ABSTRACT: A discovery of flavour-changing Higgs-boson decays would constitute an undeniable signal of new physics. We derive model-independent constraints on the tch and tuh couplings that arise from the bounds on hadronic electric dipole moments. Comparisons of the present and future sensitivities with both the direct LHC constraints and the indirect limits from D -meson physics are also presented.

1 Introduction

The recent discovery of a Higgs-like state by ATLAS [1] and CMS [2] opens up the exciting possibility to search for flavour-changing neutral current (FCNC) interactions involving the exchange of this new boson. Within the quark sector of the Standard Model (SM) such transitions are absent at tree level and suppressed at loop level both by the Glashow-Iliopoulos-Maiani mechanism and the small inter-generational mixing as encoded in the Cabibbo-Kobayashi-Maskawa (CKM) matrix. The resulting SM branching ratios are largest for top-quark decays, but even in this case remain utterly small, amounting to $\text{Br}(t \rightarrow ch) \simeq 3 \cdot 10^{-15}$ and $\text{Br}(t \rightarrow uh) \simeq 2 \cdot 10^{-17}$ [3] (see also [4]). Finding evidence for FCNC Higgs-boson decays taking place at measurable rates, would hence inevitably imply physics beyond the SM (BSM), presumably related to new dynamics close to the TeV scale.

As a matter of fact, various well-motivated BSM scenarios such as two Higgs doublet models [5], supersymmetric extensions of the SM [6, 7], warped extra dimensions [8, 9] or models based on the idea of partial compositeness [10] can give rise to additional contributions to the $t \rightarrow c(u)h$ rates that are orders of magnitude in excess of the SM expectations. The relevant interactions can be parameterised by the following Lagrangian

$$\mathcal{L} \supset - \sum_{q=c,u} (Y_{tq} \bar{t}_L q_R h + Y_{qt} \bar{q}_L t_R h) + \text{h.c.}, \quad (1.1)$$

where the couplings Y_{tq} and Y_{qt} are in general complex, L and R indicate whether the quarks are left-handed or right-handed and h is the physical Higgs-boson field. Irrespectively of

the underlying dynamics, the above FCNC Higgs-boson couplings can be probed directly at the LHC by measuring tree-level decays of the top quark [11–15] or indirectly through precision measurements of low-energy observables [16] if these receive corrections from loops involving the top quark and the Higgs boson.

The main goal of this paper is to derive and to compare the direct and indirect constraints that apply in the case of the $t \rightarrow c(u)h$ transitions. Our particular focus will thereby be on CP-violating observables such as electric dipole moments (EDMs). In the context of lepton-flavour violation the contributions to EDMs from complex flavour-violating couplings of the Higgs boson have received notable attention lately (see e.g. [16–18]), while, to the best of our knowledge, the bounds on the tuh couplings (1.1) that arise from the EDM of the neutron have only been considered in [16]. Our work refines this analysis and extends it to the case of the tch interactions. In both cases we resum large leading logarithms, which in the latter case requires to perform a two-loop calculation, while considering one-loop effects is sufficient in the former case. We also present a systematic study of direct as well as indirect CP violation in the D -meson sector that is induced by the FCNC Higgs-boson couplings (1.1). These calculations allow us to derive model-independent bounds on certain combinations of the flavour-changing couplings Y_{tq} and Y_{qt} that apply to all BSM scenarios where the observables under consideration receive the dominant contribution from FCNC interactions involving the Higgs boson and the top quark.

The outline of this article is as follows. In Section 2 we deduce model-independent constraints on the tch and tuh couplings that arise from direct and indirect probes. Our conclusions are presented in Section 3. In Appendix A we estimate the size of electroweak corrections to hadronic EDMs, while in Appendix B indirect bounds arising from FCNCs involving down-type quarks are studied. Matching corrections to the Weinberg operator related to the exchange of a neutral and a charged scalar are presented in Appendix C.

2 Model-independent analysis

Below we will derive model-independent bounds on the tch and tuh couplings. In Section 2.1 will review the existing limits that are provided by the current LHC data. The expected future sensitivity that may arise from a high-luminosity upgrade of the LHC (HL-LHC) is also discussed. The calculations needed to derive the indirect constraints that result from the non-observation of hadronic EDMs are presented in Sections 2.2 and 2.3. The limits that stem from D -meson physics are examined in Section 2.4. Like in the case of the collider bounds we will also discuss the future prospects of the indirect constraints.

2.1 LHC constraints

In the presence of (1.1) and assuming that the branching ratio of $t \rightarrow bW$ is close to unity, one obtains for the $t \rightarrow c(u)h$ branching fractions (see e.g. [19])

$$\begin{aligned} \text{Br}(t \rightarrow qh) &\simeq \frac{\sqrt{2}}{4G_F m_W^2} \frac{(1 - x_{h/t})^2 x_{W/t}}{(1 - x_{W/t})^2 (1 + 2x_{W/t})} \left[|Y_{tq}|^2 + |Y_{qt}|^2 + \frac{4\sqrt{x_{q/t}}}{1 - x_{h/t}} \text{Re}(Y_{tq} Y_{qt}) \right] \\ &\simeq 0.26 \left[|Y_{tq}|^2 + |Y_{qt}|^2 \right], \end{aligned} \quad (2.1)$$

with $q = c, u$. Here $x_{a/b} \equiv m_a^2/m_b^2$ and we have employed $G_F = 1.167 \cdot 10^{-5} \text{ GeV}^{-2}$ as well as the pole masses $m_t = 173.2 \text{ GeV}$, $m_h = 125 \text{ GeV}$ and $m_W = 80.4 \text{ GeV}$ to obtain the final result. Furthermore, the numerically subleading term proportional to $\text{Re}(Y_{tq}Y_{qt})$ in the first line of (2.1) has been neglected.

Recently the CMS collaboration performed a search for $t \rightarrow qh$ which is based on 19.5 fb^{-1} of $\sqrt{s} = 8 \text{ TeV}$ data and uses a combination of multilepton and diphoton plus lepton final states [12]. These measurements result in the following 95% confidence level (CL) upper limits

$$\text{Br}(t \rightarrow ch) < 0.56\%, \quad \text{Br}(t \rightarrow uh) < 0.45\%. \quad (2.2)$$

where the former bound has been derived in [12], while the latter exclusion has been found in [15]. The quoted bounds translate into the limits

$$\sqrt{|Y_{tc}|^2 + |Y_{ct}|^2} \lesssim 0.14, \quad \sqrt{|Y_{tu}|^2 + |Y_{ut}|^2} \lesssim 0.13, \quad (2.3)$$

on the tch and tuh couplings entering (1.1). Bounds complementary to those given in (2.2) have been obtained by the ATLAS collaboration [13] and in [14]. Using a data sample corresponding to an integrated luminosity of 20.3 fb^{-1} at $\sqrt{s} = 8 \text{ TeV}$ and 4.7 fb^{-1} at $\sqrt{s} = 7 \text{ TeV}$, ATLAS utilised the $h \rightarrow \gamma\gamma$ channel to arrive at the 95% CL bound $\text{Br}(t \rightarrow ch) < 0.83\%$, which implies $\sqrt{|Y_{tc}|^2 + |Y_{ct}|^2} \lesssim 0.18$. The analysis [14] finally infers a limit $\text{Br}(t \rightarrow ch) < 2.7\%$ at 95% CL by performing a recast of a CMS anomalous multilepton search which utilises 4.7 fb^{-1} of $\sqrt{s} = 7 \text{ TeV}$ data [20]. The corresponding limit on the FCNC top-quark couplings reads $\sqrt{|Y_{tc}|^2 + |Y_{ct}|^2} \lesssim 0.32$.

Constraints on the interactions in (1.1) also derive from vector boson plus Higgs production as recently emphasised in [15]. Employing the CMS data samples data corresponding to integrated luminosities of 19.5 fb^{-1} at $\sqrt{s} = 8 \text{ TeV}$ and 5.0 fb^{-1} at $\sqrt{s} = 7 \text{ TeV}$ [22], one obtains $\text{Br}(t \rightarrow ch) \lesssim 1.2\%$ and $\text{Br}(t \rightarrow uh) \lesssim 0.7\%$ corresponding to $\sqrt{|Y_{tc}|^2 + |Y_{ct}|^2} \lesssim 0.21$ and $\sqrt{|Y_{tu}|^2 + |Y_{ut}|^2} \lesssim 0.16$ at 95% CL [15]. Additional information on the FCNC top-Higgs couplings can also be gained from the non-observation of anomalous single top-quark production (see e.g. [16]). Recasting the CMS multilepton search which employs 19.5 fb^{-1} of data collected at $\sqrt{s} = 8 \text{ TeV}$ [11], the analysis [15] finds the 95% CL upper limits $\text{Br}(t \rightarrow ch) \lesssim 1.5\%$ and $\text{Br}(t \rightarrow uh) \lesssim 1.0\%$, which give rise to the bounds $\sqrt{|Y_{tc}|^2 + |Y_{ct}|^2} \lesssim 0.23$ and $\sqrt{|Y_{tu}|^2 + |Y_{ut}|^2} \lesssim 0.19$. Notice that the latter limits are competitive with the one found in (2.3) from $t \rightarrow jh$ decays.

At a HL-LHC with an integrated luminosity of 3000 fb^{-1} at $\sqrt{s} = 14 \text{ TeV}$, the bounds on flavour-changing top-quark decays are expected to improve significantly. For instance, the study [23] quotes the following 95% CL upper limit

$$\text{Br}(t \rightarrow qh) \lesssim 2.0 \cdot 10^{-4}, \quad (2.4)$$

based on the multilepton sample, i.e. $t\bar{t} \rightarrow bW + qh \rightarrow b\ell\nu + q\ell\ell X$. A slightly weaker bound of $\text{Br}(t \rightarrow qh) \lesssim 5 \cdot 10^{-4}$ at 95% CL [23] seems to be attainable in the diphoton channel $t\bar{t} \rightarrow bW + qh \rightarrow b\ell\nu + q\gamma\gamma$ (see also [24] for a recent study). Using (2.1) the HL-LHC projection (2.4) leads to

$$\sqrt{|Y_{tq}|^2 + |Y_{qt}|^2} \lesssim 2.8 \cdot 10^{-2}. \quad (2.5)$$

This limit sets the future standard that any other constraint on the FCNC couplings (1.1) has to be compared to. Further recent collider studies of flavour-changing Higgs-boson couplings to the top quark can be found in [25–28].

2.2 EDM constraints on top-charm-Higgs couplings

Integrating out the top quark and the Higgs boson at a scale $\mu_t = \mathcal{O}(m_t)$, the FCNC couplings (1.1) lead to effective interactions of the form

$$\begin{aligned} \mathcal{L}_{\text{eff}} \supset & -d_q(\mu_t) \frac{i}{2} \bar{q} \sigma^{\mu\nu} \gamma_5 q F_{\mu\nu} - \tilde{d}_q(\mu_t) \frac{ig_s(\mu_t)}{2} \bar{q} \sigma^{\mu\nu} T^a \gamma_5 q G_{\mu\nu}^a \\ & - w(\mu_t) \frac{1}{3} f^{abc} G_{\mu\sigma}^a G_\nu^{b,\sigma} \tilde{G}^{c,\mu\nu}, \end{aligned} \quad (2.6)$$

where $q = u, d$, while $\tilde{G}^{a,\mu\nu} = \frac{1}{2} \epsilon^{\mu\nu\alpha\beta} G_{\alpha\beta}^a$ is the dual field-strength tensor of QCD, with $\epsilon^{\mu\nu\lambda\rho}$ the fully anti-symmetric Levi-Civita tensor ($\epsilon^{0123} = 1$). T^a are the colour generators normalised as $\text{Tr}(T^a T^b) = \delta^{ab}/2$.

The initial condition $\tilde{d}_c(\mu_t)$ of the charm-quark chromoelectric dipole moment (CEDM) is obtained from the one-loop diagram shown on the left-hand side of Figure 1. A straightforward calculation gives

$$\tilde{d}_c(\mu_t) = \frac{1}{32\pi^2} \frac{m_t}{m_h^2} f_1(x_{t/h}) \text{Im}(Y_{tc} Y_{ct}), \quad (2.7)$$

with

$$f_1(x) = \frac{x-3}{(x-1)^2} + \frac{2}{(x-1)^3} \ln x. \quad (2.8)$$

Our result (2.7) agrees with the findings of [29, 30]. It furthermore resembles the expressions given in [16, 18] after a suitable replacement of charge factors and couplings as well as taking the limit $x_{t/h} \rightarrow 0$. Notice that $\tilde{d}_c(\mu_t)$ is enhanced by the top-quark mass which provides the necessary chirality flip to generate a dipole transition.

Finding the matching condition $w(\mu_t)$ of the Weinberg operator requires the computation of two-loop diagrams in the full theory. An example graph is display on the right in Figure 1. Setting the charm-quark mass to zero, we obtain the compact expression

$$w(\mu_t) = \frac{g_s^3(\mu_t)}{(32\pi^2)^2} \frac{1}{m_h^2} f_2(x_{t/h}) \text{Im}(Y_{tc} Y_{ct}), \quad (2.9)$$

with

$$f_2(x) = -\frac{x^2 - 5x - 2}{3(x-1)^3} - \frac{2x}{(x-1)^4} \ln x. \quad (2.10)$$

To cross-check our result (2.9) we have also calculated the two-loop contribution to the neutron EDM from neutral and charged Higgs-boson exchange finding perfect agreement with the original computations [36, 37] (see also [30] for a recent discussion). For completeness we present the corresponding analytic results in Appendix C.

The Weinberg operator in (2.6) mixes under renormalisation into the quark EDMs and CEDMs, while the opposite is not the case. However, the coefficient w receives a finite

Figure 1. Left: One-loop contribution to the CEDM of the charm quark. Right: Example of a two-loop contribution to the Weinberg operator. The black squares in both graphs indicate the tc couplings introduced in (1.1).

matching correction at each heavy-quark threshold from the corresponding CEDM. At the one-loop level, one finds [29, 31, 32]

$$\delta w(m_c) = \frac{g_s^3(m_c)}{32\pi^2} \frac{\tilde{d}_c(m_c)}{m_c}, \quad (2.11)$$

when the charm quark is integrated out. Here $m_c = 1.3 \text{ GeV}$ is the $\overline{\text{MS}}$ charm-quark mass. The relevant diagrams are given in Figure 2. The phenomenological importance of the charm-quark threshold correction (2.11) has been stressed recently in [35] (see also [30, 33, 34] for related discussions of the relevance of the top-quark and bottom-quark threshold corrections). Notice that the initial condition $w(\mu_t)$ is compared to the threshold correction $\delta w(m_c)$ suppressed by a factor of $m_c/m_t \simeq 1/125$. As we will see below this implies that the contributions to the hadronic EDMs arising from the Weinberg operator are fully dominated by infrared physics associated to scales of the order of the charm-quark mass.

The combined effects of the finite shift (2.11) in $w(m_c)$ and the subsequent renormalisation group (RG) evolution (see e.g. [38]) to the hadronic scale $\mu_H = 1 \text{ GeV}$ will induce non-zero contributions also for the EDMs and CEDMs of the down quark and up quark. Performing 5-flavour, 4-flavour and 3-flavour running, we obtain in leading-logarithmic (LL) approximation

$$\begin{aligned} \frac{d_d(\mu_H)}{e} &= 2.3 \cdot 10^{-8} \tilde{d}_c(m_t) + 1.0 \cdot 10^{-4} \text{ GeV } w(m_t), \\ \frac{d_u(\mu_H)}{e} &= -2.1 \cdot 10^{-8} \tilde{d}_c(m_t) - 9.1 \cdot 10^{-5} \text{ GeV } w(m_t), \\ \tilde{d}_d(\mu_H) &= 1.8 \cdot 10^{-6} \tilde{d}_c(m_t) + 7.0 \cdot 10^{-4} \text{ GeV } w(m_t), \\ \tilde{d}_u(\mu_H) &= 8.2 \cdot 10^{-7} \tilde{d}_c(m_t) + 3.1 \cdot 10^{-4} \text{ GeV } w(m_t), \\ w(\mu_H) &= 1.7 \cdot 10^{-2} \text{ GeV}^{-1} \tilde{d}_c(m_t) + 0.41 w(m_t), \end{aligned} \quad (2.12)$$

where we have identified $\mu_t = m_t = 163.3 \text{ GeV}$. The given numerical coefficients correspond to $\alpha_s(m_t) = 0.109$, $\alpha_s(m_b) = 0.213$, $\alpha_s(m_c) = 0.319$, $\alpha_s(\mu_H) = 0.362$, $m_d(\mu_H) = 5.4 \cdot 10^{-3} \text{ GeV}$ and $m_u(\mu_H) = 2.4 \cdot 10^{-3} \text{ GeV}$. We recall that the RG evolution tends to

Figure 2. One-loop diagrams leading to a correction to the Weinberg operator at the charm-quark threshold. The black square denotes the insertion of the charm-quark CEDM.

suppress the coefficients $d_q(\mu)$, $\tilde{d}_q(\mu)$ and $w(\mu)$. Terminating the running at $\mu_H = 1$ GeV rather than at the charm-quark threshold $m_c = 1.3$ GeV hence leads to weaker constraints on $|\text{Im}(Y_{tc}Y_{ct})|$. The same is true in the case of the EDM constraints on the tuh couplings that will be discussed in the next subsection.

In terms of $d_q(\mu_H)$, $\tilde{d}_q(\mu_H)$ and $w(\mu_H)$ the neutron EDM [39] takes the following form

$$\begin{aligned} \frac{d_n}{e} = (1.0 \pm 0.5) \left\{ 1.4 \left[\frac{d_d(\mu_H)}{e} - 0.25 \frac{d_u(\mu_H)}{e} \right] + 1.1 \left[\tilde{d}_d(\mu_H) + 0.5 \tilde{d}_u(\mu_H) \right] \right\} \\ + (22 \pm 10) \cdot 10^{-3} \text{ GeV } w(\mu_H), \end{aligned} \quad (2.13)$$

while for deuteron [40] one has

$$\begin{aligned} \frac{d_D}{e} = (0.5 \pm 0.3) \left[\frac{d_d(\mu_H)}{e} + \frac{d_u(\mu_H)}{e} \right] + \left[5_{-3}^{+11} + (0.6 \pm 0.3) \right] (\tilde{d}_d(\mu_H) - \tilde{d}_u(\mu_H)) \\ - (0.2 \pm 0.1) (\tilde{d}_d(\mu_H) + \tilde{d}_u(\mu_H)) + (22 \pm 10) \cdot 10^{-3} \text{ GeV } w(\mu_H). \end{aligned} \quad (2.14)$$

Inserting the results (2.12) into the general expression (2.13) for the EDM of the neutron, we then find

$$\left| \frac{d_n}{e} \right| = \left| 2.0 \cdot 10^{-4} \tilde{d}_c(m_t) + 5.4 \cdot 10^{-3} \text{ GeV } w(m_t) \right| \simeq 5.8 \cdot 10^{-23} \text{ cm } |\text{Im}(Y_{tc}Y_{ct})|. \quad (2.15)$$

In order to obtain conservative bounds on the tch couplings, we have set the numerical coefficients (1.0 ± 0.5) and $(22 \pm 10) \cdot 10^{-3} \text{ GeV}$ in (2.13) to 0.5 and $12 \cdot 10^{-3} \text{ GeV}$. The final result in (2.15) also holds for $|d_D/e|$ which implies that in the case of a non-zero charm-quark CEDM the contribution to (2.14) from the Weinberg operator is the by far largest correction. Notice furthermore that the contribution from the Weinberg operator itself is almost entirely due to the threshold correction $\delta w(m_c)$ with the initial condition $w(m_t)$ amounting to a relative effect of less than 1‰ only.

The present 90% CL bound on the EDM of the neutron reads [41]

$$\left| \frac{d_n}{e} \right| < 2.9 \cdot 10^{-26} \text{ cm}, \quad (2.16)$$

while a limit on $|d_D/e|$ does not exist at the moment. Using (2.15) the latter bound can be translated into the inequality

$$|\text{Im}(Y_{tc}Y_{ct})| \lesssim 5.0 \cdot 10^{-4}. \quad (2.17)$$

The expected future sensitivities on the EDM of the neutron is $|d_n/e| \lesssim 10^{-28}$ cm [42], whereas in the case of deuteron even a limit of

$$\left| \frac{d_D}{e} \right| \lesssim 10^{-29} \text{ cm}, \quad (2.18)$$

might be achievable in the long run [43]. Such a precision would allow to set a bound of

$$|\text{Im}(Y_{tc}Y_{ct})| \lesssim 1.7 \cdot 10^{-7}. \quad (2.19)$$

A factor 300 improvement of the current bound (2.16) on the neutron EDM would instead result in $|\text{Im}(Y_{tc}Y_{ct})| \lesssim 1.7 \cdot 10^{-6}$.

2.3 EDM constraints on top-up-Higgs couplings

In the case of the tuh couplings the calculation of the EDM of the neutron and deuteron is simplified by the fact that a up-quark EDM and CEDM is already generated from integrating out the top quark and the Higgs boson. The initial condition $d_u(\mu_t)$ of the up-quark EDM is obtained from a one-loop diagram similar to the graph on the left-hand side of Figure 1, but with the gluon replaced by a photon. In accordance with the literature [16, 18, 29, 30], we find

$$d_u(\mu_t) = \frac{Q_u e m_t}{32\pi^2 m_h^2} f_1(x_{t/h}) \text{Im}(Y_{tu}Y_{ut}). \quad (2.20)$$

Here $Q_u = 2/3$ denotes the electric charge of the up quark and the loop function f_1 has been given in (2.8). The result for the matching corrections $\tilde{d}_u(\mu_t)$ and $w(\mu_t)$ are readily obtained from (2.7) and (2.9) by the replacements $Y_{tc} \rightarrow Y_{tu}$ and $Y_{ct} \rightarrow Y_{ut}$ of the FCNC Higgs-boson couplings. Since $w(\mu_t)$ has numerically a negligible impact on the hadronic EDMs, we set this contribution to zero in what follows.

At LL accuracy the up-quark EDM and CEDM at the hadronic scale are given in terms of the high-scale coefficients by

$$\frac{d_u(\mu_H)}{e} = 0.82 \frac{d_u(m_t)}{e} - 0.46 \tilde{d}_u(m_t), \quad \tilde{d}_u(\mu_H) = 0.90 \tilde{d}_u(m_t), \quad (2.21)$$

while $d_d(\mu_H) = \tilde{d}_d(\mu_H) = w(\mu_H) = 0$ at the one-loop order. Inserting these results into (2.13), we arrive at

$$\left| \frac{d_n}{e} \right| = \left| -0.14 \frac{d_u(m_t)}{e} + 0.33 \tilde{d}_u(m_t) \right| \simeq 6.7 \cdot 10^{-20} \text{ cm } |\text{Im}(Y_{tu}Y_{ut})|, \quad (2.22)$$

in the case of the neutron and at

$$\left| \frac{d_D}{e} \right| = \left| 0.66 \frac{d_u(m_t)}{e} - 2.54 \tilde{d}_u(m_t) \right| \simeq 6.0 \cdot 10^{-19} \text{ cm } |\text{Im}(Y_{tu}Y_{ut})|, \quad (2.23)$$

for deuteron. In order to obtain these semi-analytic expressions we have set the factor (1.0 ± 0.5) entering the expression for d_n/e to 0.5 and chose the multiplicative factors in (2.14) such that the cancellation between the up-quark EDM and CEDM in d_D/e is maximised. Using the formulas (2.22) and (2.23) to bound $|\text{Im}(Y_{tu}Y_{ut})|$ results therefore in conservative upper limits.

It follows that the existing limit (2.16) on the neutron EDM already give rise to the very strong limit

$$|\text{Im}(Y_{tu}Y_{ut})| \lesssim 4.3 \cdot 10^{-7}. \quad (2.24)$$

This bound is weaker by a factor of around 10 than the limit quoted in [16]. This discrepancy can be resolved by noticing that in the latter article only the contribution of d_u to d_n is included, large logarithms are not resummed and a naive estimate of the neutron EDM is utilised. All these approximations tend to enhance the impact of the tuh couplings (1.1) on the prediction of d_n .

By achieving the sensitivity (2.18) on the EDM of deuteron this bound would further improve, leading to

$$|\text{Im}(Y_{tu}Y_{ut})| \lesssim 1.7 \cdot 10^{-11}. \quad (2.25)$$

Neutron EDM measurements, on the other hand, are expected to reach a sensitivity of $|\text{Im}(Y_{tu}Y_{ut})| \lesssim 1.5 \cdot 10^{-9}$ within a time scale of a few years.

2.4 Constraints from FCNC charm-up transitions

Certain combinations of the couplings (1.1) such as the product $Y_{ut}^*Y_{tc}$ can be probed by D -meson physics. In what follows we will consider both CP violation in the $\Delta C = 1$ and $\Delta C = 2$ sectors.

In the former case a useful constraint arises from the difference ΔA_{CP} between the two direct CP asymmetries in $D \rightarrow K^+K^-$ and $D \rightarrow \pi^+\pi^-$. This observable can receive sizeable corrections from the chromomagnetic dipole operator

$$Q_8 = \frac{g_s}{(4\pi)^2} m_c \bar{u}_L \sigma^{\mu\nu} T^a c_R G_{\mu\nu}^a, \quad (2.26)$$

and its chirality-flipped partner \tilde{Q}_8 obtained by $L \leftrightarrow R$. These operators appear in the effective $\Delta C = 1$ Lagrangian as follows $\mathcal{L}_{\text{eff}} \supset -4G_F/\sqrt{2}(C_8 Q_8 + \tilde{C}_8 \tilde{Q}_8)$. The initial condition of the Wilson coefficient of Q_8 is determined from a one-loop diagram similar to the graph on the left-hand side of Figure 1, but with the outgoing charm quark replaced by an up quark. We find

$$\Delta C_8(\mu_t) = \frac{\sqrt{2}}{16G_F} \frac{m_t}{m_c} \frac{Y_{ut}^* Y_{tc}}{m_h^2} f_1(x_{t/h}), \quad (2.27)$$

with f_1 given in (2.8). The result for the new-physics contribution $\Delta \tilde{C}_8(\mu_t)$ is obtained from the above expression by the interchange $Y_{ut} \leftrightarrow Y_{tc}$.

Since the charm quark is too heavy for chiral perturbation theory to be applicable and too light for heavy-quark effective theory to be trusted, precise theoretical predictions in

D -meson decays are notoriously difficult. As a result the bounds derived below are plagued by $\mathcal{O}(1)$ uncertainties, which should be clearly kept in mind. Following [44] we write

$$|\Delta A_{\text{CP}}| \simeq 0.94 |\text{Im}(\Delta C_8(m_t))| \simeq \frac{|\text{Im}(Y_{ut}^* Y_{tc})|}{4.0 \cdot 10^{-4}} \%, \quad (2.28)$$

where for simplicity we only have incorporated the contribution from Q_8 . In order to set an upper bound on $|\text{Im}(Y_{ut}^* Y_{tc})|$, we will require that

$$|\Delta A_{\text{CP}}| \lesssim 1\%. \quad (2.29)$$

which in view of the present world average $\Delta A_{\text{CP}} = -(0.33 \pm 0.12)\%$ [45] seems like a conservative choice. It follows that

$$|\text{Im}(Y_{ut}^* Y_{tc})| \lesssim 4.0 \cdot 10^{-4}. \quad (2.30)$$

Since the future sensitivity of $|\Delta A_{\text{CP}}|$ to the tch and tuh couplings is largely dependent on theoretical progress concerning the understanding of hadronic physics, which is hard to predict, we do not attempt to make any projection in this case.

In the presence of (1.1) the D - \bar{D} mixing amplitude receive contributions from box diagrams with Higgs-boson and top-quark exchange. The phenomenologically most important contribution comes from the mixed-chirality operator

$$Q_4 = (\bar{c}_L u_R)(\bar{c}_R u_L), \quad (2.31)$$

due to its large anomalous dimension and a chiral enhancement of its hadronic matrix element. Normalising the associated effective Lagrangian as $\mathcal{L}_{\text{eff}} \supset -4G_F/\sqrt{2} C_4 Q_4$, we find in agreement with [16] the matching correction

$$\Delta C_4(\mu_t) = \frac{1}{32\pi^2} \frac{\sqrt{2}}{4G_F} \frac{f_3(x_{t/h})}{m_h^2} Y_{tc}^* Y_{ut}^* Y_{tu} Y_{ct}, \quad (2.32)$$

with

$$f_3(x) = \frac{4x}{(x-1)^2} - \frac{2x^2 + 2x}{(x-1)^3} \ln x. \quad (2.33)$$

Allowing the new-physics contribution to saturate the experimental bounds on CP violation in D - \bar{D} mixing, one arrives at [46]

$$|\text{Im}(\Delta C_4(m_t))| \lesssim 3.3 \cdot 10^{-10}, \quad (2.34)$$

which corresponds to a bound of

$$\sqrt{|\text{Im}(Y_{tc}^* Y_{ut}^* Y_{tu} Y_{ct})|} \lesssim 4.1 \cdot 10^{-4}. \quad (2.35)$$

Note that in [16] a bound on $\sqrt{|Y_{tc}^* Y_{ut}^* Y_{tu} Y_{ct}|}$ has been derived which is a factor of about $\sqrt{5}$ weaker than the latter limit. This is a simple consequence of the fact (see e.g. [46]) that the constraint arising from CP violation in D -meson mixing is by a factor of 5 stronger than the bound coming from the CP-conserving measurements.

Observable	Coupling	Present bound	Future sensitivity
LHC searches	$\sqrt{ Y_{tc} ^2 + Y_{ct} ^2}$	0.14	$2.8 \cdot 10^{-2}$
	$\sqrt{ Y_{tu} ^2 + Y_{ut} ^2}$	0.13	$2.8 \cdot 10^{-2}$
d_n	$ \text{Im}(Y_{tc}Y_{ct}) $	$5.0 \cdot 10^{-4}$	$1.7 \cdot 10^{-6}$
	$ \text{Im}(Y_{tu}Y_{ut}) $	$4.3 \cdot 10^{-7}$	$1.5 \cdot 10^{-9}$
d_D	$ \text{Im}(Y_{tc}Y_{ct}) $	—	$1.7 \cdot 10^{-7}$
	$ \text{Im}(Y_{tu}Y_{ut}) $	—	$1.7 \cdot 10^{-11}$
ΔA_{CP}	$ \text{Im}(Y_{ut}^*Y_{ct}) $	$4.0 \cdot 10^{-4}$	—
$D-\bar{D}$ mixing	$\sqrt{ \text{Im}(Y_{tc}^*Y_{ut}^*Y_{tu}Y_{ct}) }$	$4.1 \cdot 10^{-4}$	$1.3 \cdot 10^{-4}$

Table 1. Summary of the most powerful constraints on the tqh couplings with $q = c, u$. To obtain the 95% CL upper limits we have assumed a Higgs-boson mass $m_h = 125$ GeV and neglected other possible contributions to the processes under considerations beyond those arising from (1.1).

Future measurements of CP violation in $D-\bar{D}$ mixing at LHCb [47] and Belle II [48] are expected to improve the current bound (2.34) by at least a factor of 10. Such an improvement would result in

$$\sqrt{|\text{Im}(Y_{tc}^*Y_{ut}^*Y_{tu}Y_{ct})|} \lesssim 1.3 \cdot 10^{-4}, \quad (2.36)$$

if one again allows the new-physics contribution (2.32) to saturate the future limit on CP violation in the $\Delta C = 2$ sector.

2.5 Summary of constraints

In Table 1 we summarise the most stringent limits on the FCNC Higgs-boson couplings (1.1) arising from collider physics (see Section 2.1), hadronic EDMs (see Sections 2.2 and 2.3) and CP violation in D -meson physics (see Section 2.4). Whenever possible we give both the present bound and a projection of the future sensitivity.

3 Conclusions

The LHC discovery of the Higgs boson furnishes new opportunities in the search for physics beyond the SM. Since in the SM flavour-changing Higgs couplings to fermions are highly suppressed, discovering any evidence of a decay like $t \rightarrow ch$ would strongly suggest the existence of new physics not far above the TeV scale. In fact, both ATLAS and CMS have already provided their first limits on the $t \rightarrow c(u)h$ branching ratios (see e.g. [11–15]). While these recent results still allow for branching ratios in excess of around 0.5%, the searches for flavour-changing top-Higgs interactions will mature at the 14 TeV LHC and it is expected that the current limits on the $t \rightarrow c(u)h$ branching ratios can be improved by roughly two

order of magnitude. By achieving such a precision these searches would become sensitive to the (maximal) $t \rightarrow ch$ rates predicted in an assortment of new-physics scenarios [3, 5–10].

In this article we have emphasised the complementary between high- p_T and low-energy precision measurements in extracting information about the properties of the flavour-changing top-Higgs couplings. By considering a model-independent parameterisation of these interactions, we have obtained bounds on certain combinations of the tch and tuh couplings that derive from the measurements of hadronic EDMs and CP-violating observables in the D -meson sector. While the limits on the tuh interactions due to the neutron EDM and charm-quark physics have been previously considered [16], our constraints on the tch couplings are novel. The derivation of the latter bounds is based on a complete two-loop matching calculation and includes the resummation of large leading QCD logarithms by means of renormalisation group techniques. Given the model-independent character of our calculations, the derived limits can be used to constrain the parameter space of all beyond the SM scenarios where the considered quantities receive the dominant CP-violating contributions from flavour-changing top-Higgs interactions. The presented results hence should prove useful in monitoring the impact that further improved precision measurements of low-energy observable have in extracting information on the tch and tuh couplings.

Acknowledgments

We are grateful to Filippo Sala and Jure Zupan for clarifying discussions concerning their works [35] and [16], respectively. MG acknowledges partial support by the UK Science & Technology Facilities Council (STFC) under grant No. ST/G00062X/1. UH would like to thank the organisers of “The top-charm frontier at the LHC” for an entertaining workshop that renewed his interest in flavour-changing top-Higgs interactions. He also acknowledges the warm hospitality and support of the CERN theory division.

A Electroweak corrections to hadronic EDMs

In the presence of the tch couplings (1.1) the EDM of the neutron and deuteron receive electroweak corrections at the two-loop level. The size of the induced effects can be estimated by inserting the effective charm-quark photon (gluon) interactions corresponding to d_c (\tilde{d}_c) into the two one-loop graphs in which the photon (gluon) is emitted from the internal charm-quark line, i.e. those with W -boson and would-be Goldstone boson exchange. Such a calculation leads to [49]

$$d_d(\mu_H) \simeq -\frac{\alpha}{4\pi} \frac{|V_{cd}|^2}{s_W^2} \frac{m_d m_c}{m_W^2} d_c(\mu_t) \ln x_{c/W}, \quad (\text{A.1})$$

in LL approximation. An analogue expression holds for $\tilde{d}_d(\mu_H)$. Here $|V_{cd}| \simeq 0.22$ denotes the relevant CKM matrix element and $s_W^2 \simeq 0.23$ is the sine of the weak mixing angle. Notice that d_d is chirally suppressed by both the down-quark and charm-quark mass which signals that (A.1) is formally a dimension-8 contribution.

Numerically, one finds from (2.13) that

$$\left| \frac{d_n}{e} \right| \simeq 3.2 \cdot 10^{-28} \text{ cm } |\text{Im}(Y_{tc}Y_{ct})|, \quad (\text{A.2})$$

where for simplicity we have used $\alpha = 1/137$, evaluated the quark masses m_d and m_c at the hadronic scale and left the logarithm in (A.1) unresummed. Comparing (A.2) to (2.15) we see that electroweak contributions to d_n/e can be ignored for all practical purposes, because they are by more than five orders of magnitude smaller than the QCD effects. The same statement also holds in the case of the EDM of deuteron. These findings agree with those of [35].

B FCNC transitions in the down-type quark sector

The tch couplings in (1.1) can also be probed by quark FCNC transitions in the down-type quark sector. Although the resulting constraints turn out to be not very restrictive, we will for completeness discuss as an example the inclusive $B \rightarrow X_s \gamma$ decay.

In the case of $B \rightarrow X_s \gamma$ one has to consider both the EDM and CEDM interactions in (2.6) as well as the magnetic dipole moment and chromomagnetic dipole moment of the charm quark:

$$\mathcal{L}_{\text{eff}} \supset -\mu_c(\mu_t) \frac{1}{2} \bar{c} \sigma^{\mu\nu} c F_{\mu\nu} - \tilde{\mu}_c(\mu_t) \frac{g_s(\mu_t)}{2} \bar{c} \sigma^{\mu\nu} T^a c G_{\mu\nu}^a. \quad (\text{B.1})$$

By employing the results of [50] we find that the new-physics contribution to the Wilson coefficient of the electromagnetic dipole operator

$$Q_7 = \frac{e}{(4\pi)^2} m_b \bar{s}_L \sigma^{\mu\nu} b_R F_{\mu\nu}, \quad (\text{B.2})$$

takes the form

$$\Delta C_7(\mu_t) \simeq \frac{m_c}{2e} \frac{V_{cs}^* V_{cb}}{V_{ts}^* V_{tb}} \left[\mu_c(\mu_t) - i d_c(\mu_t) (4 \ln x_{c/W} + 5) \right]. \quad (\text{B.3})$$

The expression for $\Delta C_8(\mu_t)$ which multiplies the chromomagnetic dipole operator Q_8 is obtained from (B.3) by the replacements $e \rightarrow 1$, $\mu_c(\mu_t) \rightarrow \tilde{\mu}_c(\mu_t)$ and $d_c(\mu_t) \rightarrow \tilde{d}_c(\mu_t)$. We see that to LL accuracy only the charm-quark EDM and CEDM contribute to $\Delta C_7(\mu_t)$ and $\Delta C_8(\mu_t)$, respectively. Numerically, the enhancement of the contribution of $d_c(\mu_t)$ ($\tilde{d}_c(\mu_t)$) with respect to $\mu_c(\mu_t)$ ($\tilde{\mu}_c(\mu_t)$) amounts to a factor of around 28. In our numerical analysis we therefore include only the LL terms. Since $\Delta C_8(\mu_t)$ enters the predictions for the branching ratio of $B \rightarrow X_s \gamma$ first at the next-to-leading logarithmic order, we neglect this contribution. Finally, we also identify $V_{cs}^* V_{cb} = -V_{ts}^* V_{tb}$, which holds to excellent approximation.

Using now (2.20), which also applies in the case of the charm quark, we obtain from (B.3) in LL accuracy

$$|\Delta C_7(m_t)| \simeq 2.1 \cdot 10^{-4} |\text{Im}(Y_{tc}Y_{ct})| \lesssim 1.0 \cdot 10^{-7}, \quad (\text{B.4})$$

where in order to arrive at the final result we have utilised the current bound (2.16) on the neutron EDM. This result should be compared to the present 90% CL limit

$$|\Delta C_7(m_t)| < 0.37, \quad (\text{B.5})$$

following from a global analysis of $b \rightarrow s\gamma, \ell^+\ell^-$ data [51]. Our bound is consistent with the result on the top-quark EDM $|d_t/e|$ derived in [33], but weaker by a factor of around $m_t/m_c \simeq 125$ than the limit on $|d_c/e|$ quoted in [35]. The estimate (B.4) shows clearly that indirect probes of the tch couplings via quark FCNC transitions in the down-type quark sector will never be able to compete with the constraints arising from hadronic EDMs.

C Two-loop matching corrections for the Weinberg operator

In this appendix we present the results for the matching corrections to the Weinberg operator resulting from Feynman diagrams involving the exchange of a neutral and a charged scalar. The expressions for the corresponding initial conditions have been calculated originally in the classic papers [36, 37] in terms of twofold Feynman parameter integrals. Below we will give analytic results for these integrals.

In the case of neutral scalar S^0 exchange, we parameterise the relevant interactions in the following way

$$\mathcal{L} \supset -Y_{qq} \bar{q}_L q_R S^0 + \text{h.c.} \quad (\text{C.1})$$

Performing the matching at a scale $\mu_{S^0} = \mathcal{O}(m_{S^0})$, we obtain for the initial condition of the Weinberg operator the result

$$w(\mu_{S^0}) = \frac{g_s^3(\mu_{S^0})}{(4\pi)^4} \frac{2}{m_q^2} \text{Im}(Y_{qq}^2) h(x_{q/S^0}), \quad (\text{C.2})$$

with

$$h(x) = \frac{2x^2 - 3x}{8(4x - 1)^2} - \frac{6x^3 - 5x^2 - x}{4(4x - 1)^3} \ln x + \frac{6x^4 - 6x^3 + 3x^2}{4(4x - 1)^3} \phi\left(\frac{1}{4x}\right). \quad (\text{C.3})$$

We note that our function $h(x_{q/S^0})$ corresponds to $h(m_q, m_{S^0})$ as defined in [37]. The function ϕ entering (C.2) stems from the two-loop scalar tadpole with two different masses. The corresponding analytic expression reads [52]

$$\phi(u) = \begin{cases} 4\sqrt{\frac{u}{1-u}} \text{Cl}_2(2\sin^{-1}(\sqrt{u})), & u \leq 1, \\ \frac{\frac{\pi^2}{3} - \ln^2(4u) + 2\ln^2\left(\frac{1}{2}\left[1 - \sqrt{1 - \frac{1}{u}}\right]\right) - 4\text{Li}_2\left(\frac{1}{2}\left[1 - \sqrt{1 - \frac{1}{u}}\right]\right)}{\sqrt{1 - \frac{1}{u}}}, & u > 1, \end{cases} \quad (\text{C.4})$$

where $\text{Cl}_2(u) = \text{Im}[\text{Li}_2(e^{iu})]$ denotes the Clausen function and Li_2 is the usual dilogarithm. In the limit of light or heavy internal quark the function (C.3) can be approximated by the corresponding Taylor expansion

$$h(x) \simeq \begin{cases} -\frac{x}{4} \left(\ln x + \frac{3}{2}\right), & x \rightarrow 0, \\ \frac{1}{16} \left(1 + \frac{1}{3x}\right), & x \rightarrow \infty. \end{cases} \quad (\text{C.5})$$

We stress that in order to obtain the correct result for $w(\mu_{S_0})$ in the case $x \rightarrow 0$, one has to take into account two-loop diagrams in the effective theory. The corresponding matrix element will cancel the $1/m_q^2$ dependence in (C.2), resulting in a vanishing initial condition of the Weinberg operator. Notice however that a non-zero coefficient $w(\mu_H)$ is induced through operator mixing and threshold corrections. Details on the RG-improved calculation of $w(\mu_H)$ in the case of $x \rightarrow 0$ can be found in Appendix B of [34].

The interactions relevant for the case of charged scalar S^+ exchange can be written as

$$\mathcal{L} \supset - (Y_{qq'} \bar{q}_L q'_R + Y_{q'q} \bar{q}_R q'_L) S^+ + \text{h.c.}, \quad (\text{C.6})$$

where q (q') denotes a up-type (down-type) quark. In this parametrisation the matching correction to the Wilson coefficient of the Weinberg operator takes the form

$$w(\mu_{S^+}) = \frac{g_s^3(\mu_{S^+})}{(4\pi)^4} \frac{2}{m_q m_{q'}} \text{Im} (Y_{qq'} Y_{q'q}^*) h'(x_{q/S^+}, x_{q'/S^+}), \quad (\text{C.7})$$

where

$$\begin{aligned} h'(y, z) = & \frac{y^4 - y^3(4z + 5) + y^2(6z^2 + 5z + 7) - y(4z^3 - 5z^2 + 10z + 3) + (z - 3)(z - 1)^2 z}{16 \left((1 - y - z)^2 - 4yz \right)^2} \\ & + \frac{y(-3(y^2 + 3y - 6)z^2 + (y^3 + 16y^2 - 9y - 8)z + (3y - 8)z^3 + (y - 1)^3 - z^4)}{4 \left((1 - y - z)^2 - 4yz \right)^3} \ln y \quad (\text{C.8}) \\ & + \frac{3y^2 z(-y^3 + y^2(z + 1) + y(z^2 - 4z + 1) - (z - 1)^2(z + 1))}{4 \left((1 - y - z)^2 - 4yz \right)^4} \psi \left(\frac{1}{y}, \frac{z}{y} \right) + (y \leftrightarrow z). \end{aligned}$$

In [37] the loop function corresponding to $h'(x_{q/S^+}, x_{q'/S^+})$ is denoted by $h'(m_q, m_{q'}, m_{S^+})$. The function ψ arises from the two-loop scalar tadpole integral involving three different mass scales. It is given by [52]

$$\psi(v, w) = \begin{cases} -2\sqrt{-\lambda^2} \left[\text{Cl}_2 \left(2 \cos^{-1} \left[\frac{-1+v+w}{2\sqrt{vw}} \right] \right) + \text{Cl}_2 \left(2 \cos^{-1} \left[\frac{1+v-w}{2\sqrt{v}} \right] \right) \right. \\ \quad \left. + \text{Cl}_2 \left(2 \cos^{-1} \left[\frac{1-v+w}{2\sqrt{w}} \right] \right) \right], & \lambda^2 \leq 0, \\ \lambda \left[\frac{\pi^2}{3} - \ln v \ln w \right. \\ \quad + 2 \ln \left(\frac{1}{2} [1 + v - w - \lambda] \right) \ln \left(\frac{1}{2} [1 - v + w - \lambda] \right) & \lambda^2 > 0, \\ \quad \left. - 2 \text{Li}_2 \left(\frac{1}{2} [1 + v - w - \lambda] \right) - 2 \text{Li}_2 \left(\frac{1}{2} [1 - v + w - \lambda] \right) \right], \end{cases} \quad (\text{C.9})$$

with $\lambda \equiv \sqrt{(1 - v - w)^2 - 4vw}$. Note that the result for $\lambda^2 \leq 0$ ($\lambda^2 > 0$) in (C.9) was obtained in the region $\sqrt{v} + \sqrt{w} \geq 1$ ($\sqrt{v} + \sqrt{w} \leq 1$). By permutation of the mass parameters it is however straightforward to find the analytic results in the remaining regions. In the

limit of infinitesimally small (large) mass m_q , the function $h'(y, z)$ behaves like

$$h'(y, z) \simeq \begin{cases} \frac{z^2 - 3z}{8(z-1)^2} + \frac{z}{4(z-1)^3} \ln z, & y \rightarrow 0, \\ \frac{1}{8} \left(1 - \frac{1}{z}\right), & y \rightarrow \infty. \end{cases} \quad (\text{C.10})$$

Notice that for $y \rightarrow 0$ one has $h'(y, z) \simeq z/8 f_1(z)$ with f_1 given in (2.8). The appearance of the loop function f_1 is not accidental, since the term in (C.7) proportional to $1/m_q$ has to cancel after including matrix elements in the effective theory. These complications are avoided if the calculation is performed with $m_q = 0$, as done in Section 2.2. In such a calculation all diagrams in the effective theory lead to scaleless integrals which evaluate to zero in dimensional regularisation. In consequence, the initial condition $w(\mu_{S^+})$ is then obtained directly from the two-loop graphs in the full theory.
