25 185 2007 (flood expansion), and July/August 2007 (high water; Mackay *et al.*, 2012), whereas no
26
27 186 samples were available for the ‘low water’ phase (Marazzi, 2014). In Campaign 2, we took
28
29 187 69 samples in 8 seasonally and occasionally flooded floodplains in the distal reaches (BOR
30
31 188 and SAN) by pushing a plexiglass tube (6 cm in diameter, 0.5 m in length) through the
32
33 189 macrophytes or water column in May 2009 (flood expansion), July/August 2009 (high water),
34
35 190 October 2009 (flood recession) and February 2010 (low water). We preserved all the samples
36
37 191 in Lugol’s iodine solution in 30 mL (Campaign 1) and 50 mL (Campaign 2) tubes,
38
39 192 transported them back to the laboratory, and stored them in a refrigerator until analysis. We
40
41 193 measured water depth (cm) using a graduated metal pole (Campaign 1; Mackay *et al.*, 2011),
42
43 194 and a stadia rod (Campaign 2; Siziba *et al.*, 2011). The Okavango P data were volumetric
44
45 195 water concentrations. In Campaign 1, we analysed TP ($\mu\text{g L}^{-1}$) at the Okavango Research
46
47 196 Institute in unfiltered samples using an air segmented flow analyser after persulphate
48
49 197 digestion (Mackay *et al.*, 2011). In Campaign 2, we analysed total dissolved phosphorus
50
51 198 (TDP; $\mu\text{g L}^{-1}$) in samples filtered with GF/C paper, using the ascorbic acid procedure (APHA,
52
53
54
55
56
57
58
59
60

1
2
3 199 1998). These P measurements were made for different purposes; TP was measured to identify
4
5 200 controls of diatom abundance (Mackay *et al.*, 2012), and of diversity, biomass and abundance
6
7 201 of algae (Marazzi, 2014), and TDP to assess the response of microinvertebrates to flooding
8
9 202 (Siziba *et al.*, 2011; 2012).

10
11
12 203

13
14 204 Everglades

15
16 205 To determine spatial patterns of algal richness in the Everglades, between September and
17
18 206 December 2005-2011 we collected 947 algal samples from 165 sites in four main regions,
19
20 207 representative of the 5,000 km² area of this wetland: 1. LKO: Lake Okeechobee; 2. LOX: the
21
22 208 Arthur R. Marshall Loxahatchee National Wildlife Refuge (Water Conservation Area 1,
23
24 209 WCA 1) and Pal Mar (PAL); 3. the Everglades National Park (ENP): Pennsuco (PEN),
25
26 210 Lostman's Creek (LMC), the 'Oligohaline' area (OLG), Southern Marl Prairie (SMP), Shark
27
28 211 River Slough (SRS) and Taylor Slough (TSL); 4. Out_ENP: Holey Land Wildlife
29
30 212 Management Area (HOL), Water Conservation Areas (WCAs) 2 and 3 (Table 1; Fig. 1b).

31
32 213 Using generalized random-tessellation stratification (Stevens & Olsen 2004), we chose a
33
34 214 representative set of locations (800 m x 800 m principal sampling units, PSU), within which
35
36 215 we sampled three sites in a habitat drawn from a pool of GPS coordinates (Philippi, 2005). At
37
38 216 sites where depth was < 1 m, and vegetation not too dense to hamper the formation of
39
40 217 periphyton, and our movement in the field, we threw a 1 m³ enclosure, open both at the top
41
42 218 and bottom (Gunderson, 1994), and collected samples of periphytic algae with a 120 mL
43
44 219 plastic beaker from floating or benthic periphyton mats, depending on the depth (Jordan,
45
46 220 Coyne & Trexler, 1997). Where no mats were present, we took flocculent detritus from the
47
48 221 benthos, as this also hosts algae (Pisani, Yamashita & Jaffé, 2011); we then transported the
49
50 222 samples back to the laboratory and froze them until analysis. We measured water depth (cm)
51
52 223 with a metal ruler, and TP concentrations in the periphyton ($\mu\text{g g}^{-1}$ dry weight) by means of
53
54
55
56
57
58
59
60

1
2
3 224 colorimetry after dry combustion (EPA, 1983) because water column concentrations are often
4
5 225 below detection in this extremely oligotrophic wetland (Gaiser *et al.*, 2004).
6
7
8 226

9
10 227 Site classification

11 228 To assess algal richness patterns across the major hydrological gradient present in each
12
13 229 wetland, we classified each site by hydroperiod (flooding duration). Using information from
14
15 230 Murray-Hudson *et al.* (2015) based on a 1989-2007 data series for the Okavango, and mean
16
17 231 annual hydroperiod data from the Everglades Depth Estimation Network (EDEN;
18
19 232 <http://sofia.usgs.gov/eden/>) for the Everglades, we grouped sites in three hydroperiod classes
20
21 233 of flooding duration: 1) < 90 days, 2): 90-240 days, and 3): 240-365 days. In the Okavango,
22
23 234 we sampled open water, marginal vegetation or floodplain; in the Everglades, open water,
24
25 235 freshwater marsh/prairie or shrubland (groups derived from vegetation classes; Pearlstine *et*
26
27 236 *al.*, 2002). In the Okavango, we collected 25% of the algal samples from sites with
28
29 237 hydroperiod class 1 (HP 1; mean depth=71 cm), 50% from HP 2 (mean depth=107 cm), and
30
31 238 25 % from HP 3 sites (mean depth=229 cm); in the Everglades, we took 4% of the samples
32
33 239 from HP 1 sites (mean depth=25 cm), 41% from HP 2 (mean depth=28 cm), 44% from HP 3
34
35 240 sites (mean depth=57 cm), while hydroperiod data was not available in the rest of the sites. In
36
37 241 the Okavango, we took 32% of the samples from open waters, 14% from marginal vegetation
38
39 242 sites, and 54% from floodplains; in the Everglades, we took 7% of the samples from open
40
41 243 waters, 75% from marsh/prairie sites, and 15% from shrublands (Table 1).
42
43
44
45
46
47

48 244

49 245 Algal analyses

50 246 Okavango Delta

51
52 247 Prior to microscopy, we resuspended algae by shaking the tubes for 2 minutes. We then filled
53
54 248 chambers of 5, 10 or 15 mL volume (depending on cell density) and let them settle for at least
55
56
57
58
59
60

1
2
3 249 8 to 12 hours to obtain a random distribution of the algal units (i.e. cells, coenobia, colonies,
4
5 250 and filaments; European Standard, 2005). One of us (LM) identified and counted at least 400
6
7 251 algal units at 100x and 400x magnification using an inverted microscope (Utermöhl, 1958),
8
9 252 scanning the chamber in random fields of view. We identified taxa to the lowest possible
10
11 253 taxonomic unit (genus, species or variety) using John, Whitton & Brook (2002), Cronberg *et*
12
13 254 *al.* (1996), Coesel & Van Geest (2008; 2009), and other sources (see Marazzi, 2014).
14
15
16
17

18 256 Everglades

19
20 257 We modified standard methods for preparing wet mounts for counting algae (APHA *et al.*,
21
22 258 2005) for periphyton from frozen samples (Stevenson & Bahls, 1999). We homogenized
23
24 259 thawed samples with a hand blender, and dried samples onto a cover glass. When CaCO₃
25
26 260 crystals were noticeable on the slide, we added a solution of 0.01 mL 10% HCl, dried the
27
28 261 cover slip, and inverted it onto a microscope slide in 0.02 ml of water, then sealed it by
29
30 262 ringing the glass with fingernail polish (Stevenson, McCormick & Frydenborg, 2002). One of
31
32 263 us (FACT) counted at least 500 algal units (i.e. cells, coenobia, colonies, and filaments of
33
34 264 100µm) at 1000x magnification, using a compound light microscope, and identified them to
35
36 265 the lowest possible taxonomic unit (genus, species, or variety) using Prescott (1962),
37
38 266 Komárek & Hindak (1975) and Komárek & Anagnostidis (1986, 1989, 1999).
39
40
41
42

43 267

44 268 Statistical methods

45
46
47 269 To determine whether the algae observed were planktonic, benthic or planktonic/benthic (not
48
49 270 clearly classifiable as either planktonic or benthic; Fig. 2), we used Wehr, Sheath & Kociolek
50
51 271 (2015). To standardize comparisons among sites within wetlands, we estimated richness as
52
53 272 the value of the asymptote of the species accumulation curve, using abundances of taxa
54
55 273 identified at variety, species, genus, or higher levels. We used the Chao 1 estimator (Chao,
56
57
58
59
60

1
2
3 274 1984; Equation 1), a non-parametric estimator appropriate for analysis of microorganisms,
4
5 275 using the R package iNEXT (available online at: <https://chao.shinyapps.io/iNEXT/>).

6
7 276

$$8 \quad 277 \quad \hat{S}_{Chao1} = S_{obs} + \left(\frac{F_1 - 1}{S_{obs}} \right) \frac{F_1(F_1 + 1)}{F_1(F_1 + 1)} \quad (1)$$

9
10 278

11
12 279 where F_1 is the number of taxa that have exactly 1 individual when all samples are pooled
13
14 280 (singletons or uniques), and F_2 is the number of taxa with two individuals (doubletons or
15
16 281 duplicates). We used the results of our estimates to compare the controls of algal richness in
17
18 282 the Okavango and the Everglades.

19
20 283 To identify significant differences between estimated algal richness among sites in
21
22 284 different regions and habitats, and with different hydroperiod class within each wetland (see
23
24 285 ‘*Site classification*’), we used the parametric One-Way ANOVA and Tukey HSD tests when
25
26 286 variables were normally distributed, and with homogeneous variance (assessed via the
27
28 287 Kolmogorov-Smirnov test), and the non-parametric Kruskal-Wallis (K.W.) and Mann
29
30 288 Whitney-U (M.W.U.) tests, when variables were either not normal and/or had non-
31
32 289 homogeneous variance (p-value=0.05).

33
34 290 To identify statistically significant predictors of mean estimated algal richness (i.e. the
35
36 291 total number of taxa, and the richness of each major phylum) among the continuous
37
38 292 environmental variables (no multicollinearity observed) over the sampling period (depth, %
39
40 293 depth change, and P), and the categorical variables hydroperiod class and habitat, we
41
42 294 undertook multiple linear regression analysis with stepwise selection (p-value=0.05). To
43
44 295 explain variations of richness across space, we used the mean values of estimated richness,
45
46 296 and environmental conditions by site over the sampling years. To account for the different
47
48 297 length of the environmental gradients (continuous variables) in the wetlands, we used the
49
50 298 deviations from the respective means (i.e. Z-scores; log- or square-root transformed if not
51
52
53
54
55
56
57
58
59
60

1
2
3 299 normally distributed). We used SPSS[®] (version 17) for statistical tests, regressions, and for
4
5 300 Fig. 3; ArcGis[®] (version 10.3) for the maps, and Excel[®] for the other figures (version 2013).
6

7 301

8
9 302 Indicator species analysis

10 303 To inform future comparisons of algal community structure beyond richness, we used

11 304 indicator species analysis to classify the algal taxa observed in relation to their relative

12 305 abundance and site-specific P concentrations and hydroperiod, according to the CSR

13 306 framework applied to periphytic (Biggs *et al.*, 1998) and planktonic algae (Reynolds, 2006).

14 307 Indicator species analysis combines information on species relative abundance in preassigned

15 308 groups, and the faithfulness of occurrence of species in these groups. Following Dufrêne &

16 309 Legendre (1997), we produced indicator values for algal taxa (varieties, species, genera and

17 310 higher taxonomic levels), and tested their statistical significance using a Monte Carlo

18 311 technique (p-value=0.05).
19
20
21
22
23
24
25
26
27
28
29
30
31

32 312 We aggregated sites in four metagroups using PC-ORD 6 (McCune & Mefford, 2011),

33 313 according to their hydroperiod and P conditions (to which algal life-history strategies

34 314 respond): C = low desiccation disturbance (longer hydroperiod, i.e. >240 days, equivalent to

35 315 hydroperiod class 3 in both wetlands; Table 1), low nutrient stress (higher P); S = high

36 316 disturbance (shorter hydroperiod, i.e. < 240 days, equivalent to hydroperiod classes 1 and 2 in

37 317 the Okavango, and 2 in the Everglades; Table 1), high stress (lower P); R = high disturbance

38 318 (shorter hydroperiod), low stress (higher P; see Table 2). In the Okavango, P was below

39 319 upper limits for oligotrophy in water (TP < 10-15 $\mu\text{g L}^{-1}$) only in a few sites, thus we

40 320 classified sites as mesotrophic (TP < 47 $\mu\text{g L}^{-1}$) and eutrophic (TP \geq 47 $\mu\text{g L}^{-1}$; South

41 321 African “Trophic Status Assessment”; Van Ginkel, 2002). We classified 16 sites in Campaign

42 322 2 as eutrophic with certainty as their TDP concentrations were \geq 47 $\mu\text{g L}^{-1}$. However, 24

43 323 sites had mean TDP <47 $\mu\text{g L}^{-1}$ over the sampling period (mean 30 $\mu\text{g L}^{-1}$); we classified
44
45
46
47
48
49
50
51
52
53
54
55
56
57
58
59
60

1
2
3 324 these as mesotrophic, under the conservative assumption that the unmeasured Particulate
4
5 325 Phosphorus (PP) concentrations would not have been sufficiently high to make these sites fall
6
7 326 into the eutrophic category. For the Everglades, we set the 'lower/higher' periphyton P limit
8
9 327 following Gaiser (2009): $TP < 250 \mu\text{g g}^{-1}$ and 'higher P' as $TP \geq 250 \mu\text{g g}^{-1}$. This was done
10
11 328 to statistically identify CSR indicator taxa for nutrient stress (P scarcity) and desiccation
12
13 329 disturbance (i.e. shorter hydroperiods mean higher desiccation risk for algae).

14
15
16 330 To consolidate our preliminary list of CSR taxa, we cross-checked it with information on
17
18 331 the typical cell size of C, S, and R algae in the periphyton (Biggs *et al.*, 1998), and
19
20 332 phytoplankton (Reynolds, 2006). Cell size is a basic morphological information with
21
22 333 ecological value, as smaller/larger algae tend to grow faster/slower (Reynolds, 2006). Other
23
24 334 important features were only present in one source, e.g. mode of attachment, growth form,
25
26 335 reproduction type (Biggs *et al.*, 1998), and dispersal (Reynolds, 2006), and thus were not
27
28 336 used. Among benthic taxa, we retained: i) for S and R taxa, algae with comparably small cells
29
30 337 to those listed by Biggs *et al.* (1998; Fig. 2); ii) in the C group, algae with medium to large
31
32 338 cells (Biggs *et al.*, 1998). Among planktonic taxa, using our biovolume data, and following
33
34 339 Reynolds (2006; Box 5.1), we retained small algae (biovolume of the algal units, i.e., cells,
35
36 340 coenobia, colonies, or filaments: 10^{-1} - $10^3 \mu\text{m}^3$) in the C group, and medium-large algae
37
38 341 (biovolume of the algal units: 10^3 - $10^5 \mu\text{m}^3$) in the S and R groups. We retained all the
39
40 342 planktonic/benthic taxa identified, as applying either cell size criterion would be arbitrary.

41
42
43 343 To test hypotheses a, b, and c, we used estimated algal richness, depth, depth change, TP
44
45 344 concentrations, hydroperiod class, and habitat type. To test hypothesis d, we used algal
46
47 345 relative abundance data, hydroperiod and TP, as well as information from prior work on the
48
49 346 CSR framework (Biggs *et al.*, 1998; Reynolds, 2006).

53
54
55 348

349 Results

350 In the Okavango, the algae observed were a mix of planktonic and planktonic/benthic algae,
351 dominated by Chlorophyta (Fig. 2a; Table S1). By contrast, in the Everglades, benthic algal
352 richness was highest, dominated by Bacillariophyta (“Observed richness” in Fig. 2b, Tables
353 S2), which also comprised the largest proportion of benthic algal richness in the Okavango
354 (Fig. 2a). The mean site-specific algal richness estimated using the Chao 1 estimator
355 (“Estimated richness” in Fig. 3, 4, and 5; see “Statistical methods”) was 76 in the Okavango
356 and 21 in the Everglades; Kruskal Wallis, K.W.: χ^2 : 109.77, Mann-Whitney U, M.W.U.:
357 $p < 0.001$). In the Okavango, algal richness was higher in BOR and SAN (shorter
358 hydroperiod) than in UPH, LPH (longer hydroperiod), and in XAK than LPH (One-Way
359 ANOVA: $F=8.225$; $p < 0.001$; Tukey HSD: $p < 0.005$; Fig. 1a, Table 3, and Fig. 4a). In the
360 Everglades, richness was significantly higher in sites with higher TP in LOX than LKO,
361 Out_ENP, and ENP, and in Out_ENP than in sites with lower TP in ENP (One-Way
362 ANOVA: $F=29.193$; $p < 0.001$; Tukey HSD: $p < 0.005$; Fig. 1b, Table 3, and Fig. 4b). The site-
363 specific coefficients of variation of water depth change were not statistically significantly
364 different between wetlands (Kruskal-Wallis test: $\chi^2=0.544$; $p=0.461$). In the Okavango, mean
365 water TP was $39 \mu\text{g L}^{-1}$ in 2006-2007 from UPH, LPH, XAK, BOR, and SAN, and $TDP=48$
366 $\mu\text{g L}^{-1}$ in 2009-2010 from BOR, and SAN); in the Everglades, mean periphyton TP was 615
367 $\mu\text{g g}^{-1}$ (Table 3).

368 Site-specific algal richness was not significantly predicted by water depth change in either
369 wetland (Table 4), and did not exhibit the expected negative unimodal relationship posited by
370 the intermediate disturbance hypothesis (Fig. 3). Regression analyses showed that, among the
371 tested variables, water depth (negative relationship) and TP (positive relationship) were the
372 most important controls of richness in the Okavango and Everglades, respectively. In the
373 Okavango, total richness and Chlorophyta richness increased in shallower sites, while

1
2
3 374 Bacillariophyta richness decreased with higher P at whole-wetland scale (Table 4); in BOR,
4
5 375 Bacillariophyta and Chlorophyta richness decreased and increased with higher P, respectively
6
7 376 (Table 4). In the Everglades, total richness increased with higher TP at whole-wetland scale,
8
9
10 377 and within Out_ENP and ENP; richness of Bacillariophyta, and Chlorophyta in LOX and
11
12 378 ENP increased in deeper sites, and cyanobacteria richness increased with hydroperiod class in
13
14 379 LOX (Table 4). TP in LKO was about six times higher than in the other Everglades regions
15
16 380 (Table 3), but it did not significantly predict algal richness in this region (Table 4). Richness
17
18 381 was not statistically significantly different across habitats in either wetland (Fig. 5). However,
19
20 382 in the Okavango, seasonal floodplains of intermediate depth had the highest algal richness
21
22 383 (97 taxa); here vascular plant richness was estimated to be higher (240 species) than in deeper
23
24 384 permanently flooded sites (205 species), and in less frequently flooded, shallower grasslands
25
26 385 (213 species; see Table 3 in Ramberg *et al.*, 2006); the latter two groups of sites also had
27
28 386 fewer algal taxa (Fig. 5). In the Everglades, algal richness was the same (22 taxa) in deeper
29
30 387 habitats (open waters) that have, on average, 3.2 macrophyte taxa, as in shallower
31
32 388 (marshes/prairies, and shrublands) habitats, with 3.6 macrophyte taxa (Joel Trexler,
33
34 389 unpublished data).

38
39 390 We pre-classified 84 CSR taxa in the Okavango, of which 9 competitive (C), no stress-
40
41 391 tolerant (S), and 75 ruderal (R), and 45 in the Everglades (15 C, 1 S and 1 stress-disturbance
42
43 392 tolerant), and 28 R (Table S3). Of these taxa, 65% in the Okavango (55) and 58% in the
44
45 393 Everglades (26) met the expectations on their cell size for benthic (Biggs *et al.*, 1998) and
46
47 394 planktonic algae (Reynolds, 2006), and were thus included in the final list (Table 5): 6 C, 0 S,
48
49 395 and 49 R taxa in the Okavango, and 15 C, 1 S, 1 stress-disturbance tolerant, and 9 R taxa in
50
51 396 the Everglades (Fig. 6 a and b). Also, in the Okavango, the share of R desiccation-resistant
52
53 397 indicator taxa was much higher (89%) than in the Everglades (35%), where hydroperiod
54
55 398 tends to be longer (Table 5). In the Okavango, we classified species of larger diatoms
56
57
58
59
60

1
2
3 399 (*Eunotia*, *Frustulia*, and *Stauroneis*), and a *Micrasterias* species as C taxa indicating longer
4
5 400 hydroperiod and higher P (low desiccation disturbance, and low P scarcity stress); species of
6
7 401 coenobial green algae, such as *Pediastrum* and *Scenedesmus*, and of desmids (e.g.
8
9 402 *Cosmarium*, and *Staurastrum*), but also Euglenophyta, Cryptophyta, cyanobacteria,
10
11 403 Pyrrophyta, and Xanthophyta, as R taxa indicating shorter hydroperiod and higher P; whereas
12
13 404 no stress-tolerant taxa emerged from our analysis (Table 5). In the Everglades, we classified
14
15 405 two large diatom species, and various green algae (particularly desmids), as C taxa that
16
17 406 indicate low desiccation disturbance and low P scarcity stress; small diatoms (e.g. species of
18
19 407 *Encyonopsis*, *Eunotia*, and *Nitzschia*), two desmids (*Cosmarium* and *Micrasterias*), and the
20
21 408 cyanobacterium *Johannesbaptistia*, as R taxa that indicate high desiccation disturbance and
22
23 409 low P scarcity stress; *Scytonema* emerged as a stress/disturbance tolerant taxon (Table 5).

410

411 **Discussion**

412 Hydrology

413 Comparisons of algal richness controls across the two wetlands revealed that mean site-
414 specific richness did not follow the negative unimodal relationship predicted by intermediate
415 disturbance hypothesis (Connell, 1978). Water depth changes were higher in the Okavango
416 than in the Everglades, which is likely due to the much more heavily managed water flows
417 (Estenoz & Bush, 2015), and smaller flood amplitude (Junk et al., 2006) in the latter. Depth
418 change did not significantly predict algal richness, and depth was a weak predictor of
419 richness in the Okavango (Table 4). Contrary to our hypothesis, algal richness was not
420 highest in sites where water depth change over recent years (a proxy for hydrological
421 disturbance) was intermediate in the Okavango or in the Everglades (Fig. 3). Our data do not
422 concur with observations of higher algal richness or diversity with intermediate water depth
423 changes in temperate floodplain lakes, measured, for example, as rate of daily water level

1
2
3 424 change (Paidere *et al.*, 2007) or amplitude of water level fluctuations (Gruberts *et al.*, 2005);
4
5 425 in subtropical floodplain systems, species richness was also associated with flood pulse
6
7 426 disturbances (Rodrigues & Bicudo, 2001a; O'Farrell *et al.*, 2003). Expectations of the
8
9 427 intermediate disturbance hypothesis were however not met, for example, in a hypertrophic
10
11 428 lake in Spain, where hydrological disturbance was measured as frequency and intensity of
12
13 429 mixing events (Rojo & Alvares-Cobelas, 1993); other studies only found partial support, for
14
15 430 example, in lakes in Germany where disturbance was measured as mixing events (Sommer,
16
17 431 1993), and Texas, where rainfall, inflow, and water level change corresponded to disturbance
18
19 432 (Grover & Chrzanowski, 2004). Environmental and ecological complexity, and the
20
21 433 consequent methodological challenges of measuring disturbance most likely impact the shape
22
23 434 of the relationships observed. Although we did not find support for the intermediate
24
25 435 disturbance hypothesis with the sampling frequency used (4 times a year over 4 years in the
26
27 436 Okavango, and once a year over 7 years in the Everglades), processes occurring at finer
28
29 437 temporal scales may determine highest richness with intermediate hydrological disturbance.
30
31
32
33

34 438 Therefore, collecting algal samples weekly or bi-weekly over several years as
35
36 439 recommended by Sommer *et al.* (1993) would enable us to assess with higher temporal
37
38 440 resolution the extent to which algal richness depends on water level fluctuations in these
39
40 441 flood pulsed wetlands; such sampling could be undertaken at key sites where biological and
41
42 442 environmental variables are already monitored. Although algal richness shows only a weak
43
44 443 increase with mean water depth in the Okavango, and no increase with mean water depth in
45
46 444 the Everglades, maintaining and restoring the flood pulse of these wetlands, respectively
47
48 445 (which vital nutrient flows and habitats depend on) is likely important for the preservation of
49
50 446 their algal diversity.
51
52
53
54
55
56
57
58
59
60

1
2
3 449 Phosphorus

4
5 450 Algal richness was mostly controlled by water depth in the Okavango, and by TP in the
6
7 451 Everglades. In the Okavango, higher P concentrations increased Chlorophyta richness in the
8
9 452 BOR region; this is likely due to nutrient mobilization via flooding which indirectly increases
10
11 453 productivity, and thus richness (Davidson *et al.*, 2012). In the Everglades, richness increased
12
13 454 with higher periphyton TP, which accurately reflects P availability to algae that rapidly
14
15 455 uptake it from the water (Gaiser *et al.*, 2004). Here, P loads from agricultural sources tend to
16
17 456 cause a replacement of cohesive periphyton mats dominated by cyanobacteria with floating
18
19 457 mats with more Chlorophyta, and higher richness (Pan *et al.*, 2000; Stevenson *et al.*, 2008;
20
21 458 Gaiser *et al.*, 2011). Therefore, our results meet the expectations of species-energy theory, i.e.
22
23 459 higher richness with higher resource provision (Wright, 1983). The key underpinning
24
25 460 ecological mechanism may be that abundant nutrients allow the formation of complex
26
27 461 biofilms with understory and overstory benthic algae (Passy, 2008), where large filamentous
28
29 462 algae provide attachment substrata for other species (Hillebrand, 2003).

30
31
32
33
34 463 The patterns we observed concur with a study in a floodplain wetland in the Upper Paraná
35
36 464 River basin (Rodrigues & Bicudo, 2001b in Rodrigues & Bicudo, 2001a). Algal richness was
37
38 465 shown to increase with low N in the N-limited Otamendi wetland (Argentina; deTezanos
39
40 466 Pinto *et al.*, 2015); thus collecting algal richness, and nutrient data (TN and TP, but also
41
42 467 dissolved forms of P and N), in subtropical wetlands with different nutrient limitation can
43
44 468 help expand our comparisons. We demonstrated that higher P increases total algal richness in
45
46 469 the Everglades, and Chlorophyta richness in the Okavango (Table 4); however, high
47
48 470 agricultural P loads continue to threaten the Everglades, and increased tourism with
49
50 471 unsustainable waste management may negatively impact the Okavango ecosystems (Darkoh
51
52 472 & Mbaiwa, 2014). Therefore, preservation and restoration activities in these wetlands remain
53
54 473 crucial to maintain, if not enhance, the respective diversity of their algal communities.
55
56
57
58
59
60

474 Habitat

475 Shallower habitats did not show significantly higher algal richness than deeper habitats, and
476 habitat type was not a significant control of richness in either wetland. We speculate that in
477 the Okavango, more diverse vascular plants may increase algal richness in shallow
478 floodplains by providing benthic taxa with different substrata for attachment. Relationships
479 between macrophyte abundance and diversity, and algal diversity were observed in other
480 wetlands at temperate (Borics *et al.*, 2003), and subtropical latitudes (Izaguirre *et al.*, 2004;
481 Rodrigues & Bicudo, 2004 in Murakami *et al.*, 2009). Complex microhabitats on plants, for
482 example due to high leaf surface area, create numerous ecological niches for a variety of
483 organisms, including algae (Thomaz & Cunha, 2010; Kovalenko *et al.*, 2012). On the other
484 hand, where plant density or biomass are too high, light penetration may become limiting for
485 algae (Izaguirre *et al.*, 2004), thus potentially reducing their diversity. Therefore, to isolate
486 the influence of habitat type and heterogeneity on algal richness, we recommend the
487 collection of data on plant and sediment substrata, and the development of habitat complexity
488 metrics on, e.g. surface area, and structure of plant leaves and stems (Kovalenko *et al.*, 2012),
489 and indices accounting for plant abundance and diversity (Thomaz & Cunha, 2010). Such
490 data can help predict how modified hydrology may alter floodplain landscapes, and algal
491 community structure in these and other wetlands in view of ongoing and future threats.

492

493 Life-history strategies

494 Most of our CSR indicator taxa had varying relative abundances across gradients of
495 desiccation and P scarcity that well reflected the expectations of the CSR framework applied
496 on algae; benthic C taxa were larger than S and R taxa, while S and R planktonic algae were
497 larger than C taxa. In the Okavango, the R taxa *Aulacoseira ambigua*, and *A. granulata*
498 indicated higher P, consistent with Mackay *et al.* (2012). In the Everglades, one taxon

1
2
3 499 indicated both desiccation and P scarcity (*Scytonema*, most likely *S. hoffmanii*), as previously
4
5 500 observed by Gaiser *et al.* (2011). Some of the small algae we identified as indicator taxa have
6
7 501 been previously classified as R-strategists in Lake Okeechobee (LKO; Fig. 1b), e.g.
8
9 502 *Achnanthes minutissima* (now called *Achnantheidium minutissimum*; Tables S1-S2), and
10
11 503 species of *Lyngbya*, *Fragilaria* and *Chroococcus* (Carrick & Steinman, 2001). *Fragilaria* and
12
13 504 *A. minutissimum* have been also classified as R taxa in temperate streams (Biggs *et al.*, 1998).
14
15 505 In the Okavango, the share of R desiccation-resistant algae among indicator taxa was much
16
17 506 higher than in the Everglades (Table 5), as was expected due to sampling sites having shorter
18
19 507 hydroperiod in the Okavango (Table 1). Our R taxa in the Everglades (e.g. benthic diatoms),
20
21 508 were concentrated in shorter hydroperiod sites, analogous to observations made by Carrick &
22
23 509 Steinman (2001) in shallow epipelagic habitats in LKO. Despite differences between C, S, and
24
25 510 R in nutrient requirements, and surrounding environmental gradient structure in the benthos
26
27 511 and plankton (Law *et al.*, 2014; Tapolczai *et al.*, 2016), overall, 63% of the CSR taxa we
28
29 512 classified matched expectations on algal cell size for periphyton (Biggs *et al.*, 1998) and
30
31 513 phytoplankton (Reynolds, 2006). Therefore, our CSR classification approach is promising for
32
33 514 future comparisons in the same sites, and applications in other wetlands.

42

41 516 Limitations and outlook

42
43 517 This study provides a replicable and theory-informed template to design further comparative
44
45 518 research to examine controls of algal richness at finer temporal and habitat scales than those
46
47 519 analysed in this study. As we sampled algae in water in the Okavango, and in periphyton
48
49 520 mats in the Everglades, the total algal richness is underestimated in each study; thus we
50
51 521 recommend that future work jointly sample algae in water, and on plant and sediment/soil
52
53 522 substrata. In the Everglades, TP comprises P in algal cells, and carbonates to which P is
54
55 523 chemically adsorbed; as water TP is often below detection limits, periphyton TP remains
56
57
58
59
60

1
2
3 524 however the best measure of P availability to algae in the Everglades (Gaiser *et al.*, 2004).
4
5 525 The periphyton mat is the environmental matrix for benthic algae, analogous to the water
6
7 526 column (in which TP is usually measured) for planktonic algae. Our approach to classify
8
9 527 CSR indicator taxa can be further developed taking into account other features than cell size,
10
11 528 such as shape, surface/volume ratio, and life-forms; these influence growth rate, buoyancy
12
13 529 regulation, light capture, nutrient uptake, and susceptibility to grazing (Reynolds, 2006), and
14
15 530 are thus important elements for elaborating joint classification of planktonic and benthic
16
17 531 algae. The much higher mean algal richness in the Okavango than in the Everglades is likely
18
19 532 in part due to methodological differences between the studies. Further research with
20
21 533 standardized protocols would help understand whether the Everglades' lower richness may be
22
23 534 due not only to its extreme oligotrophy, but also to its young geological history and
24
25 535 peninsular character.
26
27
28

29 536 Our findings provide a robust baseline for future comparisons of algal richness, and life-
30
31 537 history strategy distribution in relation to hydroperiod and P; measuring N would allow a
32
33 538 deeper understanding of the role of limiting nutrients on richness and CSR strategies. In the
34
35 539 Okavango, upstream hydropower plants could attenuate the flood pulse, thus impacting the
36
37 540 Delta's algal communities (Milzow *et al.*, 2009; Mackay *et al.*, 2012; Darkoh & Mbaiwa,
38
39 541 2014). In the Everglades, water purification schemes, and controlled water releases are
40
41 542 already restoring water quality and flow with potential widespread return of characteristic
42
43 543 benthic algal communities adapted to very low P (Gaiser *et al.*, 2011). Taxonomically and
44
45 544 functionally diverse algae likely enhance these wetlands' resilience to environmental change,
46
47 545 as complementary species make primary production and other ecosystem functions more
48
49 546 efficient (Cardinale *et al.*, 2009). Continued monitoring of these wetlands' algal communities
50
51 547 is therefore key to assess the effectiveness of their conservation and management, and detect
52
53 548 future environmental change impacts.

21 **Table 5.** List of the C, S and R and stress - and disturbance tolerant taxa identified via
 22 indicator species analysis (in bold italics the indicator taxa identified in both wetlands).

Strategy	Okavango
Competitive (C) 1 Planktonic/Benthic (P/B), 5 Benthic (B)	Bacillariophyta - (B): <i>Eunotia flexuosa</i> , <i>Frustulia rhomboides</i> , <i>F. saxonica</i> , <i>Frustulia sp.</i> , <i>Stauroneis phoenicenteron</i> Chlorophyta - (P/B): <i>Micrasterias foliacea</i>
Stress-tolerant (S)	-
Ruderal (R) 28 Planktonic (P), 20 Planktonic/Benthic (P/B), 1 Benthic (B)	Bacillariophyta - (P): <i>Aulacoseira ambigua</i> , <i>Aulacoseira granulata</i> Chlorophyta - (P): <i>Botryococcus sp.</i> , <i>Chlamydomonas sp.</i> , <i>Chlorococcum sp.</i> , Chlorococcales, <i>Coelastrum sp.</i> , <i>Crucigeniella crucifera</i> , <i>Eremosphaera sp.</i> , <i>E. viridis</i> , <i>Oocystis sp.</i> , <i>Pediastrum angulosum</i> , <i>P. boryanum</i> , <i>P. duplex</i> , <i>Scenedesmus falcatus</i> , <i>S. maximum</i> , <i>S. obtusus</i> , <i>S. planctonicum</i> , <i>S. serratus</i> , <i>Tetraedron caudatum</i> (P/B): <i>Cosmarium contractum</i> , <i>C. obsoletum</i> , <i>C. pseudopyramidatum</i> , <i>C. regnesii</i> , <i>C. trilobulatum</i> , <i>Euastrum bidentatum</i> , <i>E. binale</i> , <i>E. denticulatum</i> , <i>E. elegans</i> , <i>Euastrum sp.</i> , <i>Hyalotheca sp.</i> , <i>Micrasterias pinnatifida</i> , <i>Staurastrum furcatum</i> , <i>S. margaritaceum</i> , <i>S. tetracerum</i> , <i>Stauroidesmus convergens</i> , <i>S. dickiei</i> , <i>S. subulatus</i> , <i>Teilingia granulata</i> Cryptophyta - (P): <i>Rhodomonas lacustris</i> cyanobacteria - (P): <i>Lyngbya sp.</i> Euglenophyta - (P): <i>Euglena limnophila</i> , <i>E. proxima</i> , <i>Phacus sp.</i> , <i>P. pusillus</i> Xanthophyta - (P): <i>Goniochloris sp.</i> ; (B): <i>Tribonema sp.</i> Pyrrophyta - (P): <i>Peridinium sp.</i> (P); (P/B): <i>Amphidinium sp.</i>
Strategy	Everglades
Competitive (C) 3 Planktonic, 8 Planktonic/Benthic, 4 Benthic	Bacillariophyta – (B): <i>Encyonopsis ftsfp02</i> , <i>Eunotia flexuosa</i> Chlorophyta - (P): <i>Pediastrum tetras</i> , <i>Scenedesmus bijuga</i> , <i>Tetraedron minimum</i> (P/B): <i>Cosmarium sp.</i> , <i>C. calcareum</i> , <i>C. ocellatum</i> , <i>C. phaseolus</i> , <i>C. pyramidatum</i> , <i>Staurastrum cyathipes</i> , <i>S. excavatum</i> , <i>S. longibrachiatum</i> (B): <i>Oedogonium (small)</i> cyanobacteria - (B): <i>Lyngbya sp.</i>
Stress-tolerant (S) 1 Benthic	Bacillariophyta - (B): <i>Nitzschia serpentiraphe</i>
Ruderal (R) 1 Planktonic, 2 Planktonic/Benthic, 6 Benthic	Bacillariophyta – (B): <i>Diploneis parma</i> , <i>Encyonopsis microcephala</i> , <i>Eunotia incisa</i> , <i>Fragilaria nana</i> , <i>Nitzschia amphibia</i> , <i>N. nana</i> Chlorophyta - (P/B): <i>Cosmarium inaequalis</i> , <i>Micrasterias crux-mellitensis</i> cyanobacteria - (P): <i>Johannesbaptistia sp.</i>
Stress/disturbance tolerant 1 Planktonic/Benthic (P/B)	cyanobacteria - (P/B): <i>Scytonema sp.</i>

23 FIGURE LEGENDS

24

25 **Fig. 1 a) and b).** Map of estimated algal richness in the a) Okavango and b) Everglades,
26 respectively located in NW Botswana and SE USA, as shown in the inset maps. a) Okavango
27 (site averages); UPH= Upper Panhandle; LPH=Lower Panhandle; XAK=Xakanaxa;
28 BOR=Boro; SAN=Santantadibe; b) Everglades; LKO=Lake Okeechobee;
29 LOX=Loxahatchee; Out_ENP=Outside of Everglades National Park (including the Water
30 Conservation Areas, WCA 2 and 3); ENP=Everglades National Park. The total area of the
31 Okavango is 28,000 km² while today's Everglades' area is ~ 5,000 km², reduced from its
32 original pre-drainage size of > 10,000 km² by agriculture and urbanization (Junk *et al.*, 2006).
33 Due to their outstanding geographic features and biodiversity, both these wetlands are
34 protected as World Heritage sites (<http://whc.unesco.org/>), and are included in the Ramsar
35 Convention on Wetlands of International Importance (<http://www.ramsar.org/>).

36

37 **Fig. 2 a) and b).** Observed species richness of planktonic, planktonic/benthic, and benthic
38 algae by phylum in the a) Okavango and b) Everglades.

39

40 **Fig. 3.** Mean site-specific estimated algal richness in relation to mean water depth change
41 (%). Okavango (empty circles); Everglades (black fill triangles). Depth change was not a
42 significant predictor in either wetland (linear regression p-values > 0.05; quadratic models
43 did not yield better results).

44

45 **Fig. 4 a) and b).** Mean site-specific estimated algal richness across groups of sites with
46 different hydroperiod class (HP) and phosphorus (P) for Fig. 6 (C=competitive; S=stress-
47 tolerant; R=ruderal; SD=stress and disturbance tolerant). Significant differences (Kruskal-
48 Wallis, K.W., and Mann Whitney U, M.W.U., tests: p<0.05): Okavango: Total (K.W.: $\chi^2=$

1
2
3 49 9.061), Chlorophyta (Chl; K.W.: $\chi^2=11.097$) and cyanobacteria (Cya; K.W.: $\chi^2=12.482$);
4
5 50 Other phyla: K.W.: $\chi^2=8.440$. Statistically significant post-hoc differences in phylum mean
6
7 51 richness as per M.W.U. tests ($p<0.05$) are marked with (in decreasing order) a and b; total
8
9 52 richness with A and B. Everglades: Total ($\chi^2=36.275$), Bacillariophyta (Bac; K.W.:
10
11 $\chi^2=10.139$), Chl (K.W.: $\chi^2=22.474$), and Cya (K.W.: $\chi^2=10.380$). Statistically significant post-
12
13 53 hoc differences in phylum mean richness as per M.W.U. tests ($p<0.05$) are marked with (in
14
15 54 decreasing order) aa, a and b; total richness with AA, A and B.

17 55
18
19 56

20
21 **Fig. 5.** Mean estimated habitat-specific algal richness in the Okavango and Everglades. No
22
23 57 statistically significant differences ($p\text{-value}=0.05$) were found within each wetland.
24
25 58
26 59

27
28 **Fig. 6 a) and b).** Summary of the distribution of competitive (C), stress-tolerant (S), ruderal
29
30 60 (R) indicator taxa, and stress-disturbance tolerant (SD) at sites with varying desiccation
31
32 61 disturbance and P scarcity in the a) Okavango, and b) Everglades. The number of C, S, and R
33
34 62 indicator taxa in each wetland is included.

Table S1. List of all the algal taxa observed in the Okavango Delta (main source of authorities: www.algaebase.org; information on planktonic / benthic mostly from Wehr J.D., Sheath R.G. & Kociolek J.P. (Eds). (2015). "Freshwater algae of North America. Ecology and classification". Academic Press, San Diego).

BACILLARIOPHYTA		Planktonic / Benthic
Species	Authority	
<i>Achnantheidium minutissimum</i>	(Kützing) Czarnecki 1994	B
<i>Amphora libyca</i>	Ehrenberg 1840	B
<i>Amphora ovalis</i>	Kützing 1844	B
<i>Amphora pediculus</i>	(Kützing) Grunow in Schmidt 1875	B
<i>Asterionella formosa</i>	Hassall (1850)	P
<i>Aulacoseira ambigua</i>	(Grunow) Simonsen 1979	P
<i>Aulacoseira granulata</i>	(Ehrenberg) Simonsen 1979	P
<i>Caloneis bacillum</i>	(Grunow) Cleve 1894	B
<i>Caloneis tenuis</i>	(W.Gregory) Krammer	B
<i>Caloneis undulata</i>	(W.Gregory) Krammer	B
<i>Craticula cuspidata</i>	(Kützing) Mann 1990	B
<i>Cymatopleura solea</i>	(Brébisson and Godey) W. Smith (1851)	B
<i>Cymbella cuspidata</i>	Kützing 1844	B
<i>Cymbella naviculiformis</i>	(Auerswald) Cleve (1894)	B
<i>Epithemia adnata</i>	(Kützing) Brébisson 1838	B
<i>Eunotia alpina</i>	(Nägeli) Hustedt in Schmidt <i>et al.</i> 1913	B
<i>Eunotia arcus</i>	Ehrenberg 1837	B
<i>Eunotia asterionelloides</i>	Hustedt 1952	B
<i>Eunotia bilunaris</i>	(Ehrenberg) Schaarschmidt 1880	B
<i>Eunotia exigua</i>	(Brébisson ex Kützing) Rabenhorst 1864	B
<i>Eunotia faba</i>	(Ehrenberg) Grunow in van Heurck 1881	B
<i>Eunotia flexuosa</i>	(Brébisson ex Kützing) Kützing 1849	B
<i>Eunotia incisa</i>	W.Smith ex W.Gregory 1854	B
<i>Eunotia intermedia</i>	(Krasske) Nörpel and Lange-Bertalot	B
<i>Eunotia minor</i>	(Kützing) Grunow in van Heurck 1881	B
<i>Eunotia muscicola</i>	Krasske 1939	B
<i>Eunotia naegellii</i>	Migula 1907	B
<i>Eunotia okavangoi</i>	Cholnoky	B
<i>Eunotia pectinalis</i>	(Kützing) Rabenhorst 1864	B
<i>Eunotia praerupta</i>	Ehrenberg 1843	B
<i>Eunotia rhomboidea</i>	Hustedt 1950	B
<i>Eunotia serra</i>	Ehrenberg 1837	B
<i>Eunotia soleirolii</i>	(Kützing) Rabenhorst 1864	B
<i>Fragilaria africana</i>	Hustedt	P
<i>Fragilaria crotonensis</i>	Kitton 1869	P
<i>Fragilaria ulna</i>	(Nitzsch) Lange-Bertalot 1980	P/B
<i>Frustulia rhomboides</i>	(Ehrenberg) De Toni 1891	B
<i>Frustulia saxonica</i>	Rabenhorst 1853	B
<i>Gomphonema angustum</i>	C. Agardh 1831	B
<i>Gomphonema augur</i>	Ehrenberg 1840	B
<i>Gomphonema clevei</i>	Fricke in Schmidt <i>et al.</i> 1902	B
<i>Gomphonema globiferum</i>	Meister 1913	B
<i>Gomphonema gracile</i>	Ehrenberg 1838	B
<i>Gomphonema hebridense</i>	W.Gregory 1854	B
<i>Gomphonema lanceolatum</i>	Kützing 1844	B
<i>Gomphonema olivaceum</i>	(Hornemann) Brébisson 1838	B
<i>Gomphonema parvulum</i>	(Kützing) Kützing 1849	B
<i>Gomphonema pfannkuchae</i>	Cholnoky	B
<i>Gomphonema resendei</i>	Moura	B
<i>Gomphonema subtile</i>	Ehrenberg 1843	B

BACILLARIOPHYTA		Planktonic / Benthic
<i>Gomphonema truncatum</i>	Ehrenberg 1832	B
<i>Gyrosigma spencerii</i>	(W.Smith) Griffith and Henfrey 1856	B
<i>Hantzschia amphioxys</i>	(Ehrenberg) Grunow	B
<i>Meridion circulare</i>	(Greville) C.Agardh 1831	B
<i>Navicula cryptocephala</i>	Kützing 1844	B
<i>Navicula cryptotenella</i>	Lange-Bertalot in Krammer and Lange-Bertalot 1985	B
<i>Navicula halophila</i>	(Grunow) Cleve 1894	B
<i>Navicula laevis</i>	Kützing 1844	B
<i>Navicula menisculus</i>	Schumann 1867	B
<i>Navicula radiosa</i>	Kützing 1844	B
<i>Navicula veneta</i>	Kützing 1844	B
<i>Neidium ampliatum</i>	(Ehrenberg) Krammer in	B
<i>Neidium productum</i>	(W.Smith) Cleve 1894	B
<i>Nitzschia acicularis</i>	(Kützing) W.Smith 1853	B
<i>Nitzschia linearis</i>	(C.Agardh) W.Smith 1853	B
<i>Nitzschia pellucida</i>	Grunow 1880	B
<i>Nitzschia perminuta</i>	(Grunow) M.Peragallo 1903	B
<i>Nitzschia recta</i>	Hantzsch ex Rabenhorst 1862	B
<i>Nitzschia scalaris</i>	(Ehrenberg) W.Smith 1853	B
<i>Nitzschia sigma</i>	(Kützing) W.Smith 1853	B
<i>Nitzschia sigmoidea</i>	(Nitzsch) W.Smith 1853	B
<i>Nitzschia subacicularis</i>	Hustedt	B
<i>Nitzschia vermicularis</i>	(Kützing) Hantzsch in Rabenhorst 1860	B
<i>Pinnularia abaujensis</i>	(Pantocsek) R.Ross 1947	B
<i>Pinnularia braunii</i>	(Grunow) Mills 1934	B
<i>Pinnularia divergentissima</i>	(Grunow) Cleve 1895	B
<i>Pinnularia gibba</i>	Ehrenberg 1843	B
<i>Pinnularia interrupta</i>	W.Smith 1853	B
<i>Pinnularia lundii</i>	Hustedt 1954	B
<i>Pinnularia maior</i>	Kützing (Rabenhorst) 1997	B
<i>Pinnularia mesolepta</i>	(Ehrenberg) W.Smith 1853	B
<i>Pinnularia nobilis</i>	(Ehrenberg) Ehrenberg 1843	B
<i>Pinnularia subcapitata</i>	W.Gregory 1856	B
<i>Pinnularia subrostrata</i>	(A.Cleve) Cleve-Euler 1955	B
<i>Pinnularia viridis</i>	(Nitzsch) Ehrenberg 1843	B
<i>Rhopalodia gibba</i>	(Ehrenberg) O. Müller (1895)	B
<i>Sellaphora bacillum</i>	(Ehrenberg) D.G.Mann 1989	B
<i>Sellaphora pupula</i>	(Kützing) Mereschkovsky 1902	B
<i>Stauroneis anceps</i>	Ehrenberg 1843	B
<i>Stauroneis phoenicenteron</i>	(Nitzsch) Ehrenberg 1843	B
<i>Stauroneis producta</i>	Grunow in van Heurck 1880	B
<i>Surirella capronii</i>	Brébisson ex F.Kitton	B
<i>Surirella elegans</i>	Ehrenberg	B
<i>Surirella linearis</i>	W.Smith 1853	B
<i>Synedra acus</i>	Kützing 1844	P/B
<i>Synedra amphicephala</i>	Kützing 1844	P/B
<i>Synedra capitata</i>	Ehrenberg (1836)	P/B
<i>Synedra nana</i>	F.Meister 1912	P/B
<i>Synedra rumpens</i>	Kützing 1844	P/B
<i>Tabellaria fenestrata</i>	(Lyngbie) Kützing 1844	P

7 **Table S2.** List of all the algal taxa observed in the Everglades (asterisks indicate species also
 8 found in the Okavango Delta (main source of authorities: www.algaebase.org; information on planktonic / benthic
 9 mostly from Wehr J.D., Sheath R.G. & Kociolek J.P. (Eds). (2015). "Freshwater algae of North America. Ecology and
 10 classification". Academic Press, San Diego).

BACILLARIOPHYTA		
Species	Authority	Planktonic / Benthic
<i>Achnanthes caledonica</i>	Lange-Bertalot in Lange-Bertalot & Moser 1994	B
<i>Achnanthes gracillima</i>	Hustedt 1927	B
<i>Achnantheidium minutissimum</i> *	(Kützing) Czarnecki 1994	B
<i>Amphora ovalis</i> *	Kützing 1844	B
<i>Amphora sulcata</i>	Gregory 1854	B
<i>Amphora coffaeiformis</i>	(C.Agardh) Kützing	B
<i>Amphora holsatica</i>	Hustedt 1925	B
<i>Amphora veneta</i>	Kützing 1844	B
<i>Anomoeoneis sphaerophora f. costata</i>	(Kützing) A.-M.Schmid 1977	B
<i>Bacillaria paxillifer</i>	(O.F.Müller) T.Marsson 1901	B
<i>Brachysira aponina</i>	Kützing 1836	B
<i>Brachysira brebissonii</i>	R.Ross in Hartley 1986	B
<i>Brachysira neoacuta</i>	Lange-Bertalot 1994	B
<i>Brachysira neoexilis</i>	Lange-Bertalot in Lange-Bertalot & Moser 1994	B
<i>Brachysira serians</i>	(Brébisson) Round & D.G.Mann 1981	B
<i>Caponea caribbea</i>	A.C.Podzorski	B
<i>Cocconeis placentula</i>	Ehrenberg 1838	B
<i>Cyclotella meneghiniana</i>	Kützing 1844	P
<i>Diademsis confervacea</i>	Kützing 1844	B
<i>Diploneis oblongella</i>	(Nägeli ex Kützing) Cleve-Euler in Cleve-Euler & Osvald 1922	B
<i>Diploneis parma</i>	Cleve 1891	B
<i>Diploneis puella</i>	(Schumann) Cleve 1894	B
<i>Encyonema evergladianum</i>	Krammer 1997	B
<i>Encyonema silesiacum</i>	(Bleisch) D.G.Mann in Round, Crawford & Mann 1990	B
<i>Encyonema silesiacum var. elegans</i>	Krammer	B
<i>Encyonopsis floridana</i>	Krammer	B
<i>Encyonopsis microcephala</i>	(Grunow) Krammer 1997	B
<i>Encyonopsis subminuta</i>	Krammer & E.Reichardt 1997	B
<i>Eunotia camelus</i>	Ehrenberg	B
<i>Eunotia flexuosa</i> *	(Brébisson ex Kützing) Kützing 1849	B
<i>Eunotia incisa</i> *	W.Smith ex W.Gregory 1854	B
<i>Eunotia monodon</i>	Ehrenberg 1843	B
<i>Eunotia naegeli</i> *	Migula 1907	B
<i>Eunotia rabenhorstiana var. elongata</i>	(Patrick) D.Metzeltin & Lange-Bertalot 1998	B
<i>Eunotia zygodon</i>	Ehrenberg 1843	B
<i>Fragilaria minuscula</i>	(Grunow) D.M.Williams & 1987	B
<i>Fragilaria nana</i>	Lange-Bertalot 1991	B
<i>Fragilaria synegrottesca</i>	Lange-Bertalot 1993	B
<i>Fragilariformis virescens</i>	(Ralfs) Williams & Round	B
