Abstract

Image registration is one important task in many image processing applications. It aims to align two or more images so that useful information can be extracted through comparison, combination or superposition. This is achieved by constructing an optimal transformation which ensures that the template image becomes similar to a given reference image. Although many models exist, designing a model capable of modelling large and smooth deformation field continues to pose a challenge. This paper proposes a novel variational model for image registration using the Gaussian curvature as a regulariser. The model is motivated by the surface restoration work in geometric processing [Elsay and Esedoglu, *Multiscale Model. Simul.*, (2009), pp. 1549-1573]. An effective numerical solver is provided for the model using an augmented Lagrangian method. Numerical experiments can show that the new model outperforms three competing models based on, respectively, a linear curvature [Fischer and Modersitzki, *J. Math. Imaging Vis.*, (2003), pp. 81-85], the mean curvature [Chumchob, Chen and Brito, *Multiscale Model. Simul.*, (2011), pp. 89-128] and the diffeomorphic demon model [Vercauteren et al., *NeuroImage*, (2009), pp. 61-72] in terms of robustness and accuracy.

Key words: Image registration, Non-parametric image registration, Regularisation, Gaussian curvature, surface mapping.

1 Introduction

Image registration along with image segmentation are two of the most important tasks in imaging sciences problems. Here we focus on image registration. Much research work has been done; for an extensive overview of registration techniques see [28, 18, 20]. The methods can be classified into parametric and non-parametric image registration based on the geometric transformation. For the first category, the transformation is governed by a finite set of image features or by expanding a transformation in terms of basis functions. The second category (which is our main concern in this paper) of non-parametric image registration methods is not restricted to a certain

parametrisable set. The problem is modelled as a functional minimisation via the calculus of variations. Given two images, the reference R and template T , the functional consists of a distance measure $\mathcal{D}(T, R, \mathbf{u})$ and a regularisation term $\mathcal{S}(\mathbf{u})$ where $\mathbf{u} = (u_1(\mathbf{x}), u_2(\mathbf{x}))$ is the sought displacement vector at pixel $\mathbf{x} \in \Omega \subset \mathbb{R}^2$. The term $\mathcal{S}(\mathbf{u})$ removes the ill-posedness of the minimisation problem. We use the squared L^2 norm of the distance measure to quantify the differences between T and R as follows

$$\mathcal{D}(T, R, \mathbf{u}) = \frac{1}{2} \int_{\Omega} (T(\mathbf{x} + \mathbf{u}(\mathbf{x})) - R(\mathbf{x}))^2 d\Omega. \quad (1)$$

The distance measure in equation (1) is the sum of the squared difference (SSD) which is commonly used and optimal for mono-modal image registration with Gaussian noise. For multi-modal image registration where T, R cannot be compared directly, other distance measures must be used [8]. Generally, the regularisation terms are inspired by physical processes such as elasticity, diffusion and motion curvature. As such, elastic image registration was introduced in [1] which assumed that objects are deformed as a rubber band.

In previous works, higher order regularisation models [7, 3] were found to be the most robust while the diffeomorphic demon model [22] offers the most physical transform in terms of (nearly) bijective mapping. Diffusion and total variation regularisation models based on first order derivatives are less complicated to implement but are at a disadvantage compared to higher order regularisation models based on second order derivatives due to two reasons. First, the former methods penalise rigid displacement. They cannot properly deal with transformations with translation and rotation. Second, low order regularisation is less effective than high order one in producing smooth transformations which are important in several applications including medical imaging. The work of [5, 6, 7] proposed a high order regularisation model named as a linear curvature, which is an approximation of the surface (mean) curvature and the model is invariant to affine registration. This work was later refined in [11, 9, 10] where a related approximation to the sum of the squares of the principal curvatures was suggested and higher order boundary conditions were recommended. Without any approximation to the mean curvature, the works in [3, 2] developed useful numerical algorithms for models based on the nonlinear mean curvature regularisation and observed advantages over the linear curvature models for image registration; however the effect of mesh folding (bijective maps) was not considered. The diffeomorphic demon model [23] is widely used due to its property of bijective maps; however the bijection is not precisely imposed. Another useful idea of enforcing bijection, beyond the framework we consider, is via minimising the Beltrami coefficient which measures the distortion of the quasi-conformal map of registration transforms [12].

In this paper we propose a high order registration model based on Gaussian curvature and hope to achieve large and smooth deformation without mesh folding. Although the Gaussian curvature is closely related to the mean curvature, it turns out our new model based on the Gaussian curvature is much better. The motivation of the proposed model comes from two factors. Firstly, we are inspired by the work of Elsey and Esedoglu [4] in geometry processing where Gaussian curvature of the image surface is used in a variational formulation. The authors proposed the Gaussian curvature as a natural analogue of the total variation of Rudin, Osher and Fatemi (ROF) [19] model in geometry processing. Aiming to generalise the ROF model to surface fairing where the convex shapes in 3D have similar interpretation to the monotone functions in 1D problems for the ROF model, they showed that, based on the Gauss Bonnet

theorem, the complete analogy of the total variation regularisation for surface fairing is the energy functional of the Gaussian curvature. A very important fact pointed out in [4] stated that the mean curvature of the surface is *not* a suitable choice for surface fairing because the model is not effective for preserving important features such as creases and corners on the surface (although the model is still effective for removing noise). Their claims are also supported by the work of [13] where the authors illustrated several advantages of Gaussian curvature over mean curvature and total variation in removing noise in 2D images. First, Gaussian curvature preserves important structures such as edges and corners. Second, only Gaussian curvature can preserve structures with low gradient. Third, the model is effective in removing noise on small scale features. Thus, we believe that Gaussian curvature is a more natural physical quantity of the surface than mean curvature. Here we investigate the potential of using Gaussian curvature to construct a high order regularisation model for non-parametric image registration of mono-modal images.

The outline of this paper is as follows. In §2 we review the existing models for non-parametric image registration with focus on the demon, linear and mean curvature models. In §3 we introduce the mathematical background of Gaussian curvature for surfaces. In §4 we introduce a Gaussian curvature model and a numerical solver to solve the resulting Euler-Lagrange equations. We show in §5 some numerical tests including comparisons. Finally, we discuss the parameters' selection issue for our model in §6 and present our conclusions in §7.

2 Review of Non-parametric Image Registration

In image registration, given two images T and R (which are assumed to be compactly supported and bounded operators $T, R : \Omega \subset \mathbb{R}^d \rightarrow \mathbb{R}^+$), the task is to transform T to match R as closely as possible. Although we consider $d = 2$ throughout this paper, with some extra modifications, this work can be extended to $d = 3$. In non-parametric image registration, the transformation is denoted by φ where φ is a vector valued function

$$\varphi(\mathbf{x}) : \mathbb{R}^2 \rightarrow \mathbb{R}^2$$

where $\mathbf{x} = (x, y)$. To separate the overall mapping from the displacement field, we will define

$$\varphi(\mathbf{x}) = \mathbf{x} + \mathbf{u}(\mathbf{x})$$

where $\mathbf{u}(\mathbf{x})$ is the displacement field. Thus, finding $\mathbf{u}(\mathbf{x})$ is equivalent to finding φ . A non-parametric image registration model takes the form

$$\min_{\mathbf{u}(\mathbf{x})} \mathcal{J}_\gamma(\mathbf{u}(\mathbf{x})) = \mathcal{D}(T, R, \mathbf{u}(\mathbf{x})) + \gamma \mathcal{S}(\mathbf{u}(\mathbf{x})) \quad (2)$$

where the distance measure \mathcal{D} is given as in (1) and the choice of regulariser $\mathcal{S}(\mathbf{u}(\mathbf{x}))$ differentiates different models. Here $\mathbf{u}(\mathbf{x})$ is searched over a set \mathcal{U} of admissible functions that minimise \mathcal{J}_γ in (2). Usually, the set \mathcal{U} is a linear subspace of a Hilbert space with Euclidean scalar product.

The force term $\mathbf{f}(\mathbf{u})$, to be used by all models, is the gradient of (1) with respect to the displacement field $\mathbf{u}(\mathbf{x})$

$$\mathbf{f}(\mathbf{u}) = (f_1(\mathbf{u}), f_2(\mathbf{u}))^T = (T(\mathbf{x} + \mathbf{u}(\mathbf{x})) - R(\mathbf{x})) \nabla_{\mathbf{u}} T(\mathbf{x} + \mathbf{u}(\mathbf{x})) \quad (3)$$

108 which is non-linear. Different regularisation terms $\mathcal{S}(\mathbf{u}(\mathbf{x}))$ will lead to different non-parametric
 109 image registration models. Below we list three popular models selected for tests and comparisons.

110 **Model LC.** The first one is the linear curvature model by [6, 7, 15, 5], where

$$\mathcal{S}^{\text{FMC}}(\mathbf{u}) = \int_{\Omega} [(\Delta u_1)^2 + (\Delta u_2)^2] d\Omega. \quad (4)$$

111 This term is an approximation of the surface curvature $\iota(u_l)$ through the mapping $(x, y) \rightarrow$
 112 $(x, y, u_l(x, y))$, $l = 1, 2$ where

$$\iota(u_l) = \nabla \cdot \frac{\nabla u_l}{\sqrt{|\nabla u_l|^2 + 1}} \approx \Delta u_l \quad (5)$$

113 when $|\nabla u_l| \approx 0$. The Euler Lagrange equation for (2) with \mathcal{S}^{FMC} as the regularisation term is
 114 given by a fourth order PDE

$$\gamma \Delta^2 \mathbf{u} + \mathbf{f}(\mathbf{u}) = 0 \quad (6)$$

115 with boundary conditions $\Delta u_l = 0, \nabla \Delta u_l \cdot \mathbf{n} = 0$, $l = 1, 2$ and \mathbf{n} the unit outward normal vector.
 116 The model consists of the second order derivative information of the displacement field which
 117 results in smoother deformations compared to those obtained using first order models based on
 118 elastic and diffusion energies. It is refined in [11, 9, 10] with nonlinear boundary conditions. The
 119 affine linear transformation belongs to the kernel $\mathcal{S}^{\text{FMC}}(\mathbf{u})$ which is not the case in elastic or
 120 diffusion registration.

121 **Model MC.** Next is the mean curvature model [3, 2]

$$\mathcal{S}^{\text{MC}}(\mathbf{u}) = \int_{\Omega} [\mathbb{k}(\iota(u_1)) + \mathbb{k}(\iota(u_2))] d\Omega$$

122 where $\mathbb{k}(s) = \frac{1}{2}s^2$ and ι is as defined in (5). The Euler Lagrange equation for (2) with \mathcal{S}^{MC} as
 123 the regularisation term is given by:

$$\gamma \nabla \cdot \left(\frac{1}{\sqrt{|\nabla u_l|^2 + 1}} \nabla \mathbb{k}'(\iota(u_l)) - \frac{\nabla u_l \cdot \nabla \mathbb{k}'(\iota(u_l))}{(\sqrt{|\nabla u_l|^2 + 1})^3} \nabla u_l \right) + f_l(\mathbf{u}) = 0, \quad l = 1, 2 \quad (7)$$

124 with boundary condition $\nabla u_l \cdot \mathbf{n} = \nabla \iota(u_l) \cdot \mathbf{n} = 0$, $l = 1, 2$. One can use the multigrid method
 125 to solve equation (7) as in [3]; refer also to [2] for multi-modality image registration work.

126 **Model D.** Finally Thirion [21] introduced the so-called demon registration method where
 127 every pixel in the image acts as the demons that force a pulling and pushing action in a similar
 128 way to what Maxwell did for solving the Gibbs paradox in thermodynamics. The original demon
 129 registration model is a special case of diffusion registration but it has been much studied and
 130 improved since 1998; see [17, 15, 25, 14]. The energy functional for the basic demon method is
 131 given by

$$\mathcal{S}(\mathbf{u}) = \|R(\mathbf{x}) - T(\mathbf{x} + \tilde{\mathbf{u}} + \mathbf{u})\|^2 + \frac{\sigma_i^2}{\sigma_x^2} \|\mathbf{u}\|^2 \quad (8)$$

132 where $\tilde{\mathbf{u}}$ is the current displacement field, σ_i^2 and σ_x^2 account for noise on the image intensity
 133 and the spatial uncertainty respectively. Equation (8) can be linearised using first order Taylor
 134 expansion,

$$\mathcal{J}(\mathbf{u}) = \|R(\mathbf{x}) - T(\mathbf{x} + \tilde{\mathbf{u}}) + J\mathbf{u}\|^2 + \frac{\sigma_i^2}{\sigma_x^2} \|\mathbf{u}\|^2 \quad (9)$$

135 where J is given by

$$J = -\frac{\nabla R + \nabla T(\mathbf{x} + \tilde{\mathbf{u}})}{2}$$

136 for an efficient second order minimisation. The first order condition of (9) leads to the new update
137 for $\tilde{\mathbf{u}}$

$$\mathbf{u} = -\frac{R(\mathbf{x}) - T(\mathbf{x} + \tilde{\mathbf{u}})}{\|J\|^2 + \frac{\sigma_y^2}{\sigma_x^2}} J.$$

138 The additional use of \mathbf{v} for $\varphi = \exp(\mathbf{v})$ helps to achieve a nearly diffeomorphic transformation
139 (mapping), where \mathbf{v} is the stationary velocity field of the displacement field \mathbf{u} ; see [24]. It should
140 be remarked that the three main steps of the model cannot be combined into a single energy
141 functional.

142 In a discrete setting, since the image domain Ω is a square, all variational models are discretised
143 by finite differences on a uniform grid. Refer to [3, 15]. The vertex grid is defined by

$$\Omega^h = \{\mathbf{x}_{i,j} = (x_i, y_j) \mid 0 \leq i \leq N_1 - 1, 0 \leq j \leq N_2 - 1\}$$

144 where we shall re-use the notation T and R for discrete images of size $N_1 \times N_2$.

145 3 Mathematical Background of the Gaussian curvature

146 In differential geometry, the Gaussian curvature problem seeks to identify a hypersurface of \mathbb{R}^{d+1}
147 as a graph $z = u(\mathbf{x})$ over $\mathbf{x} \in \Omega \subset \mathbb{R}^d$ so that, at each point of the surface, the Gaussian curvature
148 is prescribed. Let $\kappa(\mathbf{x})$ denote the Gaussian curvature which is a real valued function in $\Omega \subset \mathbb{R}^d$.
149 The problem is modelled by the following equation

$$\det(D^2u) - \kappa(\mathbf{x})(1 + |Du|^2)^{(d+2)/2} = 0 \quad (10)$$

150 where D is the first order derivative operator. Equation (10) is one of the Monge-Ampere equa-
151 tions. For $d = 2$, we have

$$\kappa(\mathbf{x}) \equiv -\kappa^{GC} = \frac{u_{xx}u_{yy} - u_{xy}u_{yx}}{(1 + u_x^2 + u_y^2)^2}. \quad (11)$$

152 In [4], the authors define a regularisation term using the Gaussian curvature of a closed surface
153 based on the Gauss-Bonnet theorem.

154 **Theorem 3.1 Gauss-Bonnet Theorem.** *For a compact C^2 surface $\partial\Sigma$, we have*

$$\int_{\partial\Sigma} \kappa^{GC} d\sigma = 2\pi\chi$$

155 where $d\sigma$ is the length element to the surface and χ is the Euler characteristic of the surface.

156 Using this Theorem, it was shown in [4] that the complete analogy of the total variation regu-
157 larisation for surface fairing is the energy functional of the Gaussian curvature. The analogous
158 term \mathcal{S} , to the total variation of a function, that appears in the ROF model [19], is given by

$$\mathcal{S} = \int_{\partial\Sigma} |\kappa(\mathbf{x})| d\sigma$$

159 where $d\sigma$ is the length element to the surface $\partial\Sigma$.

160 Gaussian curvature is one of the fundamental second order geometric properties of a surface.
 161 According to the Gauss's Theorema Egregium, Gaussian curvature is intrinsic. For a local iso-
 162 metric mapping $f : \partial\Sigma \rightarrow \partial\Sigma'$ between two surfaces, Gaussian curvature remains invariant i.e. if
 163 $p \in \partial\Sigma$ and $p' \in \partial\Sigma'$, then $\kappa^{GC}(p) = \kappa^{GC}(p')$ and the mapping f is smooth and diffeomorphic.

164 We can also use a level set function to define the Gaussian curvature. Denote by ϕ the zero level
 165 set of the surface generated through the mapping $(x, y) \mapsto (x, y, u(x, y))$. Then $\phi = u(x, y) - z$
 166 and $\nabla\phi = (u_x, u_y, -1)^T$ where $u_x = \frac{\partial u}{\partial x}$ and $u_y = \frac{\partial u}{\partial y}$. The Gaussian curvature of the level set is
 167 given by

$$\kappa^{GC} = \frac{\nabla\phi H^*(\phi) \nabla\phi^T}{|\nabla\phi|^4} \quad (12)$$

168 where $\nabla\phi = (\phi_x, \phi_y, \phi_z)^T$, $|\nabla\phi| = \sqrt{\phi_x^2 + \phi_y^2 + \phi_z^2}$, $H(\phi)$ is the Hessian matrix and $H^*(\phi)$ is the
 169 adjoint matrix for $H(\phi)$. We have

$$H(\phi) = \begin{bmatrix} u_{xx} & u_{xy} & 0 \\ u_{yx} & u_{yy} & 0 \\ 0 & 0 & 0 \end{bmatrix}, \quad H^*(\phi) = \begin{bmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & u_{xx}u_{yy} - u_{yx}u_{xy} \end{bmatrix}.$$

170 Then,

$$\kappa^{GC} = \frac{u_{yx}u_{xy} - u_{xx}u_{yy}}{(u_x^2 + u_y^2 + 1)^2}.$$

171 This is why we set $\kappa^{GC} = -\kappa(\mathbf{x})$ in equation (11). We shall use $|\kappa^{GC}|$ to measure the Gaus-
 172 sian curvature as in [4] for a monotonically increasing function (since the functional should be
 173 nonnegative).

174 4 Image Registration based on Gaussian Curvature

175 Before introducing our new image registration model, we first illustrate some facts to support the
 176 use of Gaussian curvature.

177 4.1 Advantages of a Gaussian curvature

178 **The total variation and Gaussian curvature.** We use the volume based analysis introduced
 179 in [13] to compare two denoising models, respectively based on Gaussian curvature and the total
 180 variation:

$$\frac{\partial u}{\partial t} = \nabla \cdot \left(\kappa \left(\left| \frac{u_{xy}^2 - u_{xx}u_{yy}}{(u_x^2 + u_y^2 + 1)^2} \right| \right) \nabla u \right), \quad (13)$$

$$\frac{\partial u}{\partial t} = \nabla \cdot \frac{\nabla u}{|\nabla u|}. \quad (14)$$

182 Consider, for each $\alpha > 0$, the time change of the volume $v_{t,\alpha} = \{(x, y, z) \mid 0 < z < |u(x, y, t) - \alpha|\}$
 183 which is enclosed by the surface $z = u(x, y, t)$ and the plane $z = \alpha$. Assume $|u(x, y, t) - \alpha| =$
 184 $(u(x, y, t) - \alpha)s$ with s either positive ($s = 1$) or negative ($s = -1$) at all points. Denote by
 185 $c_{t,\alpha}$ the closed curve defined by the level set $u(x, y, t) = \alpha$ and accordingly by $d_{t,\alpha}$ the 2D region
 186 enclosed by $c_{t,\alpha}$. The volume change in $v_{t,\alpha}$ in time is given by

$$V = \frac{\partial}{\partial t} \int_{v_{t,\alpha}} dz dA = \frac{\partial}{\partial t} \int_{v_{t,\alpha}} \int_0^{|u(x,y,t)-\alpha|} dz dA = \frac{\partial}{\partial t} \int_{d_{t,\alpha}} |u(x, y, t) - \alpha| dA$$

187 where dA is the area element. We now consider how V changes from evolving (13) or (14).

188 If u is the solution of equation (14), then from Gauss' theorem

$$V = \frac{\partial}{\partial t} \int_{d_{t,\alpha}} |u(x, y, t) - \alpha| dA = s \int_{d_{t,\alpha}} \frac{\partial u}{\partial t} dA = s \int_{d_{t,\alpha}} \nabla \cdot \frac{\nabla u}{|\nabla u|} dA = s \int_{c_{t,\alpha}} \frac{\nabla u}{|\nabla u|} \cdot \mathbf{n} d\sigma$$

189 where $d\sigma$ is the length element and \mathbf{n} is the unit normal vector to the curve $c_{t,\alpha}$ which is repre-
190 sented as $\mathbf{n} = s \frac{\nabla u}{|\nabla u|}$. Then

$$V = s^2 \int_{c_{t,\alpha}} \frac{\nabla u}{|\nabla u|} \cdot \frac{\nabla u}{|\nabla u|} d\sigma = \int_{c_{t,\alpha}} d\sigma = |c_{t,\alpha}|$$

191 where $|c_{t,\alpha}|$ is the length of the curve $c_{t,\alpha}$. Furthermore, the volume variation in time is

$$\int_{d_{t+\delta t,\alpha}} |u(x, y, t + \delta t) - \alpha| dA \approx \int_{d_{t,\alpha}} |u - \alpha| dA + s\delta t \int_{d_{t,\alpha}} \frac{\partial u}{\partial t} dA = \int_{d_{t,\alpha}} \left[|u - \alpha| + \delta t \frac{|c_{t,\alpha}|}{|d_{t,\alpha}|} \right] dA$$

192 where $|d_{t,\alpha}|$ denotes the area of the region $d_{t,\alpha}$. We can see that the change in u from t to $t + \delta t$ is
193 proportional to the ratio $\frac{|c_{t,\alpha}|}{|d_{t,\alpha}|}$. So, when this ratio is large (indicating possibly a noise presence),
194 the total variation model reduces it and hence removes noise. However, important features of u
195 which have a large level set ratio are removed also and so not preserved by the total variation
196 model (14).

197 Using similar calculations to before for the Gaussian curvature scheme (13), we have

$$\begin{aligned} V &= \frac{\partial}{\partial t} \int_{d_{t,\alpha}} |u(x, y, t) - \alpha| dA = s \int_{d_{t,\alpha}} \nabla \cdot \left(\kappa \left(\left| \frac{u_{xy}^2 - u_{xx}u_{yy}}{(u_x^2 + u_y^2 + 1)^2} \right| \right) \nabla u \right) dA \\ &= s \int_{c_{t,\alpha}} \left(\kappa \left(\left| \frac{u_{xy}^2 - u_{xx}u_{yy}}{(u_x^2 + u_y^2 + 1)^2} \right| \right) \nabla u \right) \cdot \mathbf{n} d\sigma = \int_{c_{t,\alpha}} \left(\kappa \left(\left| \frac{u_{xy}^2 - u_{xx}u_{yy}}{(u_x^2 + u_y^2 + 1)^2} \right| \right) \right) |\nabla u| d\sigma. \end{aligned} \quad (15)$$

198 From here, we observe that the quantity V for the subdomain $v_{t,\alpha}$ is dependent on the product of
199 the variation *and* the Gaussian curvature on the level curve. The function κ in (15) controls and
200 scales the speed of the volume change in contrast to the total variation scheme where V depends
201 only on the variation of the level curve. Consider a point $p = (x_0, y_0, \alpha)$ where $\alpha = u(x_0, y_0)$.
202 Gaussian curvature $\kappa = \kappa_1 \kappa_2$ based on two principal curvatures κ_1 and κ_2 where κ_1 is the
203 curvature of the level curve passing the point p and κ_2 is the curvature of the path which passes
204 the point and κ_2 is orthogonal to the level curve. If the Gaussian curvature on one level curve is
205 zero then there is no change in V regardless of variation on the level curves. In contrast, with the
206 total variation, if there is a variation in the level curve, then there is a change in V . Based on
207 this observation, we believe that the Gaussian curvature model is better than the total variation
208 model for preserving features on surfaces.

209 **The mean curvature and Gaussian curvature.** The mean curvature (MC) $\iota = (\kappa_1 + \kappa_2)/2$
210 is also widely used. Next, we show that, though closely related, Gaussian curvature (GC) is better
211 than mean curvature for surfaces in three ways.

212 First, Gaussian curvature is invariant under rigid and isometric transformations. In contrast,
213 mean curvature is invariant under rigid transformations but not under isometric transforma-
214 tions. Rigid transformations preserve distance between two points while isometric transforma-
215 tions preserve length along surfaces and preserve angles between curves on surfaces. To illustrate

216 invariance, consider a surface

$$z_1(x, y) = ax^2 + by^2,$$

217 whose Gaussian curvature and mean curvature are respectively

$$\kappa = \frac{0 - (2a)(2b)}{(1 + 4a^2x^2 + 4b^2y^2)^2}, \quad \iota = \frac{(1 + 4b^2y^2)(2a) + (1 + 4a^2x^2)(2b)}{(1 + 4a^2x^2 + 4b^2y^2)^{3/2}}.$$

218 If we flip the surface upside down (isometric transformation) where $z'_1(x, y) = -ax^2 - by^2$, we
 219 will have the same value for the Gaussian curvature and a different value for the mean curvature.
 220 Thus, Gaussian curvature is invariant under isometric transformation.

221 Second, Gaussian curvature can be used to localise the tip of a surface better than mean
 222 curvature. Consider

$$z_2(x, y) = -\frac{1}{2}(x^2 + y^2)$$

223 as shown in Figure 1 (a). Then, we compute the mean and Gaussian curvature for the surface as
 224 depicted in Figures 1 (b) and (c) respectively. For Figure 1 (b), we display the negative of the
 225 mean curvature for better assessment and visualisation. For both figures, the maximal values are
 226 given at the center of the tip. The value given by the Gaussian curvature is sharper than that of
 227 the mean curvature. The highest point of the Gaussian curvature is better distinguished from its
 neighbourhood compared to the highest point of the mean curvature.

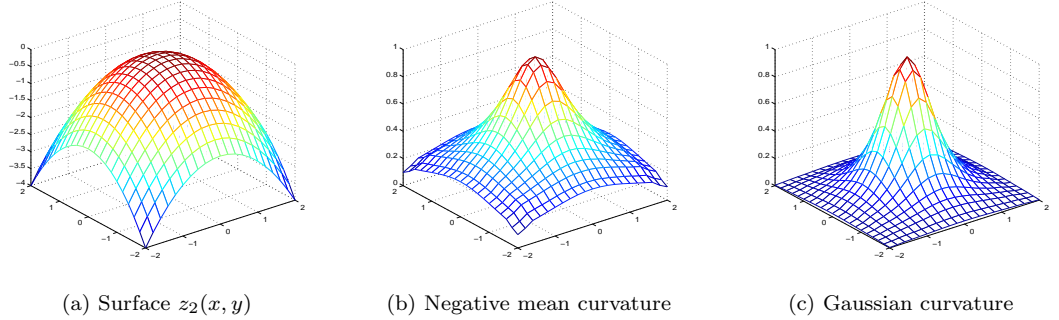

Figure 1: Representation of a surface with GC and MC. (a) shows a surface model with a tip point. (b) is the negative mean curvature and (c) is the Gaussian curvature. The highest point in (c) is better localised than in (b).

228

229 Third, Gaussian curvature can locate saddle points better than mean curvature. Take

$$z_3(x, y) = -\frac{1}{2}(x^2 - y^2)$$

230 as one example. The surface along with its mean and Gaussian curvatures are given in Figures
 231 2 (a), (b) and (c) respectively. The mean curvature for this surface appears complex where the
 232 largest value is not at the saddle point and the saddle point cannot be easily located. However,
 233 Gaussian curvature gets its highest value at the saddle point and is therefore able to accurately
 234 identify the saddle point within its neighbourhood.

235 In addition to these three examples and observations, a very important fact point out in [4]
 236 stated that the mean curvature of the surface is not a suitable choice for surface fairing because
 237 the model is not effective for preserving important features such as creases and corners on the
 238 surface (although the model is effective for removing noise). This is true when we are referring

Figure 2: Location of a surface's saddle point by GC and MC. (a) is the surface with a saddle point. (b) is the negative mean curvature and (c) is the negative Gaussian curvature. The highest point in (b) is not at the saddle point and for (c), the saddle point is better distinguishable from its neighbourhood.

to surface fairing (surface denoising) but not necessarily true for 2D image denoising. From the recent works done in image denoising [4, 13], we observed several advantages of Gaussian curvature over total variation and mean curvature. Therefore, we might conjecture that Gaussian curvature may outperform existing models in image registration. To our knowledge there exists no previous work on this topic.

4.2 The proposed registration model

Now we return to the problem of how to align or register two image functions $T(\mathbf{x}), R(\mathbf{x})$. Let the desired and unknown displacement fields between T and R be the surface map $(x, y) \rightarrow (x, y, u_l(x, y))$ where $l = 1, 2$ and with $\mathbf{u} = (u_1, u_2)$. We propose our Gaussian curvature based image registration model as

$$\min_{\mathbf{u} \in C^2(\Omega)} \mathcal{J}_\gamma(\mathbf{u}(\mathbf{x})) = \frac{1}{2} \int_{\Omega} (T(\mathbf{x} + \mathbf{u}) - R(\mathbf{x}))^2 d\Omega + \gamma \mathcal{S}^{\text{GC}}(\mathbf{u}(\mathbf{x})) \quad (16)$$

where

$$\mathcal{S}^{\text{GC}}(\mathbf{u}(\mathbf{x})) = \sum_{l=1}^2 \mathcal{S}^{\text{GC}}(u_l), \quad \mathcal{S}^{\text{GC}}(u_l) = \int_{\Omega} \left| \frac{u_{l,xy}u_{l,yx} - u_{l,xx}u_{l,yy}}{(u_{l,x}^2 + u_{l,y}^2 + 1)^2} \right| d\Omega.$$

The above model (16) leads to two Euler Lagrange equations:

$$\begin{cases} \gamma \nabla \cdot \left(\frac{4|u_{1,xy}u_{1,yx} - u_{1,xx}u_{1,yy}|}{\mathcal{N}_1^3} \nabla u_1 \right) + \gamma \nabla \cdot \mathbf{B}_{1,1} + \gamma \nabla \cdot \mathbf{B}_{1,2} + f_1 = 0 \\ \gamma \nabla \cdot \left(\frac{4|u_{2,xy}u_{2,yx} - u_{2,xx}u_{2,yy}|}{\mathcal{N}_2^3} \nabla u_2 \right) + \gamma \nabla \cdot \mathbf{B}_{2,1} + \gamma \nabla \cdot \mathbf{B}_{2,2} + f_2 = 0 \end{cases} \quad (17)$$

where

$$\begin{aligned} \mathcal{N}_l &= u_{l,x}^2 + u_{l,y}^2 + 1, \quad \mathbf{B}_{l,1} = \left(\left(-\frac{\mathcal{S}_l u_{l,yy}}{\mathcal{N}_l} \right)_x, \left(\frac{\mathcal{S}_l u_{l,xy}}{\mathcal{N}_l} \right)_x \right) \\ \mathbf{B}_{l,2} &= \left(\left(\frac{\mathcal{S}_l u_{l,yx}}{\mathcal{N}_l} \right)_y, \left(-\frac{\mathcal{S}_l u_{l,xx}}{\mathcal{N}_l} \right)_y \right), \quad \mathcal{S}_l = \text{sign}(u_{l,xy}u_{l,yx} - u_{l,xx}u_{l,yy}) \\ \mathbf{f} &= (f_1, f_2)^T = (T(\mathbf{x} + \mathbf{u}) - R(\mathbf{x})) \nabla_{\mathbf{u}} T(\mathbf{x} + \mathbf{u}), \quad l = 1, 2 \end{aligned}$$

252 and boundary conditions $\nabla u_l \cdot \mathbf{n} = 0$, $l = 1, 2$, where \mathbf{n} is the normal vector at the boundary $\partial\Omega$.
 253 Derivation of the resulting Euler-Lagrange equations for this model can be found in Appendix A.
 254 The equations are fourth order and nonlinear with anisotropic diffusion. Gradient descent type
 255 methods are not feasible and one way to solve them is by a geometric multigrid as in [3]. Here,
 256 instead, we present a fast and efficient way to solve the model (16) on a unilevel grid.

257 4.3 Augmented Lagrangian Method

258 The augmented Lagrangian method (ALM) is often used for solving constraint minimisation
 259 problems by replacing the original problem with an unconstrained problem. The method is
 260 similar to the penalty method where the constraints are incorporated in the objective functional
 261 and the problem is solved using alternating minimisation of each of the sub-problems. However,
 262 in ALM, there are additional terms in the objective functional known as Lagrange multiplier
 263 terms arising when incorporating the constraints. Similar works on the augmented Lagrangian
 264 method in image restoration can be found in [26, 27].

265 To proceed, we introduce two new dual variables \mathbf{q}_1 and \mathbf{q}_2 where $\mathbf{q}_1 = \nabla u_1(\mathbf{x})$ and $\mathbf{q}_2 =$
 266 $\nabla u_2(\mathbf{x})$. Consequently we obtain a system of second order PDEs which are more amenable to
 267 effective solution.

268 We obtain the following refined model for Gaussian curvature image registration

$$\begin{aligned} \min_{u_1, u_2, \mathbf{q}_1, \mathbf{q}_2} \mathcal{J}(u_1, u_2, \mathbf{q}_1, \mathbf{q}_2) &= \mathcal{D}(T, R, \mathbf{u}(\mathbf{x})) + \gamma \mathcal{S}^{GC}(\mathbf{q}_1) + \gamma \mathcal{S}^{GC}(\mathbf{q}_2) \\ \text{s.t } \mathbf{q}_1 &= \nabla u_1(\mathbf{x}), \mathbf{q}_2 = \nabla u_2(\mathbf{x}) \end{aligned}$$

269 and further reformulate $\mathcal{J}(u_1, u_2, \mathbf{q}_1, \mathbf{q}_2)$ to get the augmented Lagrangian functional

$$\begin{aligned} \mathcal{L}^{GC}(u_1, u_2, \mathbf{q}_1, \mathbf{q}_2; \boldsymbol{\mu}_1, \boldsymbol{\mu}_2) &= \frac{1}{2} \|T(\mathbf{x} + \mathbf{u}(\mathbf{x})) - R(\mathbf{x})\|_2^2 + \gamma \mathcal{S}^{GC}(\mathbf{q}_1) + \gamma \mathcal{S}^{GC}(\mathbf{q}_2) \\ &\quad + \langle \boldsymbol{\mu}_1, \mathbf{q}_1 - \nabla u_1 \rangle + \langle \boldsymbol{\mu}_2, \mathbf{q}_2 - \nabla u_2 \rangle \\ &\quad + \frac{r}{2} \|\mathbf{q}_1 - \nabla u_1\|_2^2 + \frac{r}{2} \|\mathbf{q}_2 - \nabla u_2\|_2^2 \end{aligned} \quad (18)$$

270 where $\boldsymbol{\mu}_1, \boldsymbol{\mu}_2$ are the Lagrange multipliers, the inner products are defined via the usual integration
 271 in Ω and r is a positive constant. We use an alternating minimisation procedure to find the optimal
 272 values of $u_1, u_2, \mathbf{q}_1, \mathbf{q}_2$ and $\boldsymbol{\mu}_1, \boldsymbol{\mu}_2$ where the process involves only two main steps.

273 **Step 1.** For the first step we need to update $\mathbf{q}_1, \mathbf{q}_2$ for any given $u_1, u_2, \boldsymbol{\mu}_1, \boldsymbol{\mu}_2$. The objective
 274 functional is given by

$$\min_{\mathbf{q}_1, \mathbf{q}_2} \gamma \mathcal{S}^{GC}(\mathbf{q}_1) + \gamma \mathcal{S}^{GC}(\mathbf{q}_2) + \langle \boldsymbol{\mu}_1, \mathbf{q}_1 \rangle + \langle \boldsymbol{\mu}_2, \mathbf{q}_2 \rangle + \frac{r}{2} \|\mathbf{q}_1 - \nabla u_1\|^2 + \frac{r}{2} \|\mathbf{q}_2 - \nabla u_2\|^2.$$

275 This sub-problem can be solved using the following Euler Lagrange equations:

$$\begin{cases} -\gamma \left(\left(\frac{(-q_{1,1})_y}{\Gamma_1^2} \right)_x + \left(\frac{(-q_{1,1})_x}{\Gamma_1^2} \right)_y \right) - \gamma \frac{4S_1 D_1 q_{1,2}}{\Gamma_1^3} + \mu_{1,2} + r(q_{1,2} - (u_1)_y) = 0, \\ -\gamma \left(\left(\frac{(q_{1,2})_y}{\Gamma_1^2} \right)_x + \left(\frac{(-q_{1,2})_x}{\Gamma_1^2} \right)_y \right) - \gamma \frac{4S_1 D_1 q_{1,1}}{\Gamma_1^3} + \mu_{1,1} + r(q_{1,1} - (u_1)_x) = 0 \end{cases} \quad (19)$$

276 where $D_1 = \det(\nabla \mathbf{q}_1) = (q_{1,1})_x (q_{1,2})_y - (q_{1,1})_y (q_{1,2})_x$, $\Gamma_1 = 1 + u_{1,x}^2 + u_{1,y}^2$ and $S_1 = \text{sign}\left(\frac{D_1}{(\|\nabla u_1\|^2 + 1)^2}\right)$.

277 We have a closed form solution for this step, if solving alternately, where

$$\begin{aligned} q_{1,1} &= \frac{\Gamma_1^3 \left(-\gamma \left(\left(\frac{(q_{1,2})_y}{\Gamma_1^2} \right)_x + \left(\frac{-(q_{1,2})_x}{\Gamma_1^2} \right)_y \right) + \mu_{1,1} - r(u_1)_x \right)}{-r\Gamma_1^3 + \gamma 4S_1 D_1}, \\ q_{1,2} &= \frac{\Gamma_1^3 \left(-\gamma \left(\left(\frac{(q_{1,1})_y}{\Gamma_1^2} \right)_x + \left(\frac{-(q_{1,1})_x}{\Gamma_1^2} \right)_y \right) + \mu_{1,2} - r(u_1)_y \right)}{-r\Gamma_1^3 + \gamma 4S_1 D_1}. \end{aligned}$$

278 Similarly, we solve $q_{2,1}, q_{2,2}$ from

$$\begin{cases} -\gamma \left(\left(\frac{(-q_{2,1})_y}{\Gamma_2^2} \right)_x + \left(\frac{-(q_{2,1})_x}{\Gamma_2^2} \right)_y \right) - \gamma \frac{4S_2 D_2 q_{2,2}}{\Gamma_2^3} + \mu_{2,1} + r(q_{2,2} - (u_2)_y) = 0, \\ -\gamma \left(\left(\frac{(q_{2,2})_y}{\Gamma_2^2} \right)_x + \left(\frac{-(q_{2,2})_x}{\Gamma_2^2} \right)_y \right) - \gamma \frac{4S_2 D_2 q_{2,1}}{\Gamma_2^3} + \mu_{2,1} + r(q_{2,1} - (u_2)_x) = 0 \end{cases} \quad (20)$$

279 where $D_2 = \det(\nabla \mathbf{q}_2) = (q_{2,1})_x (q_{2,2})_y - (q_{2,1})_y (q_{2,2})_x$, $\Gamma_2 = 1 + u_{2,x}^2 + u_{2,y}^2$ and $S_2 = \text{sign}\left(\frac{D_2}{(\|\nabla u_2\|^2 + 1)^2}\right)$.

280 **Step 2.** For the second step we need to update u_1, u_2 for any given $\mathbf{q}_1, \mathbf{q}_2$ and $\boldsymbol{\mu}_1, \boldsymbol{\mu}_2$ with
281 the following functional

$$\min_{u_1, u_2} \frac{1}{2} \|T(\mathbf{x} + \mathbf{u}) - R(\mathbf{x})\|_2^2 - \langle \boldsymbol{\mu}_1, \nabla u_1 \rangle - \langle \boldsymbol{\mu}_2, \nabla u_2 \rangle + \frac{r}{2} \|\mathbf{q}_1 - \nabla u_1\|^2 + \frac{r}{2} \|\mathbf{q}_2 - \nabla u_2\|^2.$$

282 Thus, we have the following Euler Lagrange equations:

$$\begin{cases} -r\Delta u_1 + f_1 + \nabla \cdot \boldsymbol{\mu}_1 + r\nabla \cdot \mathbf{q}_1 = 0 \\ -r\Delta u_2 + f_2 + \nabla \cdot \boldsymbol{\mu}_2 + r\nabla \cdot \mathbf{q}_2 = 0 \end{cases} \quad (21)$$

283 with Neumann boundary conditions $\nabla u_l \cdot \mathbf{n} = 0, l = 1, 2$. To solve equation (21), first, we linearise
284 the force term \mathbf{f} using Taylor expansion

$$\begin{aligned} f_l(u_1^{(k+1)}, u_2^{(k+1)}) &= f_l(u_1^{(k)}, u_2^{(k)}) + \partial_{u_1} f_l(u_1^{(k)}, u_2^{(k)}) \delta u_1^{(k)} + \partial_{u_2} f_l(u_1^{(k)}, u_2^{(k)}) \delta u_2^{(k)} + \dots \\ &\approx f_l(u_1^{(k)}, u_2^{(k)}) + \sigma_{l,1}^{(k)} \delta u_1^{(k)} + \sigma_{l,2}^{(k)} \delta u_2^{(k)} \end{aligned}$$

285 where

$$\sigma_{l,1}^{(k)} = \partial_{u_1} f_l(u_1^{(k)}, u_2^{(k)}), \sigma_{l,2}^{(k)} = \partial_{u_2} f_l(u_1^{(k)}, u_2^{(k)}), \delta u_1^{(k)} = u_1^{(k+1)} - u_1^{(k)}, \delta u_2^{(k)} = u_2^{(k+1)} - u_2^{(k)}.$$

286 Second, we approximate $\sigma_{l,1}^{(k)}$ and $\sigma_{l,2}^{(k)}$ with

$$\begin{aligned} \sigma_{l,1}^{(k)} &= \left(\partial_{u_l} T(\mathbf{x} + \mathbf{u}^{(k)}) \right) \left(\partial_{u_1} T(\mathbf{x} + \mathbf{u}^{(k)}) \right) \\ \sigma_{l,2}^{(k)} &= \left(\partial_{u_l} T(\mathbf{x} + \mathbf{u}^{(k)}) \right) \left(\partial_{u_2} T(\mathbf{x} + \mathbf{u}^{(k)}) \right). \end{aligned}$$

287 The discrete version of equation (21) is as follows

$$\mathbf{N}^h(\mathbf{u}^{h,(k)}) \mathbf{u}^{h,(k+1)} = \mathbf{B}^h(\mathbf{u}^{h,(k)}) \quad (22)$$

288 where

$$\mathbf{N}^h(\mathbf{u}^{(k)}) = \begin{bmatrix} -r\mathcal{L} + \sigma_{11}^h(\mathbf{u}^{h,(k)}) & \sigma_{12}^h(\mathbf{u}^{h,(k)}) \\ \sigma_{21}^h(\mathbf{u}^{h,(k)}) & -r\mathcal{L} + \sigma_{22}^h(\mathbf{u}^{h,(k)}) \end{bmatrix},$$

$$\mathbf{B}^h(\mathbf{u}^{(k)}) = \begin{bmatrix} -G_1^h + f_1^h(u_1^{(k)}, u_2^{(k)}) + \sigma_{11}^h(\mathbf{u}^{(k)})u_1^{h,(k)} + \sigma_{12}^h(\mathbf{u}^{h,(k)})u_2^{h,(k)} \\ -G_2^h + f_2^h(u_1^{(k)}, u_2^{(k)}) + \sigma_{21}^h(\mathbf{u}^{(k)})u_1^{h,(k)} + \sigma_{22}^h(\mathbf{u}^{h,(k)})u_2^{h,(k)} \end{bmatrix},$$

289 \mathcal{L} is the discrete version of the Laplace operator Δ and G_l^h is the discrete version of

$$\nabla \cdot \boldsymbol{\mu}_l + r \nabla \cdot \mathbf{q}_l, \quad l = 1, 2.$$

290 Third, we solve the system of equation (22) using a weighted pointwise Gauss Siedel method

$$\mathbf{u}^{h,(k+1)} = (1 - \omega)\mathbf{u}^{h,(k)} + \omega \left(\mathbf{N}^h(\mathbf{u}^{(k)}) \right)^{-1} \mathbf{B}^h(\mathbf{u}^{(k)})$$

291 where $\omega \in (0, 2)$ and we choose $\omega = 0.9725$.

The iterative algorithm to solve (18) is now summarised as follows.

Algorithm 1 Augmented Lagrangian method for the Gaussian Curvature Image Registration.

1. Initialise $\boldsymbol{\mu}_1 = \boldsymbol{\mu}_2 = \mathbf{0}, \mathbf{u}(\mathbf{x}) = 0, \gamma, r$.
 2. For $k = 0, 1, \dots, IMAX$
 - (a) Step 1: Solve (19-20) for $(\mathbf{q}_1^{(k+1)}, \mathbf{q}_2^{(k+1)})$ with $(u_1, u_2) = (u_1^{(k)}, u_2^{(k)})$.
 - (b) Step 2: Solve (21) for $(u_1^{(k+1)}, u_2^{(k+1)})$ with $(\mathbf{q}_1, \mathbf{q}_2) = (\mathbf{q}_1^{(k+1)}, \mathbf{q}_2^{(k+1)})$.
 - (c) Step 3: Update Lagrange multipliers.
 $\boldsymbol{\mu}_1^{(k+1)} = \boldsymbol{\mu}_1^{(k)} + r(\mathbf{q}_1^{(k+1)} - \nabla u_1^{(k+1)}), \boldsymbol{\mu}_2^{(k+1)} = \boldsymbol{\mu}_2^{(k)} + r(\mathbf{q}_2^{(k+1)} - \nabla u_2^{(k+1)})$
 3. End for.
-

292

293 5 Numerical Results

294 We use two numerical experiments to examine the efficiency and robustness of the Algorithm
 295 1 on a variety of deformations. To judge the quality of the alignment we calculate the relative
 296 reduction of the similarity measure

$$\varepsilon = \frac{\mathcal{D}(T, R, \mathbf{u})}{\mathcal{D}(T, R)}$$

297 and the minimum value of the determinant of the Jacobian matrix J of the transformation,
 298 denoted as \mathcal{F}

$$J = \begin{bmatrix} 1 + u_{1,x} & u_{1,y} \\ u_{2,x} & 1 + u_{2,y} \end{bmatrix}, \quad \mathcal{F} = \min(\det(J)). \quad (23)$$

299 We can observe that when $\mathcal{F} > 0$, the deformed grid is free from folding and cracking.

300 All experiments were run on a single level. Experimentally, we found that $r \in [0.02, 2]$ works
 301 well for several types of images. As for the stopping criterion, we use $tol = 0.001$ for the residual of
 302 the Euler-Lagrange equations (19)-(21) and the maximum number of iterations is 30. Experiments
 303 were carried out using Matlab R2014b with Intel(R) core (TM) i7-2600 processor and 16G RAM.

5.1 Test 1: A Pair of Smooth X-ray Images

Images for Test 1 are taken from [16] where X-ray images of two hands of different individuals need to be aligned. The size of images are 128×128 and the recovered transformation is expected to be smooth. The scaled version of the transformation and the transformed template image is given in Figures 3 (d) and (e) respectively. The transformation is smooth and the model is able to solve such a problem. For comparison, the transformed template images for the diffeomorphic

Figure 3: Test 1 (X-ray hand). Illustration of the effectiveness of Gaussian curvature with smooth problems. On the top row, from left to right: (a) template, (b) reference and (c) the difference before registration. On the bottom row, from left to right: (d) the transformation applied to a regular grid, (e) the transformed template image and (f) the difference after registration. As can be seen from the result (e) and the small difference after registration (f), Gaussian curvature is able to solve smooth problems.

demon method, linear, mean and Gaussian curvatures are shown in Figures 4 (a), (b), (c) and (d) respectively. We can observe that there are some differences of these images inside the red boxes where only Gaussian curvature delivering the best result of the features inside the boxes. The enlargements of the red boxes in Figure 4 are shown in Figure 5 for all models where the best result is given by the Gaussian curvature for both parts of the hand.

We summarised the results for Test 1 in Table 1 where ML and SL stand for multi and single level respectively. For all models, γ is chosen as small as possible such that $\mathcal{F} > 0$. We can see that the fastest model is the diffeomorphic demon, followed by linear and mean curvature. The current implementation for Gaussian curvature is on single level and the model uses augmented Lagrangian method which has four dual variables and four lagrange multipliers terms. Thus, it requires more computational time than the other models.

Figure 4: Test 1 (X-ray hand). Comparison of Gaussian curvature with competing methods. The transformed template image using (a) Model D, (b) Model LC, (c) Model MC and (d) Gaussian curvature. Note the difference of these three images inside the red boxes.

Measure	Model D		Model LC		Model MC	GC
	ML	SL	ML	SL	SL	SL
γ	1.6	1.6	0.1	0.5	0.0001	0.0001
Time (s)	15.19	186.48	84.33	12.98	275.3	953.15
ε	0.1389	0.1229	0.0720	0.3780	0.0964	0.0582
\mathcal{F}	0.0600	0.1082	0.3894	0.1973	0.6390	0.3264

Table 1: Quantitative measurements for all models for Test 1. ML and SL stand for multi and single level respectively. γ is chosen as small as possible such that $\mathcal{F} > 0$ for all methods. $\mathcal{F} > 0$ indicates the deformation consists of no folding and cracking of the deformed grid. We can see that the smallest value of ε is given by Gaussian curvature (GC).

5.2 Test 2: A Pair of Brain MR Images

We take as Test 2 a pair of medical images of size 256×256 from the Internet Brain Segmentation Repository (IBSR) <http://www.cma.mgh.harvard.edu/ibsr> where 20 normal MR brain images and their manual segmentations are provided. We choose the particular pair of individuals with different sizes of ventricle to illustrate a large deformation problem. Figure 6 shows the test images and the registration results using Gaussian curvature model. We can see that the model is able to solve real medical problems involving large deformations, which is particularly important for atlas construction in medical applications. Figure 7 shows the transformed template images for all four methods. We can see that Gaussian curvature gives the best result inside the red boxes in comparison with the diffeomorphic demon, the linear and mean curvature models as depicted

Figure 5: Test 1 (X-ray hand). Comparison of transformed templates in zoomed-in boxes and their local ε values: (a) Model D, (b) Model LC, (c) Model MC and (d) Gaussian curvature. Gaussian curvature has the smallest ε value.

in Figure 7 (d). The enlargements of the red boxes in Figure 7 are shown in Figure 8 where we can observe that the Gaussian curvature gives better alignment for both parts of the brain.

Measure	Model D		Model LC		Model MC	GC
	ML	SL	ML	SL	SL	SL
γ	1.2	1.4	0.16	2.0	0.0001	0.0001
Time (s)	23.89	209.00	275.04	35.70	830.22	1053.7
ε	0.2004	0.7580	0.1128	0.4283	0.1998	0.1062
\mathcal{F}	0.0277	0.0387	0.3157	0.0148	0.8240	0.0138

Table 2: Quantitative measurements for all models for Test 2. ML and SL stand for multi and single level respectively. γ is chosen to be as small as possible such that $\mathcal{F} > 0$ for all models. $\mathcal{F} > 0$ indicates the deformation consists of no folding and cracking of the deformed grid. We can see that the smallest value of ε is given by Gaussian curvature (GC).

The values of the quantitative measurements for Test 2 are recorded in Table 2 where the lowest values of ε are given by the Gaussian curvature model indicating higher similarity between the transformed template result and the reference image. However, our proposed model required more time than the other models since the model consists more variables than the others.

6 Discussions

Gaussian curvature has been proposed as a novel regulariser for a variational image registration model. We have presented an efficient numerical scheme using the augmented Lagrangian method to solve the model, though the scheme is not yet optimal in efficiency. All of the experimental results indicate that Gaussian curvature obtains improved results over mean curvature, linear

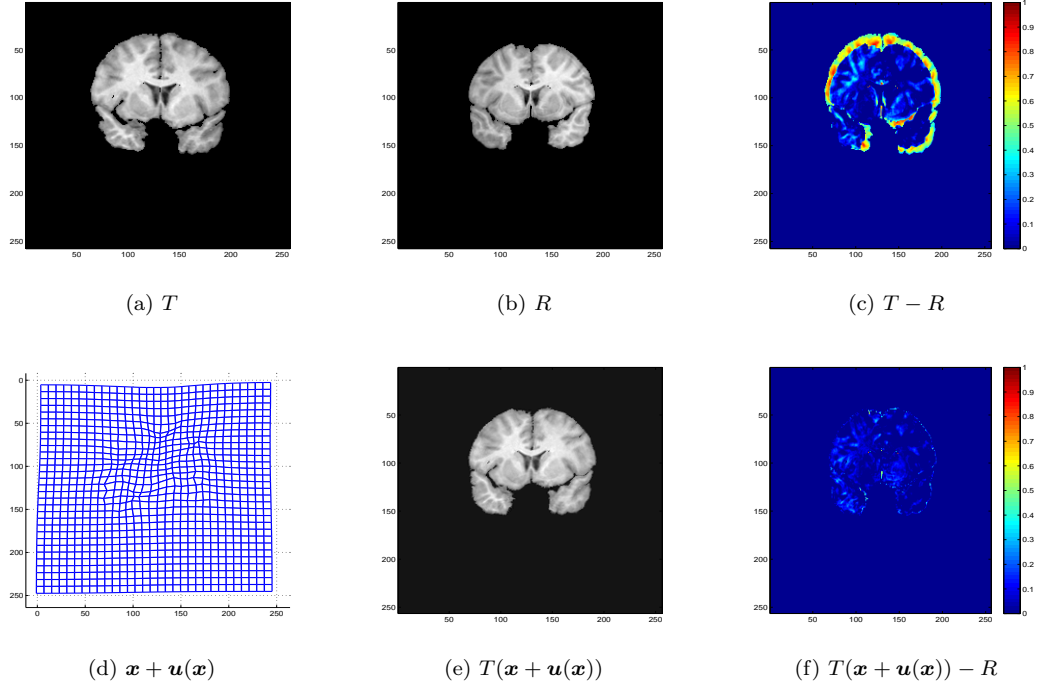

Figure 6: Test 2: A pair of Brain MR images. Illustration of the effectiveness of Gaussian curvature with real medical images. On the top row, from left to right: (a) template, (b) reference and (c) the difference before registration. On the bottom row, from left to right: (d) the transformation applied to a regular grid, (e) the transformed template image and (f) the difference after registration. As can be seen from the result (e) and the small difference after registration (f), Gaussian curvature can be applied to real medical images and is able to obtain good results.

curvature and the demon method for mono-modal image registration. The model can be extended to multi-modality image registration by changing the distance measure; we show one such result for a pair of multi-modality images in Figure 11 for the Gaussian curvature model with mutual information [2, 18] as the distance measure. We now discuss briefly the two parameters γ and r .

Parameter γ . The regularisation parameter γ controls the smoothness of the deformation field. As with all inverse problems, the choice of such a parameter is important. Noting that extremely large γ leads to smooth but yet little deformation and extremely small γ leads large but non-smooth deformation, our selection strategy is based on a continuation idea of starting from a large γ_0 and reducing it till some prescribed value γ^* and before $\mathcal{F} \leq 0$. To illustrate the idea, in Figure 9, we show experiments with varying values of γ with a fixed $r = 0.02$. From the figure, we observe that decreasing γ will decrease the value \mathcal{F} and ε until at a value $\gamma = \gamma^*$ (in Figure 9, $\gamma^* = 0.0001$). We also observe how the functional \mathcal{J} in equation (16) evolving during the iteration. The results is shown in Figure 9 (c) for Test 1 using $\gamma = 0.0001$ and $r = 0.02$. The functional \mathcal{J} and the fitting term \mathcal{D} are decreasing and the regularisation term \mathcal{S}^{GC} is increasing indicating the convergence of the model. Decreasing γ beyond γ^* leads slow reduction of \mathcal{F} and ε in this example but for others, reduction of \mathcal{F} may be fast and $\mathcal{F} \leq 0$ may be reached.

Parameter r . The parameter r used in the ALM stabilises the minimisation problem in a quadratic energy term based on the distance between ∇u_l and \mathbf{q}_l . A large value of r brings ∇u_l and \mathbf{q}_l close together and produces a high level of dissimilarity between R and T as shown in

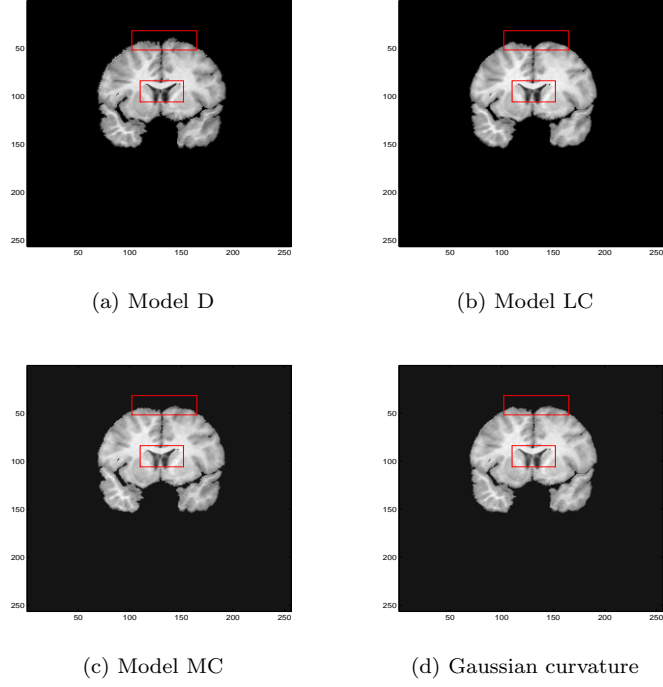

Figure 7: Test 2: A pair of Brain MR images. Comparison of Gaussian curvature with competing methods. The transformed template image using (a) Model D, (b) Model LC, (c) Model MC, and (d) Gaussian curvature. Notice the differences of these three images inside the red boxes. Considerably more accurate results are obtained, particularly within these significant regions, by employment of the Gaussian curvature model.

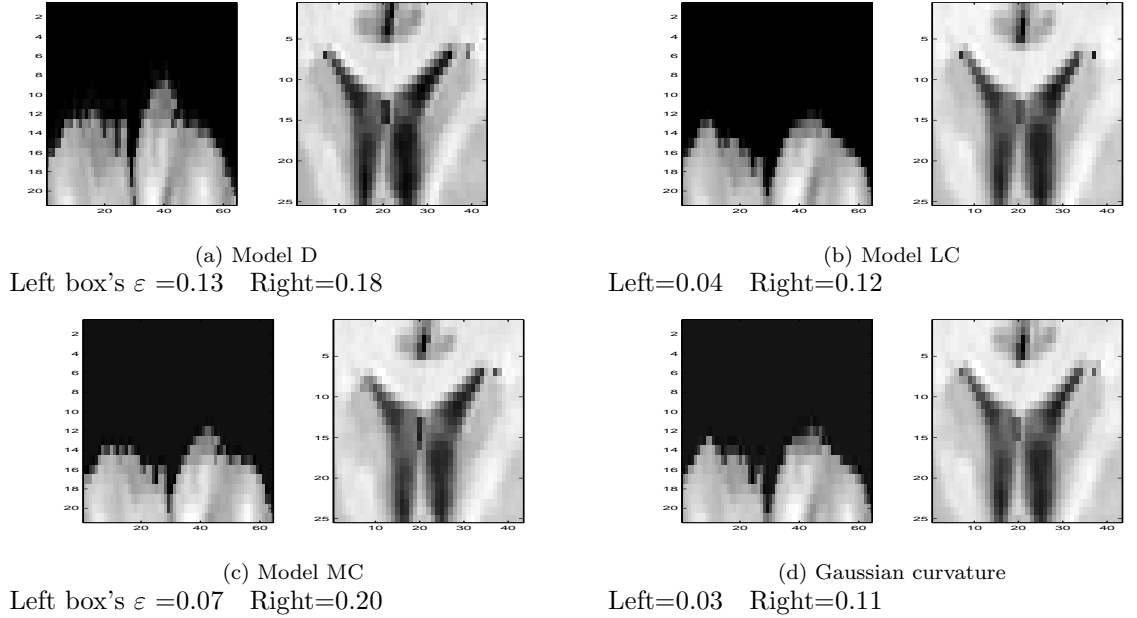

Figure 8: Test 2: A pair of Brain MR images. Comparison of transformed templates in zoomed-in boxes and their local ε values: (a) Model D, (b) Model LC, (c) Model MC and (d) Gaussian curvature. Again Gaussian curvature has the smallest ε value.

Figure 9: The effects on the values of \mathcal{F} and ε for various values of γ are shown in (a) and (b). We obtain these figures using $r = 0.02$ for Test 1 and it confirms that γ controls the smoothness of the deformation field. The iteration history for Test 1 is shown in (c). Since the functional \mathcal{J} decreasing, it confirms the convergence of the proposed model.

Figure 10: The effects on the value of \mathcal{F} , n_1 , n_2 and ε for various values of r . In (a), \mathcal{F} decrease with decreasing value of r . We should use the value of r , such that $\mathcal{F} > 0$ to avoid mesh folding. In (b), we can see that increasing the value of r will decrease the difference between \mathbf{q}_1 , \mathbf{q}_2 and ∇u_1 , ∇u_2 . From (c), with a large value of r , we have smaller residual indicated by n_2 . In (d), although small $r = 0.002$, gives a very small ε , but since $\mathcal{F} < 0$ for this value of r , we choose the optimal value of r to be $r = 0.02$.

361 Figure 10. It also controls the smoothness of the deformation field. Define

$$n_1 = \frac{1}{|\Omega|} \text{mean} (\mathbf{q}_1 - \nabla u_1, \mathbf{q}_2 - \nabla u_2) \quad (24)$$

362 and n_2 as the average residual of three equations (19), (20) and (21). With a very small r ,
 363 the residual increases and could produce mesh folding even if the value of ε is small. Thus, an

364 optimal value of r to ensure that ε is small and $\mathcal{F} > 0$ is necessary. Our selection idea is again
365 continuation: start with a large value of r (for example $r = 2$) and check n_2 . If n_2 is close to zero
366 we reduce r by factor (e.g. 10). Otherwise we increase r . The procedure stops when a prescribed
367 number of steps is reached. In Figure 10 for Test 1 (with a fixed $\gamma = 0.008$), we vary the value
368 $r \in [0.002, 2]$ and plot four quantities against r . This procedure of selecting r was done on a coarse
369 grid (here 16×16), with a small number of iterations. Thus, the computational cost is low. For
370 Tests 1-2, we obtain $r = 0.02$ through this procedure.

371 **A brief summary.** The linear curvature model is relatively easy to solve, based on ap-
372 proximation of the mean curvature. The mean curvature model for image registration is highly
373 nonlinear, making it challenging to solve. The Gaussian curvature resembles the mean curvature
374 in many ways, though different, but its model appears to deliver better quality than the mean
375 curvature. The diffeomorphic demon model is equivalent to the second order gradient descent
376 on the SSD as shown in [17]. The model is only limited to mono-modality images and it is not
377 yet applicable to multi-modality images. Our Gaussian curvature model however can be easily
378 modified to work with multi-modality images by replacing the SSD by a mutual information or
normalised gradient fields based regularizer; an optimal solver is yet to be developed.

Figure 11: Results of Gaussian curvature image registration for multi-modality images. The model is able to register multi-modality images with mutual information as the distance measure.

379

380 7 Conclusions

381 We have introduced a novel regularisation term for non-parametric image registration based on
382 the Gaussian curvature of the surface induced by the displacement field. The model can be

effectively solved using the augmented Lagrangian and alternating minimisation methods. For comparison, we used three models: the linear curvature [6], the mean curvature [3] and the demon algorithm [24] for mono-modality images. Numerical experiments show that the proposed model delivers better results than the competing models.

Appendix A – Derivation of the Euler-Lagrange Equations

Let $q_1 = u_x$ and $q_2 = u_y$; then we can write the Gaussian curvature regularisation term as

$$\mathcal{S}^{GC}(q_1, q_2) = \int_{\Omega} \left| \frac{q_{1,x}q_{2,y} - q_{1,y}q_{2,x}}{(1 + q_1^2 + q_2^2)^2} \right| dx dy.$$

From the optimality condition $\frac{d\mathcal{S}^{GC}(q_1, q_2)}{dq_1} = \frac{d\mathcal{S}^{GC}(q_1, q_2)}{dq_2} = 0$, then $\frac{d}{d\epsilon_1} \mathcal{S}^{GC}(q_1 + \epsilon_1 \varphi_1, q_2) \Big|_{\epsilon_1=0} = 0$ and $\frac{d}{d\epsilon_2} \mathcal{S}^{GC}(q_1, q_2 + \epsilon_2 \varphi_2) \Big|_{\epsilon_2=0} = 0$. In details,

$$\begin{aligned} \frac{d}{d\epsilon_1} \int_{\Omega} \left| \frac{(q_1 + \epsilon_1 \varphi_1)_x q_{2,y} - (q_1 + \epsilon_1 \varphi_1)_y q_{2,x}}{(1 + (q_1 + \epsilon_1 \varphi_1)^2 + q_2^2)^2} \right| dx dy \Big|_{\epsilon=0} = \\ \int_{\Omega} S \frac{d}{d\epsilon_1} \left[\frac{(q_1 + \epsilon_1 \varphi_1)_x q_{2,y} - (q_1 + \epsilon_1 \varphi_1)_y q_{2,x}}{(1 + (q_1 + \epsilon_1 \varphi_1)^2 + q_2^2)^2} \right] dx dy \Big|_{\epsilon=0} = 0 \end{aligned} \quad (25)$$

where $S = \text{sign} \left(\frac{q_{1,x}q_{2,y} - q_{1,y}q_{2,x}}{(1 + q_1^2 + q_2^2)^2} \right)$. From (25),

$$\begin{aligned} \int_{\Omega} S \left[\frac{\varphi_{1,x}q_{2,y} - \varphi_{1,y}q_{2,x}}{(1 + q_1^2 + q_2^2)^2} + (q_{1,x}q_{2,y} - q_{1,y}q_{2,x})(-4\varphi_1 q_1 (1 + q_1^2 + q_2^2)^{-3}) \right] dx dy \\ = \int_{\Omega} \frac{S\varphi_{1,x}q_{2,y}}{\Gamma^2} - \frac{S\varphi_{1,y}q_{2,x}}{\Gamma^2} - \frac{4SDq_1\varphi_1}{\Gamma^3} dx dy = 0, \end{aligned}$$

where $\Gamma = 1 + q_1^2 + q_2^2$, $D = q_{1,x}q_{2,y} - q_{1,y}q_{2,x}$.

Using the Green theorem $\int_{\partial\Omega} \phi \boldsymbol{\omega} \cdot \mathbf{n} ds - \int_{\Omega} \phi \text{div}(\boldsymbol{\omega}) dx dy = \int_{\Omega} \nabla \phi \cdot \boldsymbol{\omega} dx dy$, we have,

$$\int_{\Omega} \frac{S\varphi_{1,x}q_{2,y}}{\Gamma^2} - \frac{S\varphi_{1,y}q_{2,x}}{\Gamma^2} dx dy = \int_{\partial\Omega} \varphi_1 \left(\frac{Sq_{2,y}}{\Gamma^2}, \frac{Sq_{2,x}}{\Gamma^2} \right) \cdot \mathbf{n} ds - \int_{\Omega} \varphi_1 \text{div} \left(\frac{Sq_{2,y}}{\Gamma^2}, \frac{Sq_{2,x}}{\Gamma^2} \right) = 0$$

where $\phi = \varphi_1$, $\boldsymbol{\omega} = \left(\frac{Sq_{2,y}}{\Gamma^2}, \frac{Sq_{2,x}}{\Gamma^2} \right)$. Setting the boundary integral to zero, then we derive

$$\int_{\Omega} \varphi_1 \text{div} \left(\frac{Sq_{2,y}}{\Gamma^2}, \frac{Sq_{2,x}}{\Gamma^2} \right) = 0.$$

Finally, we use the fundamental lemma of calculus of variation to get:

$$\nabla \cdot \left(\frac{Sq_{2,y}}{\Gamma^2}, \frac{Sq_{2,x}}{\Gamma^2} \right) - \frac{4SDq_1}{\Gamma^3} = 0.$$

Similarly, for $\frac{d}{d\epsilon_2} \mathcal{S}^{GC}(q_1, q_2 + \epsilon_2 \varphi_2) \Big|_{\epsilon_2=0} = 0$, we finally obtain equation (17). \square
