The reactions of M'O(acac)₂ [M' = Ti, V; acac = acetylacetonato anion] with equimolar amounts of MF₅ (M = Nb, Ta) in CH₂Cl₂ afforded Ti(acac)₂F₂, **1a**, and [V(acac)₃][MF₆] (M = Nb, **4a**; M = Ta, **4b**), respectively. MOF₃ (M = Nb, **2a**; M = Ta, **2b**) were co-produced from MF₅/TiO(acac)₂. The intermediate species [TaF₄{OTi(acac)₂}₂][TaF₆], **3**, was intercepted in the course of the formation of **1a** from TiO(acac)₂/TaF₅. NbCl₅ reacted with TiO(acac)₂ yielding selectively the previously reported [NbO(acac)Cl₂]_x, **5**, and Ti₂(acac)₂(μ -Cl)₂Cl₄, **6**. Complex **6** was alternatively obtained from the addition of a two-fold excess of TiCl₄ to VO(acac)₂. The 1:1 reactions of TiX₄ (X = F, Cl) with TiO(acac)₂ led to **1a**,**b** and VOX₂ (X = F, **1a**; X = Cl, **1b**) and TiOX₂ (X = F, **7a**; X = Cl, **7b**). The 1:1 combination of TiX₄ (X = F, Cl) with VO(acac)₂ led to **1a**,**b** and VOX₂ (X = F, **8a**; X = Cl, **8b**). The µ-oxido compounds (C₆F₅)₃B–O–M'(acac)₂ (M' = Ti, V) underwent fragmentation by [PF₆]⁻ in chlorinated solvent, yielding POF₃, **9**, and [B(C₆F₅)₃F]⁻, **10**, according to NMR studies; **1a** and V(acac)₃⁺, respectively, were detected as the metal-containing species. Electrochemical studies were carried out aimed at the full characterization of the products and the observation of possible degradation pathways.

Introduction

In principle, the direct combination of a metal-containing Lewisbase fragment of the type [M–O] with an oxophilic metal species (Lewis acid, M') affords a [M–O–M'] adduct. This strategy has been employed for the preparation of O-bridged [M–O–M'] derivatives,¹ comprising either two transition metal centres ² or a transition metal adjacent to a main group element such as boron ³ and phosphorous. ⁴ [M–O–M'] compounds are potential intermediates in oxygen atom transfer reactions,⁵ including the synthesis of diverse metal derivatives employed in homogeneous catalysis.⁶

Recently, we have been involved in the study of the reactivity of niobium and tantalum pentahalides, MX_5 (M = Nb, Ta; X = F, Cl, Br, I),^{7,8} with potential oxygen donor ligands.⁹ According to our findings, the high reactivity of MX₅ towards O-containing species frequently renders the O-to-metal coordination just the preliminary step of subsequent fragmentation of the oxygen substrate. Thus, oxygen abstraction by the metal centre has been observed in a number of cases, resulting in formation of the oxidohalide unit $[MOX_3]$ (X = Cl, Br).¹⁰ Interestingly, when the Oabstraction reaction is carried out with opportune stoichiometry, stable oxido-bridged dinuclear adducts of formula X5M-O- $MX_3(O-O)$ [M = Nb, Ta; X = Cl, Br; $O-O = MeO(CH_2)_2OMe$, MeOCH₂CO₂Me, (MeCO₂)CH=CH(CO₂Me), $CH_2(CO_2Me)_2$] are obtained. Spectroscopic and X-ray evidence suggest that the latter dinuclear compounds could be viewed as coordination adducts of the inorganic oxygen ligand $O=MX_3(O-O)$ with MX_5 .

In the light of this preface, we became interested in the reactivity of MX_5 with coordination complexes containing a metaloxygen moiety. Our choice fell on M'O(acac)₂ (M' = Ti,^{11, 12} V; acac = acetylacetonato), on account of their easy availability and their proved capability to bind Lewis acidic species.¹³ As a natural extension, the group 4 tetrahalides TiX_4 (X = F, Cl) were included in the investigation.¹⁴

We show herein that the reactions of M'O(acac)₂ with high-valent metal halides occur with *highly selective* interchange of ligands between the different metal centres. Evidence will be provided for the establishment of metal–O–M' interaction in the course of those reactions proceeding with oxygen transfer. The electrochemistry section will describe the electrochemical behaviour of the previously reported compounds M'O(acac)₂ (M' = Ti, V), (C₆F₅)₃B–O–M'(acac)₂ and **1a,b**, and of the new ones **3** and **4a,b**. Our outcomes supply novel, possible procedures for the synthesis of mixed-ligand early transition metal derivatives.

Results and Discussion

Synthesis and Characterization

The group 5 metal pentafluorides MF_5 (M = Nb, Ta) reacted with TiO(acac)₂ in chlorinated solvent affording Ti(acac)₂F₂, **1a**, and MOF₃ (M = Nb, **2a**; M = Ta, **2b**) in good yields, see Equation (1). The previously reported compound **1a**¹⁵ has been identified by elemental analysis and NMR spectroscopy (see Experimental for details), and characterized by X-ray diffractometry (Figure 1 and Table 1).¹⁶ Evidence for the formation of **2a,b** have been collected by IR spectroscopy (band around 1000 cm^{-1 17}) and analysis of the metal content (see Experimental).

$$MF_5 + TiO(acac)_2 \rightarrow Ti(acac)_2F_2 + MOF_3$$
(1)
1a (M = Nb, 2a; Ta, 2b)

It should be noted that the procedures available in the literature for the preparation of **2a,b** usually require severe conditions.^{17,18}

Complex **1a** displays a distorted octahedral geometry with the F-ligands in mutual *cis*-position, as previously found in Ti(acac)₂Cl₂ ^{15b, 19} and in the closely related complexes *cis*-Ti[κ^2 -RC(O)CHC(O)R']₂Cl₂ (R = Me, R' = Ph; R = R' = ^tBu, Ph).²⁰

The reaction described in Equation (1) is the result of selective interchange of ligands between different metal centres: the oxygen transfer from $TiO(acac)_2$ to MF_5 is counterbalanced by two fluorines following the opposite direction. This fact reflects the increase of the metal-oxygen bond energy on going from Ti (668 kJ mol⁻¹) to Nb (726.5 kJ mol⁻¹) and Ta (839 kJ mol⁻¹).²¹

It is reasonable that the interaction between MF₅ and TiO(acac)₂ begins with the formation of a [M-O-Ti] adduct (see Introduction). Such an adduct could be isolated in good yield in the reaction involving TaF5, and thus identified as $[TaF_4{OTi(acac)_2}_2][TaF_6]$, 3 (Scheme 1). It is noteworthy that a good number of $[TaF_4(L)_x][TaF_6]$ complexes (x = 2-4) have been described as obtained by the addition of O- ^{9,22} or S-donors ²³ to TaF₅. The molar conductivity value of **3** (in CH_2Cl_2 solution) manifests the ionic nature.^{9,22b} In addition, the ¹⁹F NMR spectrum clearly shows the resonance due to the $[{\rm TaF}_6]^-$ anion at typical chemical shift ($\delta = 38.4$ ppm);^{9,22,23} instead no¹⁹F signal has been found for the $[TaF_4]^+$ moiety, in analogy with previous findings for similar salts.²⁴ The ¹H and ¹³C NMR spectra of **3** (in CD₂Cl₂) contain the resonances of the bidentate acac moieties shifted to high frequency with respect to those seen in TiO(acac)₂,²⁵ as result

of the TiO–Ta bond formation. The solid state IR spectrum displays one single carbonyl absorption at 1530 cm⁻¹ (Figure S3 within Supplementary Information). Based on a comparison of the IR spectra of TiO(acac)₂ and **3** (see Figures S3 and S1; the Ti–O–Ti stretching frequency in TiO(acac)₂ falls at 817 cm^{-1 26}), it may be concluded that the titanyl moiety has comparable bond order in such compounds.¹¹ Further evidence for the formation of **3** will be discussed in the Electrochemistry Section. Compound **3** belongs to the rare family of titanyl-Lewis acid addition compounds, that includes $(C_6F_5)_3B$ –O–Ti(acac)₂.¹³

Compound **3** is not stable in CH_2Cl_2 solution at room temperature, slowly converting into **1a** and $TaOF_3$ (Scheme 1). This fact prevented X-ray quality crystals from being obtained.

Scheme 1. Titanium to tantalum oxygen transfer.

Our study went on with the reactions of MF_5 with VO(acac)₂ in dichloromethane, leading to the clean isolation of the complexes $[V(acac)_3][MF_6]$ (M = Nb, **4a**; M = Ta, **4b**) in good yields (Scheme 2). A non soluble material was obtained as co-product, whose identity could not be ascertained (see Experimental).

$$\frac{MF_5}{M = Nb, Ta} \xrightarrow{VO(acac)_2} [V(acac)_3][MF_6] \\ M = Nb, 4a, Ta, 4b$$

Scheme 2. The reactions of MF₅ with VO(acac)₂.

Although the hexacoordinated $[V(acac)_3]^+$ cation ²⁷ and the $[MF_6]^-$ anions ^{9,22b} are known species, the ionic derivatives **4a**,**b** are new compounds that have been characterized by various techniques (see Experimental). Salient feature of the solid state IR spectra (Figures S4 and S5) is the disappearance of the absorption due to the [V=O] moiety as found in the parent compound $VO(acac)_2$ (v = 992 cm⁻¹, see Figure S2). The absorption related to the carbonyl moieties has been recognized around 1520 cm⁻¹. The ¹H and ¹³C NMR spectra of **4a,b** (in CDCl₃) exhibit one single set of resonances due to the equivalent acac ligands; otherwise the ¹⁹F NMR spectra clearly show the typical resonances related to the MF_6^- anions. 4a,b are well-soluble in chlorinated solvents, conferring intense violet colour to their solutions, and can be easily isolated in the solid state as microcrystalline materials. X-ray analysis was carried out on 4b, confirming the identity of the compound, ²⁸ however severe twinning prevented accurate determination of geometric parameters.

The 1:1 molar reaction of NbCl₅ with TiO(acac)₂ occurs with selective transfer of oxygen ligands from Ti to Nb, accompanied by reverse Cl migration. Hence the compounds [NbO(acac)Cl₂]_x, $5^{,29}$ and Ti₂(acac)₂(μ -Cl)₂Cl₄, **6**, which were prepared in the past by different procedures, have been recognized as the major products of the reaction (Scheme 3). The niobium(V) compound **5** was clearly identified by elemental analysis and by the IR (solid state) absorptions at 1545 and 815 cm⁻¹, due respectively to the C=O and the Nb–O stretching vibrations.²⁹ The titanium(IV) derivative **6** was crystallized from pentane/CH₂Cl₂ at low temperature and identified by ¹H NMR (resonances at 6.00 and 2.19 ppm), IR (intense band at 1554 cm⁻¹) and by comparison of the collected X-ray data with those deposited with the Cambridge Crystallographic Data Centre (Refcode CLACIT).³⁰

Scheme 3. Titanium to niobium oxygen ligands transfer.

The study of the reactivity of M'O(acac)₂ (M' = Ti, V) with metal halides was extended to titanium tetrahalides. Thus the 1:1 molar reactions of TiO(acac)₂ with TiX₄ (X = F, Cl) gave Ti(acac)₂X₂ (X = F, **1a**; X = Cl, **1b**^{15,31}) and TiOX₂ (X = F, **7a**,³² X = Cl, **7b**³³) in high yields, see Equation 2. **1** and **7** could be efficiently separated from each other, in the respective cases, by exploiting their different solubilities in the reaction medium. Compound **1b** was crystallized from pentane/CH₂Cl₂ at low temperature and characterized by elemental analysis, ¹H-NMR spectroscopy (CDCl₃ solution; resonances at 6.01, 2.17 ppm) and by comparison of the obtained X-ray data with those deposited with the Cambridge Crystallographic Data Centre (Refcodes QIHXEX, ZZZEBO).³⁰

$\begin{aligned} \text{TiX}_4 + \text{TiO}(\text{acac})_2 &\rightarrow \text{Ti}(\text{acac})_2 X_2 + \text{TiOX}_2 \quad (X = F, \text{Cl}) \quad (2) \\ \textbf{1a,b} \quad \textbf{7a,b} \end{aligned}$

We moved to examine the 1:1 reaction of VO(acac)₂ with TiX₄ (X = F, Cl). The formation of the hypothetical vanadium derivatives V(acac)₂X₂ (X = F, Cl³⁴) was not observed (Scheme 4, pathway a). Instead **1a,b** were selectively obtained and identified (Scheme 4, pathway b); in addition, the oxido-halides VOX₂ (X = F, **8a**;³⁵ X = Cl, **8b**³⁶) were recognized as co-products in the respective cases. These outcomes indicate that selective interchange of X and *acac* ligands (Scheme 4, pathway b) rather than oxygen transfer (Scheme 4, pathway a) takes place between the metal centres. The same mechanism might be operative in the reactions indicated in Equation 2.

Scheme 4. Reactions of TiX4 with VO(acac)2.

When the reaction of TiCl₄ with VO(acac)₂ was performed by using a Ti/V > 2 molar ratio, the crystalline, dinuclear compound **6** ⁵⁰ was recovered in good yield in the place of Ti(acac)₂Cl₂ [Equation (3)]. VOCl₂ was found to be the reaction co-product.

$$2\text{TiCl}_4 + \text{VO}(\text{acac})_2 \rightarrow \text{Ti}_2(\text{acac})_2(\mu\text{-Cl})_2\text{Cl}_4 + \text{VOCl}_2 \tag{3}$$

$$6 \qquad 8b$$

Electrochemistry

To the best of our knowledge, no cyclic voltammetric study has been performed on $TiO(acac)_2$ heretofore, while the literature data related to $VO(acac)_2$ are rather sparse.³⁷ Therefore we decided to start our investigation with the study of the CV behaviour of M'O(acac)_2 (M' = Ti, V).

We found that TiO(acac)₂ underwent a reduction process at -1.79 V in CH₂Cl₂ solution in the presence of [NⁿBu₄][PF₆] as supporting electrolyte (Table 2).³⁸ Instead the vanadium(IV) analogue underwent a reversible one-electron oxidation at +0.66 V, and one irreversible reduction at -2.32 V (*vs.* FeCp₂)³⁹ (Table 2). Analysis of the cyclic voltammetric response with scan rates varying between 0.02 and 1.00 V s⁻¹ has confirmed the electrochemically-reversible nature of the reduction of TiO(acac)₂ (the peak-to-peak separation ΔE_p approaches the theoretical value of 59 mV⁴⁰). This reduction is complicated by a

subsequent chemical reaction $(i_{pa}/i_{pc} = 0.8 \text{ at } 0.10 \text{ V s}^{-1})$.

Table 2. Formal electrode potentials (V, vs. FeCp₂^a) and peak-to-peak separations (mV) in 0.2 M [N^{*n*}Bu₄][PF₆]/CH₂Cl₂ solution for the cited redox changes.

^a Under the cited experimental conditions, the redox process relative to the ferrocene/ferrocenium couple was observed at +0.39 V *vs.* SCE. ^b Measured at 0.1V s⁻¹. ^e Partially chemically-reversible process. ^d Peak potential value for irreversible processes. ^e In [NⁿBu₄][BPh₄]/CH₂Cl₂ solution. ^f In [NⁿBu₄][ClO₄]/CH₂Cl₂ solution.

In view of the hypothetical bonding similarities between the stable [B–O–M'] compounds $(C_6F_5)_3$ B–O–M'(acac)₂ (M' = Ti, V) ¹³ and the possible intermediates formed in the reactions between M'O(acac)₂ and metal halides, we decided to examine the electrochemical behaviour of $(C_6F_5)_3$ B–O–M'(acac)₂.

Green crystals of $(C_6F_5)_3B-O-V(acac)_2$ dissolved into a CH₂Cl₂ solution of $[N^nBu_4][PF_6]$ (supporting electrolyte) giving a deep-violet solution. This latter exhibited a voltammetric profile with two reversible monoelectronic reductions at +0.24 and -2.02 V. Otherwise, the yellow titanium species $(C_6F_5)_3B-O-Ti(acac)_2$ dissolved into CH₂Cl₂/ $[N^nBu_4][PF_6]$ to give a yellow solution. The voltammetric profile of this latter solution did change in some minutes: the initial reversible reduction at -0.56 V ($i_{pa}/i_{pc} = 0.94$ at 0.10 V s⁻¹) and the irreversible one at -2.40 V progressively disappeared, while a new reduction wave at -1.29 V became evident.

These outcomes indicate that the electrolyte $[N^n Bu_4][PF_6]$ is not inert towards $(C_6F_5)_3B-O-M'(acac)_2$; therefore, we considered $[N^n Bu_4][BPh_4]$ as alternative electrolyte. Hence green $(C_6F_5)_3B-O-V(acac)_2$ dissolved into $CH_2Cl_2/[N^n Bu_4][BPh_4]$ to give a light-green solution. Subsequent cyclic voltammetry showed one reversible reduction process at -0.90 V (complicated by a subsequent chemical reaction, $i_{pa}/i_{pc} = 0.8$ at 0.10 V s⁻¹), followed by an irreversible reduction at -2.36 V. These reductions were no longer appreciable after some minutes. The light-yellow solution of $(C_6F_5)_3B-O-$ Ti(acac)₂ in $[N^n Bu_4][BPh_4]/CH_2Cl_2$ showed only irreversible reduction processes at potentials lower than -1.5 V. Based on all of these evidences, we have assigned the reductions at -0.90 V and at -0.56 V to $(C_6F_5)_3B-O-V(acac)_2$ and $(C_6F_5)_3B-O-Ti(acac)_2$, respectively (Table 2).

We are able to conclude that the coordination to the strongly electron-deficient $B(C_6F_5)_3$ enhances the tendency of M'O(acac)₂ (M = Ti, V) to be reduced. Furthermore, the so formed $[(C_6F_5)_3B-O-M'(acac)_2]$ frames are susceptible to reaction with $[PF_6]^-$ (Scheme 5). Thus NMR experiments were carried out in order to shed light on this point. According to the NMR outcomes, O/F interchange takes place between $[(C_6F_5)_3B-O-M'(acac)_2]$ and $[PF_6]^-$, cleanly affording $[B(C_6F_5)_3F]^-$, 9,⁴¹ and POF₃, 10.⁴² In addition, the reaction of $(C_6F_5)_3B-O-Ti(acac)_2$ with $[PF_6]^-$ selectively produces 1a (detected by NMR analysis) in high yield, while the cation $[V(acac)_3]^+$ has been recognized (NMR, UV-Vis) from (C₆F₅)₃B-O-V(acac)₂/[PF₆]⁻. Accordingly, the voltammetric profile of the mixture $(C_6F_5)_3B-O-$ V(acac)₂/[NⁿBu₄][PF₆] displayed two distinct one-electron reductions at +0.24 V and at -2.02 V, with features of chemical reversibility in the CV time scale. Such reductions have been attributed to V(IV)/V(III) and V(III)/V(II) couples.43 Coherently, the same pattern, due to the $[V(acac)_3]^+$ cation, has been found for $[V(acac)_3][MF_6]$, **4a,b**, in $CH_2Cl_2/[N^nBu_4][PF_6]$.

Scheme 5. Reactivity of $(C_6F_5)_3B-O-M'(acac)_2$ (M' = Ti, V) with [NEt₄][PF₆].

When freshly prepared **3** was dissolved into CH₂Cl₂/[NⁿBu₄][PF₆], the voltammetric profile of the solution changed with time (Figure 2a), in accordance with the results reported in the previous Section (Scheme 1). More precisely, the CV recorded immediately after the dissolution showed a reversible reduction at -0.57 V ($i_{pa}/i_{pc} = 0.88$ for scan rate v = 0.1 V s⁻¹), accompanied by an irreversible reduction at more negative potential (-2.37 V). Such electrochemical behaviour represents a significant proof for the existence of the [Ta–O–Ti] skeleton in **3**; in fact, a very similar CV is exhibited by the [B–O–Ti] adduct (C₆F₅)₃B–O–Ti(acac)₂ (Table 2). The absence of processes involving the [TaF₆]⁻ anion in **3** is consistent with the observation that a solution of [S(NMe₂)₃][TaF₆]^{22b} in CH₂Cl₂/[NⁿBu₄][PF₆] showed no reduction peaks until the solvent discharge occurring at *ca.* –2.6 V.⁴⁴

The signals due to $[TaF_4{OTi(acac)_2}_2]^+$ decreased their intensity within 20 minutes, while a new wave became evident at -1.29 V (Figure 2a). This wave remained the only observable redox process after some hours, and was attributed to **1a**. In fact the CV trace of **1a** in the range +1.4 to -2.6 V is characterized by one monoelectronic reduction process at -1.29 V, complicated by a subsequent chemical reaction ($i_{pq}/i_{pc} = 0.84$ for scan rate v = 0.1 V s⁻¹), see Figure 2b.

Figure 2. Cyclic voltammograms recorded at Pt electrode in CH_2Cl_2 solution of: a) 3 immediately after dissolution (black), after 10' (red), after 20' (blue); b) 1a. Supporting electrolyte: [N^{*n*}Bu₄][PF₆] (0.2 mol dm⁻³); scan rates = 0.1 V s⁻¹.

In order to verify the number of electrons involved in the reduction process occurring at -1.29 V, a solution of **1a** was subjected to controlled potential coulometry ($E_w = -1.4$ V). By monitoring the electrolysis progress with cyclic voltammetry, we noticed that the height of the cathodic peak at -1.29 V decreased proportionally to the advancement of coulometry. Moreover a new anodic reversible peak at -0.58 V and a cathodic irreversible peak at -2.4 V appeared. The

wave corresponding to the reduction of **1a** completely disappeared after consumption of 0.5 mol of electrons *per* mole of complex.

The blue colour of the solution and the appearance of the reversible oxidation at -0.58 V have suggested the formation of a Ti(III) species; otherwise the irreversible reduction at -2.4 V has been tentatively assigned to $[\text{Ti}(\text{acac})_2\text{F}_3]^-$. As a matter of fact, a superimposable voltammetric profile in the negative scan (0 / -2.6 V) was obtained when the mixture **1a**/TASF (TASF, $[(Me_2N)_3S][Me_3SiF_2]$, is a well-established F⁻ transferer ^{45,22b}), was examined by CV under the same experimental conditions.

In other words, the reduction of **1a** seems to occur according to Scheme 6: fluoride abstraction by **1a** from the complex **1a**⁻ presumably generates the Ti(III) complex Ti(acac)₂F and the hard to reduce Ti(IV) anion [Ti(acac)₂F₃]⁻. Attempts to isolate these species for further characterization were unsuccessful.

$$\operatorname{Ti}(\operatorname{acac})_{2}F_{2} \xrightarrow[-1.29 V]{} [\operatorname{Ti}(\operatorname{acac})_{2}F_{2}]^{-} \xrightarrow{\operatorname{Ti}(\operatorname{acac})_{2}F_{2}} \operatorname{Ti}(\operatorname{acac})_{2}F + [\operatorname{Ti}(\operatorname{acac})_{2}F_{3}]^{-}$$
1a

Scheme 6. Reduction of Ti(acac)₂F₂, 1a.

The voltammetric response of Ti(acac)₂Cl₂, **1b**, in CH₂Cl₂/[NⁿBu₄][PF₆] solution showed one reversible reduction at $-0.69 \text{ V}(i_{p}a/i_{p}c = 0.9 \text{ at scan rate of } 0.1 \text{ V/s})$. The intensity of this wave promptly decreased, while new reduction processes became evident at -0.93 and -1.29 V. We have assigned the reduction at -1.29 V to the difluoride complex **1a** and the reduction at -0.93 V to the mixed halide Ti(acac)₂ClF, both formed by F⁻ abstraction from the supporting electrolyte. Former investigation on the chemistry of **1b** demonstrated the possibility of easy, partial or complete, replacement of chloride ligands in the presence of a potential fluoride source.⁴⁶ It has to be noted that the voltammetric response of **1b** in CH₂Cl₂/[NⁿBu₄][ClO₄] solution remained unchanged for several hours and exhibited only the reduction at -0.69 V.

We attempted to detect short-lived M–O–V adducts in the course of the reactions of MF_5 with VO(acac)₂ (Scheme 2). Cyclic voltammograms were collected immediately after the mixing of the reagents in the electrochemical cell. A quick colour change of the solution from light-blue to deep-violet accompanied the dissolution of MF_5 , and the voltammetric profile typical of $[V(acac)_3]^+$ was observed. This fact points out that oxygen transfer from vanadium to M centre takes place readily, thus preventing the recognition of redox changes due to short-lived M–O–V adducts.

Conclusions

In this paper, we have described the chemistry of titanium(IV) and vanadium(IV) oxide bis-acetylacetonates, M'O(acac)₂, with TiX₄ (X = F, Cl), MF₅ (M = Nb, Ta), and NbCl₅, respectively. All of the reactions, driven by thermodynamic factors, take place with selective interchange of ligands between the different metal centres, and represent novel routes for the preparation of halo-acetylacetonato or oxido-halide complexes of groups 4-5 metals. The interchange of ligands is presumably initiated by the formation of an oxido-bridged adduct, which could be detected (Ta-O-Ti adduct) in the case of the reaction between TaF₅ and TiO(acac)₂. This feature has found support in the fact that compounds M'O(acac)₂ do not undergo oxygen loss in the presence of [PF₆]⁻, unless they are preliminarily activated by coordination to a Lewis acid such as B(C₆F₅)₃.

Electrochemical analyses have assisted the characterization of the new compounds and have allowed the study of degradation pathways. The electrochemical outcomes demonstrate that the coordination of a Lewis acid to $MO(acac)_2$ (M = Ti, V) enhances the

tendency of the latter to be reduced. By a parallel study of the electrochemical behaviours of $(C_6F_5)_3B-O-Ti(acac)_2$ and $[TaF_4{OTi(acac)_2}_2][TaF_6]$, dissolved into $CH_2Cl_2/[N''Bu_4][PF_6]$, the quick formation of $Ti(acac)_2F_2$ from the tantalum adduct has been ascertained. V-containing intermediate products, analogous to $[TaF_4{OTi(acac)_2}_2][TaF_6]$, could not be recognized due to fast *O*-transfer. A detailed description of the electrochemical behaviours of $TiO(acac)_2$ and $Ti(acac)_2X_2$ (X = F, Cl) has been reported for the first time.

Experimental Section

General Features

All of the manipulations of air and/or moisture sensitive compounds were performed under atmosphere of pre-purified argon using standard Schlenk techniques. The reaction vessels were oven dried at 150 °C prior to use, evacuated (10⁻² mmHg) and then filled with argon. MX_5 (M = Nb, Ta, X = F; M = Nb, X = Cl), TiX₄ (X = F, Cl), M'O(acac)₂ (M = Ti, V) and $[(Me_2N)_3S][Me_3SiF_2]$ (TASF) were commercial products (Sigma-Aldrich), stored under argon atmosphere as received and used without further purification. $[N^{n}Bu_{4}][PF_{6}]$ (Fluka, puriss. electrochemical grade), $[N^{n}Bu_{4}][BPh_{4}]$ (Sigma-Aldrich, 99%) and [NⁿBu₄][ClO₄] (Fluka, puriss. Electrochemical grade) were used as purchased. Ferrocene (FeCp₂, Fc),⁴⁷ (C₆F₅)₃B–O–V(acac)₂,¹³ and (C₆F₅)₃B–O–Ti(acac)₂ ¹³ were prepared according to the literature. Solvents were distilled before use under argon atmosphere from appropriate drying agents. Infrared spectra were recorded at 298 K either on FT IR-Perkin Elmer Spectrum One Spectrometer equipped with UATR sampling accessory, or on FT IR-Perkin Elmer Spectrum 100 Spectrometer equipped with CsI beam splitter. UV-VIS spectra were recorded with Perkin-Elmer Lambda EZ201 spectrophotometer at 293 K. ¹H, ¹³C and ¹⁹F NMR spectra were recorded on Varian Gemini 200BB instrument at 293 K, unless otherwise stated. Chemical shifts for ¹H and ¹³C were referenced to the non-deuterated aliquot of the solvent; chemical shifts for ¹⁹F were referenced to external CFCl₃; chemical shifts for ³¹P were referenced to external H₃PO₄. Conductivity measurements were carried out on CH2Cl2 solutions ca. 0.010 M with Eutech Con 700 Instrument (cell constant = 1.0 cm^{-1}), at 298 K.48 Carbon and hydrogen analyses were performed on Carlo Erba mod. 1106 instrument. The content of niobium and tantalum was analyzed as M₂O₅, obtained by high temperature treatment of the solid sample with HNO₃ solution, followed by calcination in a platinum crucible. The titanium content was determined spectrophotometrically by measuring the 410 nm absorbance of an aqueous solution after treatment with few drops of 30% aqueous H_2O_2 . The chloride content was determined by the Mohr method ⁴⁹ on solutions prepared by dissolution of the solid in aqueous KOH at boiling temperature, followed by cooling down to room temperature and addition of HNO3 up to neutralization. ESI MS spectrum was recorded on Waters Micromass ZQ 4000 with sample dissolved in CH₃CN.

Unless otherwise indicated, electrochemical measurements were performed on 0.2 M dichloromethane solutions of $[N^nBu_4][PF_6]$ as supporting electrolyte. Cyclic voltammograms were performed with a Princeton Applied Research (PAR) 273A Potentiostat / Galvanostat, interfaced to a personal computer, employing PAR M270 Electrochemical Software. All measurements were carried out in a three-electrode home-built cell at room temperature ($20 \pm 5^{\circ}$ C). The working and the counterelectrode consisted of a platinum disk electrode and a platinum wire spiral, respectively, both sealed in a glass tube. A quasi-reference electrode of platinum was employed as reference. The Schlenk-type construction of the cell maintained anhydrous and anaerobic conditions. The cell was predried by prolonged heating under vacuum and filled with argon. A 0.2 M CH₂Cl₂ solution of [NⁿBu₄][PF₆] under argon was then

introduced into the cell and the working electrode was repeatedly cycled between the anodic and the cathodic limits of interest until no change in the charging current. The substrate was introduced to obtain a 1 mM solution, and voltammograms were recorded at sweep rate = 100 mV s⁻¹. After several voltammograms were obtained on the substrate solution, a small amount of ferrocene was added, and the voltammogram was repeated. The E° values of the analyzed compounds were determined placing the $E_{1/2}$ of the ferrocene couple at 0.0 V.

Controlled potential coulometry was performed in H-shaped cell with anodic and cathodic compartments separated by a sinteredglass disk. The working macroelectrode was a platinum gauze; a platinum-spiral was used as the counterelectrode.

Reactivity of MF_5 (M = Nb, M = Ta) with TiO(acac)₂.

1) Synthesis of $Ti(acac)_2F_2$, 1a, and MOF_3 (M = Nb, 2a; M = Ta, 2b). A solution of TiO(acac)₂ (0.131 g, 0.500 mmol) in 1,2dichloroethane (15 mL) was treated with MF₅ (M = Nb, Ta; 0.500 mmol). The mixture was stirred at room temperature for 12 hours. Analogous outcome was obtained by performing the reaction at reflux temperature for 4 hours. The resulting precipitate was filtered, thus the light-orange solution was layered with heptane and stored at -30°C. A yellow-orange crystalline precipitate of $Ti(acac)_2F_2$, **1a**¹⁵ (0.106 g, 75% yield), was obtained after 3 days. Compound 1a was identified by elemental analysis, NMR spectroscopy and X-ray diffractometry. Anal. Calcd. for $\hat{C}_{10}H_{14}F_2O_4T_1$: C, 42.28; H, 4.97; Ti, 16.85. Found (from the reaction with NbF₅): C, 42.49; H, 4.63; Ti, 17.02. ¹H NMR $(CD_2Cl_2) \delta 5.93$ (s, 1 H, CH); 2.13 (s, 6 H, CH₃) ppm. ¹³C{¹H} NMR (CD₂Cl₂) δ 194.0 (CO); 107.0 (CH); 25.8 (CH₃) ppm. ¹⁹F NMR (CD₂Cl₂) δ 231.6 ppm. The reaction precipitate was washed with 1,2-dichloroethane (3 x 10 mL), dried in vacuo and identified as MOF_3 (M = Nb, 2a; M = Ta, 2b) by metal analysis and IR spectroscopy.¹⁷ **2a** (yield 65%). Anal. Calcd. for F_3 NbO: Nb, 56.00. Found: Nb, 55.20. IR (solid state): $v = 994s (v_{Nb=0}) \text{ cm}^{-1}$. 2b (yield 61%). Anal. Calcd. for F₃OTa: Ta, 71.26. Found: Ta, 69.92. IR (solid state): $v = 1020s (v_{Ta=0}) \text{ cm}^{-1}$.

2) Isolation and characterization of [TaF₄{OTi(acac)₂}₂][TaF₆], 3. A NMR tube was charged with TaF₅ (0.055 g, 0.200 mmol), TiO(acac)₂ (0.052 g, 0.200 mmol) and CD₂Cl₂ (0.70 mL), in the order given. The tube was sealed and shaken in order to homogenize the content. After 30 minute, NMR analysis of the resulting yellow solution pointed the formation of 3. ¹H NMR (CD₂Cl₂) δ 6.22 (s, 1 H, CH); 2.27 (s, 6 H, CH₃) ppm. ¹³C{¹H} NMR (CD₂Cl₂) δ 194.4 (CO); 109.7 (CH); 25.7 (CH₃) ppm. ¹⁹F NMR (CD₂Cl₂) δ 38.4 (s, TaF₆) ppm. Conversion of 3 into 1a was completed after heating the tube at 50°C for 4 hours.

A CH₂Cl₂ solution (28 mL) of **3** was obtained from equimolar amounts of TaF₅ and TiO(acac)₂ (0.800 mmol). Conductivity analysis was as follows: $A_M = 6.0$ S cm² mol⁻¹. An aliquot (0.3 mL) of the solution, mixed with CD₂Cl₂ (0.4 mL), was analyzed by ¹H NMR, confirming the formation of **3**. The remaining portion of the solution was dried under vacuo thus giving a pale-orange powder. Yield: 0.353 g, 82%. Anal. Calcd. for C₂₀H₂₈F₁₀O₁₀Ta₂Ti₂: C, 22.32; H, 2.62; Ti, 8.90. Found: C, 22.05; H, 2.41; Ti, 9.06. IR (solid state): $v = 1530vs (v_{C=0})$, 1422m, 1293s, 1033m, 933m, 811m-s, 782s, 670vs cm⁻¹.

Reactivity of MF₅ (M = Nb, Ta) with VO(acac)₂. Synthesis of $[V(acac)_3][MF_6]$ (M = Nb, 4a; M = Ta, 4b). A solution of VO(acac)₂ (0.215 g, 0.811 mmol) in 1,2-dichloroethane (15 mL) was added of NbF₅ (0.154 g, 0.820 mmol). After 6 h stirring at room temperature, the resulting dark-violet solution was separated from a dark precipitate by filtration. IR analysis on the precipitate suggested the presence of a mixture of non identifiable products. The solution was concentrated (2 mL), layered with pentane and stored at -30° C. The product 4a was obtained as a

microcrystalline dark-violet material after 4 days. Yield: 0.212 g, 71%. Anal. Calcd. for $C_{15}H_{21}F_6NbO_6V$: C, 32.45; H, 3.81. Found: C, 32.13; H, 3.90. IR (solid state): v = 1520vs (v_{C=O}), 1421m-s, 1359m, 1280s, 1168w, 1030m, 934m, 780m, 664s cm⁻¹. ¹H NMR (CDCl₃) δ 6.38 (s, 1 H, CH); 2.35 (s, 6 H, CH₃) ppm. ¹⁹F NMR (CDCl₃, 183 K) δ 103.2 ppm (decet, ¹J_{NbF} = 350 Hz, NbF₆⁻) ppm. UV-Vis (CH₂Cl₂): $\lambda_{max} = 560$ nm. $A_M = 8.7$ S cm² mol⁻¹. ESI-MS (ES⁺): 348 [M⁺, 25%], 249 [M⁺-acac, 100%] *m/z*.

Compound **4b** was obtained by a procedure analogous to that described for the synthesis of **4a**, from VO(acac)₂ (0.250 g, 0.943 mmol) and TaF₅ (0.260 g, 0.942 mmol). Yield: 0.273 g, 68%. Anal. Calcd. for C₁₅H₂₁F₆O₆TaV: C, 28.01; H, 3.29. Found: C, 27.75; H, 3.24. IR (solid state): v = 1521vs (v_{C=0}), 1419s, 1359m, 1281vs, 1168w, 1031s, 934s, 780ms, 663vs cm⁻¹. ¹H NMR (CDCl₃) δ 6.33 (s, 1 H, CH); 2.33 (s, 6 H, CH₃) ppm. ¹⁹F NMR (CDCl₃) δ 42.6 ppm (s, TaF₆⁻) ppm. UV-Vis (CH₂Cl₂): $\lambda_{max} = 560 \text{ nm. } \Lambda_M = 6.3 \text{ S cm}^2 \text{ mol}^{-1}$.

Reactivity of NbCl₅ with TiO(acac)₂. Synthesis of [NbO(acac)Cl₂]_x, **5**, and Ti₂(acac)₂(μ -Cl)₂Cl₄, **6**. A suspension of NbCl₅ (0.115 g, 0.426 mmol) in CH₂Cl₂ (12 mL) was treated with TiO(acac)₂ (0.112 g, 0.427 mmol). The mixture was stirred at room temperature for 3 hours, during which progressive turning of the colour to orange was observed. Then the mixture was filtered in order to separate a yellow solid from an orange solution. The solid was washed with heptane (2 x 10 mL), thus it was identified as **5** (yield 69%) on the basis of IR spectroscopy ²⁹ and elemental analysis. Anal. Calcd. for C₅H₇Cl₂NbO₃: C, 21.53; H, 2.53; Cl, 25.42; Nb, 33.31. Found: C, 21.78; H, 2.39; Cl, 25.29; Nb, 33.13. The solution was layered with pentane in a Schlenk tube. Orange crystals of **6** were obtained after storing the Schlenk for 3 days at -30° C. Yield: 0.072 g, 67%. The identity of **6** was established by X-ray analysis (on a single crystal) ^{50, 51} and IR and NMR spectroscopy.⁵¹

Reactivity of TiX_4 (X = F, Cl) with $TiO(acac)_2$. Synthesis of $Ti(acac)_2X_2$ (X = F, 1a; X= Cl, 1b) and $TiOX_2$ (X = F, 7a; X= Cl, 7b). TiX₄ (0.700 mmol) was added to a solution of TiO(acac)₂ (0.183 g, 0.698 mmol) in 1,2-dichloroethane (15 mL). The mixture from TiF₄ was stirred overnight at room temperature, while the one from TiCl₄ was heated at reflux temperature for 2 hours. The final mixture was filtered in order to separate a solution from a solid. The solid was washed with 1,2-dichloroethane (3 x 10 mL) and then dried under vacuo. IR spectroscopy 52,53 and Ti analysis (Anal. Calcd. for F2OTi 46.99, found 46.60; Anal. Calcd. for Cl₂OTi 35.52, found 35.33) on the solid pointed out the formation of 7a,b in high yield (ca. 80%). The light-orange solution was dried under vacuo, thus giving a residue of Ti(acac)₂X₂. Yield: 0.155g, 78% (1a); 0.184 g, 83% (1b). Compounds 1a,b were identified by elemental analysis, ¹H NMR spectroscopy ¹⁵ and Xray diffractometry (the crystals were obtained from dichloromethane solutions layered with pentane and stored at -30 °C).⁵⁴ Anal. Calcd. for C₁₀H₁₄F₂O₄Ti (1a): C, 42.28; H, 4.97; Ti, 16.85. Found: C, 42.14; H, 4.83; Ti, 16.39. Anal. Calcd. for $C_{10}H_{14}Cl_2O_4Ti$ (1b): C, 37.89; H, 4.45; Cl, 22.37; Ti, 15.10. Found: C, 37.63; H, 4.67; Cl, 22.19; Ti, 15.21.

Reactivity of TiX₄ (X = F, Cl) with VO(acac)₂. Synthesis of Ti(acac)₂X₂ (X = F, 1a; X= Cl, 1b), Ti₂(acac)₂(μ -Cl)₂Cl₄, 6, and VOX₂ (X = F, 8a; X = Cl, 8b). TiX₄ (0.700 mmol) was added to a solution of VO(acac)₂ (0.185 g, 0.698 mmol) in 1,2-dichloroethane (15 mL). The mixture from TiF₄ was stirred overnight at room temperature, while the one from TiCl₄ was heated at reflux temperature for 2 hours. The final mixture was filtered in order to separate a solution from a solid. The latter was identified as VOX₂, 8a,b, by IR spectroscopy ^{35,55} and, in the case of 8b, by Cl analysis (anal. calcd. for Cl₂OV: Cl, 51.44; found: Cl,

50.70). The solution was layered with heptane in a Schlenk tube and maintained at -30 °C for one week. Thus compounds 1a,b were recovered as crystalline yellow solids. Yield: 0.161 g, 81% (1a); 0.157 g, 79% (1b). Compound 1a was identified by elemental analysis, ${}^{1}H$ and ${}^{19}F$ NMR spectroscopy, while compound 1b was identified by elemental analysis, ¹H NMR and single-crystal X-ray diffractometry. Anal. Calcd. for C10H14F2O4Ti (1a): C, 42.28; H, 4.97; Ti, 16.85. Found: C, 42.83; H, 5.06; Ti, 16.69. Anal. Calcd. for $C_{10}H_{14}Cl_2O_4Ti$ (1b): C, 37.89; H, 4.45; Cl, 22.37; Ti, 15.10. Found: C, 38.01; H, 4.49; Cl, 22.03; Ti, 14.90. In a different experiment, TiCl₄ (1.200 mmol) was added to a solution of VO(acac)₂ (0.600 mmol) in dichloromethane (10 mL). The mixture was stirred for 4 hours at room temperature. The final mixture was filtered in order to separate a solution from a solid. The solid was identified as **8b** by IR ⁵⁵ and Cl analysis (anal. calcd. for Cl₂OV: Cl, 51.44; found: Cl, 50.53). The filtrated solution was layered with heptane in a Schlenk tube. Thus compound $Ti_2(acac)_2(\mu\text{-}Cl)_2Cl_4$, 6, was obtained as a crystalline solid after storing the Schlenk at -30°C for one week. Yield: 0.094 g, 62%. The identity of the product 6 was ascertained by means of elemental analysis, IR, NMR ⁵¹ and X-ray. Anal. Calcd. for $C_{10}H_{14}Cl_6O_4Ti_2$: C, 23.71; H, 2.79; Cl, 41.98; Ti, 18.89. Found: C, 23.64; H, 2.92; Cl, 41.73; Ti, 18.96.

Reactivity of $(C_6F_{5})_3B-O-M'(acac)_2$ (M' = Ti, V) with $[NEt_4][PF_6]$.

1) M' = V. Formation of $[V(acac)_3]^+$, $[B(C_6F_5)_3F]^-$, 9, and POF₃, 10. A green solution of the complex $(C_6F_5)_3B$ -O-V $(acac)_2$ (0.350 g, 0.450 mmol) in toluene (8 mL) was treated with $[NEt_4][PF_6]$ (0.125 g, 0.454 mmol). The mixture was stirred at room temperature for 30 minutes, and progressive turning to darkviolet was noticed. The final mixture was filtered in order to remove insoluble material, thus a dark-violet solution was obtained. The cation $[V(acac)_3]^+$ was clearly identified by electrochemistry (Table 2) and UV-Vis spectroscopy (intense band at 560 nm).²⁷

In a different experiment, [NEt₄][PF₆] (0.150 mmol) was added to a solution of (C₆F₅)₃B–O–V(acac)₂ (0.150 mmol) and benzene (C₆H₆, 0.150 mmol) in CDCl₃ (0.70 mL) in a NMR tube. The tube was sealed and shaken in order to homogenize the content. After 3 hours, NMR analysis was carried out on the dark-violet mixture. ¹H NMR (CDCl₃) δ 6.30 (s, 1 H, *CH*), 2.40 (s, 6 H, *CH*₃) ppm ([V(acac)₃]⁺; 40% yield relative to C₆H₆). ¹⁹F NMR (CDCl₃) δ -88.6 (d, ¹J_{PF} = 1073 Hz, POF₃); -136.5, -161.4, -166.0 [s, B(C₆F₅)₃F⁻]; -189.9 [br, B(C₆F₅)₃F⁻] ppm. ³¹P NMR (CDCl₃) δ -33.9 (q, ¹J_{PF} = 1072 Hz, *P*OF₃) ppm.

2) M' = Ti. Formation of Ti(acac)₂F₂, 1a, [B(C₆F₅)₃F]⁻, 9, and POF₃, 10. The reaction of [NEt₄][PF₆] (0.150 mmol) with (C₆F₅)₃B– O–V(acac)₂ (0.150 mmol) was performed in CDCl₃ (0.70 mL) in the presence of benzene (C₆H₆, 0.150 mmol), by the same procedure as that described for (C₆F₅)₃B–O–V(acac)₂/[NEt₄][PF₆]. ¹H, ¹⁹F and ³¹P NMR analyses on the light-orange solution pointed out the clean formation of 1a (88% yield relative to C₆H₆), 9 and 10.

X-ray Crystallographic Study. Crystal data and collection details for Ti(acac)₂F₂·0.5C₂H₄Cl₂, **1a**·0.5C₂H₄Cl₂, are reported in Table 3. The diffraction experiments were carried out on a Bruker APEX II diffractometer equipped with a CCD detector and using Mo-K α radiation. Data were corrected for Lorentz polarization and absorption effects (empirical absorption correction SADABS).⁵⁶ Structures were solved by direct methods and refined by fullmatrix least-squares based on all data using F^2 .⁵⁷ All nonhydrogen atoms were refined with anisotropic displacement parameters. H-atoms were placed in calculated positions and treated isotropically using the 1.2 fold U_{iso} value of the parent atom except methyl protons, which were assigned the 1.5 fold U_{iso} value of the parent C-atom. The $C_2H_4Cl_2$ unit is located on an inversion centre and only half of a molecule is independent.

- 7 The pentafluorides of niobium and tantalum have tetranuclear structures in the solid state (ref. 8a) while the corresponding chlorides are dinuclear in the solid state and mononuclear in the vapour phase

(ref. 8b). For sake of simplicity, these compounds will be mentioned by the empirical formulas MX_5 throughout this paper

- Titanium(IV) oxide bis-acetylacetonate is dinuclear in the solid state, bearing two Ti-O-Ti units (ref. 12). For sake of simplicity, such compound will be mentioned by the empirical formula TiO(acac)₂ throughout this paper.

- 14 All of the compounds found as products in the reactions described in this paper have been numerated, while starting materials have not. Products 1a,b, 2a,b, 5-10 were previously obtained by different routes. Putatively assumed species cited in the Electrochemistry Section could not be further characterized and are not numerated.

- 28 The crystals of $[V(acac)_3][TaF_6]$, **4b**, showed severe twinning which prevented full solution and refinement. Nonetheless, after analysing different crystals and partially solving them in different space groups, it is reasonable to conclude that they contain the $[V(acac)_3]^{+}$ cation and the $[TaF_6]^{-}$ anion. Best information has been obtained by solving the structure in the space group *C*2 a = 10.669(9) Å, b = 18.361(9) Å, c = 10.509(9) Å, β = 90.065(10)° with both pseudo-merohedral and racemic twinning. Alternatively, the same structure has been solved in the space group *P*-31*c* a = b = 10.618(4) Å, c = 10.509(6) Å with non-merohedral twinning
