9 **Abstract:** Cooling system for mine refuge chamber provides comfortable environment for miners  
10 to avoid heat damage. The existing cooling systems have their own application scopes and  
11 limitations. The coupled cooling method of Latent Heat Thermal Energy Storage (LHTES)  
12 combined with Pre-cooling of Envelope (PE) is a new free cooling method which is suitable for  
13 high-temperature, passive, impact and other harsh environment. Then, to improve the thermal  
14 comfort and reduce energy consumption, the effect of the pre-cooling temperature, melting  
15 temperature of PCM, aspect ratio and amounts of PCM unit on the indoor temperature are  
16 investigated in a systematic manner. Furthermore, the system is optimized and the generalized  
17 results for the evaluation parameter are given. Analysis of the results may lead to following main  
18 conclusions: (i) the method really controls the indoor temperature and the saving amount of PCM  
19 is more than 50% compared to the traditional LHTES systems; (ii) the Temperature Control(TC)  
20 performance of PCM would drop significantly if it melts more than 80%; (iii) under current  
21 operating conditions, the optimal melting temperature is about 29°C and the aspect ratio of PCM  
22 unit is 60:500; (iv) per 1°C the pre-cooling temperature dropped, 19% the actual amount of PCM  
23 decreased for the case studied.

77 **1. Introduction**

78 In Aircraft, defense engineering, mine refuge and some other facilities <sup>[1-2]</sup>, there still exists  
 79 some special spaces with high-temperature and no-power in certain circumstances. Taking the  
 80 underground mine refuge chamber <sup>[1]</sup> as an example, it's an important emergency rescue shelter,  
 81 which provides sufficient time for the trapped miners to wait for the rescue. When the mine  
 82 accident happens, the refuge chamber will become an isolated, hot and humid space, depending on  
 83 the internal as well as the environmental condition and there is no power supply. As shown in  
 84 Table 1, the existing cooling methods, which consist of CO<sub>2</sub> phase change cooling, the explosion  
 85 proof electrical air conditioning, the ventilation cooling and the ice storage cooling, have their  
 86 own application scopes and limitations <sup>[3]</sup>. LHTES system also cannot control the temperature  
 87 independently due to the large cold loads <sup>[4]</sup> or the small operating temperature range.

88 Table 1. Evaluation and application of four cooling methods.

cooling methods	advantages	disadvantages	application
CO <sub>2</sub> phase change cooling	No need of electric power; Stability	The risk of leakage; Regular inspection and replacement are needed; The difficulty to maintain The refrigerator may not work when the gas explosion occurs;	Where the ambient temperature is below 31°C
Explosion proof air conditioning	Excellent cooling effect; Convenient adjustment	Intrinsically safe high power battery is needed	Metallic/ nonmetallic Mine
Ventilation cooling	No safety hazard; With air purification function	Ventilation ducts may be damaged; Poor cooling effect in a deep buried depth	Shallow mine
Ice storage cooling	No safety hazard; Stability	Compressor is easily eroded; High maintenance cost; Taking up large valuable living space; The fan is needed	Any conditions

88

Fig. 1. Schematic of the coupled cooling method of LHTES combined with PE: (a) PE in peacetime; (b) Heat storage of LHTES and envelope in working time.

To solve this problem, a new coupled cooling method of LHTES combined with pre-cooling of envelope is proposed by Yuan et al [5]. As shown in Fig. 1(a), the envelope is pre-cooled by forced-air in peacetime and the PCM of suitable temperature are encapsulated into units to store cold. As shown in Fig. 1(b), fully using sensible heat storage capacity of envelope and latent heat storage capacity of PCM can control the temperature in working time.

The coupled cooling method can not only expand the operating temperature difference of PCM, but also bear numerous cold loads to reduce the amount of PCM by pre-cooling the envelop. This method meets the requirements of safety, no power, stability and reliability under special environment and widens the application range of LHTES system for temperature control.

In order to save energy, the natural cold source, such as low-temperature water (the water temperature is less than 15°C), cold air (winter), snow or ice, should be fully utilized. When the natural cold source cannot meet the pre-cooling demand, the cold air from the mining working face should be partly shunted into the refuge chamber. And intermittent cold storage technology can be used since the thermal diffusivity of the rock is small and there is no heat source in the room. As a consequence, the indoor temperature could not have a remarkable rise during a rest period.

In theory, LHTES can not only reduce the mismatch between supply and demand but also improve the performance and reliability of energy systems [6]. In fact, many places of LHTES should be optimized and improved in the application process. Over the past decades, extensive research efforts have been made on the sensitivity analysis and optimization for different LHTESs [7-12].

114 Sensitivity analysis and optimization of the PCM unit can enhance the effectiveness of heat  
115 transfer. The operation characteristics and influencing factors of the PCM unit mainly involve the  
116 natural convection, the arrangement of fins and the change of unit structure. To improve the  
117 thermal storage performance of the circular finned tube, the influence factors such as the fin pitch,  
118 the fin height, the fin thickness and the inner radius of the tube, were numerically investigated by  
119 Wang et al <sup>[13]</sup>. A recent study of Yuan et al <sup>[14]</sup> mainly focused on the fin angle's influence on the  
120 heat storage rate of annular PCM unit. Their results showed that there existed maximum melting  
121 heating rate when the fins are vertical. Borderon et al <sup>[15]</sup> designed a new PCM-air heat transfer  
122 ventilation system based on the night ventilation unit. To ensure the air heat exchanger can adapt  
123 to different climatic conditions, running different ventilation conditions should correspond to the  
124 external environments to achieve the optimum utilization of cold. Solgi et al <sup>[16]</sup> also studied the  
125 PCM-air heat exchanger and tried to find the suitable condition to start the night ventilation. It was  
126 found that the composite PCM for heat storage will greatly reduce the indoor load.

127 The operation characteristics and influencing factors of the PCM envelope mainly focused on  
128 the selection of PCM and the layout mode. Kheradmand et al <sup>[17]</sup> applied the mixed phase change  
129 mortar to building facades, and tested the performance and energy conservation by a combined  
130 numerical and experimental method. Results showed that joining the phase change mortar would  
131 be helpful in reducing indoor load and maintaining the stability of the indoor temperature. Chaiyat  
132 et al <sup>[18-19]</sup> studied the concrete wall with phase change micro capsule in different areas. It was  
133 concluded that there was more load reduction in summer than that in winter, and different energy  
134 savings are demonstrated in different areas. Kong et al <sup>[20]</sup> investigated the influence of two  
135 different installation forms of shape-stabilized PCM on the indoor thermal comfort. One is the  
136 panels installed on the outside surface of walls and roofs (PCMOW) with acid capric contained,  
137 the other is the panels installed on the inside surface of walls and roofs (PCMIW) with capric acid  
138 (95 wt%) and 1-dodecanol (5 wt%) contained. Their experimental and numerical results showed  
139 that the PCMIW system has a better control effect than that of the PCMOW system. Zhou et al <sup>[21]</sup>  
140 used the enthalpy model to calculate a solar room with the shape-stabilized PCM plates and then  
141 analyzed the effect of melting temperature of PCM, heat transfer coefficient, the position and  
142 thickness of PCM plates etc. on indoor temperature. They found that the PCM plate can be fully  
143 stored in the daytime and released at night to improve the indoor comfort.

144 Unlike common LHTESs, there are unique application environment and control target for the  
145 coupled cooling method. The coupled cooling method consists of two processes: the pre-cooling  
146 process and the coupled cooling process. And the coupled cooling process includes the heat  
147 transfer among PCM units, envelop, air and heat sources in a closed space. Therefore, to improve  
148 the operation efficiency and reduce energy consumption, the sensitivity analysis and optimization  
149 of the coupled cooling system, new tasks, should be done.

150 To solve the cooling problem in high-temperature, passive, impact and other harsh  
151 environments, based on the new coupled cooling method of LHTES combined with pre-cooling  
152 envelop and the numerical simulation model which considering the heat source, Surrounding Rock  
153 (SR), PCM and air heat transfer, the thermal performance of the coupled cooling method is  
154 analyzed and an evaluation parameter of heat tolerance is proposed to evaluate the temperature  
155 control effect using a mine refuge chamber as a case study. A parametric study is undertaken into  
156 exploring the impact of other factors, such as pre-cooling temperature of SR, melting temperature  
157 of PCM, aspect ratio and amounts of PCM unit, on indoor temperature in a systematic manner.  
158 Optimization of the coupled cooling system is also conducted.

## 159 **2. Model and parameter settings**

### 160 *2.1 Mathematical model*

161 The coupled cooling process includes the heat transfer among phase change units, SR, air and  
162 heat sources in a closed space. In the current work, the phase change units hang on the wall with  
163 the form of plates and the back ventilation is adopted to enhance the convective heat transfer. For  
164 the purpose of briefness, the following major assumptions are employed <sup>[22]</sup>: i) The ratio of the  
165 length to the width is more than 2 and the chamber is assumed to be a cylinder. ii) The heat source  
166 is constant and the effect of radiation is negligible. iii) The material of the surrounding rock is  
167 homogeneous and isotropic and neglecting the heat transfer caused by the moisture transfer  
168 through the envelope. iv) Ignore the influence of temperature fluctuation from ground surface  
169 because the embedded depth is 400~600 m. Other simplifications are described in the rest of the  
170 paper.

171 2.1.1. Heat transfer model of SR

172 The equation for calculating the changes in the temperature of SR in vector form is:

$$173 \quad \frac{\partial t}{\partial \tau} = a \frac{\partial^2 t}{\partial r^2} + \frac{1}{r} \cdot \frac{\partial t}{\partial r} \quad (1a)$$

174 The boundary conditions are

$$175 \quad \begin{cases} -\lambda_w \frac{\partial t(r_i, \tau)}{\partial r} = h_w [t_f - t(r_i, \tau)] \\ t(r_o, \tau) = t_0 \end{cases} \quad (1b)$$

176 with initial condition is

$$177 \quad t(r, 0) = t_0 \quad (1c)$$

178 where,  $t_0$  is the initial temperature,  $\tau$  is the time,  $a$  is the thermal diffusivity,  $r$  is the radius of the  
 179 SR,  $r_i$  is the inner wall radius,  $\lambda_w$  is the thermal conductivity,  $t_f$  is the air temperature,  $r_o$  is the  
 180 outer surface radius.  $h_w$  is the natural convective heat transfer coefficient between the air and inner  
 181 wall, which can be calculated by the formula (2) and (3) [23]:

$$182 \quad Nu = \frac{hl}{\lambda_a} \quad (2)$$

$$183 \quad Nu = 0.59(GrPr)^{1/4} \quad (3)$$

184 where,  $Nu$  is the Nusselt number,  $l$  is the feature size,  $\lambda_a$  is the thermal conductivity of air.  
 185  $Gr = g\alpha_v \Delta t^3 / \nu^2$  is the Grashof number, where  $g$  is the acceleration of gravity,  $\alpha_v$  is the air volume  
 186 expansion coefficient,  $\Delta t$  is the temperature difference,  $\nu$  is the dynamic viscosity,  $Pr$  is the Planck  
 187 number.

188 2.1.2. Heat transfer model of PCM plate

189

190 Fig. 2. Computational domain and boundary conditions at the vertical mid-plate of PCM plate.

191 PCMs are encapsulated by aluminum plate and the thickness of the plate is 1.5 mm. The  
 192 geometry of the PCM plate is designed as follows (not including the aluminum plate): the length  
 193  $L_{PCM}$  is 600 mm, the height  $H_{PCM}$  is 500 mm, and the thickness  $W_{PCM}$  is 60 mm. As shown in Fig.2,  
 194 the vertical mid-plane of the PCM plate is selected as the computational domain.

195 Since the PCMs are encapsulated by aluminum plate, the heat transfer of the outer aluminum  
 196 surface of the PCM plate is convection, and the interface between the aluminum surface and the  
 197 PCM is the coupled interface. There exists heat conduction, convection and melting processes in  
 198 the PCM plate, so the enthalpy-porosity model was used to solve the two dimensional heat transfer  
 199 equations. The equations of enthalpy-porosity model can be seen in Yuan et al <sup>[14]</sup>.

200 2.1.3. Model of indoor air

201 The energy conservation equation is used to calculate the temperature of the air:

202 
$$C_a \rho_a V_a \frac{\partial t_f}{\partial \tau} = q + q_w + q_{PCM} \quad (4)$$

203 where,  $C_a$  is the specific heat of air;  $q$  is the indoor heat flux;  $q_w$  is the convective heat flux  
 204 between air and SR;  $q_{PCM}$  is the convective heat flux between air and PCM plate.  $q$ ,  $q_w$ ,  $q_{PCM}$  are  
 205 calculated by the following formula:

206 
$$q = N_p q_p \quad (5)$$

207 
$$q_w = h_w A_{i,w} (t_w - t_f) \quad (6)$$

208 
$$q_{PCM} = N_{PCM} h_{PCM} A_{PCM} (t_{PCM} - t_f) \quad (7)$$

209 where,  $N_p$  is the number of people in refuge chamber;  $q_p$  is per capita heat generation rate  
 210 (including equipment);  $A_{i,w}$  is area of the inner wall;  $N_{PCM}$  is the number of PCM plates;  $A_{PCM}$  is  
 211 the area of the outer surface of one PCM plate.

212 *2.2. Numerical solution method*

213  
 214 Fig. 3. Computational Grid of PCM plate.

215 In the current study, the heat conduction, convection and melting processes are coupled in the  
 216 PCM plate, so the PCM plate model is set as the main model. The air temperature and convection  
 217 heat transfer coefficient, calculated by User Define Function (UDF), are in the form of boundary  
 218 conditions in the main model. The calculation model of PCM plate is 2D. The calculation software  
 219 is ANSYS Fluent14.0. The calculation is based on the melting and solidification model. The  
 220 influence of natural convection is considered in the PCM unit, and the density calculation is based

221 on the Boussinesq assumption. The heat transfer of outer aluminum surface of the PCM plate is  
222 convection, and the convection heat transfer temperature and coefficient are  $t_f$  and  $h_{PCM}$ ,  
223 respectively. The interface between the aluminum surface and the PCM is the coupled interface.  
224 The time step is 1s, and the total number of steps is 345600. Fig.3 shows the 2D computational  
225 grid of PCM plate and the number of grids is 100,000.

### 226 2.3. Model validation

227 To verify the correctness of the numerical model, the calculated result is compared with the  
228 experimental data of Wu et al [24]. The experiment was carried out in a rectangle ferruginous box  
229 with a size of 1 m×0.9 m×1.2 m during 96 h. The indoor heat source is 170W. The initial  
230 temperature was 15°C, and 3 thermocouples were built-in to detect the temperature distribution.  
231 The melting temperature of PCM is 28°C. More PCM properties can be seen in Wu et al [24].

232

233 Fig. 4. Comparison of the experimental and numerical melt fractions.

234 Fig. 4 shows the comparison of the temperature variation between the experimental data and  
235 numerical result and close agreement is achieved. It can be seen clearly that there is a mutation  
236 when the temperature reaches 29°C for the simulation result and that is a slow transition for the  
237 experimental result. This is because the real PCM melts in a temperature range, not at a  
238 temperature point.

239 2.4. Parameter settings

240  
241 Fig. 5. Schematic diagram of 3D model of mine refuge chamber with PCM plate.

242 Refuge chamber is an emergency rescue system. According to the Chinese policy, the  
243 temperature inside the chamber can not exceed 35°C within 96 h. Take the refuge chamber with  
244 48 people as an example (shown in Fig. 5), the inner wall of the refuge chamber hangs PCM plates.  
245 Parameters of mine refuge chamber are listed in Table 2.

246 Table 2. Parameters of mine refuge chamber.

Symble	Description	Value	Calculation method
$L_R$	Length of refuge chamber	17 m	
$W_R$	Width of refuge chamber	4 m	
$H_{R1}$	Height of side wall	2.8 m	
$H_{R2}$	Height of vault	3.5 m	
$r_i$	Equivalent radius of inner wall	2 m	$r_i=(S/\pi)^{1/2}$
$\rho$	Density of surrounding rock	2400 kg/m <sup>3</sup>	
$c_P$	Specific heat of surrounding rock	902 J/(kg·K)	
$\lambda$	Thermal conductivity of surrounding rock	2 W/(m·K)	
$t_0$	Initial temperature	30°C	
$t_c$	Control temperature	35°C	
$t_{pc}$	Pre-cooling temperature	25°C	
$N_P$	Stipulated number of personnel	48	
$q_p$	Heat generation of each person	116W	

247 PCM is RT 26<sup>[25]</sup>, and more relevant materials' parameters are summarized in Table 3. For a  
248 preliminary design of the number of PCM plates, there is a need to calculate the dynamic heat flux  
249 of SR according to the heat transfer model. Afterwards, it is calculated that the average indoor  
250 load is 1528 W. Combined data in Table 2 and PCM plate's parameter, the estimated number of  
251 PCM plates is 175. Considering the factor 1.1, the number of PCM plates is 190 as an initial  
252 calculated value.

Table 3. Properties of paraffin and aluminum.

Materials	Density/ kg/m <sup>3</sup>	Thermal conductivity/ W/m·K	Specific heat/ kJ/kg·K	Melting temperature/ °C	Latent heat/ kJ/kg	Dynamic viscosity/ kg/m·s
Paraffin	770/880 (Liquid/ Solid)	0.6	2	26-27	190	0.07
Aluminum	2719	202.4	871	-	-	-

### 254 3. Sensitivity analysis of coupled cooling system

255

256

Fig. 6. Melt fraction variation within 96 hours.

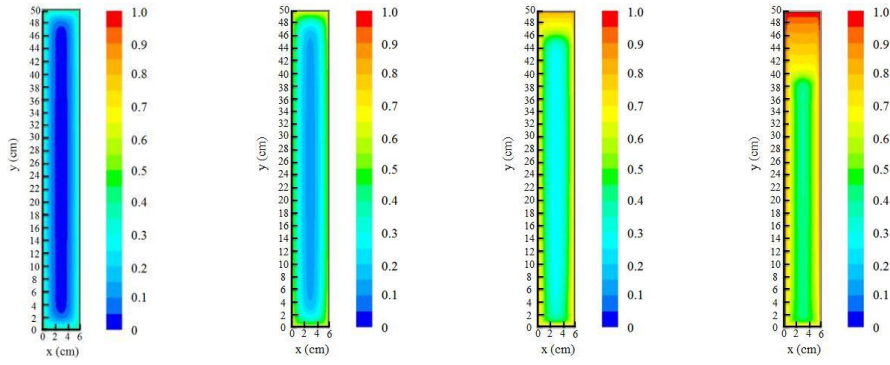

257

258

259

260

Fig. 6 demonstrates the variation of the melt fraction within 96 hours. It is found that PCM starts to melt after 0.7 hour; then the increasing rate of the melt fraction maintains unchanged and followed by a minor decrease after 50 hours. Complete melts occur after 67 hours. It is believed that the increasing rate of the melt fraction is mainly affected by the PCM melting process.

261

262

266

267

268

269

270

271

272

273

274

275

Fig.7 demonstrates the contour temperature distribution at the vertical mid-plane of the PCM plate at different time, i.e. 10, 20, 30, 40, 50, 60 and 70 hr. Within the first 30 hours, as shown in Figs. 7(a), 7(b), 7(c)), the isotherms almost parallel to the surface of the aluminum plates, which shows the heat transfer mode is heat conduction. Later on, as presented in Fig. 7(d), the upper of the PCM plate becomes more lateral isotherms, which shows the heat mode changes to heat convection. Afterwards, as illustrated in Figs. 7(e) and 7(f), the liquid PCM absorbs the heat and the temperature rises. With the assistance of natural convection, the liquid PCM rises along the aluminum plate. In this case, most isotherms become lateral, which means that natural convection plays the dominant role. When the time reaches 70 hour, as presented in Fig 7(g), the PCM completely melts.

Fig. 8. Changes of air temperature and heat flux of PCM plate within 96 hours.

276  
277

278 Fig. 8 demonstrates the variation of the air temperature and heat flux of PCM plate within 96  
279 hours. It can be clearly noted that there exist three stages with the increase of the air temperature.  
280 At the initial temperature increase stage  $\tau_1$ , within the first 0.7 hour the air temperature increases  
281 remarkable to be up to 31.4°C. At the second stage, which is the temperature control stage  $\tau_2$  from  
282 0.7 to 67 hour, the temperature increases monotonously from 31.4°C to 35.6°C which represents  
283 a 4.2°C increase. And the changes in temperature occur slowly from 0.6 hour to 50 hour. Within  
284 this Effective Temperature Control Period (ETCP)  $\tau_{21}$ , the solid and liquid PCM coexist, making a  
285 stable thermal environment. Within the third stage, which is called rapid temperature increase  
286 stage  $\tau_3$ , from 67 hour to 96 hour, the air temperature significantly rises by 3.8°C, finally reaching  
287 39.4°C. The final temperature is more than 35°C because this calculation is based on the  
288 estimated value (or initial value), which has not been optimized. The reason why the air  
289 temperature appears 3 stages is that: in the stage  $\tau_1$ , the PCM plate has not yet begun to melt, and  
290 most of the heat is absorbed by air; in the stage  $\tau_2$ , the air temperature is beyond the melting  
291 temperature and the PCM begins to melt and absorb heat, which makes the increasing rate of the  
292 air temperature slow down gradually; in the stage  $\tau_3$ , PCM has almost been melted into liquid, and  
293 the ability to absorb heat has dropped dramatically, which leads to a significant rise of air  
294 temperature.

295 Meanwhile, Fig. 8 describes the surface heat flux of PCM plate. It is also noted that the heat  
296 flux of the PCM plate has three stages, which explains that the air temperature increase phases is  
297 mainly affected by the heat flux of the PCM plate. Especially from 0.7 hour to 50 hour, the heat  
298 flux of the PCM plate rises slowly by 3.4 W/m<sup>2</sup>. In this case, the PCM uses the latent heat to make

299 the increasing rate of the air temperature slow down gradually. From 50 hour to 67 hour, the heat  
 300 flux of the PCM plate slowly decreases by  $4.3 \text{ W/m}^2$ . The reason could be that the melt fraction is  
 301 already over 80%, and the heat storage ability decreases greatly with the reduction of the  
 302 remaining PCM volume, which can be seen in Fig. 7. After 67 hours till the end, the PCM  
 303 completely melts, and the PCM can only depend on sensible heat with the speed of  $1 \text{ W/m}^2$ .  
 304 Within this time period, the air temperature rises greatly.

305 To evaluate the temperature control effect of the PCM plate, an evaluation parameter of heat  
 306 tolerance time  $\gamma$  is proposed, which combines the calculated result of the air temperature and the  
 307 formula  $\tau_e = 4.1 \times 10^8 / \bar{t}^{3.61}$ , proposed by Crane [26], where  $\tau_e$  stands for extreme endurance time.  $\gamma$  is  
 308 defined as the ratio of actual time, during which the temperature exceeded  $t_c$ , to  $\tau_e$ . Since the  
 309 ambient temperature does not vary greatly, the average time temperature is adopted instead of time  
 310 variation temperature for the sake of formula's simplicity. Besides, as previously mentioned,  
 311 Chinese government states that the indoor temperature in the refuge chamber must not exceed  
 312  $35^\circ\text{C}$ , which means  $t_c = 35^\circ\text{C}$ . Therefore, the formula is defined as follows:

$$313 \quad \gamma = \frac{\tau_{>35}}{\tau_e} = \frac{\tau_{>35} \cdot \bar{t}_{>35}^{3.61}}{4.1 \times 10^8} \quad (8)$$

314 where,  $\tau_{>35}$  refers to the time that temperature is over  $35^\circ\text{C}$  and  $\bar{t}_{>35}$  is the average temperature  
 315 that the indoor temperature is over  $35^\circ\text{C}$ .

316 It can be seen from the definition that the smaller the  $\gamma$ , the better the temperature control.  
 317 When  $\gamma$  is zero, casualty will not be caused under such temperature; when  $\gamma$  is close to 1, human  
 318 body's extreme endurance appears and this will endanger human's life; when  $\gamma$  is over 1, human  
 319 body's extreme endurance exceeds.

320 In order to maximize the usage of the thermal storage ability of PCM, and match the heat  
 321 flux of the thermal storage and indoor load, there is a need to analyze the impact factors, such as  
 322 pre-cooling temperature, melting temperature of PCM, size and amounts of PCM plates. In the  
 323 current work, an evaluation parameter of heat tolerance time  $\gamma$  is used. For each analysis, only one  
 324 factor is changed and keeps the other factors unchanged.

### 325 3.1. Effect of pre-cooling temperature

326 It is believed that the pre-cooling temperature  $t_{pc}$  can affect the PCM quantity. Thus, it is  
 327 necessary to observe the changes of the indoor estimated load at different  $t_{pc}$ . Here, the indoor  
 328 estimated load refers to the cold that PCM should bear. The finite volume method is used to  
 329 calculate the rising temperature of the SR at different  $t_{pc}$ , and then the indoor estimated load is  
 330 calculated. As for the indoor natural convection simulation, the average indoor wind speed is set to  
 331 be 0.1 m/s, the stable indoor temperature is 35°C, and six different  $t_{pc}$ , i.e. 24°C, 25°C, 26°C, 27°C,  
 332 28°C and 29°C are employed in the current study.

333  
 334 Fig. 9. Average heat flux of SR and indoor estimated load versus  $t_{pc}$  and their fitting curves.

335 Fig.9 presents the variation of the average heat flux of SR  $q_w$  and average indoor estimated  
 336 load  $q_i$  as a function of  $t_{pc}$ . It can be seen, as expected, that both the average flux of SR  $q_w$  and  
 337 average indoor estimated load  $q_i$  are a linear function of the  $t_{pc}$ . If the  $t_{pc}$  increases from 24°C to  
 338 29°C, the average indoor estimated load will increase from 1114 W to 3175 W, which equals to a  
 339 185% increase. And the average flux of SR decreases from 4443 W to 2389 W, then it equals to a  
 340 46% decrease. Their fitting formulas are showed as follows:

341 
$$q_w = 14310 - 411.2 \times t_w \quad (R^2 = 1) \quad (9)$$

342 
$$q_i = -8783 + 412.5 \times t_w \quad (R^2 = 0.9999) \quad (10)$$

343 Here,  $q_w$  decreases as the  $t_{pc}$  increases. When  $q_w=0$ , SR has no cold release, that is, the initial  
 344 temperature of SR is 35°C. According to Eq. (9), it can be calculated that  $t_w=34.8^\circ\text{C}$ , which is  
 345 close to 35°C, meaning that the fitting formula is reliable. The indoor estimated load  $q_i$  increases

346 gradually as the  $t_{pc}$  increases. When  $q_i=0$ , indoor load is completely absorbed by the SR. Based on  
 347 Eq. (10), it can be calculated that  $t_w=21.3^\circ\text{C}$ . Namely, when the  $t_{pc}$  lowers than  $21.3^\circ\text{C}$ , the indoor  
 348 hear load is zero, in this case the cooling system is not necessary.

### 349 3.2. Effect of melting temperature

350 It is recognized that the melting temperature is a key parameter to affect the thermal property  
 351 of the PCM plate. In order to investigate the effect of the size, in the current work, the other  
 352 parameters are kept the same:  $t_{pc}=25^\circ\text{C}$ ,  $N_{PCM}=190$ , the size of PCM plate is 600 mm in length, 60  
 353 mm in width and 500 mm in height and the PCM's density, latent heat, thermal conductivity and  
 354 specific heat maintain constant. The simulation is carried out with the melting temperature  
 355 increases from  $26^\circ\text{C}$  to  $31^\circ\text{C}$ .

356

357 Fig. 10. Melt fraction curves at different melting temperatures.

358 Fig.10 depicts the evolution of the melt fraction of PCM with time at six different melting  
 359 temperatures. In Fig. 10, it can be obviously observed that at the fixed time, the melt fraction  
 360 gradient is low as the melting temperature increases, It can be seen from Fig. 10 that when the  
 361 melting temperature varies from  $26^\circ\text{C}$  to  $29^\circ\text{C}$ , all the PCM completely melts within 96 hours,  
 362 and the melting time is 67.0 h, 73.5 h, 80.9 h and 89.5 h respectively. When the melting  
 363 temperature reaches  $30^\circ\text{C}$  and  $31^\circ\text{C}$ , the results in Fig. 10 clearly show that the PCM does not  
 364 completely melt, and the computed final melt fraction is approximately 0.974 and 0.864  
 365 respectively. The reason could be that when the melting temperature increases, the air temperature  
 366 will increase at the same time, which will lead to the heat transfer of air towards SR increase. As  
 367 the thermal storage of PCM decreases, the melting rate slows down.

368

369

Fig. 11. Hourly indoor temperatures for varies melting temperatures.

370

371

372

373

374

375

376

377

378

379

380

Fig.11 demonstrates the variations of indoor temperature as a function of time at six different melting temperatures, i.e., 26°C, 27°C, 28°C, 29°C, 30°C and 31°C. Sensitivity analysis in Fig.11 shows that, as the melting temperature increases, the temperature of ETCP will rise and the duration will extend. It should be noted that when the melting temperature increases from 26°C to 31°C, the average temperature of ETCP improves about 0.47°C, 0.46°C, 0.45°C, 0.45°C and 0.43°C respectively, and the duration lengthens about 6.5 h, 7.9 h, 7.1 h, 10.9 h and 13.1 h respectively. When the melting temperature reaches 30°C and 31°C, the air temperature rising stages only involve initial temperature increase stage  $\tau_1$  and temperature control stage  $\tau_2$ . The reason could be that, according to the Newton cooling formula, when the temperature difference of the air and the PCM is  $\Delta t = t_f - t_m$ , the PCM will absorb heat  $q_{PCM} = h_{PCM} A_{PCM} \Delta t$ . When the  $t_m$  increases, the air temperature  $t_f$  will increase accordingly.

381

382

Fig. 12.  $\gamma$  varies with melting temperature.

383

384

385

$\gamma$  can be used to evaluate the effect of temperature control. Fig.12 depicts the evolution of the evaluation parameter  $\gamma$  with melting temperature. It should be noticed that the  $\gamma$  value at every  $t_m$  is greater than 1 because this calculation is based on the estimated value (or initial value), which has

386 not been optimized. As stated previously, six different melting temperatures, i.e. 26°C, 27°C, 28°C,  
 387 29°C, 30°C and 31°C are explored in the current study. It can be seen clearly from Fig. 9 that the  
 388  $\gamma$  decreases from 26°C to 28°C. Starting from 28°C till the end, there is a quick increase of  $\gamma$ . As  
 389 is always the case, the melting temperature cannot be too high or too low. In the current study, the  
 390  $\gamma$  reaches the lowest at  $t_m=28$ . Therefore, in the following sensitivity analyses,  $t_m=28$  is chosen as  
 391 the calculated value.

### 392 3.3. Effect of size of PCM plate

393 Even with the same volume, different unit sizes show different influences on the heat transfer  
 394 and melting processes. In order to investigate the effect of the size, in the current work, the other  
 395 parameters are kept the same:  $t_{pc}=25^\circ\text{C}$ ,  $t_m=28^\circ\text{C}$ ,  $N_{PCM}=190$ , the length of PCM is 600 mm, and  
 396 the PCM's density, latent heat, thermal conductivity and specific heat maintain constant. Under the  
 397 operating conditions studied, four aspect ratios, i.e. W50H600, W60H500, W70H429, and  
 398 W80H375 are investigated, respectively.

399  
 400 Fig. 13. Melt fractions at different aspect ratios.

401 Fig.13 demonstrates the variation of melt fraction with time at four different aspect ratios at  
 402  $t_m=28^\circ\text{C}$ . It is noted that when the aspect ratio of PCM plate changes from 50/600 to 80/375, the  
 403 melting time is 75.9 h, 80.9 h, 85.3 h and 87.2 h respectively. According to the curves presented in  
 404 Fig.13, it could be concluded that the melting time increases with the increase of the aspect ratio  
 405 during the early stage. However, further increasing the aspect ratio ( $>70/429$ ) would result in the  
 406 decrease of the melting time rate. The reason could be that the change of the aspect ratio will lead  
 407 to the change of the area of PCM plate. The larger the aspect ratio is, the smaller the surface area

408 is. According to the Newton cooling formula, the decrease of the area will reduce the heat  
 409 absorption of the PCM. Then the melting rate of PCM will also slow down. As the variation of  
 410 surface area is not large, it can be seen from Fig.13 that the change of melting rate is also not  
 411 obvious.

412

413

Fig. 14. Hourly indoor temperature for varies aspect ratios.

414 Fig.14 illustrates the variation of indoor temperature with time at four different aspect ratios  
 415 and fixed melting temperature of 28°C. Obviously, the indoor temperature increases monotonously  
 416 during the entire process. It is found that the increase of the aspect ratio will improve the  
 417 temperature of ETCP as well as lengthen the time. When the aspect ratio changes from 50/600 to  
 418 80/375, the temperature of ETCP increases by 0.38°C, 0.23°C and 0.32°C. For the case of the  
 419 aspect ratio is more than 70/429, the duration of ETCP does not lengthen. The reason is that the  
 420 bigger the aspect ratio, the smaller the surface area  $A_{PCM}$ . According to the Newton cooling  
 421 formula, when the  $A_{PCM}$  decreases, the temperature difference  $\Delta t$  will increase accordingly. And  
 422 the  $t_m$  is a constant value, so the air temperature  $t_f$  will increase.

423

424

Fig. 15.  $\gamma$  changes with different aspect ratios.

425 Fig.15 demonstrates the variation of evaluation parameter  $\gamma$  for aspect ratios of 0.083, 0.12,  
 426 0.163 and 0.213 at fixed melting temperature of 28°C. It should be noted that the  $\gamma$  value at every  
 427 W/H ratio is greater than 1 because this calculation is based on the estimated value (or initial  
 428 value), which has not been optimized. The general trend for  $\gamma$  variation is similar to that observed  
 429 in Fig. 12. It should be also noted that there exists an optimal value of PCM size. From Fig.15, it  
 430 is demonstrated that when the aspect ratio is too low, the duration of ETCP is short, and the  
 431 temperature increases quickly in  $\tau_3$ ; whereas the aspect ratio is too high, the temperature of ETCP  
 432 is too high, and the duration does not lengthen.

### 433 3.4. Effect of number of PCM plates

434 In order to reduce the consumption of PCM and the cost as well as the occupied volume, to  
 435 seek a minimum number of PCM plates becomes a very important issue. In this study, sensitivity  
 436 analysis is conducted for seven different numbers of PCM plates: 190, 210, 228, 245, 262, 280,  
 437 298, and other parameters are kept the same:  $t_{pc}=25^\circ\text{C}$ ,  $t_m=28^\circ\text{C}$ , the size of PCM unit is  
 438 L600W60H500, PCM's density, latent heat, thermal conductivity and specific heat maintain  
 439 constant.

440  
 441 Fig. 16. Melt fraction at different numbers of PCM plates.

442 Fig.16 demonstrates the melt fraction plotted with respect to the time at seven different  
 443 numbers of PCM plates and fixed melting temperature of 28°C. Under the operating conditions  
 444 studied, obviously, the larger the number of PCM plates, the longer the melting time. According to  
 445 the curves presented in Fig.16, it is shown that when  $N_{PCM}$  increases from 190 to 298, the complete  
 446 melting time is 80.9 h, 84.3 h, 87.4 h, 90.3 h, 93.3 h and 96 h respectively. As also shown in this

447 figure, when  $N_{PCM}$  is 298, PCM does not completely melt.

448

449 Fig. 17. Hourly indoor temperatures for different numbers of PCM plates.

450 Fig.17 illustrates the variation of indoor air temperature at seven different numbers of PCM  
 451 plates, i.e. 190, 210, 228, 245, 262, 280 and 298, under the constant melting temperature (28°C).

452 It is proved that the increase of  $N_{PCM}$  will reduce the temperature of ETCP. When  $N_{PCM}$  increases  
 453 from 190 to 298, the temperature of ETCP will decrease by 0.24°C, 0.19°C, 0.17°C, 0.17°C, 0.15°C  
 454 and 0.15°C respectively; while the duration lengthens 2.8 h, 2.6 h, 2.4 h, 2.5 h, 2.5 h and 2.5 h  
 455 respectively. The reason could be that the  $A_{PCM}$ , total heat transfer area of PCM, increases with the  
 456 increase of the  $N_{PCM}$ . According to the Newton cooling formula, when the  $A_{PCM}$  increases, the  
 457 temperature difference  $\Delta t$  will decrease accordingly. And the  $t_m$  is a constant value, so the air  
 458 temperature  $t_f$  will decrease, which results in a lower air temperature. Furthermore, the increase of  
 459 the  $N_{PCM}$  will also improve the total latent heat of PCM, so the duration of ETCP will lengthen  
 460 accordingly.

461

462

Fig. 18.  $\gamma$  changes with different  $N_{PCM}$ .

463 Fig.18 illustrates the effect of number of PCM plates on the evaluation parameter  $\gamma$  at fixed  
 464 melting temperature of 28°C. Under the operating conditions studied, seven different numbers of  
 465 PCM plates, i.e.  $N_{PCM} = 190, 210, 228, 245, 262, 280$  and 298, are investigated. As shown in  
 466 Fig.18, this plot suggests that  $\gamma$  is nearly inversely proportional to the number of PCM plates. The  
 467 bigger the number of PCM plates, the lower the  $\gamma$  value. When  $N_{PCM}$  changes from 190 to 298, the  
 468  $\gamma$  value is 1.99, 1.57, 1.23, 0.92, 0.63, 0.37 and 0.13 respectively. This result may be attributed to  
 469 the increase of the number of PCM can not only reduce the temperature of ETCP, but also  
 470 increases the duration. The number of PCM plates has positive effect on temperature control, but  
 471 the higher the number, the higher the cost. To save energy consumption and cost, the next part of  
 472 the paper is to achieve the temperature control with the minimum number of PCM plates and other  
 473 optimal parameters.

#### 474 4. Optimization of coupled cooling system

475 There exist three stages with the increase of the air temperature. First, the initial temperature  
 476 increase stage  $\tau_1$  that the indoor load is mainly absorbed by air. Then the temperature control stage  
 477  $\tau_2$  that PCM begins to melt and absorb heat, assisted by thermal storage of SR. Finally, the rapid  
 478 temperature increase stage  $\tau_3$  that PCM completely melts, only rely on the thermal storage of SR.  
 479 Besides, there is an obvious stage  $\tau_{21}$ , which is called ETCP, during which the air temperature  
 480 slowly increases. Since the air temperature increases quickly after the ETCP, the increase of the air  
 481 temperature is hoped to stay in  $\tau_1$  and  $\tau_{21}$  and the curve of the air temperature is called the target  
 482 temperature curve. Fig.19 shows the comparison between the original temperature curve and  
 483 target temperature curve.

484  
 485

Fig. 19. Target air temperature rise curve.

486 It can be seen from the original temperature curve in Fig.19 that the temperature of ETCP and  
 487 the lengthening duration should be balanced in order to make it close to the target temperature  
 488 curve. Based on previous sensitivity analysis,  $t_{pc}$  presents linear influence on the indoor load; the  
 489 rise of melting temperature and the increase of aspect ratio will cause the temperature to rise and  
 490 the duration lengthens in ETCP; the increase of  $N_{PCM}$  can lower temperature and lengthen the  
 491 duration of ETCP at the same time, but the larger the  $N_{PCM}$ , the higher the cost. Therefore, the  
 492 optimal values of melting temperature and aspect ratio should be selected and a minimum number  
 493 of PCM plates are essential.

494 Combined optimization with double factors is adopted for reducing computation load. And  
 495 the sensitivity analysis shows that the size of the PCM plate has the least influence on the  
 496 temperature control. Therefore, first, the combination optimization with the melting temperature  
 497 and the size of PCM plate is conducted to find the optimal size of PCM plate. Then with the  
 498 optimal size of PCM plate, the combination optimization with the melting temperature and the  
 499 number of PCM plates is conducted to find the optimal melting temperature and minimum number  
 500 of PCM plates. Finally, the optimal design is also conducted for different  $t_{pc}$  with the optimal  
 501 size of PCM plate.

504 Fig. 20. Generalized results for the  $\gamma$  at various melting temperature and different aspect ratio:

505 (a)  $\gamma$  versus  $t_m$ ; (b)  $\gamma$  versus  $t_m * (12W/H)^{0.06}$ .

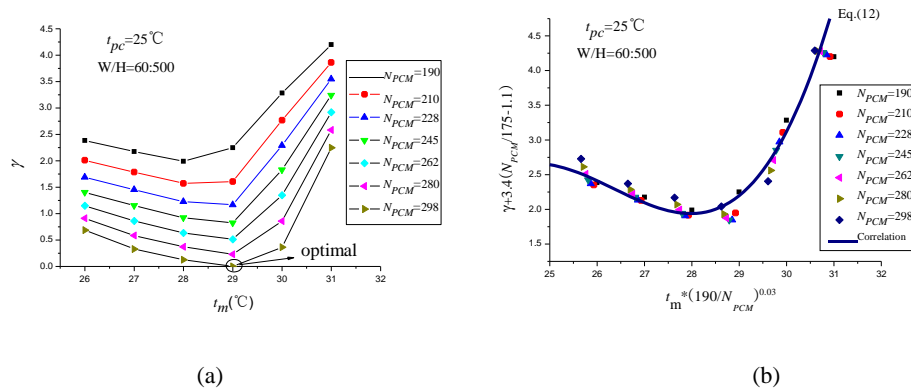

506 Fig.20(a) shows the variation of  $\gamma$  with melting temperature ranges from  $26^\circ\text{C}$  to  $31^\circ\text{C}$  at  
 507 fixed pre-cooling temperature ( $t_{pc}$ ) of  $25^\circ\text{C}$  and number of PCM plates ( $N_{PCM}$ ) of 190. For  
 508 comparison purpose, four aspect ratio conditions are used in this study, i.e.  $W/H=0.083$ ,  $0.12$ ,  
 509  $0.163$  and  $0.213$ . When the melting temperature is lower than  $28^\circ\text{C}$ , the influence of variation of

510 aspect ratio on  $\gamma$  does not change monotonically. While the melting temperature is over  $28^\circ\text{C}$ , the  
 511 greater the  $W/H$ , the smaller the  $\gamma$ . When the melting temperature is within  $26\sim 28^\circ\text{C}$ , if  $\gamma$  is  
 512 arranged from low to high, the  $W/H$  value is  $70/429$ ,  $60/500$ ,  $50/600$  and  $80/375$  respectively;  
 513 when the melting temperature is within  $29\sim 31^\circ\text{C}$ , if  $\gamma$  is arranged from low to high, the  $W/H$  value  
 514 is  $50/600$ ,  $60/500$ ,  $70/429$  and  $80/375$  respectively. Because  $\gamma$  is quite small in any kind of melting  
 515 temperature when  $W/H=60/500$ , the proportion of the aspect ratio should be the optimal.

516 In order to further explore the general principle that  $\gamma$  changes with the temperature under  
 517 different aspect ratios, Fig.20(b) demonstrates the generalized results for the  $\gamma$  at various melting  
 518 temperature and different aspect ratios. In order to investigate the relationship between the  $\gamma$  and  
 519 the melting temperature, under different aspect ratios, the following correlation, using the method  
 520 of curve fitting is proposed in Eq. (11).

$$521 \quad \gamma + 1.9(1/12 - W/H) = a_1x^3 + a_2x^2 + a_3x + a_4 \quad R^2 = 0.956 \quad (11)$$

522 where,  $x = t_m \cdot (12W/H)^{0.06}$ ,  $a_1 = -0.01863$ ,  $a_2 = 1.771$ ,  $a_3 = -55.33$ ,  $a_4 = 571.7$ .

523  
 524 (a)  $\gamma$  versus  $t_m$ ; (b)  $\gamma$  versus  $t_m \cdot (190/N_{PCM})^{0.03}$ .  
 525 Fig. 21. Generalized results for the  $\gamma$  at various melting temperature and different numbers of PCM plates:

526 (a)  $\gamma$  versus  $t_m$ ; (b)  $\gamma$  versus  $t_m \cdot (190/N_{PCM})^{0.03}$ .  
 527 Fig.21(a) shows the distribution of  $\gamma$  with different melting temperature at seven different  
 528  $N_{PCM}$ , i.e. 190, 210, 228, 245, 262, 280 and 298 for a fixed  $t_{pc}=25^\circ\text{C}$  and  $W/H=0.12$ . As expected,  
 529 the result shows that  $N_{PCM}$  has a monotonic effect on  $\gamma$  at any melting temperature. In the current  
 530 work, the optimal melting temperature is  $29^\circ\text{C}$ , and the minimum number of PCM plates is 298.  
 531 There could be three reasons to explain why the final minimum  $N_{PCM}$  is much larger than the  
 532 estimated number. Firstly, the average temperature of ETCP should be  $1\sim 2^\circ\text{C}$  lower than  $t_c$ ;  
 533 Secondly, no more than 80% of PCM is allowed to melt to ensure that the temperature increases

534 process takes place in  $\tau_1$  and ETCP. Most importantly, the indoor estimated load is actually greater  
 535 for the existence of the heat storage of PCM. Therefore, a larger number of PCM plates should be  
 536 selected than the estimated one.

537 For the purpose of briefness and engineering application, Fig.21 (b) demonstrates the  
 538 generalized results for the  $\gamma$  at various melting temperature and different numbers of PCM plates.  
 539 Under different  $N_{PCM}$ , Eq. (12) fits for all the cases that  $\gamma$  changes with melting temperature.

540 
$$\gamma + 3.4(N_{PCM}/175 - 1.1) = a_1x^3 + a_2x^2 + a_3x + a_4 \quad R^2 = 0.967 \quad (12)$$

541 where,  $x = t_m \cdot (190/N_{PCM})^{0.03}$ ,  $a_1=0.042$ ,  $a_2=-3.297$ ,  $a_3=86.540$ ,  $a_4=-751.950$ .

542 Table 4. The optimal melting temperature and the minimum number of PCM plates in three different  $t_{pc}$ .

$t_{pc}/^{\circ}\text{C}$	Melting temperature/ $^{\circ}\text{C}$	Minimum number of PCM plates
25	29	298
24	29	243
23	29	192

543 For the purpose of comparison, optimal design is also conducted for other two  $t_{pc}$  of 23 $^{\circ}\text{C}$   
 544 and 24 $^{\circ}\text{C}$ , with the PCM plate size of W60H500L600. Table 4 lists the optimal design of PCM  
 545 plate. The result clearly shows that the optimal PCM temperature needs to be kept at 29 $^{\circ}\text{C}$ , the  
 546 minimum number of PCM plates gradually drops as the pre-cooling temperature gradually slows  
 547 down. If per 1 $^{\circ}\text{C}$  decrease in pre-cooling temperature, the final demand of PCM plates can drop  
 548 18% and 20% respectively. And as showed in Fig. 22, compared with the traditional LHTES  
 549 systems (indoor thermal load is entirely borne by the PCM), the usages of PCM saved by the  
 550 coupled cooling method are 58.7%, 66.3% and 73.4%, when  $t_{pc}$  are 25 $^{\circ}\text{C}$ , 24 $^{\circ}\text{C}$  and 23 $^{\circ}\text{C}$ .

## 553 **5. Conclusions**

554 This study focuses on the new free coupled cooling method of LHTES combined with PE  
555 used in mine refuge chamber. Based on the coupled cooling method and system simulation model,  
556 the thermal performance of the new coupled cooling method is investigated. Then, the effects of  
557 some impact factors, such as pre-cooling temperature, melting temperature, size and number of  
558 PCM plates are investigated, and the coupled cooling system is optimized. Several conclusions  
559 could be summarized as follows:

560 (1) There exist three stages with the increase of the air temperature: initial temperature  
561 increase stage  $\tau_1$ , temperature control stage  $\tau_2$  and rapid temperature increase stage  $\tau_3$ . The effect  
562 of temperature control would decrease significantly if PCM melts more than 80%. Therefore, it is  
563 better to make the melt fraction no more than 80% in the selection of the number of PCM plates.

564 (2) The melting temperature and size of PCM plates should be optimized. And for the  
565 conditions in this paper, the appropriate melting temperature is about 29°C and the aspect ratio is  
566 60/500.

567 (3) The lower the pre-cooling temperature, the smaller the indoor load, the relationship of  
568 which presents linear. In this paper, when cold temperature lowers than 21°C, there is no need of  
569 any cooling system. If per 1°C decrease in pre-cooling temperature, the actual demand of PCM  
570 plates drops about 19%.

571 (4) For convenient application, the generalized results for the evaluation parameter of heat  
572 tolerance time  $\gamma$  at various melting temperature under different aspect ratios and  $N_{PCM}$  are given,  
573 respectively.

574 (5) The PCM plates absorb the pre-cooling cold and discharge it during the working time,  
575 which does improve the indoor thermal comfort degree. The use of PCM saved by the coupled  
576 cooling method is more than 50% compared to the traditional LHTES systems.

577 The result demonstrates that the new coupled cooling method can effectively control the  
578 indoor temperature and reduce the use of PCM under the condition of high-temperature and  
579 no-power. However, the cooling capacity of PCM is not matched with hourly indoor load.  
580 Therefore, it is suggested that the whole heat transfer process should be fully taken into  
581 consideration when the coupled cooling method is used. And it is better to lower the pre-cooling

582 temperature. Besides, there is a need to optimize PCM unit's parameter. The results of this paper  
583 are expected to be useful for the design and application of the coupled cooling method of LHTES  
584 combined with PE and other similar LHTESs.

## 585 **Acknowledgements**

586 Authors would like to thank the project of the National Natural Science Foundation of China  
587 entitled "A study of the characteristics of the surrounding rock cold storage-phase-change heat  
588 storage coupled cooling system for mine refuge chambers" (NO. 51378426), the Youth Science  
589 and Technology Innovation Team of Sichuan Province of Building Environment and Energy
