

INTERNATIONAL SEMINAR ON INDUSTRIAL ENGINEERING AND MANAGEMENT

December 10 - 11th, 2009, Inna Kuta Beach Hotel
Bali - Indonesia

Theme:

**Quality, Competitiveness, and Value-Added Services
in Solving Predetermined Global Crisis**

Presented by :

Supported by :

Advisory Committee :

Prof. Dr. Syahbudin (Gunadarma University)
Ir. Docki Saraswati, M.Eng (Trisakti University)
Dr.Ir.Arief Kusuma, MBA. (Indonusa Esa Unggul University)
Iman H Kartowisastro, Ph.D (Bina Nusantara University)
Prof.Ir.Hadi Sutanto (Atma Jaya Jakarta Catholic University)
Prof.Rolly Intan, DR.Eng. (Petra Christian University)

Steering Committee :

Dr.Ir.Rakhma Oktavina, M.T. (Gunadarma University)
Ir. Trirulandari SD, MM. (Trisakti University)
Iphov Kumala Sriwana, S.T., M.Si. (Indonusa Esa Unggul Univ.)
Vivi Triyanti, S.T., M.Sc. (Atma Jaya Jakarta Catholic Univiersity)
K. Gita Ayu, M.S.I.E (Bina Nusantara University)
Tanti Octavia, S.T., M.Eng. (Petra Christian University)

Chair :

Dr.Ir. Hotniar Siringoringo, M.Sc. (Gunadarma University)

Co-Chair :

Ir. Nofi Erni, M.M. (Indonusa Esa Unggul University)

Secretary :

Ir. Gunawarman Hartono, M.T. (Bina Nusantrara University)

Treasury :

Feliks Prasepta, ST, MT. (Atma Jaya Jakarta Catholic University)

Reviewer :

Prof. Dr. E.h. Dr.-Ing. Habil. Josef Schlattmann (Hamburg University of Technology, Germany)
Prof. Dr. Goh Thong Ngee (National University Singapore)
Prof. Dr. Made Londen (Institut Teknologi Sepuluh November)
Dr. Ir. Budi Hermana (Gunadarma University)
Dr. rer. nat. Sudaryanto (Gunadarma University)
Dr. Parwadi (Trisakti University)
Dr. Tiena Amran (Trisakti University)
Dr. Ir. Lily Amelia, M.Agr., M.M. (Indonusa Esa Unggul Univ.)
Ir. Nofi Erni, M.M. (Indonusa Esa Unggul University)
Prof. Dr. Hadi Sutanto (Atma Jaya Jakrta Catholic University)
Prof. Dr. Weggie Ruslan (Atma Jaya Jakarta Catholic University)
Dr. rer.nat. Siana Halim (Petra Christian University)
I Nyoman Sutapa, Drs., M.Sc. Nat. (Petra Christian University)
Bahtiar S. Abbas, Ph.D. (Bina Nusantara University)
Nunung Nurhasanah, ST, MT (Bina Nusantara University)

FOREWORD

This issue is published in line with the third International Seminar on Industrial Engineering and Management (3rd ISIEM). The articles cover a broad spectrum of topics including Quality Function Deployment, Decision Support System and Artificial Intelligent, Ergonomics, Supply Chain Management, Production System, Operation Research, and Industrial Management. The articles provide an overview of critical research issues reflecting on past achievements and future challenges. Those papers were selected from 165 abstracts. This statistics shows the high competition to get published on this proceeding.

This issue and seminar become special as more delegates come and join from various country as well as universities. We host 86 delegates both from abroad and local. We are very happy as we gather more than thrice delegates this year compare to previous year. This could be happened since more universities join as committee. First and second ISIEM are hosted only with three universities, namely Trisakti, Gunadarma, and Indonusa Esa Unggul Universities. This year event, It's hosted by six universities, i.e. Gunadarma, Trisakti, Indonusa Esa Unggul, Bina Nusantara, Atma Jaya Catholic, and Petra Christian Universities. This becomes evident to us that with cooperation we will succeed.

It is then our expectation so that to the future more universities join us as organizing committee. In this occasion, let us give special thank to Prof. Dr. E.h. Dr.-Ing. habil. Josef Schlattmann from Hamburg University of Technology, Germany. Your contribution to this seminar as reviewer, and as keynote speaker makes this event more valuable. Allow us also to thank Prof. Emeritus Adnyana Manuaba and Ir. I. Made Dana M. Tangkas from *Direktur Teknik dan PIC, Toyota Motor Manufacturing Indonesia*, for their contribution as keynote speakers. We are also grateful to all reviewers, for their commitment, effort and dedication in undertaking the task of reviewing all of the abstracts and full papers. Reviewing a large number of submissions in a relatively short time frame is always challenging. Without their help and dedication, it would not be possible to produce this proceeding in such a short time frame. I highly appreciate all members of committees (advisory, steering, and organizing committees) for mutual efforts and invaluable contribution for the success of seminar.

As closing remarks, Let's say thanks to the Lord Almighty God for all His blessing on us.

**Dr. Ir. Hotniar Siringoringo, M.Sc.
Chair**

ABSTRACT

The quality of rotational part model constructed by digitizing process depends on circumferential pitch and height direction pitch. In obtaining the most similar model of rotational product, circumferential pitch and height direction pitch must be set as low as possible. However, it will increase the required time to perform digitizing process. This paper describes an optimization of reverse engineering process, in particularly digitizing process, for a simple and complex rotational part modeling using response surface methodology. Based on the experiment results, the quality of simple part model is influenced only by height direction pitch. The optimum quality of part model is achieved by using height direction pitch equal to 2 mm. The optimum quality of part model has the value of texture is 1.5152 and the required time is 6.3891 minutes. In addition, the quality of complex part model is influenced by circumferential pitch and height direction pitch. The optimum quality of complex part model is achieved by using circumferential pitch equal to 0.36 degree and height direction pitch equal to 1.8 mm. The optimum quality of complex part model has the value of texture is 0.4313 and the required time is 8.5514 minutes.

Key words: Optimization, Reverse Engineering, Response Surface, Rotational Product.

1. INTRODUCTION

According to Y.H. Chen and C.T. Ng (1997), reverse engineering is a methodology for constructing CAD models of physical parts by digitizing an existing part, creating a computer model and then using it to manufacture the component. Motavalli (1998) describes that the main steps in reverse engineering consists of part digitization, data segmentation, and part modeling. In addition, Chang, et.al, (2008) states more detail that the typical procedure of reverse engineering consists of five steps: (1) data acquisition, (2) preprocessing (noise filtering and merging), (3) triangulation, (4) feature extraction, and (5) segmentation and surface fitting.

Reverse engineering has been implemented in various applications. Hsiao, et.al., (2003) presents reverse engineering for product form design. Rho, et.al, (2002) develop a system for reproducing 3D human busts. In addition, Barbero, et.al., (2009) present a method of reverse engineering applied to the particular case of a cam in order to recover the form and dimensions of the design of the original piece, which take into account: design intent, general

knowledge of the problem, different geometric and dimensional restrictions, and the digitized point cloud.

The productivity of the reverse engineering process heavily depends on the data acquisition process, in this case part digitizing. For data acquisition, Motavalli (1998) presents various commercial systems available for part digitization. The examples of this system are Coordinate Measuring Machine, Ultrasonic Imaging and Laser Scanners. These systems can be classified as contact systems and non-contact systems.

The mechanical contact measuring equipment, such as a Coordinate Measuring Machine equipped with a touch triggered probe, usually produces accurate results up to 10 mm or better. The measuring speed, however, is relatively slow compared with optical non-contact measuring systems. It also needs to apply probe radius compensation to the measured points. Because of the contacting force, according to Liu, et. al. (2006), soft and fragile objects cannot be measured by the touch probe.

Alternatively, optical non-contact measuring techniques with high measuring speed are used to directly obtain the

measured points on the surface of a physical object. The dimensional accuracy is usually in the range of several tenths to several hundredths of a millimeter. Obviously, bright and shining objects cannot be measured with optical measuring systems. In addition to the above-mentioned features, both mechanical contact and optical non-contact measuring techniques are not suitable for measuring hidden and internal features.

In digitizing process using non-contact system, to create the most similar model, the digitizer must generate an enormous amount of point data. However, according to Lee, et. al., (1998), for generating an enormous amount of point data, the digitizing process requires an enormous amount of time.

Referring to Bernard (1999), the critical points that influence the results of the digitizing process are the definition of the digitizing strategy and its implementation. The acquisition method is one of the important digitizing strategy and its implementation. The acquisition method involves two types of scanning method, which are rotary and plane scanning. For each of scanning methods, the value of scanning area and scanning pitch must be determined before scanning process is started. The scanning area is determined based on the dimension of the part. Meanwhile, the quality of the constructed model is influenced by the scanning pitch.

Fig. 1. Scanning Pitch of Rotary Scanning

For constructing rotational part model, the best type scanning method is rotary scanning. For rotary scanning, circumferential pitch and height direction pitch will determine the quality of the constructed model. The circumferential pitch sets the angle of adjacent scanning points or the number of scanning points on the circumference. Meanwhile, height direction

pitch sets the distance between scan points as seen in figure 1. A narrower scan pitch results in scanning of greater precision, but the scan time also becomes correspondingly longer. Conversely, a wider scan pitch yields shorter scan times, but scanning results are rougher.

Based on the problem above, this paper presents an optimization of the reverse engineering process in particularly in digitizing process for constructing rotational part model. The purpose of this research is to achieve the best part model in the shortest time. The best rotational part model in this case is the most similar rotational part model to the model generated by the smallest value of scanning pitch.

2. RESEARCH METHOD

This research applies Response Surface Methodology to find the value of circumferential pitch and height direction pitch that acquire the optimum quality of rotational part model. The design of experiment of this research is explained as follow:

- The factors of this experiment are circumferential pitch (CP) and height direction pitch (HDP).
- The units of this experiment are a glass as shown in figure 2 and a sharpener as shown in figure 3. The glass in this experiment represents simple part with maximal three configurations such as ornaments and reliefs. The sharpener represents complex part with more than three configurations.
- The responses of this experiment are texture and time. The value of the texture is influenced by the similarity between the rotational part model resulted from digitizing process and the best rotational part model. The value of the texture is calculated by performing texture comparison between the rotational part model resulted from digitizing process and the best rotational part model. The higher the value of texture means the higher the differences between the models.

In achieving more focused result, this research is constrained as follow:

1. Research is performed at Rapid Prototyping Laboratory in University of Surabaya.

2. Lased Scanner used in this research is Laser Scanner LPX 600.
3. The software used as the aid tool is Dr. PICZA 3.
4. The value of the texture is calculated by using Mat Lab 7.0.1.
5. Data of Experiment is analyzed by using MINITAB 14.
6. Required time is not measured but it is estimated based on the software calculation.

Figure 2. Glass

Figure 3. Sharpener

To find the relation between all factors and all responses, a first order experiment is performed. In the first order experiment, 2^k factorial design is applied augmented with five centre points and two more points. The factors level of the first order experiment is shown in table 1. All the levels are coded as shown in table 1. The level of every factor is determined based on the preliminary experiment and the suggestion of laser scanner vendor. The level of circumferential pitch cannot be set symmetry because of the limitation of laser scanner.

Table 1. Code and Level of CP

| | | | | | |
|--------|-------|-----|---|------|-----|
| Code | -1.36 | -1 | 0 | 1 | 1.4 |
| CP (°) | 0.36 | 3.6 | 9 | 14.4 | 18 |

Table 2. Code and Level of HDP

| | | | | | |
|----------|-------|-----|-----|-----|------|
| Code | -1.33 | -1 | 0 | 1 | 1.33 |
| HDP (mm) | 0.4 | 0.6 | 1.2 | 1.8 | 2 |

Based on the result of the first order experiment, a second order experiment may be performed. The factors level of the second order experiment is determined based on the result of the first order experiment.

3. RESULT AND DISCUSSION

After the experiments for two units of experiment have been conducted, the responses of the experiment are shown in table 3 and 4.

Table 3. Data of First Order Experiment for Simple Part

| CP | HDP | Texture | Time (min) |
|------|-----|---------|------------|
| 9 | 1.2 | 1.564 | 9 |
| 18 | 1.2 | 1.601 | 9 |
| 9 | 0.4 | 0.438 | 25 |

For simple part, the analysis of variance of texture is shown in table 5. The result indicates that there is no evidence of second order curvature in the response over the region of exploration.

According to estimated regression coefficients for texture as shown in table 6, the first order model of texture for simple part depends on only height direction pitch and the best prediction of texture model is

$$\text{Texture} = 1,722 + 2,0084 \text{ HDP} - 0,6139 \text{ HDP}^2 \quad (1)$$

Where:

HDP : height direction pitch

| Pure Error | 4 | 0.025 | 0.0063 | | |
| Total | 12 | 4.779 | | | |

According to estimated regression coefficients for texture as shown in table 8, the first order model of texture for complex part depends on circumferential pitch and height direction pitch. Furthermore, the best prediction of texture model is

$$\text{Texture} = 0,275 - 0,025 \text{ CP} + 0,6027 \text{ HDP} + 0,0088 \text{ CP}^2 - 0,2692 \text{ HDP}^2 \quad (2)$$

Where:

CP : circumferential pitch

HDP : height direction pitch

Table 8. Estimated Coefficients of Texture for Complex Part

| Predictor | Coef | SE Coef | T | P |
|----------------|----------|-------------|-------|------------------|
| Constant | 1.10451 | 0.05223 | 21.15 | 0.000 |
| A | 0.72188 | 0.04187 | 17.24 | 0.000 |
| B | -0.02613 | 0.04256 | -0.61 | 0.556 |

| S = 0.116967 | | R-Sq=97.7 % | | R-Sq(adj)=96.6 % |

Based on the model adequacy checking for simple part and complex part - to check the normality assumption, independence assumption, and non-constant variance - the analysis of variance procedure is an exact test of hypothesis of no differences in treatment means.

Then, because time is not measured and the time data is based on the estimated time from the software, the estimated time can be modeled based in the estimated regression coefficient for either simple and complex part. The estimated regression coefficient for simple and complex part are shown in table 9 and 10 respectively. In addition, the best prediction of time model for simple and complex model are shown as equation 3 and 4 respectively.

$$\text{Time} = 34,69 - 32,6708 \text{ HDP} + 9,2504 \text{ HDP}^2 \quad (3)$$

Where:

HDP : height direction pitch

$$\text{Time} = 34,04 - 51,734 \text{ HDP} + 14,7507 \text{ HDP}^2 \quad (4)$$

Where:

HDP : height direction pitch

To achieve the most similar rotational part model to the model generated by the smallest value of scanning pitch, the optimizer of Minitab 14.0 is used. The best simple rotational part model is achieved for height direction pitch equal to 2 mm. By using this value of height direction pitch, the value of the texture is 1.5152 and the required time of scanning is 6.3891 minutes. Meanwhile, the best complex rotational part model is achieved for circumferential pitch 0.36 degree and height direction pitch equal to 1.8 mm. By using these value of height direction pitch, the value of the texture is 0.4313 and the required time of scanning is 8.5514 minutes.

4. CONCLUSION

In reverse engineering process, in particularly digitizing process, for a simple rotational part modeling, the quality of simple part model is influenced only by height direction pitch. The optimum quality of part model is achieved by using height direction pitch equal to 2 mm. The optimum quality of part model has the value of texture is 1.5152 and the required time is 6.3891 minutes.

Meanwhile, the quality of complex part model is influenced by circumferential pitch and height direction pitch. The optimum quality of complex part model is achieved by using circumferential pitch equal to 0.36 degree and height direction pitch equal to 1.8 mm. The optimum quality of complex part model has the value of texture is 0.4313 and the required time is 8.5514

minutes.
