ABSTRACT

The study of soil samples taken in regions of the industrial enterprises locations in Tomsk areas was performed. The instrumental neutron-activation analysis was used for determination of the chemical composition of samples. The accumulation levels of 26 chemical elements in soils, including rare and radioactive, were determined. The level values of all of the studied elements exceeded background concentrations. The observed elements concentrations exceeded the background ones by factor ranging from 1.1 for Rb (Artificial stone plant) up to 20 for Br (Borrow pit enterprise) to 28 for Ce (Ash dump of the heat power station). The pollution of all studied areas was estimated as high on the basis of calculated values of the total pollution index. The soil geochemical peculiarities in Tomsk are established by elements accompanying production in regions of industrial enterprises locations. The soil composition reflects the specificity of the urban area with various industrial enterprises, due to certain properties of the soil, which constantly accumulates pollutants of emissions from businesses shops and vehicles.

Key words: urban soils, industrial enterprises, geochemical characteristics, concentration ratio, total pollution index

1. INTRODUCTION

The soil as one of the main components of the natural environment is constantly under negative impacts. Urban soils act as a mechanical barrier to aerogenic flows of man-made substances and are the long-term repository medium. The process of long-term contamination of urban soils causes changings in their chemical composition and acid-base characteristics [1]. The feature of urban soils pollution resides in the fact that a large number of different pollution sources (industrial enterprises, transport, placement, waste, etc.) are located on relatively small areas. The diversified industry and application of various technologies lead to accumulation in urban soils not only of the so-called "priority" elements (Zn, Cd, Pb, Cu), which usually studied, but also a large number of others [2-8].

The soil cover in the city of Tomsk is constantly exposed to both natural (water and wind erosion, waterlogging) and anthropogenic factors (chemical pollution, compaction, destruction and disposal of soils during construction, etc.). The most intense anthropogenic impact is manifested in the city areas of the industrial enterprises locations. This causes the intensity and heterogeneity of soil contamination, therefore, evaluation of the ecological-geochemical conditions of urban soils is necessary. According to the results of the areal research conducted lately in the areas of the city, the local geochemical anomalies in the percentage of some elements in soils are attributed to different industrial enterprises, and they are likely associated with the specific characters of their activities (Fig. 1). For example, the elevated relative average content of Br for the whole sampling is detected in the area of Chemical-Pharmaceutical Plant, Instrument and Lamp factories, Co – Tool plant, Sb – Sleeper impregnation plant, Ce – in the area of the coal storage of the Tomsk heat power station; Hf, Sm, Eu, La, Ce, Yb and Lu – Concrete Plants [2, 9] It should be noted that the concentrations of elements in samples of urban soils in residential blocks close to industrial premises exceed the background values by the factor of 1.1 – 48. Elevated contents halos of Cs, Sr, Sc, La, Ce, Yb and Lu in the soils are detected in the ash disposal area of the Tomsk power station in the floodplain of the river Ushayka; Cr, Rb, Sr, Tb, Sm, Eu, La, Ce, Yb and Lu - at the end of Michurin street near the premises of Matches factory, but this may be associated with the activities of various smaller factories and repair shops; Rb, Cs, Tb, La, Yb and Lu in the RAS campus, due to the various scientific laboratories and the raised relief of the territory [2]. In connection with this, it was appropriate to conduct more detailed testing of these areas to redetermine the previously detected anomalies. In addition, it was necessary to expand the boundaries of research and obtain new data.

2. EXPERIMENTAL PART

The study is based on the test of 32 samples of urban soils picked up in early summer of 2013, at the surface layer (0-10 cm) in areas of operating industrial enterprises of power, construction and petrochemical production (Fig. 2). In addition, samples were picked up at soils of conditionally background areas (the village Pobeda), located 40 km from the Tomsk city. Treatment of samples meant for analytical investigations was done according to the standard scheme.

The quantitative determination of 26 elements by the instrumental neutron activation analysis in the credentialed nuclear-geochemical laboratory of the Department of Geocology and Geochemistry, functioning on the basis of nuclear research reactor (analysts senior researchers A.F. Sudyko, L. V. Bogutskaya) was carried out. At this the internal control of the parallel definitions of the elements was provided. The determination inaccuracy for the majority of the analyzed elements did not exceed 10-15 %.

3. RESULTS AND DISCUSSION

The table shows the concentrations ratios of chemical elements in soils in the areas close to industrial enterprises calculated with regard to the background (Villige Pobeda) and the values of total pollution index (TPI).

Table
Ratios of concentrations of chemical elements in soils in the areas close to industrial facilities in Tomsk calculated with regard to the background (Villige Pobeda), and the values of total pollution index (TPI).

Area	Ratio of concentration	TPI, unic
Heat power station	Ce _{19,8} -Br _{12,3} - As _{4,2} -Co _{4,1} -Zn _{3,9} -Na _{3,9} -Tb _{3,8} -Sc _{3,2} -Fe _{3,1} -Sb ₃ -U _{2,9} -Eu _{2,8} -Th _{2,8} -Sm _{2,7} -La _{2,7} -Ca _{2,7} -Ta _{2,7} -Lu _{2,6} -Nd _{2,4} -Yb _{2,4} -Cs _{2,3} -Hf _{2,2} -Sr _{1,5} -Ba _{1,4} -Rb _{1,3} -Cr _{1,3}	73
Ash dump of heat power station	Ce ₂₈ - As _{9,5} -U _{8,4} -Sb _{5,7} -Th _{5,6} -Tb _{5,5} -Zn _{5,5} - Co _{4,7} -La _{4,5} -Sm _{4,3} -Cs _{4,2} -Sr ₄ -Ta _{3,9} -Ca _{3,8} -Fe _{3,6} -Lu _{3,4} -Ba _{3,4} -Yb _{3,3} -Eu _{3,2} -Sc _{3,2} -Nd _{2,8} -Hf _{2,1} -Rb _{1,6} -Cr _{1,2} -Hg _{1,1}	102
Borrow pit enterprise	Br _{19,9} -Sb _{16,8} -Ce ₁₅ - Zn _{7,8} - As _{4,7} -Tb _{4,2} -Co _{4,2} -La _{3,6} -Fe _{3,2} -U _{3,2} -Sc ₃ -Sm _{2,9} -Ta _{2,8} -Th _{2,8} -Eu _{2,7} -Lu _{2,6} -Ca _{2,6} -Yb _{2,5} -Cs _{2,4} -Nd _{2,2} -Hf _{2,1} -Ba _{1,7} -Cr _{1,4} -Sr _{1,4} -Rb _{1,3} -Na _{1,2} -Hg ₁	93
Construction materials plant	Ce _{19,7} -Br _{13,8} -Zn _{11,2} - Sb _{5,7} -As _{5,1} - Co _{4,5} -Tb _{4,1} -U _{3,8} -Fe _{3,4} -Sc _{3,2} -Eu _{3,2} -Sm _{3,1} -Th _{2,8} -La _{2,8} -Lu _{2,8} -Yb _{2,7} -Ta _{2,7} -Cs _{2,6} -Ca _{2,6} -Nd _{2,3} -Hf ₂ -Ba _{1,9} -Cr _{1,6} -Rb _{1,4} -Hg _{1,2} -Na _{1,1} -Sr ₁	86
Cement plant	Ce _{15,8} - Zn _{8,6} -Br _{7,7} -Sb _{5,8} - As _{4,7} -Co _{3,4} -Tb _{3,2} -Ca _{2,9} -U _{2,9} -Fe _{2,9} -Hg _{2,6} -Sc _{2,4} -Sm _{2,3} -Lu _{2,2} -Yb _{2,2} -Ta _{2,2} -Th _{2,1} -La _{2,1} -Nd ₂ -Eu _{1,9} -Hf _{1,9} -Ba _{1,7} -Cr _{1,7} -Cs _{1,6} -Sr _{1,4} -Na _{1,4} -Rb _{1,2}	65
Concrete products plant	Hg _{16,1} -Ce ₁₆ -Zn _{11,2} -Br _{11,1} - Sb ₈ -Ca _{7,8} - As _{4,6} -Tb _{3,6} -Co _{3,6} -U _{2,9} -Fe _{2,9} -Sm _{2,3} -Sc _{2,3} -Sr _{2,2} -Th _{2,2} -La _{2,2} -Ta ₂ -Lu ₂ -Eu ₂ -Yb _{1,9} -Cr _{1,7} -Nd _{1,7} -Ba _{1,7} -Cs _{1,7} -Hf _{1,6} -Rb ₁	91
Artificial stone plant	Ce _{17,7} - As _{3,9} -Co _{3,6} -Zn _{3,6} -U _{3,2} -Tb _{3,2} -Sb ₃ -Fe _{2,8} -Ca _{2,7} -Eu _{2,5} -Cr _{2,4} -Sc _{2,4} -Sm _{2,4} -La _{2,3} -Lu _{2,3} -Th _{2,3} -Ta _{2,1} -Yb _{2,1} -Ba ₂ -Nd _{1,9} -Sr _{1,9} -Hf _{1,7} -Cs _{1,7} -Na _{1,4} -Rb ₁ -Hg ₁	52
Concrete plant	Ce _{16,9} - As _{4,6} -Tb _{3,9} -Zn _{3,7} -Co _{3,6} -Fe ₃ -Sb ₃ -U _{2,9} -Ca _{2,6} -Sc _{2,6} -Br _{2,6} -Sm _{2,5} -Eu _{2,5} -Lu _{2,3} -La _{2,3} -Yb _{2,2} -Cr _{2,1} -Th ₂ -Hf _{1,9} -Ta _{1,9} -Sr _{1,8} -Cs _{1,8} -Nd _{1,7} -Ba _{1,7} -Na _{1,5} -Rb _{1,1}	54
Concrete components plant-100	Ce _{23,6} -Br _{15,5} - Zn _{6,5} -As _{5,7} - Tb _{4,6} -Sb _{4,3} -Co _{4,1} -U _{3,6} -Ca _{3,2} -Fe _{3,1} -Sc ₃ -Sm ₃ -Ta ₃ -La _{2,9} -Lu _{2,8} -Th _{2,7} -Eu _{2,6} -Yb _{2,6} -Hf _{2,4} -Nd _{2,3} -Cs _{2,2} -Ba _{1,8} -Cr _{1,3} -Sr _{1,3} -Na _{1,3} -Rb _{1,3} -Hg _{1,2}	86
Concrete components plant - 40	Ce _{20,2} -Sb _{10,8} - Tb _{5,3} -Zn _{5,3} - As _{4,9} -Co _{4,2} -Fe _{3,3} -Sc _{3,3} -Sm ₃ -Ta ₃ -La _{2,9} -Lu _{2,9} -Eu _{2,9} -Th _{2,8} -Yb _{2,7} -Ca _{2,5} -Hf _{2,5} -U _{2,4} -Cs _{2,4} -Nd _{2,3} -Br _{1,9} -Sr _{1,7} -Ba _{1,6} -Cr _{1,5} -Na _{1,5} -Rb _{1,4} -Hg _{1,3}	74
Petrochemical plant	Ce _{17,7} - Sb _{5,8} - As _{3,9} -Tb _{3,6} -Co _{3,3} -Br ₃ -Zn _{2,9} -U _{2,7} -Fe _{2,7} -Sc _{2,6} -Sm _{2,4} -Eu _{2,3} -La _{2,2} -Lu _{2,2} -Yb _{2,1} -Ca _{2,1} -Th _{2,1} -Ta ₂ -Cs _{1,9} -Nd _{1,8} -Hf _{1,8} -Sr _{1,7} -Cr _{1,4} -Ba _{1,3} -Na _{1,2} -Rb _{1,1}	52

The results of urban soils studies gave the levels of accumulation of rare, including rare earth and radioactive, elements. With relation to background concentrations the accumulation of all studied elements is observed. The minimum excess over the background is 1.1 times for the Rb (Artificial stone plant), the maximum is up to 20 times for Br (Borrow pit enterprise) and 28 times for Ce (ash pond of Tomsk heat power station). Above the regular maximum permissible concentrations for soils the contents of Zn, Co and As were detected in all studied samples. The percentage abundance in the Earth crust [10] in the samples of urban soils (for total sampling) was noted for the following elements: Cr, Sb, As, Hf. In addition, the average content of the elements Na, Br, Nd above percentage abundance values in soils were found in the area of the Heat Power Station, Zn, Br, Cs, Nd – Borrow Pit Enterprise, Br, Ba, Zn, Cs, Nd, U - Construction materials plant; Br, Zn, Hg - cement plant; Br, Zn, Hg - Concrete products plant; Ba - Artificial stone plant; Br - Concrete Plant; Br, Zn, Ce, Nd - Concrete components plant 100; Br, Zn, Tb, Nd - Concrete components plant 40; Br - Petrochemical plant; Ba, Zn, Cr, Sb, As, Cs, Hf, Tb, La, Nd, Yb, U, Th - The ash dump of the Tomsk Power Station.

The territory of the ash dump, if compared to average values in sampling, showed high contents of most of the studied elements (Ba, Co, As, Rb, Cs, Sr, Ta, Tb, Sm, Eu, La, Ce, Nd, Yb, Lu, U, Th). According to previous studies in the area of the ash dump in the floodplain of the river Ushayka the elevated concentrations of U, Cs, Sr, Sc, La, Ce, Yb, Lu and the increased value of the exposure dose [2, 11] were also noted.

In the soils around Heat power station in the higher concentration of Br, Ce, As, Sr, Na, compared with other enterprises data and average city concentrations were observed. It is known that coal, as a natural formation, used as fuel at Tomsk heat power station contains rare, including rare earth and radioactive, elements, in addition to heavy metals so it's incineration causes the increase of element's concentration in the ash of ablation [12, 13]. These elements within the sanitary protection zone of the enterprise showed lower concentrations and that can be explained by the transfer of emissions from tall stacks of Tomsk power station at long range. This is confirmed by the studies of the peculiarities of the composition of solid snow residues: concentration of rare, including rare-earth, elements increased by 2 times with distance from the power station [14, 15]. In the area of Borrow Pit Enterprise elevated concentrations of Ce, Br, Sb with regard to background ones are noted; Construction materials plant – Fe, Br, Zn, Sc, Eu, Ce; Concrete products plant – Zn, Cr, Sr. High concentrations of Hf, La, Ce, Eu, Yb and Ta were also previously recorded in the dust emissions of construction industry [15].

According to the value of the total index of soil contamination by different elements (table, Fig. 3) and its adopted gradation, the degree of pollution is high and that might correspond to the high level of population morbidity (projected) [18].

Fig. 3. The total pollution index of urban soils of the studied areas: pollution degree: 1-16 – low; 16-32 – medium; 32-128 – high; more than 128 – is very high. 1 – Ash dump of heat power station; 2 – Borrow pit enterprise; 3 – Concrete products plant; 4 – Construction materials plant; 5 – Concrete components plant-100; 6 – Concrete components plant-40; 7 – Heat power station; 8 – Cement plant; 9 – Concrete plant; 10 – Petrochemical plant; 11 - Artificial stone plant.

4. CONCLUSION

Thus, the level values of all of the studied elements in soils exceeded background concentrations. The observed elements concentrations exceeded the background ones by factor ranging from 1.1 for Rb (Artificial stone plant) up to 20 for Br (Borrow pit enterprise) to 28 for Ce (Ash dump of the heat power station). The pollution of all studied areas was estimated as high on the basis of calculated values of the total pollution index. The soil geochemical features are established by elements accompanying production in regions of industrial enterprises locations. The soil composition reflects the specificity of the urban area with various industrial enterprises, due to certain properties of the soil, which constantly accumulates pollutants of emissions from businesses shops and vehicles.
