

Review

A revision of the descriptions of ectomycorrhizas published since 1961

Received 5 March 2005; accepted 17 June 2005.

All available publications providing descriptions of ectomycorrhizas (ECM) were reviewed in order to build a database containing details on fungus forming the ECM, host tree, country where the material for description was collected, and habitat of the ECM. Other secondary data were also recorded. In all 1244 descriptions of ECM published since 1961 in 479 papers were reviewed. The number of different ECM morphotypes described was 814. Most ECM described were collected in Europe and North America. Gymnosperms were the most common tree associates, and boreal and temperate forests the most studied ecosystems. Fungal symbionts were mostly *Basidiomycota*, epigeous, and with mushroom-like morphology. The paper also addresses the gaps in ECM knowledge that mycorrhizologists should address in future studies.

INTRODUCTION

Research on ectomycorrhizas (ECM) has evolved greatly over the last 40 years. From the first morphological analyses to the latest ecological, physiological and genetic studies, the range of information now available is outstanding. Despite all the scientific advances, the identification of the fungi involved remains one of the first steps to be followed when studying ECM communities. Molecular techniques are efficient tools to achieve this aim, but the morphological and anatomical features of the ECM are still an invaluable source of information for the better understanding of the fungal component.

Many ECM morphotypes have been more or less accurately described since the beginning of ectomycorrhizal symbiosis research in the late 19th century. A few authors have tried to establish classification systems in order to develop identification keys paralleling those available for plants and animals, but this is a difficult task. Dominik (1969) made a first attempt. A few years later Zak (1973) stated that a detailed description of each ECM was essential for its identification, and that this description should be based on several collections in order to note possible variations in the ECM over different developmental stages.

In spite of these general ideas, the methodology used by each author when describing an ECM varied greatly in descriptions published before 1986, when Agerer (1986a, 1987–2002, 1994a, 1999a) began to publish guidelines for the systematic of description and identification of ECM widely used nowadays. In addition, Agerer created a binomial nomenclature system for those ECM described but not yet identified, edited a *Colour Atlas of Ectomycorrhizas* (Agerer 1987–2002) with photographs of the ECM described to facilitate identification by comparison, and developed computer software to characterize and determine ECM (Agerer & Rambold 1998).

Other approaches for the description and identification of ECM also exist. Ingleby *et al.* (1990) developed a system to name the features of ECM, and published 24 brief descriptions of ECM including photographs and drawings.

Another widely used methodology is the so-called *Concise Descriptions of North American Ectomycorrhizas*, developed by Goodman *et al.* (1996–2000). The descriptions published according to this system are more detailed than those in Ingleby *et al.* (1990), but they lack the level of detail of the system proposed by Agerer (1986a, 1987–2002, 1994a, 1999a), and are confined to the North American geographical region.

Table 1. Compilation of the 1244 ECM descriptions reviewed. ECM descriptions are ordered alphabetically by name of ECM and then by reference, with details of the host tree, the country where the material was collected, and the habitat where the ECM was found (1, field; 2, synthesized *in vitro*; 3, nursery; 4, truffle ground stand; 5, various).

Numerous descriptions of ECM have also been published in different journals following any of the systems mentioned above, but the information on the topic is typically difficult to approach due to the varied nature of the sources. Therefore, we considered it necessary to gather and review these published sources in order to build a database of the descriptions of ECM published so far useful to all mycorrhizologists. We have focused exclusively on morphological descriptions of ECM. It is outside the scope of this work to refer to other types of mycorrhizas (e.g. ectendomycorrhizas, ericoid, or arbutoid mycorrhizas) or to ECM morphotypes cited in papers dealing with molecular techniques which do not provide a morphological description. Although this revision is very extensive, some sources could not be accessed, and there may be other descriptions hidden as grey literature or in journals with little circulation. Contributions by other authors are thus expected and welcome in order to enrich the database.

MATERIALS AND METHODS

Each published source containing a description of an ECM, no matter how brief the description, was reviewed to record the following details: (1) fungus forming the ECM; (2) host tree; (3) country where the material for description was collected; and (4) habitat of the ECM, i.e. whether the ECM was collected from the field, a nursery, a truffle growing stand, or if it was synthesized *in vitro*. Only published sources were reviewed, i.e. ECM descriptions contained in theses, reports, or other kinds of unpublished material were not considered. ECM from nurseries included artificially inoculated or naturally occurring in the nursery. When an ECM morphotype was collected in more than one habitat, the term 'various' was applied. For simplicity, subspecies and varieties of fungi and host trees were not considered. In some cases, several host tree species were reported to be associated with the same ECM morphotype in the same description, but no morphological or anatomical distinction was made between ECM tips from the different tree species. In these cases, all host tree species were cited in Table 1 within the same entry. The term 'not specified' was used when several host tree species were mentioned in a paper, but there was no specific information about the tree species actually associated with each ECM described.

Other secondary data were also recorded: the division, order, sporocarp morphology and sporocarp development (epigaeous or hypogeous) of the fungus forming the ECM; whether the description was detailed (Agerer 1986a, 1987–2002, 1994a, 1999a); and whether drawings and photos were also available together with the description. The categories used for fruit body morphology were: gasteroid, mushroom (both agaricoid and boletoid), truffle (any hypogeous fungus, including *Ascomycota* and *Basidiomycota*), and other morphology (apothecial, perithecial, clavarioid,

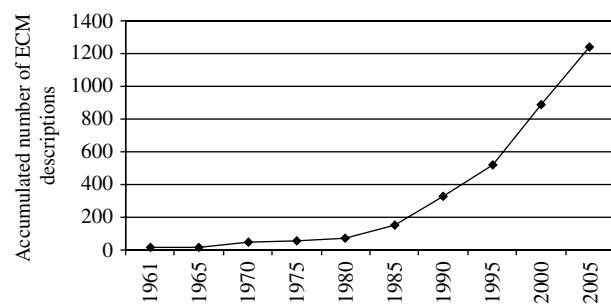

Fig. 1. Accumulated number of ECM descriptions published since 1961.

ramarioid or resupinate). Although some comments are made in this review regarding these secondary data, the data are not included in full due to space constraints, but the corresponding author will provide them if contacted.

RESULTS AND DISCUSSION

In all 1244 descriptions of ECM published in 479 papers were reviewed (Table 1). The number of different ECM morphotypes described was 814, with each ECM not identified to species level considered a different ECM. 345 ECM morphotypes were identified to species, 132 to genus, 21 to family, five to order, and 20 to division; four had another level of identification (cortinarioid, pezizalean, sebacinoid, and tomentelloid, respectively), 99 were unidentified ECM morphotypes published under a binomial name (Agerer 1986a, 1987–2002, 1994a, 1999a) or other name widely used in the literature (morphotypes AD and SB; Giraud 1988), and 188 were unidentified ECM morphotypes lacking a name. Only 330 of the 1244 descriptions reviewed were detailed (Agerer 1986a, 1987–2002, 1994a, 1999a); 379 descriptions included drawings and 771 provided photographs.

The descriptions reviewed date back to 1961, and include all papers published until May 2005, when the revision of this article was submitted. Fig. 1 shows the accumulated number of ECM descriptions published over the years, and it is important to note the sharp increase in publications from 1985 onwards, when Agerer (1986a) started to develop the more defined system.

Most of the ECM described were collected in Europe, with 862 descriptions recorded as follows: Austria, 2; Belgium, 1; Estonia, 3; France, 83; Germany, 331; Hungary, 46; Italy, 177; Poland, 28; Portugal, 14; Slovenia, 15; Spain, 93; Sweden, 2; Switzerland, 14; UK, 53. A significant number, 271 ECM, were collected in North America (Canada, 175; USA, 96). All other continents remain poorly represented: 37 ECM were collected in South America (Argentina, 3; Chile, 28; Ecuador, 6), 21 in Africa (Cameroon, 7; Morocco, 14), 37 in Asia (India, 2; Indonesia, 1; Japan, 14;

Malaysia, 10; Taiwan, 10) and 16 in Oceania (Australia, 2; New Zealand, 14). It is interesting to note that most descriptions came from Germany, Italy, and Canada. The material collected in Germany was usually described in detail following the system developed by Agerer (1986a, 1987–2002, 1994a, 1999a), and is the most extensive source of information on morphology and anatomy of ECM. In contrast, the ECM described in Canada were usually collected in ecological studies of ectomycorrhizal communities, and the descriptions provided were typically short, with the exception of those published by Goodman *et al.* (1996–2000). In Italy, research on ECM is often linked to the interest in cultivating truffles, and most ECM described were either *Tuber* species of commercial interest or competitive fungi that threaten truffle production.

Gymnosperms were the most common tree associates, recorded in 510 descriptions (*Abies*, 15; *Cedrus*, 14; *Gnetum*, 1; *Larix*, 20; *Picea*, 162; *Pinus*, 226; *Pseudotsuga*, 59; *Tsuga*, 13). Genera in the *Fagaceae* were also well represented, with 339 descriptions (*Castanea*, 3; *Castanopsis*, 1; *Cyclobalanopsis*, 1; *Fagus*, 116; *Nothofagus*, 29; *Pasania*, 1; *Quercus*, 188). Other families recorded as hosts were: *Betulaceae*, 131 (*Alnus*, 50; *Betula*, 48; *Carpinus*, 4; *Corylus*, 26; *Ostrya*, 3); *Salicaceae*, 94 (*Populus*, 87; *Salix*, 7); *Cistaceae*, 18 (*Cistus*, 3; *Fumana*, 4; *Helianthemum*, 11); *Myrtaceae*, 7 (*Eucalyptus*, 5; *Kunzea*, 1; *Leptospermum*, 1); *Leguminosae*, 7 (*Acacia*, 1; *Tetraberlinia*, 6); *Nyctaginaceae*, 6 (*Guapira*, 1; *Neea*, 5); *Dipterocarpaceae*, 11 (*Shorea*); *Rosaceae*, 1 (*Dryas*); *Tiliaceae*, 6 (*Tilia*). The remaining 113 ECM were associated with either ‘not specified’ host trees (35), or with more than one host tree species, within the same description (78). If the ECM description applied to more than one host tree species, the records were not considered individually for the count to avoid an artificial increase in the total number of descriptions. A careful analysis of the host species involved in the ECM described revealed that boreal and temperate forests are the best-known ecosystems so far, whereas there is little information on ECM communities of tropical and Mediterranean ecosystems.

Most ECM were collected from the field (899), 159 in a nursery, 81 in a truffle growing stand. Sixty five descriptions were based in ECM material synthesized *in vitro*, and in 40 descriptions, the material was collected in more than one habitat (indicated by the term ‘various’). Many ECM morphotypes collected from the field could not be identified, whereas the aim of inoculating ECM fungi in nurseries or synthesizing them *in vitro* was precisely to know the identity of the fungal symbiont beforehand. Fungi recorded in truffle growing stands were typically truffle species or their competitors.

The associated fungi recorded in the 1244 ECM descriptions reviewed were mostly *Basidiomycota* (707), 200 were *Ascomycota*, and in 337 descriptions the

fungal division could not be ascertained. As most *Ascomycota* ECM were *Tuber* species, it is clear that there is a lack of knowledge on the ECM of this fungal division. Fungal orders were represented in ECM descriptions as follows: *Agaricales*, 220; *Boletales*, 166; *Cantharellales*, 13; *Elaphomycetales*, 5; *Hymenochaetales*, 1; *Pezizales*, 150; *Phallales*, 18; *Polyporales*, 41; *Russulales*, 148; *Thelephorales*, 77; *Tremellales*, 5; unidentified order, 400.

The majority of fungal species cited were epigeous (638), with only 198 descriptions belonging to hypogeous fungi. The type of fruit body development of the fungal symbiont was unknown in the remaining 408 descriptions. These data show that, with the exception of *Tuber* species again, the ECM of hypogeous fungi are poorly known. The fact that fruit bodies of hypogeous fungi are typically difficult to find is definitely related to the scarce interest researchers have hitherto shown for ECM formed by these species.

The fruit body morphology of the associated fungus was mushroom-like in 460 ECM descriptions, gasteroid in 35, truffle-like in 198, had other morphologies in 142, and could not be assigned to any morphology in 409 descriptions. These data indicated that fungi which lack the usual ‘mushroom’ morphology or which have inconspicuous fruit bodies have been traditionally overlooked in ECM community studies (Gardes & Bruns 1996, Dahlberg, Jonsson & Nylund 1997, Stendell, Horton & Bruns 1999, Taylor & Bruns 1999, Peter *et al.* 2001).

The amount of research carried out so far on description and identification of fungi involved in ECM communities is outstanding. Nevertheless, this review reveals that many gaps in knowledge remain to be filled, and mycorrhizologists should focus on little-known geographic areas, ecosystems, host trees and fungal groups in future studies in order to face the challenges the ECM community poses.

ACKNOWLEDGMENTS

We are grateful to Steve Woodward and two anonymous referees for their useful comments on the manuscript. This revision was carried out over many years, and there are several funding bodies we wish to thank for their financial support: the Spanish Instituto Nacional de Investigaciones Agrarias y Alimentarias for a PhD grant for M. de R.; Gobierno de Navarra and Fundación Universitaria de Navarra for funding three research projects; and the Spanish Ministerio de Educación y Ciencia for a post-doctoral grant for M. de R.
