# PERCEPTION OF DIESEL ENGINE GEAR RATTLE NOISE

Brandon Sobecki, Dr. Patricia Davies, Dr. J. Stuart Bolton,  
*Ray W. Herrick Laboratories, Purdue University,*

Frank Eberhardt, *Cummins, Inc.*

# Research Motivation

- Sound quality is an important factor in the design of competitive engines
- Gear rattle is a phenomenon that can greatly affect the quality of the overall diesel engine sound
- Currently used metrics (such as A-weighted Sound Pressure Level) might not adequately address the role of gear rattle noise on the overall sound quality of the engine
- **An understanding of human's response to the gear rattle noise is needed**
- With this understanding, metrics may be developed to quantify the influence of gear rattle on overall sound

# Gear Rattle Mechanism Background

## (a) No Rattle

Taken from  
Singh, 1989  
(Fig. 3)

Stable (No Rattle) if:

$$T_{d4} > I_4 \ddot{\theta}_4(t)$$

Drag torque on  
output gear

Inertial torque  
on input gear

## (b) Rattle

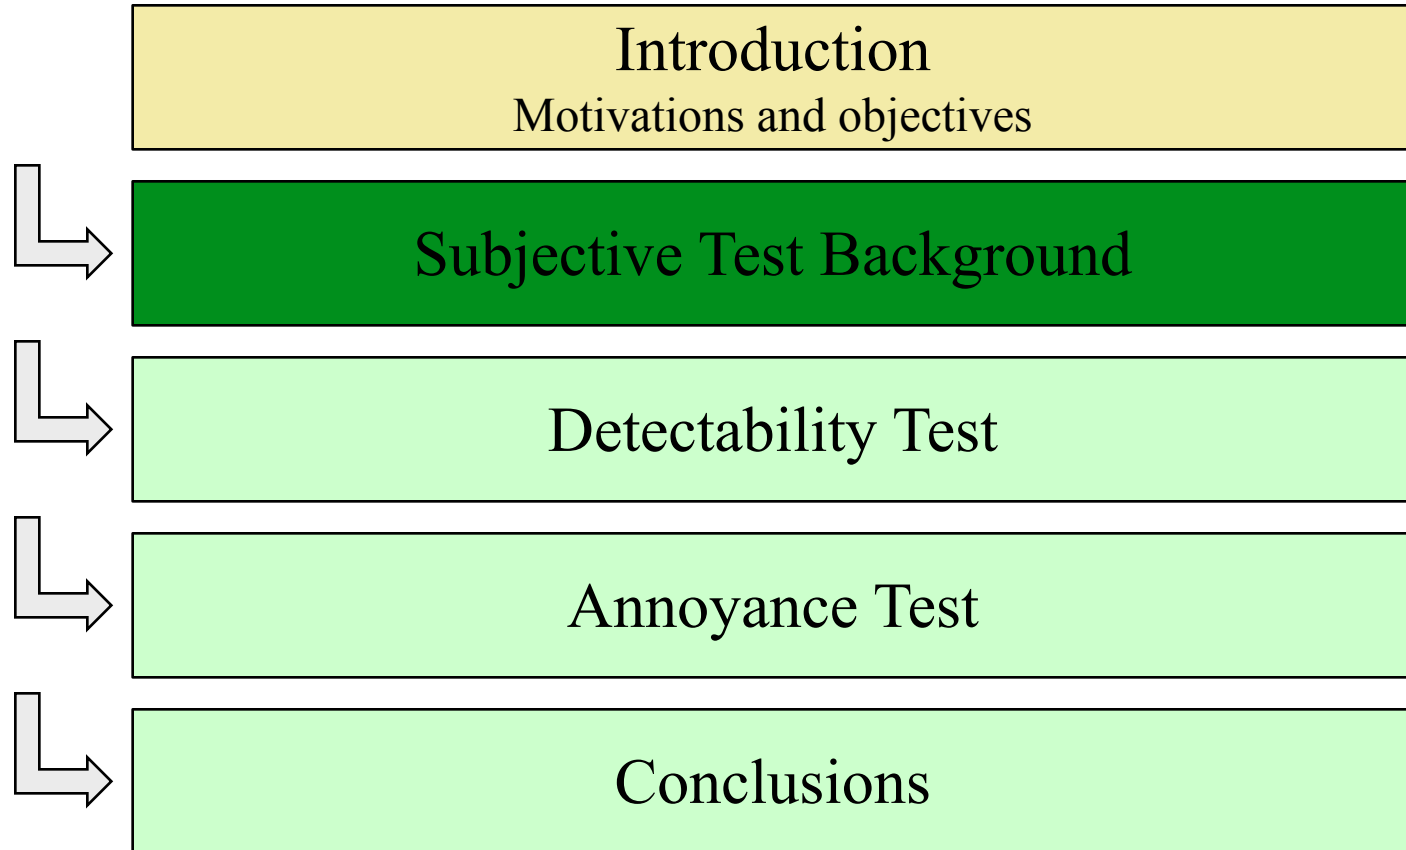

Unstable (Rattle) if:

$$T_{d4} \leq I_4 \ddot{\theta}_4(t)$$

\* Cylinder firing events cause the inertial torque to exceed the drag torque (causing an impact)

Introduction/ Motivation	Subjective Test Background	Detectability	Annoyance	Conclusions

# Outline

Introduction/ Motivation	Subjective Test Background	Detectability	Annoyance	Conclusions
-----------------------------	-------------------------------	---------------	-----------	-------------

# Subjective Test

- A subjective test was designed to
  - determine detectable levels of gear rattle
  - investigate the perception of growth and attenuation of gear rattle
  - determine the increase of annoyance ratings for sounds with increasing levels of gear rattle
- Subjective Test Setup
  - Test was conducted in a double walled sound booth at Herrick Labs
  - Signals were presented to subjects using Etymotic Research ER-2 earphones
- Subject Population
  - 40 Subjects tested in total (20 women and 19 men; 1 did not answer)
  - Median age: 24 (Ranged from 19-36)
  - 13 Subjects identified as having experience with diesel engines

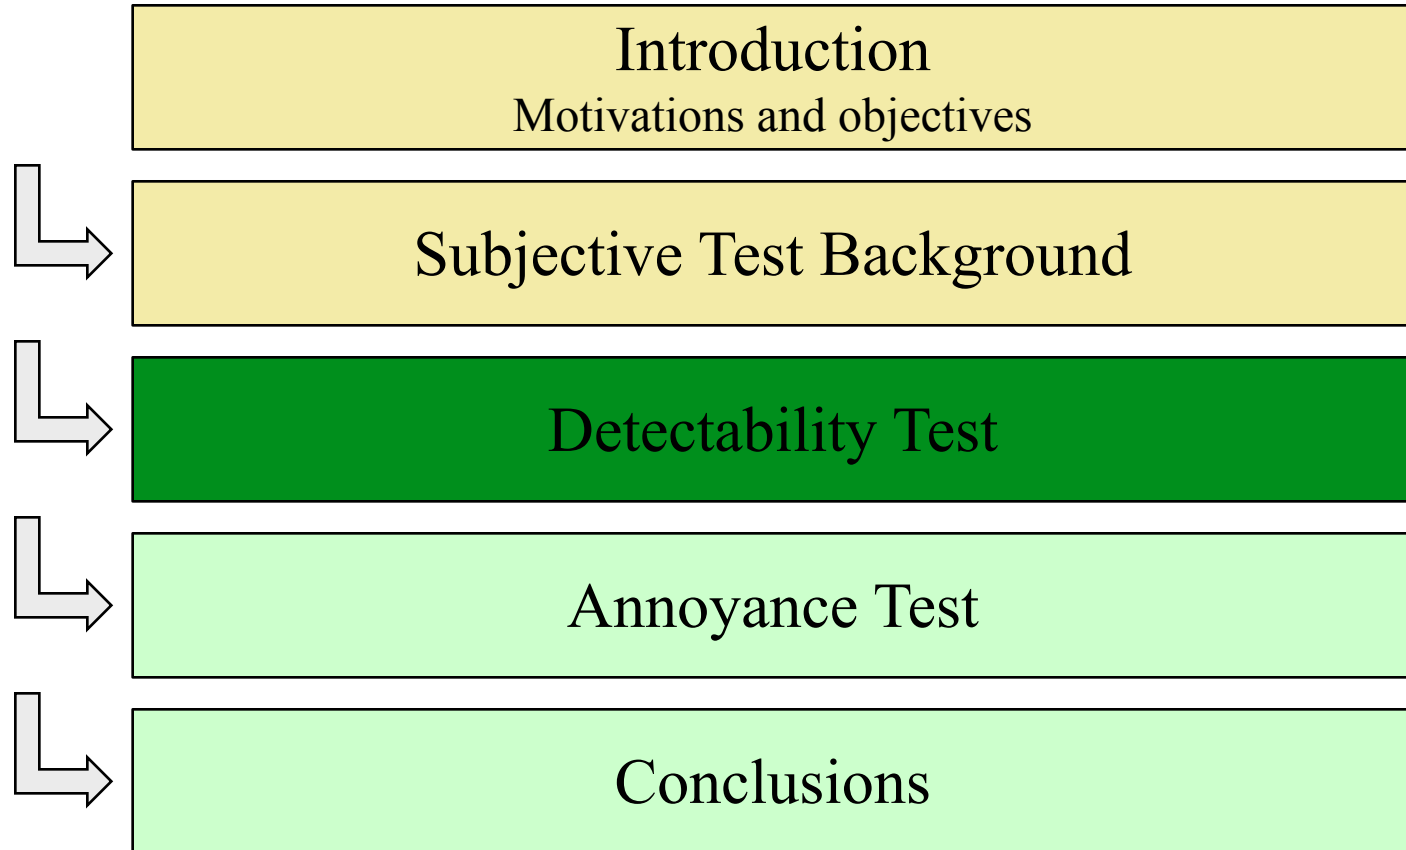

Introduction/ Motivation	Subjective Test Background	Detectability	Annoyance	Conclusions
-----------------------------	-------------------------------	---------------	-----------	-------------

# Test Procedure (IRB 1404014724)

- Signals were calibrated for consistent (and safe) playback
- Subjects were greeted, given a brief overview of the test, and signed inform consent document
- Subject's hearing was screened
- Part 1: Detectability
- Part 2: Annoyance
- Post-test comments were collected
- Subject's hearing was checked
- Subjects were compensated \$10 for their participation

Introduction/ Motivation	Subjective Test Background	<b>Detectability</b>	Annoyance	Conclusions
-----------------------------	-------------------------------	----------------------	-----------	-------------

# Detectability Test Background

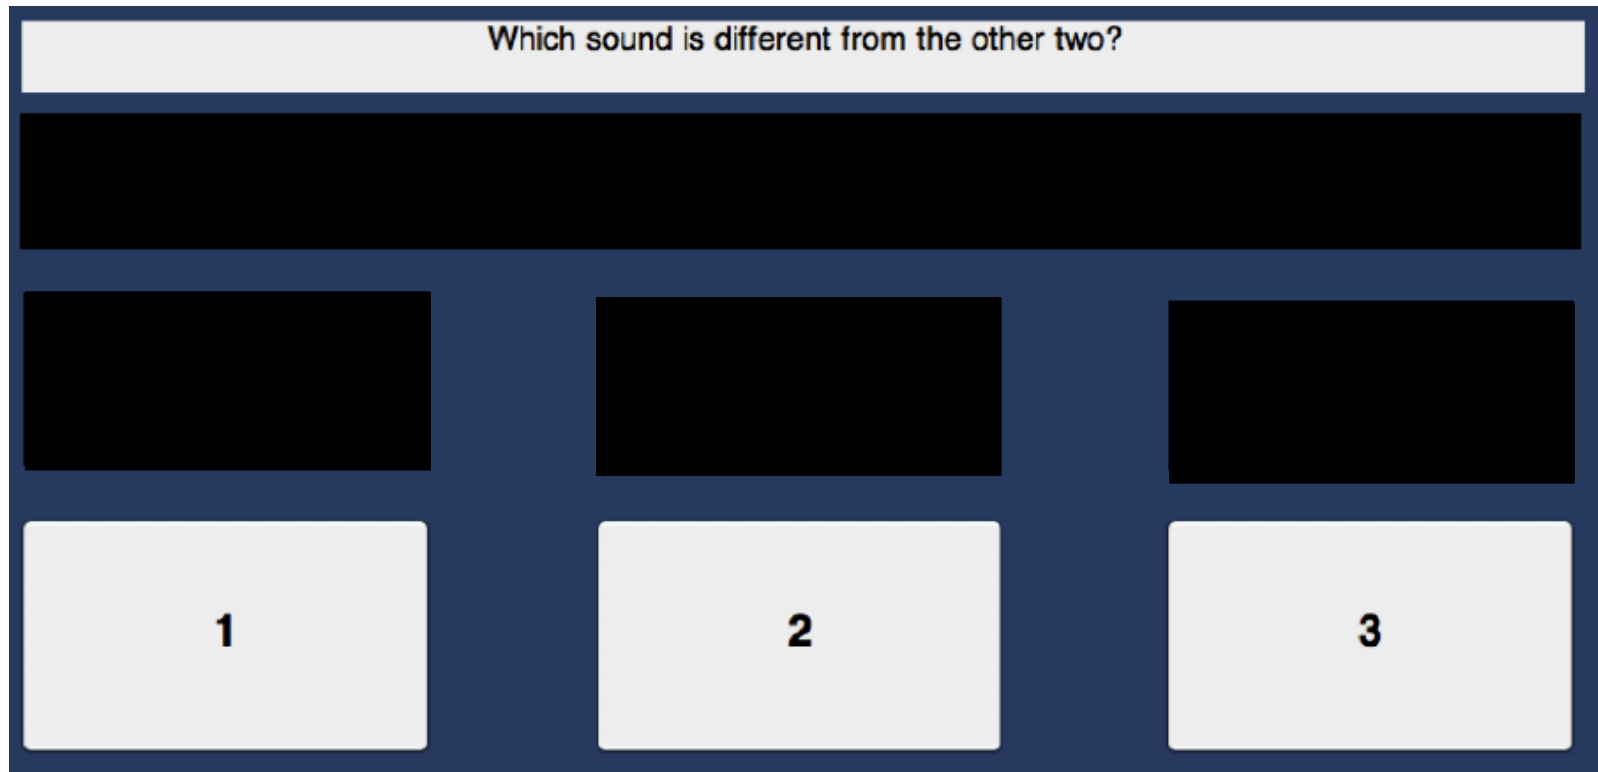

- An experiment was designed to investigate detectable levels of gear rattle in diesel engines
- A simulation method was developed to generate realistic gear rattle noise (Sobecki, Davies, Bolton, 2014)

- 3-Alternative Forced Choice (3AFC) test was used to investigate:
  - Detectable levels of gear rattle
  - Noticeable differences in gear rattle levels

Introduction/ Motivation	Subjective Test Background	Detectability	Annoyance	Conclusions
-----------------------------	-------------------------------	---------------	-----------	-------------

# Detecting Changes in Gear Rattle Level

- Each subject participated in two runs to investigate discrimination thresholds

Run	Background Engine Noise	Background Level	Control Rattle Level	Initial Stimulus Rattle Level
4	Engine 1	75 dB	75 dB	79* dB
5	Engine 1	75 dB	75 dB	71 dB

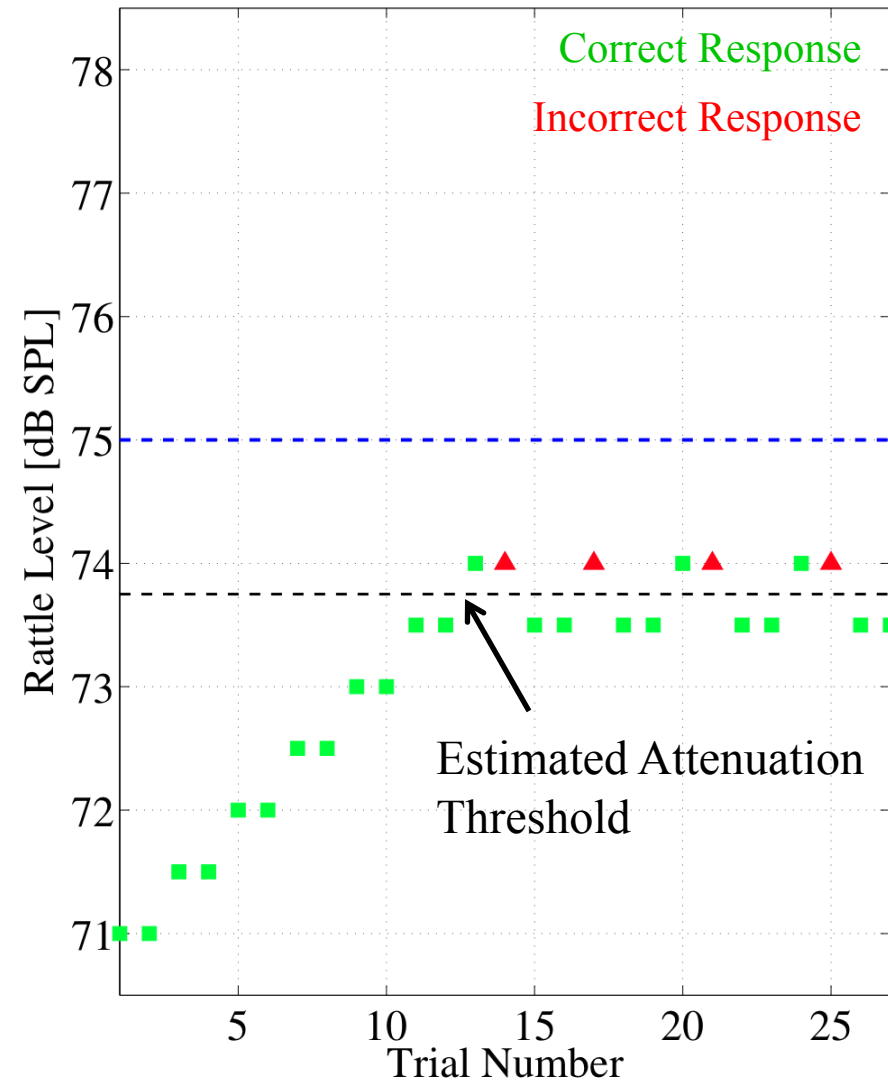

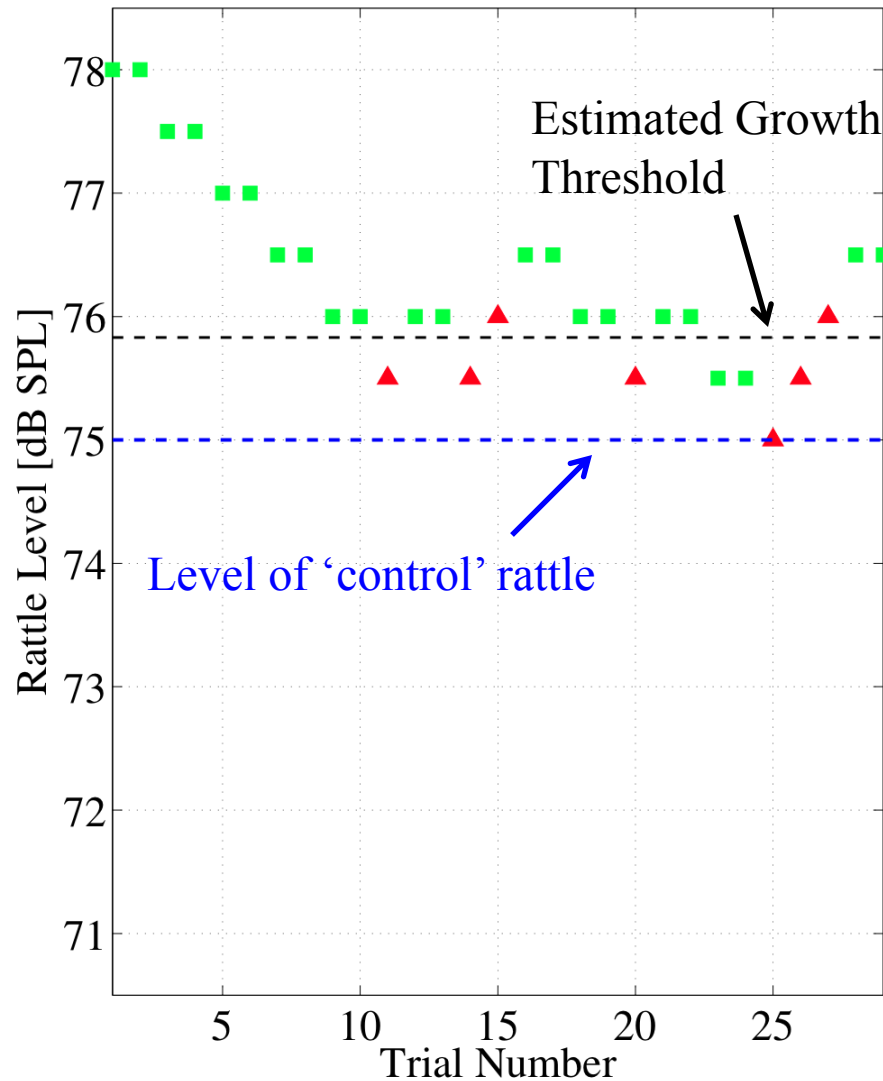

\* Set to 78 dB after 18 subjects (to allow subjects to start with ‘incorrect’ responses while maintaining safe listening levels)

# Part 2: Annoyance - Background

---

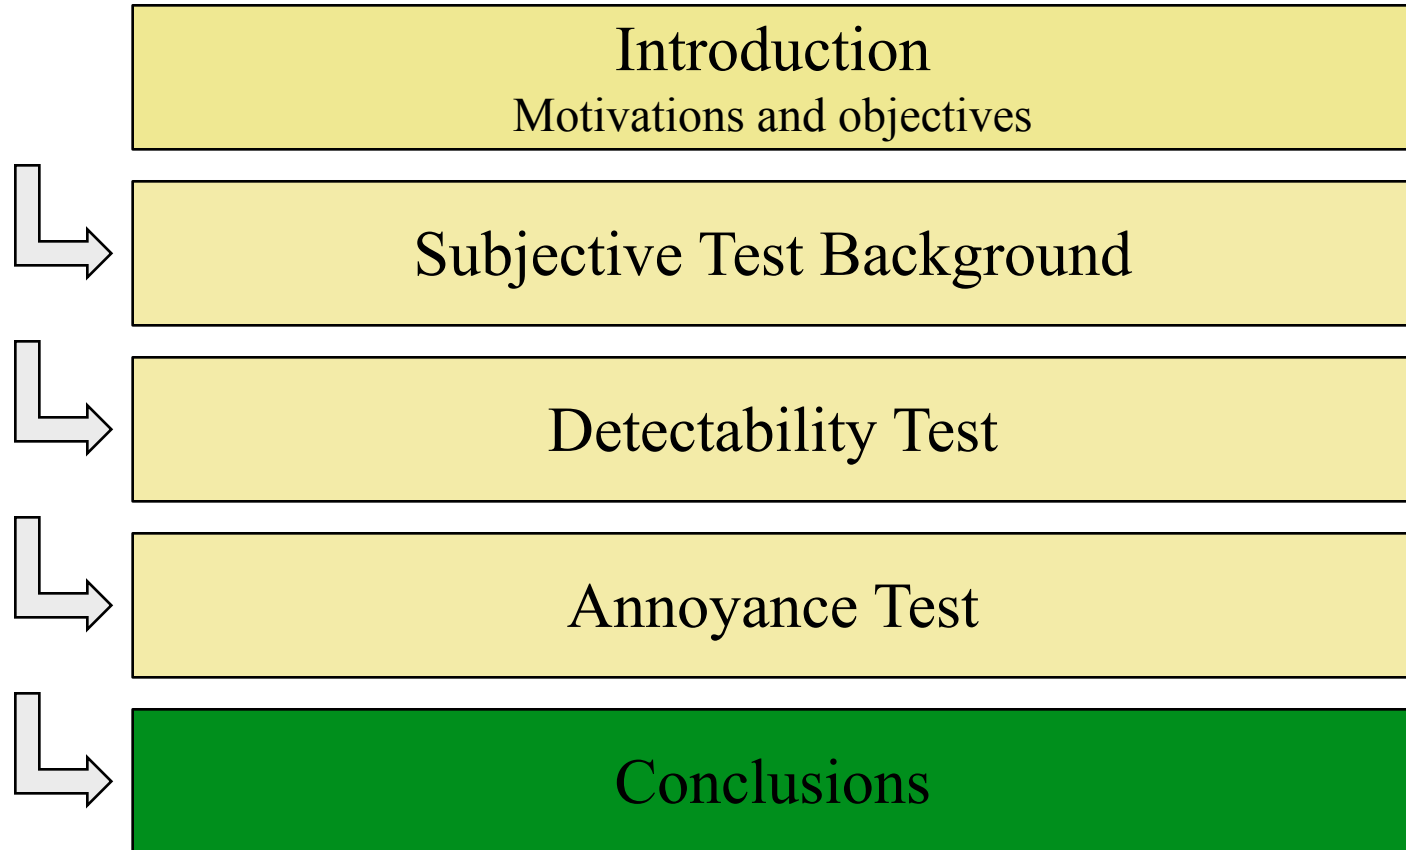

- A paired comparison test was used to investigate annoyance
  - Eight sounds (4-seconds each) were compared to every other sound in response to the question, “Which sound is more annoying?”
  - 56 total comparisons in random order
  - The BTL (Bradley-Terry-Luce) model was used to analyze the subject responses
- Signals used in paired comparison
  - 4 Gear rattle measurements  
(Baseline – Scissor Gear, 0.002, 0.006, and 0.010 inch backlashes)  
*Increasing levels of gear rattle*
  - 1 High gear rattle simulation
  - 3 Amplified Baseline measurements that were set to have equal loudness (EL) as the gear rattle measurements  
(Base .002 EL, Base .006 EL, Base .010 EL)

# Part 2: Annoyance – BTL Analysis

Introduction/ Motivation	Subjective Test Background	Detectability	<b>Annoyance</b>	Conclusions

# Outline

<b>Introduction/ Motivation</b>	<b>Subjective Test Background</b>	<b>Detectability</b>	<b>Annoyance</b>	<b>Conclusions</b>
-------------------------------------	---------------------------------------	----------------------	------------------	--------------------

# Conclusions

- In general, detectable rattle levels begin at 10 dB below the background (baseline) engine level
- A minimum change of 3 dB in rattle level (increase or decrease) is noticeable to subjects
- Diesel engine ‘experts’ responses differed from the general public
  - Better at detecting rattle by approximately 1-2 dB
  - Could detect attenuation of rattle with smaller changes (approximately 1 dB)
- Annoyance ratings increase with an increase in rattle
- Diesel ‘experts’ rated high rattle signals as more annoying than the general public

Introduction/ Motivation	Subjective Test Background	Detectability	Annoyance	Conclusions
