#### 28 ABSTRACT

29 The single minichromosome maintenance (MCM) protein found in most archaea has 30 been widely studied as a simplified model for the MCM complex that forms the catalytic 31 core of the eukaryotic replicative helicase. Organisms of the order Methanococcales are 32 unusual in possessing multiple MCM homologues. The Methanococcus maripaludis S2 33 genome encodes four MCM homologues, McmA – McmD. DNA helicase assays reveal 34 that the unwinding activity of the three MCM-like proteins is highly variable despite 35 sequence similarities and suggests additional motifs that influence MCM function are yet 36 to be identified. While the gene encoding McmA could not be deleted, strains 37 harbouring individual deletions of genes encoding each of the other MCMs display 38 phenotypes consistent with these proteins modulating DNA damage responses. M. 39 maripaludis S2 is the first archaeon in which MCM proteins have been shown to 40 influence the DNA damage response.

#### 42 INTRODUCTION

43 The eukaryotic minichromosome maintenance (MCM) complex comprises six 44 homologous proteins, MCM2 – MCM7, all of which are required for DNA replication 45 initiation and fork progression in vivo. MCM genes in eukaryotes have been 46 demonstrated to be essential through the generation of temperature sensitive and 47 degron mutants [1]. The MCMs appear to act as a nucleation point for the formation of 48 the Cdc45-MCM-GINS (CMG) multi-protein complex necessary for DNA unwinding in 49 eukaryotes [2]. Within the CMG complex, MCMs provide the replicative helicase activity 50 required by eukaryotes during chromosomal DNA replication [3]. Unwinding activity in 51 this complex is likely to be tightly controlled, as evidenced by the number of post-52 translational modifications reported for the MCM proteins [4-6]. The intracellular 53 concentration of MCMs also has an important influence on the ability of cells to cope with 54 replicative stress. Reduction of MCM concentrations reduces the ability of cells to cope 55 with replicative challenges [7-9]. MCMs are a target of the ATM/ATR DNA damage 56 checkpoint [10,11], which can be triggered by the Mre11-Rad50 complex binding to 57 double-stranded DNA breaks [12,13]. Additional evidence suggests that the MCMs, in 58 particular MCM3 [14], may directly influence DNA replication checkpoints to ensure 59 replicative integrity [15-19], although the precise role MCMs play in the modulation of 60 DNA repair pathways is still unclear. Other eukaryotic MCM paralogues have been 61 shown to have a role in the repair of meiotic DNA breaks in mice [20], mammalian DNA 62 mismatch repair [21] and the facilitation of DNA repair at homologous recombination 63 sites [22].

64

Archaeal MCM homologues have been used as simplified models for understanding the mechanisms employed by the MCM complex in DNA unwinding [23]. Biochemical analysis of archaeal MCMs has led to the identification of a number of motifs that are essential for DNA binding, ATP hydrolysis and DNA helicase activities [24-26]. In all archaea studied to date, with the exception of *Thermococcus kodakarensis*, a single functional MCM has been identified that forms a homohexameric complex possessing these activities [27].

72

Members of the archaeal order *Methanococcales* possess between two and eight MCM
 homologues [28,29]. *Methanococcus maripaludis* S2 encodes four MCM homologues
 [28,30] corresponding to ORF numbers MMP0030, MMP0470, MMP0748 and

76 MMP1024. We have named these genes mcmA, B, C and D respectively [28]. 77 Homologues of McmA and McmD are conserved in all Methanococcales species and 78 appear to have arisen from an ancient duplication [28]. Phylogenetic analysis shows that 79 the *M. maripaludis* MCMs are more closely related to one another than to MCMs from 80 other archaea (Fig. 1(a)). While archaea with multiple MCMs have been identified 81 outside the order Methanococcales, in most of these species there are truncations or 82 mutations in residues that are essential for DNA helicase activity that result in the 83 presence of only a single functional MCM protein [31,32]. An exception to this general 84 observation is in T. kodakarensis, where the genome encodes three MCMs (MCM1-3), 85 all of which are expressed, but only one of which (MCM3) is essential [33]. Deletion of 86 MCM1 or MCM2 in T. kodakarensis did not affect cell growth or viability, indicating that 87 they are non-essential for DNA replication [33]. As in T. kodakarensis, multiple 88 sequence alignments of the *M. maripaludis* proteins with other archaeal proteins show 89 that the motifs known to be required for MCM function are all conserved in McmA-D (Fig. 90 1(b)). Thus, all four of the *M. maripaludis* MCMs could potentially function as DNA 91 helicases. McmD possesses additional amino acids between the second pair of 92 cysteines within the zinc finger (Fig. 1(b)) and a C-terminal 20 amino acid insert, 93 reminiscent of an insert observed in eukaryotic MCM3 [28]. The four M. maripaludis 94 MCMs co-purify when co-expressed in *E. coli*, indicating that they can form heteromeric 95 complexes in vitro [28]. M. maripaludis represents an interesting model for studying 96 MCM function not only because it has multiple MCM homologues but, unusually for an 97 archaeon, a well-established set of genetic tools are available for this organism [34] 98 which allows both genetic and biochemical experiments to be used in the dissection of 99 MCM function.

100

101 In this study we demonstrate that at least two of the four *M. maripaludis* MCMs (McmA 102 and McmB) show robust DNA helicase activity *in vitro*. We have determined that only 103 *mcmA* appears to be essential but that mutant strains deleted for non-essential MCMs 104 show changes in cell cycle distribution and their responses to DNA damage. We have 105 demonstrated that multiple MCM proteins are required for normal proliferation in this 106 organism and that deletion of non-essential MCMs has significant effects on DNA 107 damage responses.

108

109 METHODS

#### 110 Sequence alignments and phylogenetics

111 Multiple sequence alignments were generated using ClustalX [35] and were used to

- 112 construct a neighbour-joining tree.
- 113

#### 114 Recombinant protein expression and purification

115 His-tagged proteins were expressed in Rosetta BL21(DE3) (Novagen) at 37 °C or Arctic 116 Express (RIL) (Stratagene) at 12 °C. Expression was induced at 0.8 OD<sub>600nm</sub> by 0.5 mM 117 IPTG (final concentration). Cells were sonicated in lysis buffer (50 mM Tris pH 8.0, 300 118 mM NaCl, 5% glycerol, 5 mM imidazole, 0.1 mM PMSF, 1 µg ml<sup>-1</sup> pepstatin, 1 µg ml<sup>-1</sup> 119 leupeptin, 1  $\mu$ g ml<sup>-1</sup> aprotonin) with 0.75 mg ml<sup>-1</sup> lysozyme and 5  $\mu$ g ml<sup>-1</sup> DNase. Lysate 120 was clarified by centrifugation (50000 xg) and bound to 1 ml Talon beads (Clontech), 121 washed with 10 column volumes (cv) of wash buffer (lysis buffer plus 10 mM imidazole) 122 and protein was eluted in elution buffer (lysis buffer plus 150 mM imidazole). Fractions 123 were pooled, diluted 1:3 in dilution buffer (10 mM Tris pH 8.0, 5% glycerol, 1 mM EDTA, 124 1 mM EGTA, 1 mM PMSF, 0.1%  $\beta$ -mercaptoethanol) and loaded on a 1 ml Source Q 125 column (GE Healthcare), washed with 10 cv start buffer and eluted over a 20 cv gradient 126 to 500 mM NaCl. Elution fractions were analysed by SDS-PAGE and concentrated into 127 10 mM Tris pH 7.5.

128

#### 129 Strand displacement assays

130 prepared by  $\gamma$ -<sup>32</sup>P Forked substrate DNA was labelling oligo HS2 (5'-131 TTTGTTTGTTTGTTTGTTTGTTTGTTTGCCGACGTGCCAGGCCGACGCGTCCC 132 -3') and annealing HS1 to 133 (5'GGGACGCGTCGGCCTGGCACGTCGGCCGCTGCGGCCAGGCACCCGATGGCGT 134 TTGTTTGTTTGTTTGTTTGTTT-3') as described [36]. A 10 µl reaction containing HDB 135 [27], 2.5 mM ATP, 150 mM potassium glutamate and 1 nM labelled substrate was 136 prepared on ice. 10 µl protein aliquots (0-2400 fmol hexamer) in 50 mM potassium 137 glutamate, 10 mM HEPES pH 7.6 were prepared on ice. 10 µl of the reaction mix was 138 added to each protein aliquot and incubated at 37 °C for 1 hour. Substrate alone was 139 boiled for 5 minutes then placed on ice. Reactions were stopped by the addition of 5 ul 200 mM EDTA, 1% SDS, 20% glycerol, 0.4 pmol µl<sup>-1</sup> unlabelled HS2 oligo, 1 µg µl<sup>-1</sup> 140 141 proteinase K. DNA was separated on 12% native polyacrylamide gels, dried and 142 visualised using a phosphorimager (BioRad). Results were quantified using Quantity 143 One software (BioRad).

144

#### 145 Markerless mutagenesis in *M. maripaludis* S2

Genetic manipulations were carried out using the Mm900 (S2  $\Delta hpt$ ) strain of *M. maripaludis* [37]. Deletion plasmids were constructed by cloning 500 bp of upstream and downstream flanking DNA into the *Not* I site of pCRPrtNeo including codons for the five N-terminal and C-terminal amino acids of each MCM to ensure read-through (oligonucleotide sequences available on request) [37]. Transformations and markerless mutagenesis were carried out as described [37]. New strains were streak-purified, screened by PCR and analysed by Southern blot.

153

#### 154 Southern blots

Southern blotting was carried out using DIG-labelling and detection kit according to manufacturer's instructions (Roche). Genomic DNA from individual strains was digested with the following restriction enzymes to generate appropriate fragments for probing: mcmA (*Pst* I), mcmB (*Sac* I, *Pvu* II), mcmC (*Pst* I, *Sac* I), mcmD (*Nci* I, *Xho* I). Regions of interest were detected using digoxin random hexamer-labelled probes to 500 bp flanking regions of each MCM (Fig. S1). Blots were visualised by CPSD detection (Roche) and exposing to photographic film for 1-5 minutes.

162

#### 163 Culture and cell sampling of *M. maripaludis*

*M. maripaludis* was cultured in McCas liquid media as described [37]. For batch culture of *M. maripaludis*, 2 litres of modified McCas medium was prepared in a sealed 3 litre bioreactor (Applikon Ltd.) as previously described [38]. The medium was inoculated using 5x 5 ml cultures of *M. maripaludis* at an OD<sub>600nm</sub> of 0.7-1.0. After inoculation, optical density was measured at 600nm every 2-5 hours. Sodium dithionite was added to samples before OD<sub>600nm</sub> was measured aerobically.

170

#### 171 Flow cytometry

172 1 ml of *M. maripaludis* culture was centrifuged (16000 xg, 5 minutes, room temperature). 173 The pellet was resuspended in 100  $\mu$ l of TSE buffer (10 mM Tris pH 7.5, 10 mM EDTA, 174 380 mM NaCl, 200 mM KCl). 1 ml ice cold (77% ethanol, 600 mM LiCl) was added, the 175 sample was vortexed then stored at 4 °C. Before analysis, fixed cells were pelleted 176 (16000 xg, 5 minutes, room temperature), resuspended in 1 ml buffer A (10 mM Tris pH 177 7.5, 10 mM MgCl<sub>2</sub>), spun and then resuspended in 150  $\mu$ l buffer A containing 100  $\mu$ g ml<sup>-1</sup> 178 mithramycin A / 20  $\mu$ g ml<sup>-1</sup> ethidium bromide. Stained cells were analysed by Apogee 179 A40 MiniFCM with a 50 mW 405 nm laser. 100,000-500,000 cells were analyzed for 180 each sample. Data were processed using FlowJo (Treestar).

181

#### 182 DNA damage

183 DNA damage assays were conducted under strict anaerobic conditions. For UV damage assays, 108-109 cells were diluted in McCas medium and spotted on McCas plates. 184 185 Spots were air dried and then exposed to UV (254 nm). Post-treatment, plates were 186 shielded from visible light. UV dosage was measured using a Blak-Ray UV meter (UVP, 187 Inc). For ionising radiation damage assays, aliquots of cultures were exposed to a 188 calibrated X-ray dose from an X-ray generator. After exposure to X-rays, 10<sup>8</sup>-10<sup>9</sup> cells 189 were diluted in McCas medium and spotted on McCas plates. Plates were pressurised to 190 20 PSI with a 4:1 ratio of  $H_2$ :CO<sub>2</sub> and then incubated at 37 °C for 5 days.

191

#### 192 RESULTS

#### 193 McmA and McmB display in vitro DNA helicase activity

194 To investigate whether individual MCMs possessed DNA helicase activity, hexa-195 histidine-tagged recombinant McmA, McmB and McmC were purified using affinity and 196 anion exchange chromatography (Fig. 2(a)). McmD was largely insoluble when 197 expressed recombinantly, even when protein folding was facilitated by the presence of 198 Oleispira antarctica chaparones Cpn10 and Cpn60 at 12°C. Size exclusion 199 chromatography of soluble Mcms A-C under different salt conditions support the notion 200 that these complexes might form a range of multimeric complexes in solution (Fig. S2). 201 Walker A motif lysine to glutamate (K>E) mutants were expressed and purified in the 202 same manner and used as negative controls in DNA helicase assays (Fig. 2(b)-(d)). The 203 helicase activity of individual MCMs was tested using a strand displacement assay with a 204 forked substrate containing a 25 bp double-stranded region [36]. Both McmA and McmB 205 showed protein concentration-dependent helicase activity (Fig. 2(b),(c)). The unwinding 206 activity of McmB at the highest protein concentration (82% of substrate) was slightly 207 higher than that of McmA (77% of double stranded substrate). However, McmB 208 displayed considerably higher DNA unwinding rates than McmA at lower protein 209 concentrations (Fig. 2(e)). In contrast, we were unable to detect any significant DNA 210 helicase activity in McmC over the same range of concentrations (Fig. 2(d)).

211

#### 212 McmA is essential

213 In order to ascertain whether any of the *M. maripaludis* MCMs were essential, deletions 214 of each of the four individual MCMs were undertaken using a markerless mutagenesis 215 strategy [37]. Genomic DNA was isolated from the resulting strains and analysed by 216 Southern blotting to confirm whether a deletion mutant could be generated for each 217 MCM gene. Deletion mutants were isolated for mcmB, mcmC and mcmD, demonstrating 218 that these three genes are non-essential (Fig. 3(b)-(d)). We were unable to isolate a 219 mcmA deletion strain despite screening more than 75 colonies from three independent 220 transformations, consistent with the hypothesis that this gene is essential (Fig. 3(a)). 221 This observation is supported by a recent genome-wide transposon mutagenesis study 222 in *M. maripaludis* that classified McmA as "possibly essential" [39].

223

#### 224 Deletion of non-essential MCMs results in proliferation defects

We generated growth curves for each of the  $\Delta mcm$  strains from batch cultures grown in a 3 litre anaerobic fermenter to compare to WT (Mm900, Fig. 4(a),(b)), [37]. In all cases doubling times of the  $\Delta mcm$  strains were shorter than WT, although specific growth rates and doubling times of  $\Delta mcmB$  and  $\Delta mcmD$  were very similar to those calculated for WT (Table 1).  $\Delta mcmC$  displayed an obvious decrease in calculated doubling time compared to WT of ~20% (Table 1). Lag phases for all  $\Delta mcm$  strains were longer than observed for WT (Fig. 4(a)). Further experiments are required to understand this phenomenon.

232

233 DNA content and cell size for samples taken throughout the growth period were 234 analysed by flow cytometry (Fig. 4(c)-(e)) and compared between WT and  $\Delta mcm$  cells at 235 similar optical densities across the entire growth range. The cell cycle distribution of M. 236 maripaludis is similar to that observed for Methanocaldococcus jannaschii [40]. M. 237 maripaludis cells show a broad distribution of DNA content and cell size, with no distinct 238 genome peaks visible during exponential growth in contrast to the distinct genome peaks 239 observed for Archaeoglobus fulgidus, Methanothermobacter thermautotrophicus and 240 Sulfolobus solfataricus [32,40,41]. This observation supports the previous observation 241 [42], that *M. maripaludis* cells are highly polyploid under normal growth conditions, as is 242 the case for exponentially growing bacteria [43] and halophilic archaea [44].

244 Although some consistent minor differences between WT and *AmcmB or AmcmC cells* 245 were observed, overall these deletions appeared to have no significant effects on cell 246 size or DNA content compared to WT (Fig. 4(c), (d)).  $\Delta m cmD$  cells were larger than WT 247 in all growth phases. *AmcmD* cells also possessed a greater DNA content than WT in 248 early and mid-log growth (Fig. 4(e)). AmcmD cells with a very low DNA content 249 increased dramatically in late log/stationary phase to become the dominant population. 250 This phenotype could be indicative of DNA breakage, perhaps caused by incomplete 251 DNA replication, aberrant DNA segregation, defective cell division or an inability to 252 effectively repair DNA damage accumulated during growth.

253

#### 254 MCMs mediate a DNA damage response

255 To determine whether the *AmcmD* cell cycle distribution differences we observed were 256 due to a defect in the ability of these cells to respond to DNA damage, we subjected WT 257 and mutant strains to increasing doses of UV radiation. Consistent with previous reports 258 [45] we found *M. maripaludis* S2 cells to be highly sensitive to UV damage (Fig. 5(a)). 259 This sensitivity was dramatically increased in  $\Delta m cmD$  but slightly reduced in both 260  $\Delta m cmB$  and  $\Delta m cmC$ , which were more resistant to low doses of UV damage than WT. 261 These phenotypes were confirmed by exposing the same strains to ionising radiation, 262 where  $\Delta m cm D$  also showed hypersensitivity this type of damage (Fig. 5(b)). Consistent 263 with our observations for UV damage,  $\Delta m cmB$  and  $\Delta m cmC$  showed an increased 264 resistance to ionising radiation compared to WT (Fig. 5(b)).

265

#### 266 DISCUSSION

267 We have produced recombinant protein for three highly similar McmA-type MCMs from 268 *M. maripaludis* S2. McmA and McmB displayed DNA helicase activity but McmC did not. 269 Interestingly, although measurements by size exclusion chromatography shows 270 complexes of different sizes under different conditions for McmA and McmB, they were 271 still able to unwind DNA. This situation is similar to that described for the eukaryotic 272 MCMs where a complex of MCMs 4, 6 and 7 is sufficient for in vitro helicase activity 273 (probably as a dimer of trimers), but the active complex *in vivo* is additionally modulated 274 by the presence of other MCM subunits [46]. M. maripaludis encodes multiple RecJ 275 homologues, several of which have been shown to be non-essential, and a single GINS 276 protein, which is probably essential [39]. We have previously reported the recovery of a 277 complex containing all four recombinant *M. maripaludis* Mcm proteins, supporting the 278 notion that a heteromeric complex may be formed in vivo [28]. It is also possible that 279 more than one Mcm complex is formed in vivo, providing different functions. The 280 absence of helicase activity in McmC and the faster unwinding rate of McmB suggest 281 that additional amino acids to those already identified in the MCM proteins are critical for 282 modulating helicase activity in complexes formed by individual proteins. A detailed 283 analysis of the McmC sequence compared to McmA/McmB could provide important 284 insights into the modulation of MCM helicase activity and the molecular mechanisms 285 governing this activity in eukaryotes.

286

287 Our results demonstrate that *M. maripaludis* possesses multiple functional MCMs, one of 288 which is essential, with the other three causing defects in cell proliferation and the 289 response to DNA damage when deleted. mcmA could not be deleted and displays 290 robust helicase activity in vitro. McmB had more vigorous DNA helicase activity than 291 McmA in vitro and when deleted, increased resistance to DNA damage.  $\Delta mcmC$ 292 displayed a faster growth rate than WT and increased resistance to DNA damage. In 293 contrast, *AmcmD* showed a striking increase in DNA damage sensitivity. A previous 294 shotgun proteomics study detected peptides for McmA, McmB and McmD in vivo [47]. 295 These data support our findings that McmB and McmD have functional roles in vivo. 296 While peptides for McmC were not detected, this does not definitively prove that such 297 peptides were not present. We have been unable to obtain sufficient soluble McmD to 298 conduct helicase assays, so whether McmD is an active helicase remains unknown. Our 299 previous genome context analysis revealed an upstream ORF of unknown function that 300 is likely to be operonic with mcmD in M. maripaludis S2 [28]. Interestingly, this ORF is 301 highly conserved throughout the *Methanococcales* (Fig. S3, S4), but not found in any 302 other species. The positioning of this ORF contiguous with *mcmD* is conserved among 303 the mesophilic Methanococcales. It is possible that co-expression of this smaller ORF 304 with McmD would produce soluble protein to allow biochemical analysis.

305

We have previously noted that McmD possesses a modified zinc finger and C-terminal and 20 amino acid insert and similar features are found in eukaryotic MCM3 [28]. MCM3 has been implicated in the regulation of the eukaryotic MCM complex [4], and has been shown to be a specifically phosphorylated by ATM/ATR kinases [10]. An apparent requirement for the specific proteolysis of eukaryotic MCM3 before apoptosis can be

311 induced has also been reported [48,49]. Thus the notion of a specialised Mcm as a 312 nexus for a modulatory or checkpoint decision is not without precedent. The response of 313 AmcmD to UV and ionizing radiation supports the notion that McmD is important either in 314 modulating a response to DNA damage or that McmD is important in controlling the 315 polyploidy observed in *M. maripaludis*, which in turn could influence the cell's ability to 316 repair damage through homologous recombination pathways as reported for 317 Deinococcus. The altered cell size and DNA content of *AmcmD* measured using flow 318 cytometry, supports the hypothesis that McmD may have a role in proliferation control.

319

320 *AmcmB* or *AmcmC* strains are more resistant to DNA damage than WT. This response is 321 reminiscent of phenotype observed in polyploid Haloferax volcanii when the DNA repair 322 genes mre11 and rad50 are deleted [50]. It has been suggested the Mre11-Rad50 323 complex delays the repair of damage by homologous recombination to allow DNA repair 324 to occur more rapidly using microhomology mediated end-joining, avoiding the 325 complications inherent in using homologous recombinational repair in a polyploid 326 organism. H. volcanii mre11 rad50 mutants therefore undergo homologous repair more 327 readily than WT, enhancing cell survival but reducing the recovery rate from DNA 328 damage [50]. AmcmB or AmcmC strains may bypass the preferred DNA damage 329 response to similarly undergo homologous recombination to repair DNA damage. 330 Whether the DNA repair processes that take place under these circumstances are error-331 prone or error-free and whether the long-term fitness of  $\Delta m cmB$  or  $\Delta m cmC$  strains is 332 reduced remains to be determined.

333

334 The responses to deletion of MCM genes in *M. maripaludis* have allowed us to clearly 335 describe the first example of an archaeal organism where MCMs play a role in the 336 response to DNA damage. This observation indicates that, as in eukaryotes, the multiple 337 MCMs in *M. maripaludis* have evolved to perform specialized functions. Interestingly, 338 protein interaction studies in *T. kodakarensis* show that non-essential MCM1 and MCM2 339 co-purify with proteins with known roles in DNA repair [51], although a role for these 340 MCMs in DNA repair has not be established. Our data demonstrating that multiple 341 functional MCMs are present in *M. maripaludis* indicate that this organism provides a 342 useful biochemical and genetic system that could provide further insight into eukaryotic 343 MCM function.

#### 504 **Table 1**

505 Growth rates of Mm900 (wild type) and  $\Delta mcm$  strains calculated from Fig. 4(b).

506

Strain	Specific growth rate (µ)	Doubling time (hours)
		T <sub>2</sub> =In2/µ
Mm900 (WT)	0.0029	3.98
∆mcmB	0.0032	3.61
∆mcmC	0.0036	3.20
∆mcmD	0.0030	3.85

507

508

#### 509 FIGURE LEGENDS

510

#### 511 Figure 1

512 Multiple potentially functional MCMs in *M. maripaludis*.

(a) The *Methanococcus maripaludis* MCMs are more related to each other than to other
archaeal MCMs. Phylogenetic tree of *M. maripaludis* MCMs (Mmp) compared to MCM
sequences from *Methanothermobacter thermautotrophicus* (Mth), *Archaeoglobus fulgidus* (Afu), *Sulfolobus solfataricus* (Sso), *Aeropyrum pernix* (Ape) and *Korarchaeum cryptophilum* (Kcr).
(b) *M. maripaludis* MCMs appear to contain all the sequence motifs known to be required

for helicase activity. Alignment of the sequences used in (a) in the same order showing conservation of motifs and essential residues that have been experimentally determined to be required for helicase activity. The helix-2 insert (h2-i) is not conserved at amino acid level, but is present in all sequences and shown as a box. Catalytically important amino acids are shown in bold, residues that deviate from typical motifs, but are known to support function are shaded.

525

#### 526 **Figure 2**

527 Biochemical characterisation of MCMs in *M. maripaludis*.

528 (a) SDS-PAGE gels showing purified recombinant McmA, B and C proteins after affinity

529 (Co<sup>2+</sup>) and anion exchange (AX) chromatography. (b) strand displacement assay for 530 McmA. Protein concentrations are indicated in fmol hexamer. K>E indicates Walker A

- 531 mutant of McmA (1200 fmol hexamer), -ATP is wild type protein (1200 fmol hexamer) in
- 532 the absence of ATP. (c) strand displacement assay for McmB. Lanes and protein

533 concentrations are as indicated for (b). (d) strand displacement assay for McmC. Lanes 534 and protein concentrations are as indicated for (b). (e) quantification of strand 535 displacement activities for McmA (closed circles), McmB (open circles) and McmC 536 (crosses), representative data were acquired from the figures in (b)-(d). Each experiment 537 was repeated at least three times.

538

#### 539 **Figure 3**

540 Three of the four MCMs in *M. maripaludis* can be deleted.

541 The Mm900 (WT) strain was subjected to markerless mutagenesis (Moore and Leigh, 542 2005) to delete MCM genes. Strains were recovered and subjected to Southern blot to 543 confirm whether deletion strains could be generated. In all cases, lane 1 contains 544 molecular weight markers, lane 2 WT genomic DNA, lane 3 the relevant merodiploid to 545 show that the mutagenesis was successful. (a) no deleted strains of mcmA were 546 recovered. Lanes 4-23 are WT strains recovered from markerless mutagenesis. (b) 547 AmcmB strains were identified in lanes 13, 21 and 23. (c) AmcmC strains were identified 548 in lanes 4, 6, 8, 12, 16 and 21. (d)  $\triangle m cm D$  deleted strains were identified in lanes 8, 11 549 and 20.

550

#### **551 Figure 4**

552 MCM deletions result in proliferation defects.

553 (a) Time course measurements of  $OD_{600}$  as an indication of cell number. WT (Mm900, 554 closed circles) or *M. maripaludis* strains harbouring deletions in *mcmB* (open circles). 555 mcmC (closed squares) or mcmD (open squares) were grown in a 2L batch culture and 556 sampled as indicated. (b) Exponential growth data from (a) replotted as In(OD<sub>600</sub>) for the 557 calculation of doubling times (see Table 1). Symbols as for (a), regressions shown as 558 grey dotted lines. (c) - (e) Flow cytometry indicates that deletion of non-essential MCMs 559 in *M. maripaludis* results in a proliferation phenotype. (c)  $\Delta m cm B$ , (d)  $\Delta m cm C$ , (e) 560  $\Delta m cm D$ . In each panel the profile for WT cells at a similar OD<sub>600</sub> is shown in grey, the 561 MCM deleted strain profile is shown as a black line. Discontinuities at the mid-point in 562 each curve are due to automatic switching between different photomultipliers for 563 detection of small signals in the Apogee flow cytometer used to make these 564 measurements. Within each group of panels, the left column panels show light scatter as 565 an indication of cell size; the right column panels show fluorescence as an indication of 566 DNA content. Event number is normalized. Data are plotted on a logarithmic scale. 567 Numbers indicate the OD<sub>600</sub> of deletion strain (top) compared to wild type (bottom).

568

#### 569 **Figure 5**

570  $\triangle mcm$  strains show DNA damage phenotypes.

571 (a) WT *M. maripaludis* (Mm900, closed circles), *∆mcmB* (diamonds), *∆mcmC* (triangles) 572 or *AmcmD* (open circles) strains were plated at different dilutions before being irradiated 573 with UV light (254 nm) as indicated. Surviving cells were calculated by enumerating 574 colonies formed. The mean and standard errors for three independent experiments are 575 shown. *AmcmB* and *AmcmC* strains are more resistant to low UV doses than WT, 576 whereas  $\Delta m cm D$  is more sensitive to this type of damage. (b) The same strains, 577 indicated by the same symbols as (a) were subjected to ionizing radiation (X-rays) as 578 indicated. *AmcmD* was substantially more sensitive to DNA damage than WT or the 579  $\Delta m cmB$  and  $\Delta m cmC$  strains, which were more resistant to damage. The mean and 580 standard errors for three independent experiments are shown.
