26 Abstract

Children's participation in physical activity (PA) has important positive benefits for their 27 health and academic outcomes. Within the school day, physical education (PE) is 28 increasingly endorsed as a key time for children to accumulate PA. Despite this 29 increasing emphasis, research papers and policy documents frequently identify PE 30 lessons as 'not active enough'. However, contemporary objectives for sufficient PA in 31 PE may not be based on the highest quality evidence. Furthermore, while the 32 objectives appear compatible, they contain profound differences. Continued pursuit of 33 these objectives may be detrimental to achieving positive experiences of PA in PE. 34 For instance, an exclusive focus on PA objectives may encourage teachers to prioritise 35 36 fitness-based activities over others that young people enjoy. Pursuing short-term goals for PA also risks investing limited lesson time to develop important elements of 37 physical literacy that only become developed after prolonged engagement and 38 39 practice. Importantly, what is at stake is not only achieving sufficient PA in PE, but also encouraging lifelong participation in PA and the long-term health of today's children. 40

41

Even though physical activity (PA) contributes to better health, many young people fail 42 to achieve the target of 60-minutes per day (1). The whole school day, and within that 43 Physical Education (PE), are increasingly seen as important opportunities to 44 accumulate PA (1-3). Paradoxically, even though school days including PE are more 45 active than those that are not (3), PE is frequently identified as insufficiently active (4). 46 Research papers and policy documents commonly use two objectives, advocated by 47 organisations within the UK (3) and the USA (5), to ascertain if PE is active enough 48 (Table 1). However, each objective lacks grounding in contemporary evidence and, 49 despite assumptions of their equivalence, contain profound differences. Furthermore, 50 51 over-diligent pursuit of these objectives by research and policy may result in teachers prioritising fitness-based activities over others, such as those that develop physical 52 literacy (6). This is despite increased fundamental movement skill competency, a key 53 component of physical literacy, predicting increased adolescent PA (6). 54

55

Table 1: A summary of objectives to increase activity within physical education

57

Organisation	Objective for 'sufficient' PA
Association for Physical Education (AfPE) (3)	Students should be <i>actively moving</i> for at least 50-80% of the available learning time
The U.S. Department of Health and Human Services (HHS) (5)	Students should engage in moderate-to-vigorous physical activity (<i>MVPA</i>) for >50% of the time they spend in PE class

58

The evidence underpinning current objectives (Table 1) is anachronistic, particularly 59 as objective measures of PA are now used to evaluate PA in PE (4). The Association 60 for Physical Education (AfPE) objective fails to cite evidence that informs the 61 recommended duration and intensity of PA in PE (3). The US Department for Health 62 and Human Services (HHS) objective is based on a combination of evidence - all of it 63 low quality; self-reported time spent playing sport, expert advice, interpretations drawn 64 from behavioural theory and a selection of exemplary practice (2,7). This 65 misalignment, predominantly arising from the discrepancy between self-report and 66 67 objective measurement of PA, may be one explanation why few contemporary PE lessons are deemed 'active enough' (4.8). 68

69

A plethora of research, including our own (8), fails to recognise and/or acknowledge these important differences between objectives. This issue is best illustrated by a recent meta-analysis (4), which concluded; objectively measured PA during PE met neither the HHS nor the AfPE objectives for >50% of PE in moderate-to-vigorous physical activity (MVPA). However, Table 1 clearly shows how only HHS specified a threshold of MVPA intensity.

76

As we move towards research informed practice, it is essential that objectives for PA in PE are appropriate. The uncompromising pursuit of these objectives by research and policy (4,8) is concerning as it may cause teachers to focus on PA, at the expense of fostering an enjoyment of PA or developing physical literacy (2,6). This pursuit has already led to unsubstantiated calls by OFSTED (within the UK, 9) for teachers to engage pupils in sustained periods of high-intensity PA. However, adherence literature demonstrates how sustained, high intensity PA can reduce subsequent motivation forPA.

85

A contextualised example highlights the difficulties a teacher may face when trying to 86 achieve the multifaceted outcomes of PE. Imagine this common lesson scenario; the 87 teacher asks pupils to consider how to effectively penetrate a defence in an invasion 88 game. In addition to being 'active enough', children must consider a tactical 89 appreciation of the task, communicate with teammates, allocate roles and 90 responsibilities, and review their success. In this example, the teacher is pursuing an 91 92 appropriately wide range of learner experiences, alongside encouraging PA. While some of this lesson content may have caused inactivity - and conflict with PA 93 94 objectives - it may be essential to develop the physical literacy that contributes to 95 adolescent PA (6).

96

97 Current objectives for PA in PE need refining as they are underpinned by low-quality evidence and contain unacknowledged differences in PA intensity and duration (2). 98 99 Research must move beyond considering levels of MVPA in isolation. Future research may be warranted to develop an appreciation of how much objectively measured 100 MVPA can be achieved within a typical PE lesson, while meeting the other 101 multifaceted aims of PE, for instance, the need for developing physical literacy. While 102 the quest for PA is important, this must not be at the expense of developing physically 103 104 literate young people.

105

Finally, while PE may be reasonably expected to make a substantial contribution to 106 children's daily PA, this must not sacrifice other important PE outcomes. Given their 107 108 long-term value, these other markers of PE quality - such as the enjoyment of PA, or the development of physical literacy - need to be afforded renewed priority, perhaps 109 by explicit integration into future objectives (2,10). To support the development of 110 objectively determined PA objectives, in tandem with achieving the multifaceted 111 requirements of PE, it is essential that education makes a full contribution to these 112 public health debates. Acknowledging that interventions within PE generate only small 113 increases in PA (10), it is now time to look beyond PE as a "silver bullet" for resolving 114 the inactivity crisis, toward all segments of the school day. Importantly, what is at stake 115 is not just achieving PA in PE, but encouraging lifelong participation in PA and the 116 long-term health of children. 117
