22 **Abstract**
23

24 A combined study using neutron diffraction, inelastic scattering and first principle
25 calculations describe cobalt with a very low formal oxidation state of (-I) in a slightly
26 distorted tetrahedral Co(-I)H₄-complex in BaH₂Mg₅[Co(-I)H₄]₂ and in the structurally related
27 RbH₂Mg₅[Co(-I)H₄ Ni(0)H₄]. This indicates that the electron “back donating” effect via the
28 polarisable hydride ions to the counter ions in the solid state hydrides, can be compared to
29 more conventional “back bonding” able to reduce the oxidation state down to -I. The hydrides
30 were synthesised by hot sintering of transition metal powders with corresponding binary
31 alkali- and alkaline earth hydrides. In the similarly synthesized SrH₂Mg₂[Co(I)H₅], cobalt is
32 formally +I-valent, showing a high sensitivity to differences in the counter ion framework,
33 which can also influence electrical properties.

42 **Introduction**
43

44 If electropositive alkali and alkaline earth metals are reacted under hydrogen with transition
45 metals (TM) to the right of group V, the TM is likely to form TM-hydrido complexes with the
46 valence electrons from the electropositive metals. The bonding in the complexes has mainly
47 an sd-electron character. This makes 4d- and 5d TM-hydrido complexes strong, since the soft
48 4d- and 5d orbitals are better suited to the very polarisable and soft hydride ions. The stability
49 of the corresponding ternary hydrides becomes too high for practical applications, in addition
50 these metals are prohibitively expensive. More interesting is the 3d TM-hydrido complexes.
51 The 3d-electrons are not so well suited to bonding with hydrogen and to stabilize the
52 complexes, help is needed from a strongly polarizing counter ion i. e. Mg²⁺.^{1,2} A much

3 investigated example is the Mg_2NiH_4 system. Several hundred papers have been written to
4 date and the system still attracts interest for possible hydrogen storage. In Mg_2NiH_4 nickel
5 forms an 18 electrons, tetrahedral formally zero-valent $[\text{Ni}(0)\text{H}_4]$ -complex, with the help of
6 the valence electrons from magnesium. However, the strongly polarizing Mg^{2+} has another
7 significant influence on the electronic structure of this type of hydrides. Without Mg in the
8 counterion lattice, the electronic structures of the complexes are very “molecular like” and the
9 bands can be easily identified with their molecular orbital counter parts, as they are essentially
10 flat in the electronic density of states (eDOS).² With the strongly polarizing Mg^{2+} ion the
11 bands become dispersed and overlapping. This implies unusual and interesting bonding
12 properties making Mg_2NiH_4 interesting also from a fundamental solid state physics
13 perspective. The central nickel atom is in an electron rich formal zero-valent d^{10} oxidation
14 state. Such low oxidation states usually require strong electron accepting ligands, which can
15 transfer some electron density from the central nickel atom by “back donation” to the ligand
16 orbitals. In the solid state polarizing Mg^{2+} ions can relieve some of this electron density via
17 the very polarisable hydride ion. This reduces the molecular character of the $[\text{Ni}(0)\text{H}_4]$ -
18 complex and makes the ternary hydride more stable, but also more metal like. We have
19 recently shown how subtle changes in the counter ion lattice have a profound influence on the
20 electron conductivity, switching it from a conductor to an insulator with the help of a stacking
21 fault in the lattice, that changes the band gap.³ The stabilizing influence of the Mg^{2+} ions is,
22 however, strong and the stability of Mg_2NiH_4 is still too high for any practical application to
23 have evolved. In an effort to reduce the stability, trials to partially substitute the Mg^{2+} ions
24 with less polarizing counter ions has been attempted.⁴ However, few hydrides based on 3d-
25 TM complexes have been synthesized without having magnesium as a counter ion limiting the
26 number of such hydrides found to date.

41
42
43 The purpose of the present paper was to investigate how hydrogen complexes
44 with the neighbouring transition metal cobalt reacted to substitutions of Mg^{2+} ions with softer
45 and less polarizing counter ions. A low formal oxidation state in a $[\text{Co}(-\text{I})\text{H}_4]$ -complex could
46 be stabilized in $\text{BaH}_2\text{Mg}_5[\text{Co}(-\text{I})\text{H}_4]_2$ with the help of more electropositive and less polarizing
47 Ba^{2+} ions. By substituting the Ba^{2+} ions with Rb^+ ions, the structure can essentially be retained
48 in $\text{RbH}_2\text{Mg}_5[\text{Co}(-\text{I})\text{H}_4 \text{Ni}(0)\text{H}_4]$ if a corresponding number of $[\text{Co}(-\text{I})\text{H}_4]$ -complexes are
49 substituted by $[\text{Ni}(0)\text{H}_4]$ -complexes. This indicates the importance of the electron count for
50 forming these hydrides. In $\text{SrH}_2\text{Mg}_2[\text{Co}(\text{I})\text{H}_5]$ the higher formal oxidation state of +I for
51 cobalt is maintained, when Mg^{2+} is partly substituted by with Sr^{2+} , which is not so soft as Ba^{2+}
52 and Rb^+ .

3 The electron dense complexes are hydrogen rich with interesting electron conductivity
4 properties related to how the lattice helps to relieve the high electron density in the
5 complexes. We believe that they are interesting enough to be studied in more detail and not
6 only for their high hydrogen contents.

11 **Experimental**

12 Synthesis

13 All starting materials and samples were handled inside a continuously purified argon filled
14 glove box. Heat treatment was done by placing pressed pellets of ground powders in
15 aluminium oxide tubes heated in stainless steel reactors placed in a tube furnace. The
16 temperature was monitored by contacting a thermocouple in a sealed stainless steel capillary
17 to the sample.
18
19

20 BaH_2 was made by reacting barium pieces from Sigma Aldrich to 573 K in 20 bar H_2
21 atmosphere overnight yielding white brittle pieces of BaH_2 . Mg_2CoH_5 was made by heat
22 treatment of pelletized MgH_2 and Co metal powders in the molar ratio 2:1 in 70 bar of H_2 at
23 773 K for 18 hours, resulting in black Mg_2CoH_5 .
24
25

26 Mg_2NiH_4 was produced by reacting pulverized Mg_2Ni alloy in a 40 bar H_2 atmosphere at 623
27 K. The hydride was cycled five times by releasing and restoring the hydrogen pressure over a
28 period of 8 hours to obtain a fully hydrided brown sample.
29
30

31 $BaH_2Mg_5[CoH_4]_2$ was made by mixing BaH_2 , Mg_2CoH_5 and MgH_2 in the molar ratio 1:2:1
32 using a pestle and mortar. The powder mixture was pelletized and heat treated in 70 bar H_2 at
33 833 K for 18 hours. The resulting product was a single phase black powder.
34
35

36 $RbH_2Mg_5[CoH_4][NiH_4]$ was made by mixing Rb, Mg_2CoH_5 , Mg_2NiH_4 and MgH_2 in the molar
37 ratio 1:1:1:1 using a pestle and mortar. The powder was pelletized and heat treated in 70 bar
38 H_2 at 773 K for 18 hours. The resulting product was a single phase dark purple powder.
39
40

41 $Ba_{0.5}Rb_{0.5}H_2Mg_5[CoH_4]_{1.5}[NiH_4]_{0.5}$ was prepared in the same way as $RbH_2Mg_5[CoH_4][NiH_4]$
42 to yield a single phase black powder.
43
44

45 $SrH_2Mg_2[CoH_5]$ was made by mixing powders of SrH_2 and MgH_2 and Co powder in the molar
46 ratio 1:2:1. The powder mixture was ground to a fine powder using a pestle and mortar and
47 pelletized and heat treated in 70 bar H_2 at 815 K for 18 hours. The resulting product was an
48 almost single phase black powder. To establish the optimum reaction conditions and reactant
49 ratios given above, a rather time consuming trial and error procedure was required, where the
50 reaction conditions were varied and after each run a small sample was removed for XRD

analysis. To produce samples for neutron diffraction, deuterated analogues were produced using the corresponding deuterides and D₂ gas.

Structural investigations

X-ray diffraction patterns were obtained on a Panalytical X'pert pro powder diffractometer equipped with a germanium [111] monochromator ($\lambda=1.540598 \text{ \AA}$). Indexing of the unit cells were performed using the TREOR⁵ feature in the software Panalytical Highscore Plus. From systematic extinctions, the unit cell of BaH₂Mg₅[CoH₄]₂ was assigned to the space group *Immm* (71) by choosing the highest symmetry body centred space group. The unit cell was then refined in Panalytical Highscore Plus by least squares with resulting refined lattice parameters $a=7.392(2) \text{ \AA}$, $b=11.602(4) \text{ \AA}$, $c=4.6265(9) \text{ \AA}$. For RbH₂Mg₅[CoH₄][NiH₄], the lattice parameters were refined to $a=7.345(6) \text{ \AA}$, $b=11.877(8) \text{ \AA}$ and $c=4.703(3) \text{ \AA}$ and the structure was also initially assigned to the space group *Immm* (71). The initial structures were solved in FOX⁶ and the metal atom parameters were refined in Fullprof2000.

The least squares refinement of RbH₂Mg₅[CoH₄][NiH₄] indicated a lower symmetry and the space group had to be changed to *Imm2* (44), the final agreement factors were $R_{wp}=0.0312$ and $R_p=0.0207$ for the X-ray structure refinement.

The diffraction pattern for SrH₂Mg₂[CoH₅] was indexed with a monoclinic cell with lattice parameters $a=7.818(2) \text{ \AA}$, $b=4.462(1) \text{ \AA}$, $c=6.640(2) \text{ \AA}$ and $\beta=91.27(2)^\circ$ and the space group *C12/m1* (12) was assigned from extinction criteria and choosing the highest symmetry.

To elucidate the hydrogen positions, neutron powder patterns were obtained from the corresponding deuterides at the time-of-flight instrument GEM at ISIS using a sealed cylindrical $\phi=5 \text{ mm}$ vanadium sample holder.

The initial deuterium positions were obtained using simulated annealing in FOX⁶ keeping the metal positions fixed. The full structure refinement was performed by least squares refinement in GSAS⁷.

The unit cell for BaH₂Mg₅[CoD₄]₂ was refined to $a=7.39919 \text{ \AA}$, $b=11.570691 \text{ \AA}$ and $c=4.622355 \text{ \AA}$, slightly smaller than the hydride indicating anharmonic hydrogen vibrations that are commonly observed in these types of hydrides. $R_{wp}=0.0223$ and $R_p=0.0165$ for the full structure refinement. The structure with well separated and aligned but slightly distorted tetrahedral CoD₄ complexes is shown in **Figure 1**. The complexes nearest neighbours are all Mg²⁺ ions whereas the Ba²⁺ ions are found in “BaH₂” related layers separating “Mg₅[CoD₄]₂”

1
2
3 layers. Refined atom positions are listed in **Table 1**. Distances and angles can be found in
4 **Table 2**.

5
6 The structure of $\text{RbMg}_5[\text{CoD}_4][\text{NiD}_4]$ was found to be closely related to that of
7
8 $\text{BaH}_2\text{Mg}_5[\text{CoD}_4]_2$. Due to problems with a disordered arrangement of the Co- and Ni-
9
10 complexes and a lower symmetry, the detailed structure could not be elucidated at this point.
11 The metal atom positions could, however, be refined and the main difference to the metal
12 atom structure in $\text{BaH}_2\text{Mg}_5[\text{CoD}_4]_2$ is a slight shift of one of the magnesium positions as
13 illustrated in **Figure 2**. **Table 3a** lists the metal atom positions for $\text{RbMg}_5[\text{CoD}_4][\text{NiD}_4]$.
14
15 **Table 3b** shows that partial substitutions of alkali earth/alkali- metal and transition metals
16 could be made leading to a continuous transition between the structures, if the 18-electron
17 count is kept for the complexes.
18
19

20
21 The magnesium atom shift can not be accommodated in the centrosymmetric space group
22 *Immm* (71), however, and the use of the non-centrosymmetric space group *Imm2* (44)
23 unfortunately increases the number of structural parameters to be refined, leading to
24 instability problems in the refinements. Constraining the parameters can improve the stability
25 but the result would be biased. The general picture is, however, that the tetragonal complexes
26 are kept but their orientations are more disordered than the uniform alignment in the
27 $\text{BaH}_2\text{Mg}_5[\text{CoD}_4]_2$ structure. Below it will also be shown that this leads to a smearing out of
28 the vibrational frequencies in $\text{RbMg}_5[\text{CoH}_4][\text{NiH}_4]$ compared to $\text{BaH}_2\text{Mg}_5[\text{CoH}_4]_2$ although
29 both exhibit similar general features.
30
31
32
33
34
35
36
37

38 The unit cell for $\text{SrD}_2\text{Mg}_2[\text{CoD}_5]$ was refined to $a=7.8140(3) \text{ \AA}$, $b=4.4593(2) \text{ \AA}$,
39
40 $c=6.6347(2) \text{ \AA}$ and $\beta=91.237(3)^\circ$. The space group had to be changed to *P12₁/n1* (11) for the
41 deuteride since the deuterium structure breaks the C-symmetry. The agreement factors
42 became $R_{\text{wp}}=0.0378$ and $R_{\text{p}}=0.0297$, for the full structure refinement.
43
44

45 The refined atom positions are listed in **Table 4** and distances and angles in **Table 5**. The
46 contents of the unit cell are illustrated in **Figure 3**. A summary of the lattice parameters and
47 the agreement factors for all the structures can be found in **Table 6**. All hydrides contain
48 hydrogen both in interstitial sites and bound in complexes.
49
50
51

52 **Calculations - CASTEP**

53
54 Periodic DFT calculations of the crystalline structures were carried out using the plane-wave
55 pseudopotential method implemented in the CASTEP code.^{8,9} Exchange and correlation were
56 approximated in the local density approximation (LDA) using the CA-PZ^{10,11}
57
58
59
60

parameterization. Optimized norm-conserving pseudopotentials¹² were used with a plane-wave cut-off of 990 eV. The equilibrium structure, an essential prerequisite for lattice dynamics calculations was obtained by BFGS geometry optimization after which the residual forces were converged to zero within 0.009 eV/Å. Phonon frequencies were obtained by diagonalisation of dynamical matrices computed using density-functional perturbation theory⁹ (DFPT). An analysis of the resulting eigenvectors was used to map the computed modes to the corresponding irreducible representations of the point group and assign IUPAC symmetry labels. In addition to the direct evaluation of frequencies and intensities at zero wavevector, phonon dispersion was calculated along high symmetry directions throughout the Brillouin zone. For this purpose, dynamical matrices were computed on a regular grid of wavevectors throughout the Brillouin zone and Fourier interpolation was used to extend the computed grid to the desired fine set of points along the high-symmetry paths.¹²

The program ACLIMAX¹³ was used to produce the INS spectrum from the *ab initio* results.

Inelastic neutron scattering

INS spectra were obtained with the spectrometers TOSCA¹⁴ and MAPS¹⁵ at ISIS.¹⁶ The instruments are highly complementary: TOSCA has excellent resolution at <1400 cm⁻¹ while MAPS provides access to higher energy transfer. Incident energies (E_i) of 4033 and 2420 cm⁻¹ were used. For the INS measurements the samples were loaded into indium wire sealed aluminium cans in a glovebox. The spectra were recorded at <20 K for 7-10 hours. INS spectroscopy¹⁴ has several advantages that make it valuable for the study of complex metal hydrides.¹⁶ The spectral intensity, $S(Q, \omega)$, depends on the product of the incoherent cross section and the amplitude of vibration of the atoms in the mode. Hydrogen, ¹H, is both the lightest element (hence has the largest amplitude of vibration) and has the largest cross section, thus motions that involve hydrogen will dominate the spectrum. Further, since the scattering is purely dynamic, the symmetry requirements resulting from the interaction of light with electrons that give rise to selection rules for infrared and Raman spectroscopies are absent and all modes are allowed.

Results and Discussion.

In Mg₂CoH₅ a Co(I)H₅ complex with a square planar pyramidal structure is surrounded by magnesium counter ions and the formal oxidation state is +1. By substituting some of the magnesium with the more electropositive and less polarizing barium the formal oxidation state was reduced to a surprisingly low -1 in BaH₂Mg₅(Co(-I)H₄)₂. In our DFT calculations

1
2
3 this increased the band gap from 0.3 eV to close to 1 eV. The barium could be further
4 substituted by rubidium but in order to keep the electron count correct for the 18 electron
5 complexes, cobalt has also to be partly substituted by nickel. This led to $\text{RbH}_2\text{Mg}_5[\text{Co}(-$
6 $\text{I})\text{H}_4][\text{Ni}(0)\text{H}_4]$ with a structure closely related to that of $\text{BaH}_2\text{Mg}_5[\text{Co}(-\text{I})\text{H}_4]_2$. It is further
7 possible to continuously move between these limiting compositions. (Table 3a and b) Due to
8 the disorder in the structure no DFT calculation was performed. But the colour change from
9 black to dark red with increasing Rb content indicates an increasing band gap.
10
11 In $\text{SrH}_2\text{Mg}_2[\text{CoH}_5]$ the DFT calculation shows a decreased band gap of 0.07 eV. This was
12 also corroborated by a simple measurement of the electric resistivity using a standard
13 Ohmmeter. Pressed tablets of $\text{SrH}_2\text{Mg}_2[\text{CoH}_5]$ are conducting at room temperature. However,
14 if the temperature is reduced by cooling the tablet with liquid nitrogen, the measurable
15 conductivity disappears but is restored when the temperature is increased.

16
17
18
19
20
21
22
23 **Figure 4** compares the INS spectra of the three compounds recorded on TOSCA. It can be
24 seen that while $\text{SrH}_2\text{Mg}_2[\text{Co}(\text{I})\text{H}_5]$ and $\text{BaH}_2\text{Mg}_{10}[\text{Co}(-\text{I})\text{H}_4]_2$ give well-resolved spectra while
25 the mixed complex $\text{RbH}_2\text{Mg}_{10}[\text{Co}(-\text{I})\text{H}_4 \text{Ni}(0)\text{H}_4]$ gives very broad bands with little hint of
26 any structure, consistent with the disorder present.

27
28
29
30 **Figure 5** shows the INS spectra of $\text{BaH}_2\text{Mg}_{10}[\text{Co}(-\text{I})\text{H}_4]_2$ recorded on MAPS. The lower part
31 is obtained by summing over the momentum transfer with two different incident energies.
32 With $E_i = 2420 \text{ cm}^{-1}$ the Co–H stretching modes at 1678 and 1788 cm^{-1} are easily observed,
33 while with $E_i = 4033 \text{ cm}^{-1}$ two weak bands at 3287 and 3517 cm^{-1} with a shoulder at 3466 cm^{-1}
34 are apparent. These are assigned as the first overtone of each of the stretching modes and the
35 combination mode and clearly there is significant anharmonicity present since the predicted
36 overtones would be at 3356 and 3576 cm^{-1} . This is consistent with the difference in unit cell
37 parameters of the hydrides and deuterides.
38
39
40
41
42

43 The spectra can be summarised as: M–H stretching modes $1600 - 1900 \text{ cm}^{-1}$, H–M–H bending
44 modes and H translations $700 - 1200 \text{ cm}^{-1}$, complex ion librational modes $350 - 700 \text{ cm}^{-1}$ and
45 heavy atom translation modes (acoustic and optic) $0 - 350 \text{ cm}^{-1}$. To go beyond this simple
46 description, additional information is required which can be obtained from the CASTEP *ab*
47 *initio* calculations. These were initially carried out with generalized gradient approximation
48 (GGA) and the PBE functional.¹⁷ While the geometry optimisation was straightforward, we
49 invariably found that the calculation of the vibrational transition energies resulted in
50 imaginary modes. Varying the convergence criteria or choice of pseudopotentials did not
51 change this situation. It was eventually found that all real modes could be obtained using
52
53
54
55
56
57
58
59
60

1
2
3 LDA with the CA-PZ^{10,11} functional and all the calculations reported here were carried out
4 using this approach.

5
6 **Tables 1-4** and **4-5** include the calculated structural parameters for BaH₂Mg₅[Co(-I)H₄]₂ and
7 SrH₂Mg₂[Co(I)H₅] and **Tables 7-8** those for Mg₂[Co(I)H₅]. It can be seen that in all cases the
8 calculated values are very close to those observed experimentally: bond distances are all
9 within 0.1 Å and bond angles are generally within a few degrees. For all the complexes there
10 is a tendency that the variation in bondlengths is less marked in the calculations than is
11 observed experimentally, although the trends are always correct, *e.g.* for SrH₂Mg₂[Co(I)H₅]
12 the observed Co–H distances are 1.65 and 1.52 Å, while the calculated distances are 1.603
13 and 1.566 Å. These distances are also slightly longer than are found (experimentally and
14 computationally) in Mg₂[Co(I)H₅].

15
16 For BaH₂Mg₅[Co(-I)H₄]₂ and SrH₂Mg₂[Co(I)H₅] the CASTEP calculations show that there is
17 significant dispersion in the modes as shown by the dispersion curves, **Figures 6** and **7** and
18 comparison of the observed and calculated spectra, **Figures 8** and **9**. It can be seen that the
19 spectra generated from the calculation across the entire Brillouin zone are in much better
20 agreement with the experimental spectra than those from a calculation at just the Γ -point. This
21 is a reflection that INS spectra are allowed at all momentum transfer values, not just at $Q \sim 0$
22 as for infrared and Raman spectra. The long range interactions evidenced by the spectra
23 emphasise the need for fully periodic calculations in these systems. The interaction is most
24 likely to be the result of the Coulombic interactions between the ions as was found for
25 Ba[ReH₉].¹⁸ Animations of the modes enables assignments to be made and these are given in
26 **Tables 9** and **10** for the Γ -point modes of BaH₂Mg₅[Co(-I)H₄]₂ and SrH₂Mg₂[Co(I)H₅]
27 respectively.

28
29 Since the INS spectrum is purely dynamic, we can investigate the contributions of the
30 individual species separately. By setting the cross-section of all the atoms to zero, except for
31 the atoms of interest, only the modes involving motion of those atoms will contribute to the
32 calculated INS spectrum. **Figures 10** and **11** show the results and support the assignments
33 given in **Tables 9** and **10**. Thus for BaH₂Mg₅[Co(-I)H₄]₂ the [Co(-I)H₄]⁵⁻ ion has translational
34 modes below 200 cm⁻¹, librational modes around 400 cm⁻¹, H–Co–H bending modes at 500 –
35 700 cm⁻¹ and Co–H stretching modes at 1650 – 1850 cm⁻¹. If the cobalt atom is considered in
36 isolation then the pattern looks very similar except that there is very little intensity in the
37 librational region as expected since, to a first approximation, the centre of mass is invariant
38 during a libration. The interstitial hydrides exhibit relatively pure modes at 600 – 750 cm⁻¹
39 and 900 – 1000 cm⁻¹ and account for most of the intensity in this region. The translational

2
3 modes of the magnesium ions are all at $< 450 \text{ cm}^{-1}$ with those of the barium ion largely below
4 200 cm^{-1} . As might be expected, below 450 cm^{-1} there is significant mixing of modes and
5 there are no pure modes. A similar pattern is found for $\text{SrH}_2\text{Mg}_2[\text{Co}(\text{I})\text{H}_5]$ with the Sr^{2+} , Mg^{2+}
6 and H^- modes at energies close to those found in the barium containing compound. The
7
8 librational and deformational modes of the complex ion occur at somewhat higher energies
9 than those found in the barium containing compound: librations at $500 - 700 \text{ cm}^{-1}$, $\text{H}-\text{Co}-\text{H}$
10 bending modes at $700 - 1000 \text{ cm}^{-1}$ while the $\text{Co}-\text{H}$ stretching modes at $1600 - 1850 \text{ cm}^{-1}$ are
11 at comparable energies.

13
14
15 Evidence from both INS spectra and electronic structure calculations points to a close
16 similarity in the electronic structures of the cobalt complexes in all three compounds.
17
18 **Figure 12 a,b** shows a comparison of the experimental INS spectrum of $\text{Mg}_2[\text{Co}(\text{I})\text{H}_5]$ ¹⁹ and
19 that of the $[\text{Co}(\text{I})\text{H}_5]^{4+}$ in $\text{SrH}_2\text{Mg}_2[\text{Co}(\text{I})\text{H}_5]$ generated by considering only the hydrides
20 bonded to the cobalt. It can be seen that the degree of similarity is remarkable; the only
21 significant difference is that the librational modes in the strontium complex are 10 – 20%
22 higher in energy than in the parent compound. The similarity in the transition energies of the
23 stretching modes would indicate that the bonds are also of similar strength, although the
24 degeneracies are lifted, **Figure 12 c**, by virtue of the site symmetry, C_s vs. C_{4v} . CASTEP
25 calculations of the Born effective charges of the $[\text{CoH}_5]$ units yield almost identical values
26 with diagonal components $(-4.0, -4.0, -3.9)$ [Mg] and $(-4.1, -4.0, -3.5)$ [Sr] in these two cases,
27 also indicating very similar electronic environments. By contrast with static population
28 analysis the Born charges characterize the electron dynamics and are usually close to formal
29 ionic charges. The effective charge on the corresponding cations is +2.2 ([Mg] and +2.3 [Sr].
30 Surprisingly, the barium complex that contains $[\text{Co}(\text{I})\text{H}_4]^{5-}$ ions has similar stretching
31 energies, despite the cobalt being in a lower oxidation state. In that case the Born effective
32 charges are slightly more negative at $(-4.5, -4.8, -4.7)$ on $[\text{Co}(\text{I})\text{H}_4]$, close to the formal -5,
33 with +2.8 on Ba. The electropositive counterions push different degrees of electrons on to
34 the complexes, but the polarizing Mg^{2+} ions can help to redistribute the electrons *via* the
35 hydrogen atoms. A static Hirshfeld population analysis from the DFT calculations supports
36 these trends, despite yielding results much smaller than formal ionic charge states. Ba and Sr
37 get a similar Hirshfeld charge of 0.29 e in both hydrides. $\text{Co}(\text{I})$ and $\text{Co}(\text{+I})$ get -0.33 and -
38 0.29 e, respectively. The interstitial hydrogen atoms are more ionic with a charge of -0.15 e in
39 both compounds compared to the hydrogen in the complexes, which have a charge of -0.07
40 and -0.09 in the $\text{Co}(\text{+I})$ and $\text{Co}(\text{I})$ complex, respectively. Finally the magnesium atoms in the
41 $\text{Co}(\text{I})$ hydride is less positive with a Hirshfeld charge of 0.29 e compared to 0.32 e for the

3 Co(+I) hydride. The delicate balance of these electron redistributions seems to be intricately
4 dependent on the size and electropositivity of the counter ions. It is interesting, however, that
5 the formal oxidation state has greater implication for more subtle effects such as the band gap.
6 Both $\text{Mg}_2\text{Co(I)H}_5$ and $\text{SrH}_2\text{Mg}_2[\text{Co(I)H}_5]$ have very small bandgaps and are more metallic
7 than $\text{BaH}_2\text{Mg}_5[\text{Co(-I)H}_4]_2$ and also $\text{RbH}_2\text{Mg}_{10}[\text{Co(-I)H}_4\text{Ni(0)H}_4]$ both with bandgaps above 1
8 eV.

3 Figure 11. Comparison of the experimental (Expt., black) INS spectrum of $\text{SrH}_2\text{Mg}_2[\text{Co}(\text{I})\text{H}_5]$
4 with those generated by including only the motions of the hydrides bonded to the cobalt (Co–
5 H, blue), the cobalt atoms (Co, red), the interstitial hydrides (H int, olive), the magnesium
6 ions (Mg, violet), and the strontium ions (Sr, brown), only the $0 \rightarrow 1$ transitions are shown.
7 The insets in the spectra of Co, Mg and Ba are ordinate expansions of the region $500 - 2000$
8 cm^{-1} with factors of 50, 100 and 400 respectively.
9

29 Figure 12. Comparison of the (a) experimental INS spectrum of $\text{Mg}_2[\text{Co}(\text{I})\text{H}_5]$ and (b) that of
30 the $[\text{Co}(\text{I})\text{H}_5]^{4-}$ in $\text{SrH}_2\text{Mg}_2[\text{Co}(\text{I})\text{H}_5]$ generated by considering only the hydrides bonded to
31 the cobalt. To aid the comparison all transitions ($0 \rightarrow 1, 2 \dots 10$) are included, (c) as (b) but
32 only the $0 \rightarrow 1$ transitions for the $1200 - 2000 \text{ cm}^{-1}$ region are shown.
