DIARY 1949

B. Bragge Received 1.2.49

PREFACE TO THE TWENTY-FIFTH EDITION.

Twenty-five years have now elapsed since we first produced this desk diary for the use of the medical profession.

Its popularity proves that it has served the purpose for which it was intended, i.e., a useful diary and a quick source of up-to-date information on nutrition.

NESCAFÉ.

During the past year a new product, NESCAFÉ, has been placed on the Australian market.

NESCAFÉ is a soluble coffee product in powder form. It consists of equal parts of coffee extract and added carbohydrates, mixed together and spray dried.

On account of its simplicity and economy the medical profession can confidently recommend Nescafé to replace ground coffee.

NESTLÉ'S HOMOGENIZED FOODS.

Nestlé's Homogenized Foods for young children will also be available during the coming year.

*These foods are strained and homogenized, a process which breaks up the food cells, releasing the nourishment, and reducing coarse fibres to minute particles.

The foods are in the form of a smooth purée suitable for infants.

Nestlé's Homogenized Foods are widely used in England and U.S.A. for infant feeding and under medical advice have been fed to infants at an early age.

The general recommendation in England is from four months.

We are pleased to acknowledge all extracts from scientific publications which we have used in compiling the present Edition, and also to thank those members of the Medical Profession who have made available to us helpful information.

It is our earnest endeavour to follow the latest developments in Infant Nutrition and suggestions are therefore always welcome.

* Bone and Vegetable Broth. Garden Vegetables. Carrots. Prune with Orange Juice.

NUTRITION ABSTRACTS

of current scientific papers on nutrition with special emphasis on infant and child nutrition*

* Compiled by Research Dept., Nestlé's Milk Products Inc., New York.

Nutrition of Infants and Children

A Self-Regulating Feeding Program for Infants

C. A. Aldrich and E. S. Hewitt-J. Am. Med. Assn. 135: 340, 1947

Six hundred and sixty-eight infants were put on a self-regulating schedule of feeding on leaving the hospital, and then supervised for a year in a well-baby clinic. They gained satisfactorily in weight and height. At the age of one year, 92 per cent. were considered to have excellent appetites and less than 1 per cent. poor appetites. The feeding intervals gradually lengthened until, by the age of one year, 91 per cent. were on a schedule of three meals a day. During the first two months, many infants desired food at less than four-hour intervals.

Some Factors which Influence the Duration of Breast Feeding

M. A. Norval-J. Pediat. 31: 415, 1947

Four hundred and sixty-two women who expressed a desire to nurse their infants were observed. Lactation was less successful in women over 30 years old, especially if there were no other children, although age and number of children did not affect the duration of lactation if it were established before leaving the hospital. Women living in the country nursed their infants for an average of 0.8 months longer than those living in towns. Adequacy of lactation decreased with increasing time before engorgement occurred, and was less successful in those with mild or severe engorgement than in those with moderate engorgement. The birthweight of the infant was not a factor in lactation performance. The first month is the time during which breast feeding is most apt to be discontinued.

Nutritional Disturbances and the Oral Use of Amino Acids in Infants

M. Langlois-Canad. Med. Assn. J. 57: 31, 1947

Amino acids have been given orally to some forty malnourished infants, usually suffering from severe diarrhea or acute dyspepsia. Amino acids appeared to have not only high nutritional value but also a beneficial effect on parenteral infections and the response to treatment with drugs. This type of feeding is recommended as a routine procedure.

Meat in the Diet of Young Infants

R. M. Leverton and G. Clark-J. Am. Med. Assn. 134: 1215, 1947

Eighteen six-weeks-old infants were given formulae to which about one ounce of strained meat was added, which increased the protein intake by 25 per cent. The infants were considered to be in even better physical condition than were control babies, and did not show the characteristic drop in hemoglobin.

A Comparison of Cereals and Their Value in the Feeding of Infants and Children

R. A. Benson and F. T. Kimball-Arch. Pediat. 64: 476, 1947

Twenty-five cereals commonly used for infants and children were analyzed for their contents of carbohydrate and of total available carbohydrate. The rice cereals were found to have the highest content of available carbohydrate. Moreover, they are easily digested and are rapidly converted to energy. Allergic reactions to rice are rare. When finely milled and fortified with vitamins, rice is a particularly valuable food for infants and young children.

Nutritional Requirement of the Adolescent and Its Relation to the Development of Disease

J. A. Johnston-Am. J. Dis. Child. 74: 487, 1947

Children of the same chronological age may differ widely in physiological development and pattern of growth, and such differences may be particularly noticeable at adolescence. The changing growth rates of adolescence are accompanied by changing nutritional requirements Variations in basal metabolic rates may be noted, and mild hypothyroidism is not uncommon during puberty and postpuberty. Calcium intake during puberty should be about 1.4 gm. daily, and 1,000 to 1,500 U.S.P. units of vitamin D daily is strongly recommended. A tendency to obesity may be exaggerated during adolescence, and should be treated by a diet low in calories but high in protein and calcium, with consideration of possible psychologic factors. Diminished retention of nitrogen and calcium during the period of decelerating growth rate appears to be accompanied by decreased resistance to infections. Mortality from tuberculosis increases during this period. Menstrual problems in the adolescent girl may be aggravated by nutritional aberrations, by lack of outdoor exercise, or by glandular disturbances.

The Determination of Status and Progress in Children with Nutritive Failure

A. W. Mann, S. Dreizen and T. D. Spies-J. Pediat. 31: 161, 1947

Forty-seven children 5 to 15 years of age, and 47 control children, were observed for two years. The first group either had or had had symptoms of nutritional deficiency as a result of inadequate diet; the control group were free of such symptoms and probably received adequate diets. Physical status was analyzed by the Wetzel technic, and medical examinations and dietary studies made. X-ray studies are a desirable supplement in recognition of small stature due to inheritance or to poor nutrition. The children of the first group developed more slowly than those of the second and continued to fall farther behind in rate of development during the period of observation. Since they did not suffer from a higher incidence of illness, inadequate nutrition is the most probable explanation of their slow and irregular growth rates.

Prevalence of Dental Caries in Malnourished Children. A Clinical Study

S. Dreizen, A. W. Mann, T. D. Spies and T. A. Skinner-Am. J. Dis. Child. 74: 265, 1947

The incidence of dental caries in deciduous teeth of 72 malnourished children was not significantly different from the incidence in a control group of 25 well-nourished children, nor was there a difference in 25 malnourished children who had received supplements of one quart of milk daily. Both groups of malnourished children showed less increase in caries than did the control children, or than the national average for yearly increase. "The results cannot be explained fully on the basis of present knowledge of dental caries."

Chemical Studies in Children with the Nephrotic Syndrome

S. P. Gottfried, J. F. Steinman and B. Kramer—Am. J. Dis. Child. 74: 283, 1947

Ten children with nephrosis, aged 16 months to 5 years, were studied for two years. The most effective therapy was restriction of salt intake, parenteral replacement of proteins, and peni-

cillin to combat infections. Plasma amino acid nitrogen was normal or slightly above, some disturbance of carbohydrate absorption and utilization was indicated by the glucose tolerance curves, blood lipid and carotene were high, plasma vitamin A was usually normal. Hepatomegaly was often found. Edema usually occurred at levels of serum protein below 4.0 gm./100 cc. and progressed regardless of fluctuations in serum protein. Serum cholesterol did not appear to correlate with serum protein or the extent of edema.

Changes in the Bone Marrow in Megaloblastic Anemias of Infancy Before and After Folic Acid Therapy

W. W. Zuelzer, A. Newhall and L. Hutaff-J. Lab. and Clin. Med. 32: 1217, 1947

Fifteen infants, aged five weeks to one year, having infantile megaloblastic anemia, were given folic acid daily, usually by intramuscular injection. Within 24 hours after the first injection there were definite changes in the bone marrow, followed by improvement in the peripheral blood. Serial studies of the bone marrow were made. There is evidence that erythroblasts undergo progressive structural and functional changes in the absence of the hematopoietic principle. These changes are reversible in the earlier stages.

Thiamine, Riboflavin, Nicotinic Acid, Pantothenic Acid and Biotin in the Urine of Newborn Infants

B. M. Hamil, M. Coryell, C. Roderuck, M. Kaucher, E. Z. Moyer, M. E. Harris and H. H. Williams—Am. J. Dis. Child. 74: 434, 1947

Urinary excretion of vitamins by infants was highest during the first three days, and decreased as the supply of breast milk increased. The maximum average urinary content of thiamine was 13 micrograms/100 cc., on the third day; of pantothenic acid was 213 micrograms, on the third day; of riboflavin was 140 micrograms, on the first day; of nicotinic acid was 128 micrograms, on the second day; of N'-methylnicotinamide was 3,820 micrograms, on the second day; and of biotin was 4 micrograms, on the second day. The subjects were normal healthy infants, all breast-fed. Average concentrations on the seventh day were: 2 micrograms of riboflavin, 14 micrograms of nicotinic acid, 60 micrograms of N'-methylnicotinamide, 99 micrograms of pantothenic acid, and no thiamine or biotin.

Vitamin C in the Blood and Urine of the Newborn and in the Cord and Maternal Blood

B. M. Hamil, B. Munks, E. Z. Moyer, M. Kaucher and H. H. Williams-Am. J. Dis. Child. 74: 417, 1947

The vitamin C content of maternal blood was found to be from 0.04 to 1.19 mg./100 cc. on the first day post partum, of infant's blood was 0.20 to 1.72 mg./100 cc., and of cord blood was 0.66 to 2.18 mg./100 cc. There were wide variations between individual mothers and infants during the first week. The urinary vitamin C of the infants was high during the first two days, was low by the fourth day. "The declining levels of vitamin C in the urine and plasma during the first week of life suggest that the physiologic processes of intrauterine life require greater tissue saturation of the vitamin than is necessary in the gaseous environment of extrauterine existence."

A Comparison of Vitamin C in Mothers and Their Premature Newborn Infants

L. B. Slobody, R. A. Benson and J. Mestern-J. Pediat. 31: 333, 1947

Thirty newborn premature infants were given the intradermal test and found to have good levels of vitamin C even when the mothers were depleted. Good tissue concentrations were maintained by giving 50 mg. daily of ascorbic acid.

Subjects of General Interest

Bacteriology of the Collection and Preservation of Human Milk

J. Wright-Lancet 1947 II: 121

Human milk collected by the commonly used methods had bacterial counts of from 3,700 to over 8,000,000 per ml. Such milk was often stored at room temperature and used for feeding without heat treatment. A method for collection of human milk was developed, using only boiled collecting equipment and pumps, which resulted in milk with bacterial counts of 70 to 39,000 per ml. The milk should be brought to a boil immediately after collection, then refrigerated until needed.

Tocopherols (Vitamin E) in Milk: Their Chemical Determination and Occurrence in Human Milk

M. L. Quaife-J. Biol. Chem. 169: 513, 1947

Tocopherols were determined in milk by an adaptation of the method used with blood plasma. Fifteen samples of human milk collected during the first week contained 0.13 to 3.6 mg. per 100 ml. of vitamin E. Samples collected during the first to the eighth month contained a mean of 0.14 mg. per 100 ml.

Progress of Bread and Flour Enrichment

Editorial-J. Am. Med. Assn. 135: 226, 1947

Although the majority of breads and flours are enriched, the low priced, unenriched products are used by the low income groups who are most in need of the added nutrients. Compulsory enrichment legislation has been enacted in 21 States, and its extension is urged. Milk, nonfat milk solids, yeast, corn germ, and pure vitamins can be used in bread making. Opposition to the enrichment program is ill-founded.

Further Observations on the Production of Canine Hysteria by Flour Treated with Nitrogen Trichloride (Agene Process)

E. Mellanby-Brit. Med. J. 1947 II: 288

Wheat flour "improved" by treatment with nitrogen trichloride has been shown to produce hysteria, or running fits, in dogs. The toxic substance was found to be associated with both the gliadin (alcohol soluble) and the glutelin (alcohol insoluble) fractions of gluten from agenized flour, and is not carried in the wheat fat. The symptoms are not produced in rats or mice, but are produced, somewhat less readily, in ferrets.

The Effect of Environmental Temperature on Food Selection

S. Donhoffer and J. Vonotzky-Am. J. Physiol. 150: 329, 1947

Groups of white mice were offered rations rich in either starch, casein, or lard. If environmental temperature were reduced to 10-11° C., food consumption increased, the additional food chosen being that high in carbohydrate. If environmental temperature were raised to 29-30° C., food consumption decreased, the decrease being of the high carbohydrate food.

The Effects of Dietary Caloric Restriction on Maturity and Senescence, with Particular Reference to Fertility and Longevity

Z. B. Ball, R. H. Barnes and M. B. Visscher-Am. J. Physiol. 150: 511, 1947

Female mice were fed diets so restricted in carbohydrate and fat as to supply only about two-thirds of the normal caloric intake. The average life span was significantly lengthened,

and maturation postponed. When *ad libitum* feeding was permitted at eight months—at which age normally fed controls were reaching senile sterility—they matured and attained approximately normal fertility.

Hormones and Lactation. Dried Thyroid Gland

M. Robinson-Lancet 1947 II: 385

Deficiency of thyroxine production appears to cause failure of lactation. No sign of thyroid deficiency was noted in the mothers. However, such a condition evidently was precipitated by the extra stress of lactation. In some cases more than 12 gr. daily of dried thyroid was needed. Milk production often decreased when treatment was discontinued, especially in those requiring the large doses. Administration of iodine increased lactation, and failure may thus be due to iodine deficiency rather than to a defect of the thyroid gland.

Tyrosine Tolerance Test in Pregnancy and the Puerperium

E. W. Page-Proc. Soc. Exper. Biol. and Med. 66: 79, 1947

The tyrosine tolerance test appears unsatisfactory as a measure of liver function during pregnancy and the puerperium. Eight normal women in the last two months of pregnancy, one with eclampsia, one with severe preeclampsia, seven after normal delivery, and ten control subjects of comparable ages were observed in the study. Fasting blood tyrosyl falls significantly during pregnancy, is normal in the puerperium. The tyrosine tolerance curve is lowered during pregnancy, returns to normal immediately after delivery. The tyrosine tolerance curve was not affected by eclampsia or preeclampsia. Tyrosine, unlike histidine, appeared to be reabsorbed from the renal tubules as completely in pregnant as in control subjects.

The Gastrointestinal Tract and Nutrition in Rheumatoid Arthritis

P. J. Warter, R. W. Betts and S. Horoschak-Rev. Gastroenterol. 14: 617, 1947

Chronic rheumatoid arthritis may lead to poor nutrition through subnormal gastrointestinal tract function. Ten patients with rheumatoid arthritis were given 8 tablespoons daily of a protein hydrolysate and B vitamin supplements for two months or more. Notable objective and subjective improvement followed. Seven patients gained weight, hemoglobin level rose in eight cases, sedimentation rate declined in nine cases, and in four of the five cases in which there had been edema of the joints the edema was improved or entirely relieved. Further study of nutritional factors in rheumatoid arthritis is suggested.

The Treatment of Cirrhosis of the Liver with Crude Liver Extract by the Intravenous Route

W. B. Rawls and V. C. Ancona-Rev. Gastroenterol. 14: 685, 1947

Cirrhosis of the liver may now be treated quite effectively by the use of a good diet high in protein and carbohydrates and low in fats, with supplements of B vitamins and liver extract. Twenty-two patients in this series were given crude liver extract intravenously for four months or more—a therapy considered to be safe and of definite benefit. Eighteen patients survived for at least 15 months, 4 required no treatment for from 4 to 12 months. Restoration of appetite was frequently the first sign of improvement.

Protein

Comparative Nutritive Value of Casein and Lactalbumin for Man

A. J. Mueller and W. M. Cox, Jr.-J. Nutr. 34: 285, 1947

Four normal adults were protein depleted for 12 days, then given protein supplements of 2 per cent. of casein or lactalbumin for four-day periods, alternating with four-day depletion periods. Casein and lactalbumin were of equal biological value and were equally effective in maintaining nitrogen balance.

The Effect of the Rate of Administration of Amino Acid Preparations and Blood Amino Acid Nitrogen Level on the Production of Nausea and Vomiting

C. J. Smyth, A. G. Lasichak and S. Levey-J. Lab. and Clin. Med. 32: 889, 1947

Patients given amino acid mixtures intravenously suffered less from nausea and vomiting than patients given casein hydrolysates. Amino acids could be injected quite rapidly without ill effects, while casein hydrolysates must be given much more slowly. The occurrence of nausea and vomiting depended upon the mixture used and the susceptibility of the subject, rather than upon the increased concentration of amino acids in the blood.

The Effect of Amino-Acids on Gastric Acidity

J. Feller and C. J. Tidmarsh-Canad. Med. Assn. J. 57: 23, 1947

A regular test meal and a test meal plus amino acids were given to 16 subjects—normal persons and ulcer patients. Single large doses of amino acids (50 gm.) reduced gastric acidity to 0 for one and one-half hours, which was followed by a rebound rise to high acidity. Frequent small doses of amino acids reduced gastric acidity only slightly and briefly, followed by a high secondary acidity.

Experiments with Delayed Supplementation of Incomplete Amino Acid Mixtures

E. Geiger-J. Nutr. 34: 97, 1947

In rats fed amino acid mixtures deficient in tryptophane, methionine or lysine, the lack was not compensated by feeding the missing amino acid several hours later. Evidently all the required amino acids must be present simultaneously for protein synthesis. The incomplete mixtures are not stored, but probably undergo some further irreversible metabolic change. "These results should be considered when amino acid mixtures for therapeutic feeding are prepared or administered."

The Application of Microbiological Methods to the Study of Nutrition. The Microbiological Assay of Amino-Acids

E. C. Barton-Wright-Proc. Nutr. Soc. 5: 173, 1947

Bacteria, particularly the lactic acid bacteria, have been found valuable for the assay of certain vitamins and amino acids. These methods are rapid, inexpensive, accurate and sensitive. "The analysis of the amino-acid content of rare proteins, such as viruses, should now become a practical possibility."

Carbohydrate and Fat

Metabolism of Sucrose: II

I. M. Rabinowitch—Am. J. Dig. Dis. 14: 315, 1947

Sucrose was usually more rapidly effective than dextrose in restoring blood sugar to normal in mild insulin hypoglycemia. Levulose was not effective, either alone or with dextrose. The finding is supported by measurement of the CO₂ concentration in expired air following ingestion of sucrose or dextrose, by the blood sugar time curves after 50 gm. doses of the sugars, and by serum inorganic phosphate time curves. Sucrose was also more rapidly utilized in mild diabetes. Gastric contents after ingestion of sucrose included some unidentified substances in addition to dextrose and levulose.

Changes in Blood Phosphate After Ingestion of Glucose and Fructose in Sprue

L. P. R. Fourman-Brit. Med. J. 1947 II: 411

Five normal persons and four patients with sprue were studied. In normal subjects there was a decline in inorganic phosphate of whole blood, usually associated with a fall in blood "ester" phosphate levels after absorption of either glucose or fructose. In sprue patients after ingestion of glucose or fructose, blood inorganic phosphate fell to only a small extent or even rose. There was also, in contrast to normal subjects, an increased urinary phosphate excretion.

Fat Absorption on Tropical Sprue

D. A. K. Black, J. P. Bound and L. P. R. Fourman—Quart. J. Med. 16: 99, 1947

In 28 patients with untreated early tropical sprue, fat absorption varied from 51 to 85 per cent. (normal is over 90 per cent.). Fat absorption was not improved by nicotinic acid or riboflavin injection. Fat absorption was not particularly improved during some weeks of parenteral liver injections, although the patients gained weight and there was some clinical improvement. Oral yeast extract somewhat improved fat absorption within 12 days, and may be useful in maintenance of tropical sprue patients.

Aetiology of Steatorrhoea

A. C. Frazer-Brit. Med. J. 1947 II: 641

Fat absorption may be considered defective if 90 per cent. or less is absorbed on a diet containing 50 gm. Three phases of fat absorption are discussed. In the first, or intraluminar, phase, some ingested triglycerides are partially hydrolyzed to fatty acids and lower glycerides which, with bile salts, provide the emulsifying system resulting in particles of triglyceride of less than 0.5 micra diameter. Lack of bile salts or pancreatic lipase interferes with this phase, but it proceeds normally in tropical or non-tropical sprue or regional ileitis. In the second, or intercellular, phase, the fatty material passes through the outer membrane of the cell, undergoes some phosphorylation, and passes through the inner membrane of the cell. In tropical or non-tropical sprue and gastrocolic fistula, interference with particulate absorption through the outer cell membrane has been observed. Choline deficiency may interfere with passage through the inner cell membrane. In the third, or distributive, phase, fatty acids largely pass up the portal vein, and the triglycerides are carried by the thoracic duct to the systemic circulation. The proportion of fat absorbed and distributed in one way or the other is shifted by variations in intestinal pH, the composition of the dietary fat, or obstruction of the lymphatic pathway.

Vitamins

Vitamin A Deficiencies in the Netherlands East Indies

A. G. van Veen and S. Postmus-J. Am. Dietet. Assn. 23: 669, 1947

Considerable vitamin A deficiency was found in the children of the Netherlands East Indies as shown by the incidence of xerophthalmia and hemeralopia. Children often refused the highly-seasoned soup into which vegetables were usually made, and the diet contained practically no animal products to supply preformed vitamin A. The deficiency was found less frequently when rice and cassava were not available and thus more vegetables were used. Pro-vitamins evidently were readily absorbed and converted to vitamin A. Xerophthalmia was successfully treated with red palm oil, which contained only pro-vitamins.

The Nutritional State of Patients with Peptic Ulcer as Measured by Vitamin Levels in the Blood and Urine

D. Gayer and S. Cody-Gastroenterol. 9: 54, 1947

Twenty patients hospitalized with active peptic ulcer were compared with 15 hospitalized patients having no signs of gastrointestinal or other organic disease. From determinations of blood and urine levels, there was no evidence of deficiency of vitamin A, niacin, or riboflavin, nor any indication that previous deficiencies of these factors may have contributed to the development of the ulcer. Niacin may be liberated from storage in tissues. The large amounts of milk usually taken by these patients probably contribute sufficient vitamin A and riboflavin. Niacin supplements may be indicated when nitrogen balance is being restored.

Availability of Carotene from Carrots and Further Observations on Human Requirements for Vitamin A and Carotene.

E. C. Callison and E. Orent-Keiles-J. Nutr. 34: 153, 1947

The utilization of carotene from carrots was determined in four young adults, using dark adaptation reaction as an index of vitamin A status. Vitamin A reserves were depleted by 2 to 6 months on vitamin A deficient diets, and the subjects were then given carrot supplements for two periods separated by a 13 to 16 day period of depletion. The apparent vitamin A requirement when supplied by either cooked or uncooked frozen carrots averaged 34 I.U. per kg. of body weight as determined by bioassay, 98 I.U. as determined by chemical assay. Different values were found in other studies with different food sources of vitamin A. Man may utilize carotene of carrots more efficiently than does the rat, which utilizes carotene of peas or spinach more efficiently than carotene of carrots. The carotene and vitamin A values of foods as given in food composition tables must be used with caution in evaluating the adequacy of human diets.

Utilization of Vitamin A in Water Emulsion

G. R. Halpern, J. Biely and F. Hardy-Science 106: 40, 1947

Vitamin A in water emulsion was more effective than vitamin A in oil for growth of chicks. In either case, fresh gray fish liver-oil was more active than oxidized gray fish liver-oil. Such a preparation may be valuable in cases of impaired fat metabolism.

A Study of the Fasting-Hour Excretion of Thiamine in the Urine of Normal Subjects

E. Papageorge and G. T. Lewis-J. Nutr. 34: 301, 1947

Good correlation was found between the 24-hour excretion of thiamine and "fasting-hour" excretion, as measured in 63 normal young adults. The percentage return of a 1 mg. oral test dose also correlated well with the 24-hour excretion. The "fasting-hour" excretion test is considered useful for large scale nutritional survey work. Excretion below 4 micrograms suggests inadequate thiamine intake.

The Availability of Vitamins from Yeasts. III. The Availability to Human Subjects of Riboflavin from Fresh and Dried Bakers' Yeast Varying in Viability

E. L. Price, M. M. Marquette and H. T. Parsons-J. Nutr. 34: 311, 1947

Riboflavin was absorbed only a very little from fresh raw yeast, partially from dried yeast containing live cells, but in considerable quantity from the same yeasts with no live cells. In general, fecal elimination of riboflavin was a reciprocal of the urinary excretion.

The Availability of Vitamins from Yeasts. IV. The Influence of the Ingestion of Fresh and Dried Bakers' Yeasts Varying in Viability and in Thiamine Content on the Availability of Thiamine to Human Subjects

H. N. Kingsley and H. T. Parsons-J. Nutr. 34: 321, 1947

Fresh yeast added to a basal diet appeared to impair absorption of dietary thiamine, and urinary excretion decreased. Body stores were evidently progressively depleted. Live dried yeast had the same effect. Yeast killed by drying or by boiling water treatment supplied absorbable thiamine and did not interfere with absorption of food thiamine. Evidently live yeast cells compete for thiamine in the digestive tract.

The Sparing Action of Protein on the Pantothenic Acid Requirement of the Rat. II. Urinary and Fecal Excretion of Pantothenic Acid

M. M. Nelson, F. van Nouhuys and H. M. Evans-J. Nutr. 34: 189, 1947

Pantothenic acid deficient rats on purified diets containing 64 per cent. of casein grew better, survived longer, and excreted significantly more urinary pantothenic acid than on purified diets containing 24 per cent. of casein. Intermediate responses were found at intermediate levels of dietary casein. This sparing action of a high casein diet on the pantothenic acid requirement was evidently not due to increased intestinal synthesis, to decreased loss by urinary excretion, nor to the pantothenic acid content of the casein used.

Folic Acid in the Maintenance of Pernicious Anemia

R. W. Heinle, J. T. Dingle and A. S. Weisberger-J. Lab. and Clin. Med. 32: 970, 1947

Folic acid was used on 41 patients with pernicious anemia for up to one year. Compared with previous periods of treatment with liver extract, 26 cases showed no relapse, 9 had decreased erythrocyte counts, and 6 cases improved. The nine in whom hematologic relapse occurred had been given the folic acid at intervals of three weeks or longer, by intravenous injection. Daily oral doses of 10 mg. were successful in all cases tried, and are the recommended routine. Neurologic relapse occurred in three patients, and responded to liver extract. Liver extract alone or in conjunction with folic acid therefore is the treatment of choice. Folic

acid is valuable in cases sensitive to liver, and has not been found to have toxic or allergic effects.

The Use of Folic Acid in the Treatment of Anemia of Rheumatoid Arthritis—A Preliminary Report

C. A. L. Stephens, Jr., A. L. Borden, W. P. Holbrook and D. F. Hill-Ann. Int. Med. 27: 420, 1947

All of 20 rheumatoid arthritis patients given folic acid improved as to corpuscular volume, hematocrit, hemoglobin, color index, and erthrocyte morphology. Immature leukocytes and erythrocytes appeared in the peripheral blood. The response to folic acid was not influenced by iron administration. There was a notable monocytosis. Wide variations in the effective dosage required were noted. There was no improvement in the primary disease. No toxic effects developed.

Blood Plasma Ascorbic Acid Levels on Controlled Intakes of Ascorbic Acid

M. L. Dodds and F. L. MacLeod-Science 106: 67, 1947

Forty-one young women were maintained at various levels of dietary ascorbic acid intake. At an intake of 32 mg. daily, plasma ascorbic acid ranged from 0.34 to 0.62 mg./100 ml.; at an intake of 57 mg., the plasma level was 0.51 to 0.93; at an intake of 82 mg., the plasma level was 0.74 to 1.13; and at an intake of 107 mg., the plasma level was 0.88 to 1.22 mg./100 ml. Thus plasma ascorbic acid determinations in nutrition surveys indicate only a range of intake levels.

Subperitoneal Hemorrhage from Vitamin C Deficiency Simulating Acute Surgical Abdominal Conditions

L. E. Hines-Surg., Gyn. and Obs. 85: 214, 1947

Three cases simulating acute surgical conditions were found to be due to spontaneous hemorrhages caused by nutritional deficiency, especially of vitamin C. Vitamin C deficiency can be recognized by study of the patient's diet, of possible factors interfering with absorption, of physical symptoms of scurvy, of increased capillary fragility, and of blood levels of vitamin C.

Sodium Ascorbate in the Treatment of Allergic Disturbances. The Role of the Adrenal Cortical Hormone-Sodium-Vitamin C

S. L. Ruskin-Am. J. Dig. Dis. 14: 302, 1947

The sodium salt of ascorbic acid was found to be efficacious in the treatment of allergy and asthma. Refractory cases responded better to the sodium salt than to ascorbic acid. Suprarenalectomized rats show increased sensitivity to histamine, and vitamin C has been shown to have an anti-histamine activity. A relationship is thus suggested between adrenal cortical hormone, ascorbic acid, sodium, and allergy.

Complications in Feeding Experiments

Leading Article—Lancet 1947 II: 623

Factors other than the presence or absence of vitamins influence the devlopment of deficiency states in animals. The development of rickets, for instance, depends not only upon the vitamin D intake but also the amount and ratio of dietary minerals, acidogenic factors, and anti-calcifying factors. The vitamins may also occur in different forms: vitamins D_a and D_a are not of comparable activity for different species, and various carotenoids have different vitamin A activities. Vitamin B studies are complicated by the activities of intestinal microorganisms, the presence of anti-vitamins, variations in the experimental animals, and the effects of other dietary factors such as the thiamine-sparing effect of fat. Studies of the pellagragenic effect of maize are confused by the interaction of such various factors.

DIGESTIBILITY OF INFANT FOODS PREPARED FROM COWS' MILK *

The first stage in digestion of a milk food by an infant is coagulation. This occurs whether the infant is breast fed or is being fed artificially on a food, the basis of which is cows' milk. Human milk is naturally the standard by which the digestibility of other foods must be compared. In the infant's stomach human milk coagulates in very fine clots, under the action of both enzymes and the pH of the stomach contents—the latter becoming more acid as digestion proceeds. The proteins of human milk, mainly albumin and casein, are normally present in the range of 1.5% and of this, approximately 0.5% only, is casein. Cows' milk on the other hand has a protein content of approximately 3.5%, and of this 3.0% is casein.

Casein is coagulated by rennin and acids, but not by boiling. Albumin on the other hand is coagulated by heat and acid, but not by rennin. The high percentage of casein in cows' milk means more rapid coagulation in the stomach than with human milk, and unless the protein content is reduced by modification and its physical condition changed by special treatment, the clots formed are large and indigestible.

It was a natural thought in the day when modification of cows' milk for infant feeding was first suggested that the milk should be fully modified so that the ratio between the fat, lactose and proteins would be identical with that in human milk. But this overlooked the fact that the protein of the modified milk was largely casein, and that the amino acid structure of casein differed from that of albumin. In casein, certain essential amino acids are proportionately low and pediatricians, as the result of experience, recommend more protein in relation to the other constituents, when cows' milk is the basis of modification. It is considered that a modified milk mixture of the same total solids content as human milk, should have at least 2.1% protein in comparison with the approximate figure of 1.5% of human milk. While for nutritional reasons, higher protein is necessary in a modified infant food, because of this higher protein and the fact that it is largely casein, the physical state of the protein is of very great importance, as this has a bearing on the toughness of the curd formed when coagulation takes place. Otherwise the advantages gained nutritionally by using a higher protein could be offset by a reduction in digestibility.

One aim therefore in manufacturing a milk food for infants which can be readily digested, is to see that the protein is physically altered in its reaction to enzymes and acid, so that the natural toughness of the curd of cows' milk protein is reduced, when acted on by rennin. Pasteurisation of milk, which is essential in any case to destroy pathogenic organisms which may be present, has relatively little effect in softening the curd formed by rennin. Heattreatment, to have an appreciable effect, must be taken to the stage of boiling. Homogenisation combined with heating is still more effective and, as will be demonstrated later, the special spray process of drying used in the manufacture of Lactogen and Vi-Lactogen, gives even better results than boiling a modified fluid milk for 10 minutes. This method of drying which combines pasteurisation, homogenisation and extremely rapid desiccation, not only gives a better digestibility factor, but also shows less vitamin destruction than the drastic treatment of 10 minutes boiling as normally practised under domestic conditions. These improved results come as the result of increasing the hydration or "water holding capacity" of the curd. Such curds are more voluminous and easily disintegrated. They are softer and more permeable to digestive juices.

The obvious way in which the digestibility of an infant food should be tested, would be by properly controlled infant feeding studies. Experimentation along these lines, however, is limited by the difficulties involved, and by the need of avoiding any risk to the health or well-being of the infants concerned, by the procedure necessary to obtain the required samples. It is obvious that for rapid work under comparable conditions some method of carrying out "in vitro" tests is necessary—tests which can be regarded as strictly comparable and which will serve as a practical means of assessing the digestion characteristics of an infant food. For some years past, laboratory methods of measuring the toughness of the curd, formed in cows' milk by the action of rennin at fixed acidities, have been used. Figures were obtained which were recorded in terms of the "curd tension" of the milk. By using this test it has been found that the "curd tension" of different milks does vary, and that the "curd tension" can be affected by chemical and physical means, such as by the addition of salts, by precipitation of calcium, by homogenisation and by heat-treatment, etc. Undoubtedly, on general principles milks showing soft curd characteristics are more suitable for infant feeding, but results have been too variable to regard "curd tension" tests as a reliable means of measuring digestibility.

The latest technique for measurement of digestibility takes into account other factors which also influence digestion. Briefly, such experiments are carried out in special apparatus, controlled to resemble more closely the physical and chemical conditions under which gastric digestion takes place in the infant's stomach. An effort is made in such tests, not only to approximate the enzyme strength and increasing acidity of the gastric contents, but also to imitate the peristaltic constriction of the stomach during digestion, which influences, not only particle size, but also enzyme penetration and ultimate digestibility.

In experiments carried out in this laboratory which follow the lines of the technique evolved by Doan and Dizikes,* the method used is detailed in the following paragraphs, and a graph drawn from the results obtained.

In one group, cows' milk, boiled for 10 minutes after modification to a protein content comparable with Lactogen, is compared with diluted Lactogen. In the other, cows' milk, modified to 2.1% protein, and boiled for 10 minutes, is compared with diluted Vi-Lactogen at the same protein percentage.

The results obtained are shown graphically, in terms of the particle size of curd measured at hourly intervals up to three hours. This graph demonstrates visually, curd characteristics and progressive changes during digestion. Other work has shown that if milk is only pasteurised and not boiled, particle size is larger still than in the case of boiled milk.

A comparison of these graphs demonstrates that, even boiling for 10 minutes, does not give with modified cows' milk a result as satisfactory as that produced by the special process, used in the manufacture of Lactogen and Vi-Lactogen. This can only be attributed to the special methods employed in making these two infant foods.

Our trials were made in a water-bath held at a constant temperature of 99°F. The bath was fitted with a series of rubber tubes into which the milk to be tested was placed.

Artificial peristalsis was brought about by a mechanical device which, by a rhythmic, squeezing action on the thin-walled rubber tubes, gave comparable movement to each of the milks under test.

^{*} DOAN, F. J. and DIZIKES, J. L.—Digestion Characteristics of Various Types of Milk Compared with Human Milk—Bulletin 428. Agricultural Experiment Station, State College, Pennsylvania.

Four tubes for each sample to be analysed were placed in the apparatus. After all tubes were in position, 6.0 ccs. of an artificial digestion mixture were added to each tube.

This mixture consisted of—

0.4 ccs. of normal hydrochloric acid

1.5 ccs. of rennin solution.

4.1 ccs. of a 0.3% of pepsin solution.

The tubes containing the digestion mixture were allowed to stand 5 minutes, in order to reach the bath temperature.

40 ccs. of the modified milk to be tested was added at the temperature of 99°F. to each of four tubes, and mixed well with the 6 ccs. of digestion mixture.

The milk was allowed to stand for 15 minutes during which time coagulation took place.

8 ccs. of 0.3% pepsin solution was then added to all tubes, and one tube removed from each group, for analysis.

This tube represented the zero digestion time.

The mechanical device for imitating peristalsis by squeezing the tubes was started, and run for three hours.

At half-hour intervals, 0.6 ccs. of normal hydrochloric acid was added to lower the pH.

These additions of acid lowered the pH from about 6.0 at coagulation to about 3.5 after $2\frac{1}{2}$ hours. Each hour one of the remaining tubes was removed for analysis, i.e., at 1, 2 and 3 hours.

On removal from the bath, each of the four tubes concerned in the analysis, was carefully poured into a beaker, and 10 ccs. of 40% formalin added, and the contents made up to a constant volume of 75 ccs.

The curds were then allowed to stand in order to harden the particles for purposes of particle size measurement.

After 24 hours the contents of the beaker were carefully screened through a series of sieves mounted on a Buchner vacuum funnel, the latter being fitted with a No. 3 filter paper.

The size of the sieves used was 3, 10, 20 and 40 meshes to the linear inch respectively.

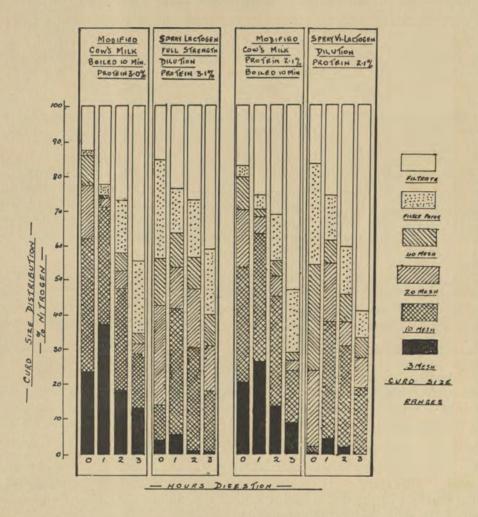

The curds on each sieve were washed thoroughly and the contents removed in rotation.

The curds held on each of the four sieves, plus those held on the filter paper, together with the filtrate itself, gave 6 graduated fractions for each tube.

A nitrogen determination on each fraction was obtained and expressed as a percentage of the total nitrogen as a means of gauging the amount of protein present.

A graph illustrating the percentage of nitrogen in each fraction was prepared and gives a comparison of the changes taking place during the period of digestion.

The darker the shading, the larger the particle size.

THE KEEPING QUALITY OF TINNED FOODS *

The earliest reference to the preservation of food in tins is as far back as 1810 or 1811. A few years after this, meat preserved in this way, was supplied to the British Navy.

In 1938, two tins, one of roasted veal and another of carrots and gravy, which had been packed in 1824, were opened after one hundred and fourteen years. The opportunity was taken to have these tins very carefully examined both chemically and bacteriologically by a selected body of scientists.

The practical result of these tests showed that the foods were still in edible condition and had retained their nourishing properties to a high degree. One surprising fact was that an appreciable amount of vitamin D still remained in the fat of the veal when compared with fresh veal fat.

No one of course wants to keep food in tins for one hundred and fourteen years! It is a fact that chemical changes take place to a variable extent in different types of tinned food on holding, and this action may affect the palatibility while not being dangerous to health. In some foods the action is more rapid than in others; the keeping quality of a food is intimately bound up in the quality of the raw materials used and the skill and scientific knowledge controlling its preparation and packing.

The economical value of tinned foods to the community cannot be fully estimated. There has been a remarkable increase in the amount preserved in this way in recent years, because in this form foods can be made available which could not be purchased on account of price, lack of transport or the fact that they are out of season.

From the nutritive angle it has been proved that canned foods provide as complete and adequate a diet as can be obtained in any other way.

Most of the world's foodstuffs are seasonal. Many foods of course, such as wheat, can be carried over into the slack period of production without any special preservation. Both fresh milk and fruit, however, deteriorate rapidly, and it is well known that much more milk is produced in summer than in winter and fruit ripens only during a few months of the year.

The fact, therefore, that perishable foods such as fruit, milk and meat can be preserved is of enormous practical importance. It means a great deal more food can be produced with safety. It evens out the effect of good and bad seasons. It minimises waste and this means economy in the budget of the world's food requirements.

Sir William Savage is regarded as one of the most distinguished authorities on the subject of canned foods, and in a recent survey concluded that there was no evidence that canned foods have had their total nutritive value affected in any way.

On the subject of vitamins, he was of the opinion that there is plenty of evidence to establish that tinned foods are not, in general, inferior in respect of vitamins to the same foods after domestic cooking.

In his summary he states: "In some cases they are definitely superior. The view that canned foods are devitalised foods (whatever that may mean) is not supported by nutritional research. It can be definitely stated that canned foods are now considerably less liable than ordinary foods to be the source of food poisoning."

The value of having food in containers which are hermetically sealed is only fully realised in war time. Foods which were regarded by the housewife as a convenience or as a means of adding variety to a meal are now of paramount national importance.

Troops must be fed in the field and in the fighting zones—in places where no fresh foods are available. Foods which will keep until required and which can be carried for thousands of miles in safety are as important as munitions. No army can fight unless it is fed.

No better example of this can be given than that of tinned milk and tinned meat, both of which are essential foods to the fighting forces.

To those who are concerned with the supply of food to the civilian population (and this means the housewife as well as the Government official), the length of time tinned foods can be expected to keep is of vital interest.

It is difficult to define what is meant by "keeping quality." Probably the simplest definition is that it should remain wholesome and retain its natural flavour and appearance.

There is no doubt that tinned meat and fruit have a long life. Condensed milks, both sweetened and unsweetened, should remain normal at least a year from the date of manufacture, but under wartime conditions, if the date of manufacture is not known, a good working rule would be to see that they are used within at least six months of purchasing and replaced from time to time with freshly purchased stocks.

Dried full cream milk and infants' foods are protected in the case of most reputable brands by an expiry date which is placed on the tin by the manufacturer simply to prevent old food remaining on the market. The date of expiry does not mean that the food is faulty as soon as the date has been reached, but, as no food can improve on holding, it is better to use these or any tinned foods within a reasonable period after purchase.

If a tin shows obvious signs of blowing or a definite escape of gas is noticed when opening, do not use it. Never use tins which have a cut or nail hole in the tinplate, or which seem to have an unusual smell. These are rare faults but they can happen.

Food such as meat, tinned fish or unsweetened condensed milk, or in fact any foods preserved solely by sterilisation, should be used shortly after opening. These foods, in order to be preserved, must be packed in absolutely airtight tins, and because the act of opening destroys the protection they should not be kept any longer than similar foods cooked in the home.

Foods such as jam or sweetened condensed milk are wholesome for several weeks after opening. This is because the cane sugar which is present has a definite preservative action. With these foods it is wiser to keep the lid up in order to allow a little circulation of air, but care must be taken to see that flies and dust cannot enter.

Milk powders keep well after opening also, but they tend to pick up moisture with exposure to the air, and on this account may go lumpy and develop unpleasant flavours. Therefore, in this case, keep the lid well closed and as a general rule try to use them up within at least a fortnight after opening.

Always keep tinned foods, both before and after opening, in a cool dry place, but do not freeze. The hotter the temperature of storage, the more quickly any food deteriorates.

After opening, any food can be held with safety in the tin in which it is packed. It is a popular misconception that it must be emptied into a glass or earthenware container.

SUMMARY OF THE KNOWN VITAMINS

Vitamin A—is a fat-soluble factor occuring particularly in fish liver oils, milk, butter and eggs. In addition, carotene or pro-vitamin A occurs in various green vegetables and in certain vegetable oils. The vitamin is growth-promoting and anti-infective. Deficiency leads to keratitis, xerophthalmia, night-blindness and reduced resistance to infection.

International unit—the growth-promoting activity for rats of 0.6 micrograms of standard β -carotene.

Vitamin B.—aneurin or thiamin is a water-soluble factor found most abundantly in yeast, liver, certain cereals, especially in the bran and germ, meats, milk and eggs. The vitamin functions in carbohydrate metabolism and deficiency leads to beri-beri and polyneuritis.

International unit—the anti-neuritic activity of 3 micrograms of a standard preparation of crystalline aneurin hydrochloride.

Vitamin C—or ascorbic acid is water-soluble and found mainly in fruits and to a lesser extent in green vegetables. Deficiency of the factor leads to scurvy.

International unit—the anti-scorbutic activity of 0.05 milligrams of standard 1-ascorbic acid.

Vitamin D—the oil-soluble anti-rachitic substance occurring in fish liver oils, milk, butter and eggs. The factor acts in the absorption of calcium and deficiency leads to rickets or osteoporosis.

International unit—the anti-rachitic activity of 1 mgm. of standard solution of irradiated ergosterol or 0.25 micrograms of crystalline Vitamin-D₂ (calciferol).

Vitamin E—oil-soluble and occurring in the embryos of seeds, especially grains or in green leaves. In rats, deficiency leads to sterility due to resorption of the fœtus and there is evidence of similar action in the human subject.

Chemical identities—a- and β -tocopherols have been shown to be active but there is no international standard on account of difficulties of estimation.

Vitamin B₂ Complex—the water-soluble, heat-stable fractions of yeast and liver. The complex has been split into a number of fractions including:

Lactoflavin (riboflavin) a yellow pigment functioning in carbohydrate metabolism and probably tissue respiration. The factor occurs most abundantly in yeast, liver and milk, and exercises a growth-promoting action in rats. There is little knowledge of effects of deficiency and no international unit.

Pellagra-Preventing Factor—probably identical with nicotinic acid which prevents or cures pellagra in man and black-tongue in dogs. Known rich sources are liver, yeast and certain grains, although maize is deficient in the factor.

Vitamins B_a, B_a, B_a and B_c—Vitamin H and Factors I, Y and Ware little-known components of the Vitamin B_a complex, considered necessary for normal nutrition of rats and/or pigeons.

Vitamin K—a fat-soluble vitamin occurring in certain green leaves and decomposing fish meal, necessary to prevent hæmorrhagic diseases in chickens and probably required in man.*

Vitamin P—a flavone compound occurring in citrus juices and red pepper and thought to have an effect on capillary permeability. It is probably required in man and functions in conjunction with Vitamin C.

Vitamin F—is used to describe certain unsaturated fatty acids, especially linoleic acid, which have been thought to have an action on the epidermal structures and on the growth of the rat.

It should be noted that vitamins A, D and E, each are known in several different chemical forms which are not necessarily of equal activity.

^{*} Chemical identification, while by no means complete, has advanced to the stage at which it can reasonably be considered that at least much of the activity due to Vitamin K, can be attributed to one or more quinone derivatives.

Vitamin Chart

VITAMIN A

(The anti-ophthalmic anti-infective Vitamin— Oil-soluble—Heat-stable, cooking or drying at usual temperature has little effect-Oxidises at higher temperatures)

Prevents infections (especially of eye and respiratory system), promotes growth and long life, appetite and digestion, and maintains vigour. It is essential for normal reproduction and lactation and for maintaining the integrity of epithelial tissue. Deficiency may result in gland and sinus infection, kidney, ureter and bladder calculi, diarrhora, physical weakness, etc.

VITAMIN B (B.)

(The anti-neuritic. anti-beri-beri Vitamin Water- and alcohol-soluble—Heat-labile. especially in alkaline

Promotes appetite and digestion, as well as growth,

by improving metabolism, and also tonicity of the digestive tract. It protects against nerve disease, e.g. polyneuritis and

beri-beri, and is necessary to the mother for normal reproduction and lactation.

Deficiency may result in impaired digestion and growth, loss of weight and vigour, subnormal temperature, fatigue, loss of muscle co-ordination, paralysis of limbs, indigestion, constipation and colitis.

Necessary for normal reproduction, influencing normal maturation of germ cell in male and normal

placental function in the female. Deficiency leads to death and resorption of the fœtus.

VITAMIN C

(The anti-scorbutic Vitamin-water-soluble-Readily oxidised at higher temperatures)

Protects against scurvy. Also necessary for the proper metabolism of bones and normal tooth development and maintenance. Deficiency leads to scurvy. hæmorrhages of mucous membrane, skin, joints, and bone marrow; spongy gums, painful swelling of joints, bone fragility, decalcification, caries, fatigue, etc.

VITAMIN D

(The anti-rachitic Vitamin-Oil-soluble-Heat-stable-Fairly resistant to oxidation)

Regulates absorption and metabolism of the Calcium and Phosphorus needed for bone formation. Similarly regulates mineral metabolism of teeth and bones. It is necessary to the pregnant mother to prevent rickets in the young.

Deficiency results in rickets and bone deformity, enlargement of the joints, beading of ribs, softening of cranial bones, etc., as well as muscular weakness, nervous instability, dental caries and so on.

VITAMIN E

(The anti-sterility Vitamin—Heat-stable, cooking, drying or sterilising has little effect-Susceptible to oxidation)

VITAMIN G (B₂)

(The anti-pellagric Vitamin—Water- and alcohol-soluble— Heat-stable)

Pellagra-preventive. Recent work points to the fact that other factors play an important part in prevention and cure of pellagra. Deficiency may cause alimentary disturbances, dermatitis, inflammation of the tongue and mouth, diarrhoea and nervous and mental disorders.

In the following table, adapted largely from "Vitamins: A Survey of Present Knowledge," Medical Research Council Special Report Series No. 167, 0 indicates the Vitamin has not been found, + that the Vitamin is present, ++ that the food is a good source, and +++ a rich source of the Vitamin. No sign indicates that the Vitamin content of the food has not been studied. The "Water-soluble B complex" has been included and only where the B1 and B2 (G) fractions have been estimated suitable entries have been made.

DIETARY STANDARDS OF THE FOOD REQUIREMENTS OF MAN

Recommended Daily Allowances for Specific Nutrients

Extracted by permission of the Council for Scientific and Industrial Research from Bulletin No. 178, p. 66, Food Composition Tables, compiled by Hedley R. Marston, Chief Nutrition Officer of the Council and Officer-in-Charge of the Animal Nutrition Laboratory of its Division of Animal Health and Nutrition and Mary C. Dawbarn, Biochemist of the Animal Products Research Foundation of the University of Adelaide, working in the Council's Nutrition Laboratory.

	Calories	Protein	Calcium	Iron	Vitamin A (a)	Triamine (b) (Vitamin B1)	Riboflavin	Nicotinic	Ascorbic acid (Vitamin C)	Vitamin D
Man (70 kg.):—		gm.	gm.	mg.	I.U.	*mg.	mg.	mg.	mg.	I.U.

Boys:— 13-15 years 16-20 years	3200 3800	85 100	1.4	15 15	5000 6000	1.6 2.0	2.4 3.0	16 20	90	(e)

These are tentative allowances toward which to aim in planning practical dietaries. These allowances can be met by a good diet of natural foods which will also provide other minerals and vitamins, the requirements for which are less well known.

- (a) Requirements may be less than the amounts stated if provided as vitamin A, and greater if the source is chiefly the provitamin, carotene. (I.U. = International Units.)
- (b) 1 mg. thiamine equals 333 I.U.
- (c) Needs of infants increase from month to month. The amounts given are for approximately 6-18 months. The amounts of protein and calcium needed are less if from breast milk.
- (d) Allowances are based on needs for the middle year in each group (as 2, 5, 8, etc.) and for moderate activity.
- (e) Vitamin D is undoubtedly necessary for older children and adults. When not available from sunshine, it should be provided probably up to the minimal amounts recommended for infants.

THE PROBLEMS OF RAW MILK

The following summary of Section F—Milk-borne Diseases—of Biennial Reviews of the Progress of Dairy Science, ("J. Dairy Research," May, 1939) gives a concise review of recent milk-borne epidemic disease.

Streptococcal Infections.

It is now believed that the majority of these milk-borne epidemics arise not from direct contamination from a human source, but by contamination from a cow suffering from mastitis due to hæmolytic streptococci of human origin.

Davis clearly showed experimentally that streptococci from human sources, placed on teat surfaces, readily ascended the teat ducts infecting the bovine udder.

In Denmark, a cow responsible for a milk-borne epidemic excreted streptococci for 13 months (excluding a dry period of 3 months) and another involved in the Doncaster (England) epidemic excreted streptococci for 6 weeks, and in both cases there were periods when symptoms of mastitis were either not evident or not pronounced although the milk was known to be infective.

In the United States, in 1936, a severe epidemic of scarlet fever type occurred in Owego, N.Y., 511 contracting the disease from raw milk, and one cow suffering from mastitis was believed responsible.

In 1937 an outbreak of septic sore throat (645 cases) occurred at West Des Moines, Iowa. At least 312 persons had consumed milk from a source infected with hæmolytic streptococci from a bovine source.

Of 32 outbreaks in 1936-7, no less than 12 were believed due at least in part to bovine carriers. In England the last serious outbreak, a mixed type of infection, in which cases of scarlet fever and sore throat were both observed, occurred in Doncaster in December, 1936. The Penneberg outbreak in Germany was traced to a milker who had been in contact with a child with scarlet fever and was responsible for 450 cases with 8 deaths. Yet another outbreak in Denmark, of 100 cases of sore throat was traced to milk which had been infected by a cow suffering from mastitis due to Lancefield group A hæmolytic Streptococcus.

Staphylococcal Infections.

Recent investigations into the etiology of bovine mastitis have shown that numerous cows are infected with staphylococci, and it is a matter for surprise that outbreaks of staphylococcal food poisoning are not more prevalent. Gwatkin et al. examining a series of cattle found considerably more than half affected with mastitis and in about 30 per cent. of these animals the staphylococcus was incriminated. In two-thirds of the cases so incriminated the staphylococcus was the only pathogenic organism isolated.

In a series of 415 cows from 5 herds, no less than 34.9 per cent. were found to be infected and for some reason infection occurred much more frequently to hind than fore quarters of the udders.

Probably due to the frequently mild nature of many staphylococcal outbreaks of food-poisoning they pass unnoticed or are only notified to the authorities at such a late stage that satisfactory specimens for full investigation are no longer obtainable.

Outbreaks have been described in England associated with milk, custard and butter. In America, raw milk and milk products such as ice-cream, cheese, cream and custard, account for most of the recorded cases. Denison described one outbreak in a school of almost 700 students, of whom 165 ate cream puffs; 57 per cent. of these pupils were taken ill and also a further 28 cases outside the school occurred in people who had had some of the same food.

Within four hours of ingestion, no less than 80 per cent. of the cases were ill, symptoms being vomiting (78 per cent. severe), pain in abdomen, diarrhoea, headache, muscle cramps and sweating.

Prevention of staphylococcal food poisoning by milk or milk products calls for heating, either to 80° C. for 15 minutes or 85° C. for 10 minutes to ensure destruction, and the greatest care taken to preclude re-infection.

An interesting observation is the fact that addition of starch to milk appears to enable staphylococci to more freely elaborate their entero-toxins.

Bovine Tuberculosis.

Griffith's interesting table, amended to include Griffith & Smith's figures shows a very variable percentage of bovine tuberculosis in an extensive series of observations, but it is noteworthy that in rural areas in parts of Scotland the figures are more than double those in city areas, 9.1 per cent. and 4.4 per cent. respectively.

While the findings of Griffith \mathcal{E} Smith point to the consumption of raw infected milk as the chief source of bovine infection, Lange, who reported some 2 per cent. of all tuberculosis deaths in Germany to be of bovine origin, lays emphasis on the importance of contact with cattle, for instance dairy farm employees, in explaining the bovine type of infection.

Recently several actual tuberculosis epidemics have been described. Swedish observers associate erythema nodosum with tuberculosis and not as a manifestation of rheumatic disease. Törnell reporting on an epidemic in the summer of 1935, found 13 women factory hands aged 17 to 29 years all tuberculin-positive and with two exceptions, the lungs on radiological examination were negative. The single common food factor was the milk supply, later found to contain tubercle bacilli.

Similarly, Stahl reported in a small Swedish community, 50 persons, chiefly children, manifesting tuberculous infection and about three times as many tuberculin-positive, all using a common milk supply, one cow of the herd suffering from tuberculous mastitis. Of the infected persons, some showed high fever over several weeks, others enlarged cervical glands and still others erythema nodosum.

Salmonella Infections.

These infections are divided into two varieties, those with a typhoid-like symptomatology, and those with food-poisoning characteristics. The United States Public Health Reports summarise milk-borne outbreaks in the following table.

U.S.A. Milk-Borne Typhoid and Para-Typhoid.

				U.S.A. MIK-D	1936	nu anu tara-	1937					
				Epidemics	Cases	Deaths	Epidemics	Cases	Deaths			
Typhoid -		-	-	15	95	5	15	161	11			
Para-typhoid	-	14.	-	1	21	0	-	-	-			

The last big epidemic associated with milk in England occurred at and around Bournemouth in 1936.

The Dublin variety of Salmonella is becoming more frequently associated with milk infections. In Wiltshire an outbreak in which more than 100 people were concerned was traced to bottled raw milk. The infection came from a single, apparently healthy cow, but the organism was repeatedly isolated from its dung.

Dysentery.

There have been only two dysentery epidemics reported as due to milk during the past two years, and one associated with ice-cream, a milk product.

In Hong-Kong, with a mortality of approximately 33 per cent., a number of young European children were affected, the Shiga bacillus being isolated from raw milk used. The second outbreak at Bedford, the symptoms being those of mild enteritis, was due to unpasteurised milk, found ultimately to be quite free from infection on the farm, but infection must have occurred on the retailer's premises. The milk was distributed to 106 households, of which 59 yielded one or more cases. The infecting organism in this instance was *B. dysenteriae Sonne*.

Brucella Infections.

The incidence of known cases varies considerably in different countries, the U.S. Public Health Service, and the Chief Medical Officer for the United States and for England respectively reported for the three years 1935-37 inclusive:—

						U.	S.A.	England.				
						Cases	Deaths	Cases	Deaths			
1935	-	-	-	-	-	2008	98	391				
1936	-	-	-	-	-	2095	107	48	_			
1937	+	-	-	-	-	2497	58	_	_			

Hagan concludes that human infections necessarily imply contact with cattle, goats and swine and their secretions, and the risk of infection through contact with animals is definitely greater than through the consumption of raw milk or cheese.

The Milk and Dairies Order 1926 should, since it makes it an offence to "sell or offer or expose for sale any milk from a cow suffering from any infection of the udder or teats which is likely to convey disease," help to eradicate these infections.

Raw milk in the spread of disease.

Extract from a paper by Sir William Savage, at the Royal Sanitary Institute, ("Journal of the Royal Sanitary Institute," July, 1938).

"The facts have been stated so often that I confine myself to a short statement. Scarlet fever, diphtheria, paratyphoid fever and enteric fever have frequently been spread by milk; bacillary dysentery and acute food poisoning rather rarely. Nearly always these diseases are spread from contamination of the milk with the special germ in question after the milk leaves the cow, but occasionally the cow is infected and so contaminates the milk.

"Outbreaks of septic sore throat spread by milk are comparatively rare, but may be very widespread, as in the Brighton-Hove outbreak, with over a thousand cases and more than 60 deaths, or in the one I investigated at Colchester, with over 600 cases. The source of infection is nearly always a cow infected with a special type of streptococcus of human origin first setting up a mastitis in the cow.

"Undulant fever in man is spread by milk through infected cows, and Professor Wilson estimates that there are about 500 cases annually. Tuberculosis in man of bovine origin is of special importance, and although there is evidence that the cases are diminishing, we cannot even now put the deaths at less than 1,700 per annum, with about 4,000 fresh infections each year, the latter involving an immense amount of suffering.

"These facts constitute a very strong case against the use of raw milk, and it is because of them that so large a proportion of the medical profession, including those in the public health service, is so insistent that these risks must be removed."

Milk-Borne Scarlet Fever in Denmark.

Extract from the "Lancet," May 6th, 1939.

"In describing a recent outbreak of scarlet fever in Denmark, Juel-Henningsen and Ernst paint a picture as vivid as that which H. H. Scott provides in 'Some Notable Epidemics.' If the plot of all these stories is more or less the same, the detective work entailed is always interesting.

"The Danish outbreak began with the notification of about 20 cases of scarlet fever in Vejle, a community of about 25,000 people. On April 14th, the outbreak culminated with the notification of about 40 cases. As most of the patients had been supplied with milk from the same dairy, its owner was questioned, and he was able at once to state which was the milk cart and which were the farms providing milk for the part of the town where infection had broken out. Medical inspection of the farms led to the discovery of a hitherto undiagnosed case of scarlet fever in a milkmaid whose hands were peeling, and one of whose ears was discharging pus.

"The prompt elimination of the milkmaid as a source of infection was doubtless the reason why the outbreak ceased as abruptly as it had begun. The bacteriological examination revealed Lancefield's group A and Griffith's type 3 Streptococcus pyogenes in the pus from the milkmaid and in 108 of the 118 cases of scarlet fever. As in most such outbreaks the infection of the milk is maintained by mastitis in one or more cows, diligent search was made for disease of the udders in those that had supplied the offending milk. But though every cow was examined twice at an interval of six days, and the aid of the State Veterinary Serum Laboratory and of the State Serum Institute was invoked, neither the cows nor their milk proved to be infected.

"The milkmaid therefore seems to have been alone responsible for this outbreak, and it is remarkable that though raw milk is a poor culture-medium for the germ in question, and the cows did not co-operate in spreading the infection, she still succeeded in giving scarlet fever to 118 persons and angina faucium to about 50 others."

Outbreaks of Sonne Dysentery due to Raw Milk.

Summary of a report by Trimble & Brothwood ("Brit. Med. Jour.," 31/12/1938).

The outbreak occurred in Preston Rural District on January 26th, 1938, and no fresh cases were reported after the milk supply was stopped on February 1st, except for two secondary infections. A total of 21 persons were affected out of 86 who were exposed to risk.

The symptoms were diarrhoea, slight abdominal pains and slimy stools, but no blood was visible. The cases were limited to the consumers of milk from one farm which had no cattle added for

over a year, and no person at the farm had previously suffered from a similar illness, although during the outbreak four of the farm employees became affected.

Bacteriological examination of the fæces of infected persons confirmed that the outbreak was due to the Sonne Dysentery organism, and it was found that in some individuals a carrier state lasting some weeks was established. Two of the 21 persons were still excreting the organisms after five weeks.

It was not possible to establish the exact source of contamination of the milk. The water used for washing the utensils was of very poor bacteriological quality and was thought to be responsible; its further use for this purpose was forbidden. None of the cows were examined bacteriologically, but since the measures which had already been taken were successful in preventing further cases it seems that this factor was not involved.

The Milk Problem.

Extracts from the Bulletin of the Health Organization-League of Nations-(Vol. VI., No. 3, 1937).

"In most countries of Europe, extensive disease prevails among the cattle. So far as milk hygiene is concerned, the three most important diseases are tuberculosis, contagious abortion and mastitis. Generally speaking, the spread and gravity of these diseases has gone hand in hand with the development of intensive milk production."

"Milk frequently contains pathogenic organisms derived from (a) the diseased udder of the cow, or occasionally the cows' fæces or uterine discharge; (b) a human case or carrier, the infection usually coming from the nasopharynx or the intestine, and gaining access to the milk by sneezing, coughing, etc., or by contaminated fingers, (c) a contaminated water-supply, (d) sometimes perhaps from rodents."

"During the years 1912-1935, records are available in Great Britain of the occurrence of 103 milk-borne outbreaks of scarlet fever, septic sore throat, diphtheria, typhoid fever, paratyphoid fever, dysentery and gastro-enteritis, affecting about 12,000 persons. During the same time, it is estimated that about 150,000 persons contracted tuberculosis of bovine origin, of which over 60,000 died, while an unascertained number, probably several thousand, suffered from undulant fever due to infection with Br. abortus."

"Our information for other countries is even less complete than that for Great Britain, but, such as it is, it points to the existence of a considerable amount of milk-borne disease, much of which is at present being overlooked. In Denmark, for example, where serious attention has only recently been devoted to the investigation of this problem, approximately 10% of all deaths from tuberculosis appear to be due to infection of bovine origin. About 500 cases of undulant fever occur annually, of which a considerable proportion is due to the consumption of infected milk. In addition, during the three years 1934-1936, nine outbreaks of epidemic milk-borne disease have occurred, affecting over 10,000 persons."

"No raw milk can ever be regarded as completely safe for human consumption. Even if produced from healthy animals, milk is so subject to contamination from human and other sources that it must always be regarded in the raw state as a potentially dangerous article of food. The only satisfactory method of ensuring the final safety of the product is to submit it to some form of heat treatment that can be relied on to destroy any pathogenic organisms that may be present."

THE NUTRITIVE VALUE OF MILK AND MILK PRODUCTS

Biological Values of Milk Products.

Henry, Houston, Kon & Osborne, ("J. Dairy Research," May, 1939), working with Evaporated Milk, Spray Dried Milk and Roller Dried Milk, reported no significant difference between the biological values of the proteins in the three processed milks.

No significant difference was found between the digestibility of the proteins of roller and spray dried milk, but those of evaporated milk were less digestible. A highly significant difference between the Vitamin B, content of evaporated milk (approximately only half) and roller and spray dried milk was recorded.

In animal experiments the dried milks were found significantly superior.

No loss of Vitamin A or of carotene, was found during processing and moreover, no decrease was found after one year's storage of the processed milks. Similarly there was no loss of riboflavin content in processing or even after sixteen months' storage.

In spray-drying a loss of 20% of the Vitamin C content of the milk was recorded, as compared with 30% loss during roller drying and evaporation. Little further change in the Vitamin C content of roller dried milk was discovered, while in spray dried milk it declined slightly after seven months' storage, and in evaporated milk there appeared to be a more definite and gradual loss. Since it is now customary to supplement Vitamin C even in breastfed infants, this destruction seems of little moment.

The Nutritive Value of Milk - Calcium Supply.

Sir. J. B. Orr, in his work "Food, Health and Income," 1936, first drew serious attention to the fact that calcium shortage was a characteristic of most diets, particularly in the poorer classes. He found that in mixed diets about two-thirds of the total calcium is usually derived from milk. Leitch, in a critical review of the calcium requirements of man, worked on this assumption and decided that the daily requirement of milk was 500 ml. from the age of six months to nine years, increasing to 1050 ml. for 15-17 years of age and then decreasing to 300 ml. for adults. For pregnant and nursing women he calculated that 800 ml. daily was required ("Nutrition Abs. & Rev.," Jan., 1937).

Howard et alia ("B. Med. J.," 8/1/38) confirmed that the diet of the poorer classes was seriously deficient in calcium. They tried the effect of graded doses of a mixture of salts of calcium and phosphorus and of milk on the growth of rats on a typical diet and concluded: "The salt mixture had no significant influence on the increase of weight of rats, but the doses of milk had a distinctly beneficial effect."

Widdowson ("J. State Med.," Aug., 1937) remarks: "Calcium is in many ways the outstanding mineral element. Its rôle as bone and tooth building material is obvious and striking, but the body needs calcium for many vital processes apart from the strengthening of the skeleton. Calcium is necessary for the clotting of the blood after injury and for maintaining the rhythmetic action of the heart. In adults the bones become to some extent a reservoir for calcium which

can be drawn upon to replenish the soft tissues and fluids in times of emergency. In the young, however, there must be a liberal supply of calcium for the developing bones and teeth. The most important source is undoubtedly milk, and a milkless diet is usually a very low calcium diet."

Influence of Milk on Utilisation of Proteins.

The experiments of Mitchell et alia ("Fundamentals of Dairy Science") illustrate the value of milk as a supplementary food especially in increasing utilisation of proteins from other sources.

They found that the proteins of maize, when present to the extent of 10% of the diet, showed 61.3% utilisation. Milk protein under similar conditions showed the high value of 84.7%. When, however, the 10% protein of the diet was composed of 7.5% maize protein and 2.5% milk protein, the total utilisation was 75.7%, which is much higher than the weighted mean and indicated an increase in the utilisation of the maize protein from 61.3% to 72.7%.

it is only reasonable to assume that deficiencies of certain amino-acids in the maize protein have been made good by the milk in order to render possible such a large increase in the biological value of the protein of maize.

The Value of Milk as a Protective Food.

The Technical Commission of the Health Committee of the League of Nations, in a recently published report ("Physiological Bases of Nutrition") record the fact that "the deficiencies of modern diets are usually in the protective foods rather than in the strictly energy-bearing foods"; the former being defined as being especially rich in "good" protein, vitamins or minerals.

"Among the protective foods are, first and most important, milk and milk products (including butter), eggs and glandular tissues; then green-leaf vegetables, fruit, fat, fish and meat (muscle)."

Milk is acknowledged to be a "rich source of calcium salts, phosphate and of Vitamin B₂, also a good source of Vitamin B₁, whilst milk fat is an excellent source of Vitamin A." Moreover, the proteins of milk are not only of the highest nutritive value but also improve the utilisation of protein derived from cereals or vegetables, and the report includes the note that:—

"Milk should form a conspicuous element of the diet of all ages. The Commission commends the tendency manifested in some countries to increase the daily intake up to one litre per day for pregnant and nursing women, as well as to provide an abundant supply for infants, children of all ages and adolescents."

(Extracts from the First Report of the Advisory Committee on Nutrition.—Ministry of Health, H. M. Stationery Office, 1937.)

"Milk is of such outstanding value that the consumption of a sufficient quantity of it may be regarded as the key to proper nutrition. Every one of the constituents of milk possesses high nutritive value and it is, therefore, most desirable that all of these should be utilised for human nutrition, more especially because the diets of many people are deficient in the nutrients supplied by milk and certain of its products. Moreover, cows' milk, the most complete food known, is elaborated from vegetable matter of little or no value for human nourishment . . . "

"Cream and butter are preparations containing higher concentrations of the fat and Vitamins A and D than milk itself. It is on these constituents that the food value of cream and butter chiefly depends. As they are not complete foods the proper place for cream and butter is as items in a mixed diet in which they make good the deficiencies of other foods in fat and in Vitamins A and D. The fats of milk are especially valuable for human nutrition."

"A food which contains all the materials essential for growth and maintenance of life in a form ready for utilisation by the body is obviously of high value. Milk alone is the food which in itself nearly fulfils these conditions, being elaborated by the mammalian mother as the sole nutriment of her offspring during the period of most rapid growth."

"The composition of cows' milk . . . contains the energy-giving nutrients, protein, fat and carbohydrate; all the known essential Vitamins, calcium, phosphorus, iron, sulphur, iodine, magnesium, potassium, sodium, chlorine and copper, some of the physiological roles of which are known, and a number of other elements, present only in minute amounts, such as manganese, zinc, and fluorine, the exact functions of which are not fully understood, but which would seem to be as necessary for normal nutrition as any of the other constituents. Even if it were possible to state the chemical composition of milk in full a very imperfect idea of its nutritive value would be obtained, because it would leave unmentioned many important physico-chemical and biological properties on which its high nutritive value largely depends. For example, the physico-chemical states of its constituents make for easy digestion and assimilation; the relationship of the different constituents to one another ensures normality of bodily function; the nature of its protein and of its mineral elements, notably calcium and phosphorus, and its high content of other inorganic elements and vitamins make for satisfactory growth and give it a very high value as a protection against disease."

"The fact that milk is a valuable human food, particularly when new tissues are being formed, has been recognised from the earliest times. Within recent years much experimental evidence has been brought forward, which has shown that cows' milk is the most valuable food known for the promotion of growth and health in children. . . . From the results of these and many other experiments too numerous to mention, on man and animals, it can be predicted that important beneficial effects would result from an increase in the consumption of milk above that at present prevailing in this country"

"Milk is in itself a well-balanced mixed diet. Its few disadvantages, which vary with the age of the person for whom it is intended, are easily overcome. All babies should be brought up on their mother's milk, but after breast feeding ceases, although cows' milk ought to form the bulk of the diet, this should be supplemented with iron, Vitamins D and C, preferably given in the form of natural foods, such as egg-yolk, orange juice and cod-liver oil. For children, adolescents and adults, a diet of milk alone is undesirable because it is deficient in energy-giving constituents relative to its bulk. For these it should be regarded as an important item in a mixed diet and not as a complete food; but on account of its growth-promoting properties it should form a larger proportion of the diet of children and adolescents than of that of adults. The expectant mother has to elaborate from her food the materials necessary for the growth of her offspring, while the nursing mother has to secrete milk to serve as the only food of her infant for at least six months. The milk requirements of the expectant or nursing mother are of a similar order to those of the growing child."

DRIED MILK

Some Medical Opinions.

(Extract from "The Infant," by Eric Pritchard, M.A., M.D., F.R.C.P., 1938).

"The time-honoured belief in the virtues of raw milk for the feeding of infants still survives in certain quarters, in spite of all the scientific evidence which proves that such virtues are quite illusory. It is, perhaps, unnecessary to point out that since dried milks, which are, of course, cooked milks, have largely superseded dairy milk — for the most part raw — in the feeding of infants, the Infant Mortality Rate in this country has steadily fallen. There are naturally many other factors besides the mere cooking of milk concerned in this highly satisfactory result, but it is quite certain that if the heating of milk seriously impaired its nutritive qualities this result would never have been achieved. The effect of heat on the nutritive properties of the various elements contained in the milk is insignificant, excepting in the case of Vitamin C, the anti-scorbutic element, which undoubtedly deteriorates under the influence of heat and oxidation, but since an independent supply of this Vitamin is invariably provided in all cases of artificial feeding, this is no argument against the use of sterilized milk if sterilization has independent advantages. As regards this latter point there cannot be two opinions. The greatest danger that exists for young infants is infection, and there can be no question that raw milk is the most prolific medium for the conveyance of infection."

(Extract from a communication from Dr. H. Kerr—"Medical Officer"—30/4/32).

"While it is not contended that dried milk is superior, or even as good as the very best and purest fresh milk, this latter is of such exceptional occurrence that dried milk is an infinitely purer and cleaner article for the use of the average family than the ordinary retail milk. That it is deficient in anti-rachitic vitamin is a mischievous assertion, founded upon insufficient knowledge. Very particular attention was paid to this point before it was ever decided to use dried milk in Newcastle, the very highest scientific assurances being first obtained."

(Extract from "Recent Advances in Diseases of Children," by Wilfred J. Pearson, D.S.O., M.C., D.M., F.R.C.P., and W. G. Wyllie, M.D., M.R.C.P.).

"There are advantages in the use of dried milks instead of the fresh variety. They are practically sterile, and are certainly to be preferred to contaminated fresh milk. The percentage of ingredients is known within reasonable limits. The nutritive values seem to be uninjured; indeed, it is probably improved, both because of the alteration in the protein, the casein being divided into minute particles during the process, and because the size of the fat globules is reduced during manufacture. The keeping qualities also are excellent. It is claimed that none of the Vitamins (A, D, B, or C) is impaired in the process."

"VI-LACTOGEN" PROCESS OF MANUFACTURE*

The vitamin content of milk depends largely on the food of the cow and exposure to sunshine, so that the supplies to the Nestlé factories can be considered ideal. Further, as the milk during the process is only exposed for a limited period to a temperature sufficient to ensure destruction of pathogenic bacteria, the vitamin content is conserved.

Cows' milk is generally accepted as having a lower iron content than human milk. A small amount of Ferri et Ammonium Citrate sufficient to give 4 p.p.m. in the reconstituted food is now being added to both "Vi-Lactogen" and "Lactogen" to make up for any possible deficiency of iron in the cows' milk used. That this policy is justified can be proved by reference to an article, "Nutritional Anaemia in Infancy," which was published in the "Medical Journal of Australia," September 27th, 1941.

As many Infant Specialists consider that a greater margin of safety, especially for Vitamin D, is desirable than is possible with fresh milk, we are now, after careful research, incorporating the concentrate of Vitamins A and D in "Vi-Lactogen" and "Lactogen."

This concentrate is prepared under strictest scientific control and contains fifty times the number of D units present in the best quality of Cod-liver Oil.‡

The amount of concentrate added is equivalent to-

497 International Units Vitamin A. and

106 ,, ,, D.

in each ounce (147 calories) of "Vi-Lactogen."

This is equal to more than a $\frac{1}{2}$ teaspoonful of Emulsion and is additional to the natural Vitamins already present in the product.

An infant at $6\frac{1}{2}$ months is given 5 ounces of "Vi-Lactogen" and thus receives 2485 International A Units and 530 International D Units of added Vitamins. Similarly at the same age, it would receive 5.4 ounces of "Lactogen," containing 2684 International A Units, and 572 International D Units of added Vitamins.

Each factory has its staff of specially trained farms' inspectors, whose duties include routine examination of cattle for disease, as well as ensuring that dairy premises, cow bails, utensils, etc., are in absolutely sanitary condition, and that each of the stringent Regulations of the Company concerning milk supply are strictly observed.

A recent development has been the appointment of qualified veterinarians to the Nestlé factories manufacturing infant foods.

All cans are washed and sterilised with live steam in automatic machinery operated by Nestlé employees.

All cows are milked in accordance with a time-table, so that the process of manufacture commences as soon as possible after milking. Most raw milk for city consumption is, on the other hand, 24 to 48 hours old before delivery to customers, and older still before it is consumed.

The raw cows' milk received at the Company's factories is submitted to very strict and searching tests in the Factory Laboratory, and unless it passes all of these, is not manufactured into "Vi-Lactogen" or "Lactogen."

^{*} Nestlé Research Laboratory.

[‡] Many observers have commented on the enormous variation in Vitamin content from sample to sample of Cod-liver Oil.

As cows' milk varies in composition even from day to day, the factory chemists rapidly analyse each batch and so balances its components by additional butter fat and milk sugar,§ that the "Vi-Lactogen," when reconstituted by the addition of hot, boiled water, closely resembles human milk. "Lactogen" has a slightly higher protein and lower milk sugar content and is made by these methods.

During manufacture and after pasteurising, the milk is homogenised to break up the large fat globules, until they become even smaller than those of human milk.

The milk is spray dried by a special process, a patent for which is held by the Nestlé Company. So gentle is the drying action that the solubility after reconstitution with water compares favourably with fluid milk. The effect of the heated air used in drying is so slight that, to ensure proper pasteurisation of the milk, this operation must be separately performed prior to drying. In the process of spray drying a jet of milk meets a current of warm air and is at once dispersed into a fine mist. Water is immediately evaporated from the tiny droplets of milk, leaving behind particles of milk powder. These fall to the bottom of the drying chamber and are automatically removed. The process is, of course, continuous.

Finally the resulting powder is packed by automatic fillers into tins for the market — it is untouched by hand at any time.

Routine bacteriological examinations carried out on the contents of the tin as packed for the market indicate a low average colony count.

The manufacturing process has removed all danger of the presence of pathogenic organisms.

Every tin is stamped on the bottom with the date by which the contents should have been used, and by this means only fresh stock remains on the market. The Nestlé organisation thus arranges for the withdrawal of overdated stock and its replacement by freshly dried "Lactogen" or "Vi-Lactogen."

This expiry date does not imply that after that date the contents of the tin is no longer suitable for use; it prevents the sale of old stocks to the public.

The chief chemical and physical characteristics of "Vi-Lactogen," the humanised milk, are:—

- 1. "Vi-Lactogen" is pure, fresh milk modified ("humanised"), fortified by the addition of a Concentrate of A and D vitamins and iron, dried by a highly scientific process.
- 2. Uniform composition, closely corresponding to that of human milk.
- 3. Reduction in size of fat globules in process of manufacture. (The usual process employed in manufacturing dried milks tends to cause the fat globules to become much larger than those in cows' milk.)
- 4. "Vi-Lactogen" is under the strictest scientific control, from the time the milk is obtained from the cows until it is finally consumed by the infant.
- 5 "Vi-Lactogen" is entirely an Australian product, manufactured by the Nestlé Company in factories situated at Smithtown, North Coast of New South Wales, and Dennington, in the Western District of Victoria, and the milk supplies are drawn from some of the world's richest pastures.

[§] As milk-sugar has been known to contain foreign matter and also small quantities of a substance which may cause digestive disturbances all lactose used in the preparation of "Vi-Lactogen" and "Lactogen" is carefully tested before use.

WHEN STARTING BABY ON "VI-LACTOGEN"

The following article giving advice to mothers is in the pamphlet included in all tins of "Lactogen" and "Vi-Lactogen."

In the first few weeks of life, baby's digestion has to learn how to function.

A mother should not be over-anxious for a quick increase in weight — perfect digestion is essential first.

If breast milk fails the only alternative is a modified milk food, such as "Vi-Lactogen."

A mother should, if she can, partly feed the baby and only make up the deficiency with "Vi-Lactogen." When this is necessary for a very young baby, the change-over to the new food needs careful handling. The natural food is breast milk and tolerance for the new food has to be established.

Do not change suddenly to the quantities given on the "Vi-Lactogen" tin. These figures are correct for average babies, but only after they have adjusted themselves to the change from breast milk.

NOTE:

- 1. Never start using any infant food at full strength. Give the full amount of water for baby's age but only half the amount of powder shown in the feeding table.
- 2. Gradually increase the amount of powder up to the figures given. The normal baby can usually reach full strength in one or two weeks, but others may need longer.
 - It is important, however, to get to full strength without delay, as baby needs this amount of powder for its normal growth.
- 3. (a) Most babies will show normal progress but if there are signs that baby has difficulty in tolerating the full strength mixture try adding one tablespoonful more of water than the table shows.
 - Baby will sometimes digest a diluted mixture more readily, provided the volume is not too much to swallow.
 - (b) Another temporary alternative is to replace one teaspoonful of "Vi-Lactogen" powder by one teaspoonful of Lactose (milk sugar) until the full strength (without added sugar) can be tolerated.
- 4. If baby is not showing satisfactory progress ask the advice of your doctor, or telephone or write to the address of our Infant Welfare Room in the State in which you live. The address is given in this pamphlet.

WATER REQUIREMENTS: Do not cut down the amount of water when starting on the food or if baby appears upset. Cut down the powder temporarily but not the quantity of water Babies need water. Give plenty of boiled water, especially during hot dry months.

"VI-LACTOGEN" FEEDING TABLE

"Vi-Lactogen" contains added Vitamins A and D and a small amount of organic Iron. Each 7 ozs. of mixed "Vi-Lactogen" contains the equivalent of half a teaspoonful of Emulsion.

Based on MEDICINAL Teaspoons and Tablespoons. Household spoons should not be used. Ask our nearest Office for free "Lactogen" Measure and copy of "The 'Lactogen' Mother Book."

FOR 4-HOURLY FEEDS

IMPORTANT.—When commencing this food mix all the water with only half the amount of "Vi-Lactogen" for first feeds, then gradually increase the amount of "Vi-Lactogen" to amount shown.

MIXING.—Place powder on top of the hot (boiled) water and stir vigorously with a fork until completely dissolved.

Analysis of "Vi-Lactogen." Data of "Vi-Lactogen." POWDER Fat 24.2 3.0 1 Medicinal Tablespoon = .31 oz. or 8.75 grm. Protein 16.9 2.1 I oz. Avoir. = 34 Medicinal Tablespoons. Lactose 53.1 I Gram = 5.15 Calories. 6.6 Ash 3.6 .45 I Tablespoon = 45 Calories.

Added Vitamin A 64 International Units per ounce of mixed food. Added Vitamin D 14

Added Organic Iron 4 parts per million of Fe per ounce of mixed food.

THE ADDITION OF COD-LIVER OIL EMULSION IS NOT NECESSARY.

TO GRADE FROM "VI-LACTOGEN" TO STANDARD "LACTOGEN."

The change-over from "Vi-Lactogen" to "Lactogen" is usually made at $5\frac{1}{2}$ months, but if thought necessary it can be made either at an earlier or a later date, and the following simple rule is useful:

Substitute 1 tablespoonful and $\frac{1}{2}$ a teaspoonful of "Lactogen" for each tablespoonful of "Vi-Lactogen" at weekly intervals, until after the fourth week full strength "Lactogen" is being fed, and then use the "Lactogen" Feeding Table. This gradually increases the protein percentage from 2.1 in the "Vi-Lactogen," by 0.3 per cent. each week until the figure of 3.1 per cent. for full strength "Lactogen" is attained.

Added Vitamin A 70 International Units per ounce of mixed food.

Added Vitamin D 15 " " " " "

Added Organic Iron 4 parts per million of Fe per ounce of mixed food.

WHY WE MAKE TWO INFANT FOODS.

Cows' milk unmodified is not suitable for infants because of its high protein and low sugar. In "Vi-Lactogen" the protein and milk sugar are modified close to breast milk composition. "Lactogen" is modified to intermediate figures. We believe that, for the very young babies, "Vi-Lactogen" is the food to recommend, but if higher protein is indicated, or the baby is weaned at 5 to 6 months, or later, then "Lactogen" should be used and continued during the early years of baby's life. Cod liver oil is not essential, as both foods, in addition to the Vitamins naturally present in the milk from which they are made, **now contain added Vitamins** A and D, and sufficient added Organic Iron to give the average amount present in human milk.

COMPARE THESE STATEMENTS.

垃

* *

"Lactogen" and "Vi-Lactogen."

Uniform in composition.

The process lowers the curd tension and causes it to form with proteolytic ferments a fine flocculent curd. Protein is proportionately lower than in cows' milk. In "Vi-Lactogen" it is only 2.1 per cent.

Lactose is added, so that "Vi-Lactogen" approximates human milk in composition in this respect.

"Lactogen" contains slightly less lactose.

Pathogenic organisms killed in process of manufacture.

Bacterial counts on dilution are very low (Nestlé Research Laboratory).

Bacterial counts tend to decrease after manufacture.

Fat globules as small as in human milk.

Remains sweet and pure. Only sufficient is mixed for each

Little danger of contamination from outside sources.

Manufactured from milk within a few hours of milking.

Raw Milk.

Butter fat figure in particular is not constant. According to Droop Richmond, variations are—minimum 1.04 per cent., maximum 12.52 per cent.

With rennet it forms a hard clot, which is very indigestible, due to greater amount of casein in cows' milk compared to human milk in which albumin predominates.

Has 4.7 per cent. Lactose, while human milk contains an average of 6.6 per cent.

Many epidemics have been traced to raw milk supplies. Bovine type of tubercle bacillus can cause tuberculosis in children.

Public Health reports on milk supplies of cities mention colony counts generally in millions.

Bacterial counts increase with enormous rapidity. "... Milk with an initial content of 30,000 per c.c. held at 68° Fahr. may possess 4,000,000 bacteria per c.c. at the end of 24 hours, or 25,000,000,000 at the end of 48 hours."†

Fat globules much larger than in human milk, and therefore less easy to digest by an infant.

Sours easily, unless held in cold storage.

Easily contaminated by flies, dust, dirty jugs, etc.

City milk is frequently 24 to 48 hours old when delivered

† (Pritchard; Physiological Feeding of Infants, page 179.) 0

3(c

2/2

"Vi-Lactogen."

The fat present is similar to that of human milk, and is therefore easily digested. Addition of a vitamin concentrate ensures ample Vitamin A and D content and avoids the need for a large excess of a foreign fat.

"Vi-Lactogen" is uniform in composition and very similar to average for human milk.

"Vi-Lactogen" is simple in use, as it only requires mixing with hot (boiled) water. Place the powder on top of the water and stir vigorously with a fork.

Cost of feeding on "Vi-Lactogen" is low.

"Vi-Lactogen" is exposed to a shorter heating period during manufacture than in boiling milk under normal household conditions.

Modified Cows' Milk.

Complete modification requires far more Cod-liver Oil than is necessary to supply vitamins. This excess is liable to upset the infant.

The final analysis of modified milk depends upon the unknown composition of the milk used.

Modified milk requires very careful measurement of milk, Cod-Liver Oil Emulsion, Lactose and of water. This involved method adds to the uncertainty of the composition of the mixture.

Cost is generally higher due to the extras required, even if a low-priced milk is used.

Milk is generally boiled for safety and frequently heated more than once.

"LACTOGEN" FOR THE NURSING MOTHER.

It is undoubted that "Lactogen" has the effect of improving the flow of breast milk in many cases. Attention has been drawn to this fact by doctors closely associated with maternity hospitals, who have tested "Lactogen" in the diet of mothers and expectant mothers.

It is not suggested that "Lactogen" acts as a direct stimulant to the mammary gland. The explanation of its value lies in the fact that it is the simplest way in which an incorrect or inadequate diet can be improved, i.e., by giving to the mother the proper components of human milk in a well-balanced and easily digestible form.

It is the experience of the majority of physicians that many mothers have little or no idea of the correct diet necessary to obtain the best results when breast feeding an infant.

"Lactogen" can be diluted to any desired strength and can be made up so that the prepared food contains considerably more solids than cows' milk, thus avoiding the discomfort caused when the latter is fed in the large quantities necessary to give equivalent nourishment.

In the maternity hospitals referred to above, "Lactogen" is also being used in a variety of ways, such as in the preparation of custards, milk puddings, and other appetising dishes, where its agreeable flavour and ease of assimilation produce the same satisfactory results.

FREE ANALYSES OF HUMAN MILK.

When breast-fed infants are not progressing there is always the possibility that the milk supply is abnormal in composition. Realising the difficulties of obtaining an analysis, we have opened a section of our Laboratory for the analysis of human milk. This service is free to Physicians. We strongly advise taking a sample from the complete contents of the breast if results of value are to be obtained, especially in regard to fat, as the percentage of this constituent increases as the gland empties. If it is difficult to obtain such a sample, we recommend a composite mixture of equal quantities taken at the beginning, middle and end of suckling.

A quantity of 1 oz. is all that is required for a complete analysis. This bulk sample should be thoroughly mixed before filling the sample bottle, and we suggest adding one drop of forty per cent. formalin to this quantity as a preservative.

At your request we will be pleased to forward bottles for sampling which will already contain the required amount of formalin. When a complete analysis is not specifically asked for, we will determine the fat percentage and total solids only. Always record your name and address or telephone number to avoid delay in advising you of results.

A complete record of all the analyses made can be seen at our Research Laboratory at any time.

The following interesting figures have been obtained each year from numerous analyses of samples of human milk since the special section of the Nestlé Research Laboratory has been opened:—

	Average 1926-41	Average 1942	Average 1943	Average 1944	Average 1945	Average 1946	Average 1947	Average 1948	Maximum	Minimum

SPECIAL RECIPES.

"Lactogen" Milk Puddings.—In making the usual cereal puddings, such as cornflour, sago, tapioca, semolina, ground rice, etc., "Lactogen" can be used with advantage to replace ordinary milk. As a general rule, prepare the "Lactogen" in the following strength: Three level household tablespoons to one cup of boiling water.

Malt Soup.—1½ tablespoons Maltogen, 1 tablespoon of flour, 4½ tablespoons "Lactogen," 15 ounces water.

Mix the Maltogen, flour and "Lactogen" together. Add sufficient water to make a smooth paste; then add remainder of water and stir. Place in a double boiler and boil for 5 to 10 minutes.

Mutton Broth.—Cover a shank with water; add I tablespoon of barley and a pinch of salt. Boil about four hours till meat comes easily from the bone. Strain and set. When cold, remove all fat and warm up. This broth is best made the day before using.

Pritchard's Vegetable and Bone Soup.—Take 1lb. of shin of veal or bone of some other young animal (chicken, lamb, etc.). Chop up so as to expose marrow and simmer gently for about eight hours with $1\frac{1}{2}$ pints of water and 1 tablespoon of malt vinegar, but no salt. Add about $\frac{1}{4}$ lb. of mixed vegetables and again simmer for one hour. Strain, make up to 1 pint, and allow to set into jelly.

(Dr. Eric Pritchard, referring to the uses of this soup in his work, "The Physiological Feeding of Infants and Children," states:—"It can be given to babies of any age . . . For ordinary healthy infants I generally order 2 to 4 ounces to be given in the 24 hours.")

Rice, Barley or Oatmeal Jelly.—Two level tablespoons of rice flour or patent barley (in the case of oatmeal jelly, $1\frac{1}{2}$ level tablespoons of oatmeal), 10 ounces of water, pinch of salt.

Mix the rice flour, patent barley or oatmeal with 1 ounce of cold water and add 9 ounces of boiling water. Stir two minutes and place in double boiler. Boil for one to two hours. Strain and keep covered in a cool place.

"Lactogen" Gruel.—Take one teaspoon of oatmeal and sprinkle into a cup of water, and boil 20 minutes to half an hour. (If for a baby under 9 months this must be strained.) Add prepared "Lactogen" to suit taste.

Baked Custard.—One egg, half a pint of prepared "Lactogen," sugar to taste. Beat up the egg, add the "Lactogen," stirring well, pour into a buttered pie dish and bake in a slow oven. A few drops of vanilla or essence of lemon may be added.

Ground Rice Custard.—Ground rice, one egg, half a pint of prepared "Lactogen." Mix one large teaspoonful of ground rice with the "Lactogen." Beat up the egg, and add this to the mixture with a little sugar. Bake in a pie dish in a slow oven.

SUGGESTIONS FOR THE USE OF VARIOUS FOODS WITH OR WITHOUT "LACTOGEN," FROM BIRTH TO TWELVE MONTHS, IN THE DIET OF THE AVERAGE INFANT.

FOOD	AGE	QUANTITY	REMARKS
"VI-LACTOGEN"	All Ages	See feeding table (page xxxviii).	When modification is practised by the addition of cod-liver oil or extra lactose "Vi-Lactogen" is indicated as simpler and more satisfactory, as only the addition of water is necessary.
"LACTOGEN"	All Ages	See feeding table (page xxxix).	"Lactogen" is a safe basic milk diet during all stages of a child's development.
MALTOGEN	All Ages	Add to "Lactogen" or "Vi-Lactogen" to 1 teaspoonful per feed (see table, page I), or replace one teaspoonful of the "Lactogen" or "Vi-Lactogen" powder by one teaspoonful of Maltogen.	Maltogen contains all the sugars formed from starch. Therefore, useful in educating the digestive functions of an infant for starch. Of value also as a corrective for constipation and in malnutrition. Contains added Vitamin B ₁ .
ORANGE JUICE	1 Month	Begin with a few drops, increasing to a half teaspoonful two or three times per day. Can be added direct to bottle or given midway between feeds. Increase to 6-8 teaspoonfuls daily at 6 months.	Dilute with twice the amount of cool boiled water. Given to supply excess of anti-scorbutic vitamin. ½ teaspoonful in 3 to 4 tablespoons of warm, boiled water one hour before feeding tends to prevent constipation. Prepare juice just before using.
RICE JELLY BARLEY ,, OATMEAL ,,	6-7 Months	Added to bottle, beginning with very small quantities, or given separately later.	It is usually advisable to start with barley or rice jelly, as they do not have the same irritating effect as the oatmeal jelly.
HOME-MADE RUSKS	6-7 Months	Very small quantity just before or after "Lactogen" feed.	The period to begin depends on the development of the teeth.
JUICE OF RAW BEEF MUTTON BROTH VEGETABLE "	6-7 Months	Begin with only a very small quantity, increasing to $\frac{1}{2}$ to 1 oz. daily.	Small quantities can be given earlier. BAKED BREAD CRUMBS can be added to the broth.
VEGETABLES	6-7 Months	Begin with small quantity added to the broth, and at 8-9 months two tablespoonfuls given separately.	Well mashed and strained peas, beans, pumpkin, marrow, cauliflower, spinach, carrots.
EGG YOLK, RAW	6-7 Months	Commence with $\frac{1}{4}$ teaspoonful added to the milk mixture.	Gradually increase to 2 teaspoonfuls.
DRY CRUSTS OF BREAD	9 Months	Only very small quantity is actually eaten.	Give usually just before "Lactogen" bottle; may be slightly buttered. Do not leave baby alone with crust.
COCOA	10 Months	Weak,	Made with "Lactogen."
"LACTOGEN" CEREAL PUDDINGS	10 Months	Two ounces, 1 meal per day.	Very small quantities can be given as early as the 7th or 8th month to inculcate starch digestion.
APPLE PULP PRUNE PULP	10 Months	One teaspoon.	Gradually increase quantity to 1 to 2 table spoons.
FIRM RIPE APPLE	12 Months	Begin with small quantity.	Begin by scraping off with a spoon.
STALE BROWN BREAD AND TOAST	12 Months	Begin with small quantity.	Lightly spread with butter, dripping, seedless jam, honey or treacle.

The "Lactogen" and "Vi-Lactogen" Mother Book which we give to mothers contains additional suggestions.

N.B.—Mothers are apt to overfeed when commencing with starchy foods. It cannot be over-emphasized that only very small amounts of supplementary foods should be added, except towards the end of the first year.

MILO.

A Fortified Tonic Food.

Percentage Composition:*

Fat	Fat Protein	Carbohydrate	Mineral Salts	Moisture	Wt. Oz.	Calories in I Med.	
11.7	12.7	68.0	4.6	3.0	Tablespoon	32.0	

Milo—Fortified Tonic Food—prepared by the Nestlé Company, is the outcome of prolonged research and investigations. The composition was determined from the results of numerous biological trials and, moreover, was approved by several distinguished dietitians before being finally adopted.

Milo is a concentrated tonic food prepared from Milk and Malted Cereals and Cocoa, fortified by the addition of Vitamin concentrates, organic Phosphates and important mineral salts—including Calcium, Magnesium, Iron, Sodium.

It is now generally accepted that many modern diets are seriously deficient in certain minerals and that such deficiencies are not only conducive to faulty metabolism but may even, in some instances, ultimately lead to specific disease. Milo is, therefore, enriched with balanced amounts of those mineral constituents which are so essential to the human organism — especially as regards the nervous system.

These elements are added in those particular combinations which can be readily utilised; for example, iron is furnished as the easily assimilated ferri et ammonium citrate, whilst an adequate phosphorus allowance is provided in the form of glycerophosphates—which can be rapidly absorbed.

The addition to Milo of magnesium is of particular clinical interest, as it is now known that this element is a constituent of all living cells. Professor Delbet of Paris has submitted evidence of his contention that certain pathological conditions are attributable to magnesium deficiency which he considers arises from a gradual decrease in the amount provided by ordinary foodstuffs.

The nerve cells in particular call for appreciable amounts of magnesium, so that Milo—on account of its richness in magnesium—is a definite fortifier of the nervous system.

Milo also furnishes a generous vitamin allowance; not only are the vitamins of the original grain and milk carefully retained, but the incorporation of cereal germ, a rich, natural source of B₁, and also of yeast, provide additional quantities of the B factors. Moverover, the product is supplemented by the addition of fish liver oil concentrates which supply Vitamins A and D in natural ratio, without impairing the taste, odour or digestibility of the Food.

Milo, when packed, contains not less than the following amounts of Vitamins and minerals:-

Vitamin A	 	500	International	Units	per	ounce
Vitamin B ₁		50	,,	"	,,	,,
Vitamin D	 	100	,,	"		
Calcium as Ca O	 	0.65	per cent.		"	,,,
Magnesium as Mg O			,, ,,			
Iron as Fe ₂ O ₃			" "			
Phosphorus as P ₂ O ₅			23 33			

^{*} Nestlé Research Laboratory.

Indications for Use.

Nervous Disorders. Milo has been specially designed as an anti-neuritic tonic food, and is invaluable in cases of neurasthenia, nervous debility and insomnia. Its B₁ content is of special interest.

Pregnancy. Milo is of particular value during pregnancy, as — apart from its general nutritive properties — it increases the calcium-phosphorus intake, and thus avoids depletion of the maternal skeleton, due to the fœtal demand.

Nursing Mothers. As Milo is a complete food, it offers the supplementary nourishment required during this period; in addition the mineral and vitamin contents are of value—not only in maintaining the general health of the mother — but also in protecting against possible deficiencies in the infant.

Senility. Milo can be included with advantage in the dietary of the aged; it is easily digested and contains an ample supply of magnesium, an element frequently indicated owing to disturbances in the calcium-magnesium balance caused by advancing age.

Convalescents, Post-operative Cases, etc. In all cases where an easily digested tonic food is indicated, Milo may be prescribed with every confidence.

Milo has excellent keeping qualities and is extremely convenient in use; it is taken in either hot or cold milk as desired. A simple way to include Milo in the diet is to recommend its use in place of cane sugar on cereals and puddings.

STERILISED CREAM.

Percentage Composition:*

Water	Fat	Solids— not fat	Cane Sugar	Wt. ozs. I Med. Tablespoon	Calories in I Med. Tablespoon
67.0	25.5	7.5		.50	38.0

Sterilised Cream is manufactured in a similar way to Ideal Milk except that concentration is not required. Although absolutely free from preservative, Nestlé's Sterilised Cream will keep indefinitely in the unopened state.

Cream, on account of its high percentage of butter fat, is rich in Vitamins A and D, and according to authorities the method of manufacture we use does not appreciably affect these Vitamins.

NESTLE'S AND GOLD MEDAL CONDENSED MILKS.

20.0	1	1.0	11.0	2.0	12.0	.0/	00.0	

In the manufacture of high-grade condensed milk the quality of the fresh milk used is of the utmost importance. We apply to all our products the same strict control throughout as outlined in the notes we have given on the manufacture of "Vi-Lactogen."

In the process of manufacture of condensed milk the fresh milk is pasteurised and then drawn by suction into large vacuum pans with a holding capacity of many tons of condensed milk. Sterilised sugar solution is drawn into the pan during evaporation of the milk.

^{*} Nestlé Research Laboratory.

By reducing the pressure with vacuum pumps rapid ebullition in the milk at low temperatures results and concentration takes place until the original 87 per cent. of water in the fresh milk is reduced to 25.5 per cent. The vacuum is broken, and the condensed milk flows by gravity to the cooling tanks, and finally to the filling and packing machines.

The low temperature of evaporation and the absence of oxygen are, no doubt, responsible for the fact that in high-grade condensed milks the Vitamins A, B, and C, also D and E are practically unaffected.

As the condensed milk has never reached temperatures higher than pasteurisation, it is not an absolutely sterile article in the strict sense of the word, **but it is free from pathogenic organisms**. Owing to the quality of the fresh milk used, and the scrupulous hygiene of our factories, our Research Laboratories frequently record colony counts of less than 17 organisms per gramme.

This figure is the more striking when compared with Public Health reports on city milk supplies.

Nestlé's Condensed Milk has long been recognised as an extremely useful food for premature infants; also children suffering from gastric disturbances show a marked tolerance for it when other foods have failed. Its freedom from pathogenic organisms makes it a safe food during hot weather.

A recommended method for premature infants when breast milk is not available is to begin by using 1 part of condensed milk by volume with 11 parts of boiled water. For example, one half medicinal tablespoonful of condensed milk (2 teaspoonfuls) plus $5\frac{1}{2}$ medicinal tablespoonfuls of water gives 6 tablespoonfuls of mixture or 3 fluid ounces — caloric value approximately 11 per ounce.

Then gradually increase strength to 1 part of condensed milk by volume with 7 parts of boiled water. For example, one medicinal tablespoonful of condensed milk plus 7 medicinal tablespoonfuls of water gives 8 tablespoonfuls of mixture or 4 fluid ounces—caloric value approximately 16 per ounce.

The composition of this full strength mixture is approximately 1.5% protein, 1.48% fat, 8.7% carbo-hydrate (2.2% lactose, 6.5% cane sugar).

The total water intake required daily for prematures is about 3 ounces per pound body weight. An adequate intake of water is important.

When used as the sole diet of an infant care shold be taken to see that the Vitamin A and D intake is adequate as the fat percentage is comparatively low, with a consequent decrease in Vitamins $\bf A$ and $\bf D$.

Directions for Preparing Nestlé's and Gold Medal Condensed Milk for Infants:

General Conclusions.

Contained in a report by the Laboratories of the Royal Institute of Public Health, London.*

- 1. The milk used in the preparation of Nestlé's Full Cream Condensed Milk is obtained under the most satisfactory conditions of supervision.
- 2. The processes of manufacture are carried out under the best hygienic conditions.
- 3. The chemical results show the condensed milk to be of good quality.
- 4. The bacteriological results show that the processes adopted are effective in the reduction and destruction of bacteria.
- 5. No evidence was obtained of the presence of the tubercle bacillus.
- 6. Evidence of the preservation of the vitamin contents was confirmed.

IDEAL MILK-(UNSWEETENED).

Percentage Composition:

• Water	Fat	Protein	Lactose	Ash	Cane Sugar	Wt. ozs. I Med. Tablespoon	Calories in I Med. Tablespoon	
§§ 71.8	8.2	7.9	10.4	1.7		.54	23.2	
**	3.8	3.7	4.9	.7			10.3	

In the manufacture of Ideal Milk, laboratory methods of sterilisation under pressure are adapted to industrial conditions. Great care and scientific control are necessary both in the preparation and sterilisation of the milk.

Without any addition, the milk is concentrated to a definite analysis in the vacuum pan and homogenised to split up the butter fat globules and effect satisfactory emulsification when diluted. It is then filled into tins and hermetically sealed. The filled tins are placed in large autoclaves and subjected to sterilising temperatures for a period of about a quarter of an hour. By this means every organism in the milk is killed; therefore, the product will keep indefinitely while sealed. After opening, as no preservative is present, the milk will sour in the same way as fresh milk, and in warm weather it should be kept on ice if not used immediately.

Ideal Milk when diluted provides a useful substitute for fresh milk for all general purposes. Of all forms of cows' milk, unsweetened milk is perhaps the least allergic. In practically every case of true milk allergy, unsweetened milk is well tolerated. ("). Pediat.," May, 1940).

NESTLE'S MALTED MILK.

Vitamin "B₁" is now added to Nestlé's Malted Milk.

Percentage Composition:

Water	Fat	Protein	Lactose	Ash	Cane Sugar	Malt Sugars	Starch	Vitamin B ₁ Int. Units per oz.	Wt. oz. I Med. Tablespoon	Calories in I Med. Tablespoon
† 2.2	9.4	12.0 1.1	11.9	2.9		61.5 5.9		150 14	.34	42.0 6.0

Nestlé's Malted Milk is made by drying a combination of whole milk with an extract of malted

* This report deals with investigations and conditions obtaining at one of our English Condenseries, but the methods of condensing and care exercised there apply equally to all factories controlled by the Company throughout the world.

§§ Concentrated.

** Diluted, 1 fluid oz. to 11 water.

† Dry.

Diluted, 14 Med. Tablespoons to 4 oz. water.

barley and wheat flour, the ratio of malt solids to milk solids being 2 to 1, the whole of the starch being completely converted by diastatic action into soluble malt carbohydrates.

The final process is an interesting one, as the whole of the desiccation to powder takes place under vacuum.

While we do not recommend Nestle's Malted Milk for routine infant feeding, nevertheless it is useful in special cases, as generally speaking tolerance for maltose is greater than for either lactose or cane sugar. The following feeding table has been found useful.

Based on level, not heaped, medicinal tablespoons.

(1 Tablespoon = 4 Medicinal Teaspoons Malted Milk = $\frac{1}{2}$ fluid ounce of water).

**		
Age 1st month	Malted Milk Med. Tablespoon 1 to 3	Med. Tablespoon 3 to 5
2nd ,, 3rd ,,	14 2	7 9
4th ,,	2½ 3	12 15
6th ,,	3½	16

The table is based on three-hourly feeding intervals allowing for one night feed during first month.

Times of feeding recommended:—6 a.m., 9 a.m., Noon, 3 p.m., 6.30 p.m., 9.30 p.m.

After 6 months, the quantities given should be increased gradually in the proportion of 1 table-spoon of Malted Milk to 4 tablespoons of water, i.e., if giving 5 tablespoons of Malted Milk, 20 tablespoons of water would be required.

Nestlé's Malted Milk is of value when low fat and protein, together with replacement of cane sugar, becomes necessary, and further, owing to the method of preparation, the vitamins of the milk and cereals are retained. When used for a prolonged period for infant feeding the supplementing of accessory food factors A and D is desirable, especially as the milk constituents are comparatively low when the product is diluted for use.

In recent years a great deal of scientific work has been carried out on the physiological effects of vitamins on human health and nutrition, which may be summarised as follows:—

Shortage of Vitamin B₁.—A shortage of Vitamin B₁, known as the anti-neuritic, growth-promoting vitamin, has been proved to cause very serious disorders. While extreme shortage which causes beri-beri and associated diseases is rarely encountered in this country, there is no doubt that modern diet and the refining of cereals can result in a lowering of the B₁ intake to dangerous levels. This has brought about in many individuals a condition of chronic deficiency.

The indigent, and those who, from idiosyncrasy eat poorly balanced diets, and food faddists, frequently seriously reduce Vitamin B₁ intake. Patients suffering from organic disease often have little appetite, or dietary restriction may limit intake, while gastro-intestinal disturbances can also impair absorption.

Finally, the B₁ requirement is greatly increased by augmented metabolic processes in febrile conditions, hyper-thyroidism, intense muscular exertion and during pregnancy and lactation.

Scientific Opinions—Well-known scientists claim that many disorders of modern life, loss of appetite, constipation, nervous and alimentary diseases can be traced to a border-line intake of Vitamin B₁. These are dietetic troubles which do not necessarily incapacitate, but which lower the general tone and cause mental and physical fatigue. Many go further and state that shortage of Vitamin B₁ is the most serious feature of present-day diet.

Adequate Intake Essential.—Vitamin B, cannot be stored for any length of time in the body. There is no appreciable reserve to be drawn on and, therefore, it is essential that the daily intake be adequate.

Modern refining of flour removes the germ of wheat because of its ill effect on the keeping quality and colour of the flour, also statistics have proven that much less flour is eaten now than formerly. Previously the body could rely on the wheat germ in flour for a reasonable B, intake, but it must now obtain the necessary B, units from other sources.

Nestlé's Malted Milk is now fortified with Vitamin B₁.—Nestlé's Malted Milk, which has always been prepared from barley malt and other cereals containing the valuable germ, has now been fortified with additional Vitamin B₁ from the richest natural sources. This means that other associated vitamins are also added; i.e., A, B₂ and E, and valuable organic phosphates of Calcium and Magnesium.

Nestlé's Malted Milk has been found particularly useful in invalid diet, in typhoid, pneumonia, and post-operative cases, where easy digestion and rapid assimilation are essential.

Nestle's Malted Milk is not only a nourishing food drink, but, as the result of this new development, has definite tonic and invigorating properties due to this increase in its Vitamin B potency.

MALTOGEN.

Malt Sugars with Vitamin B, for Infants and Adults.

Percentage Composition:*

Water	Fat	Protein	Lactose	Ash			Vitamin B ₁ Int. Units	Wt. oz.	Calories in I Med.	
water	rai	11010111			Cane Sugar	Malt Sugars	per oz.	Tablespoon	Tablespoon	
30		5.6	100.54	1.4		90.0	140	.33	36.9	

Maltogen is a dried extract prepared by the enzymic action of malt diastase on barley malt and other cereals. Not only are the natural vitamins and mineral salts retained, but these are fortified still further by cereal germ extract, rich in Vitamin B.

Maltogen contains 90 per cent. of maltose and malto-dextrins, carbohydrates which are formed in the natural process of digestion of starch.

These sugars are especially valuable in the modification of milk or "Lactogen" for infant feeding. Maltogen is ideal for premature, weak and under-nourished babies.

Maltogen is also useful where a high or mixed carbohydrate diet is indicated, as malt sugars are less liable to fermentation or to cause the development of acidosis. They are readily absorbed and better tolerated than other sugars.

^{*} Nestlé Research Laboratory.

Maltogen corrects constipation. It improves appetite and growth owing to its richness in Vitamin B₁ (the anti-neuritic Vitamin). Many infants and children show remarkable improvement when foods rich in Vitamin B are added to the diet.

Maltogen is valuable not only for modification of infant diets, but as a supplementary sugar for young children, nursing mothers, and adults on limited diets. A simple way to include Maltogen in the diet is to use it on cereals and puddings in place of cane sugar.

The following table will prove of use in prescribing the addition of this food to "Lactogen" or milk:

MALTOGEN	Diluted "LACTOGEN"	Increase in Carbohydrate
1 medicinal tea- spoonful dissolved in diluted "Lacto- gen," as shown in next column.	2 fluid oz. 3 " 4 " 5 " 6 " 7 " 8 "	3.5% 2.3% 1.8% 1.4% 1.1% .9% .8%

SUNSHINE FULL CREAM POWDERED MILK.

Percentage Composition:*

Water	Fat	Protein	Lactose	Ash	Wt. oz. I Med. Tablespoon	Calories in I Med. Tablespoon
2.5	26.3	28.0	38.0	5.2	.28	41

Sunshine Full Cream Powdered Milk is simply fluid milk from which, after pasteurising, the water has been removed by the most modern method of spray drying.

It is readily soluble and when mixed in correct proportions with water reconstitutes into a milk of excellent flavour.

 $3\frac{1}{2}$ medicinal tablespoonfuls pressed and level equal 1-oz. of Powder. 3-ozs. mixed with $18\frac{1}{2}$ fluid ozs. of water make a pint of normal milk containing 3.5% of butterfat.

There is no safer or better milk supply for young growing children, and for all household requirements.

NESTLÉ'S MILK CHOCOLATE.

Nestlé's Milk Chocolate supplies, in a concentrated form, the solid constituents of full-cream milk, finely ground cocoa bean and sugar, and is thus a most valuable supplement to the diet in those cases where extra nourishment is required. It is prepared in Australia under strict hygienic methods.

NESTLÉ'S COCOA.

Apart from its general usefulness as a nourishing beverage, when indicated in the diet of invalids and children, Nestlé's Cocoa can be confidently recommended by the Medical Profession on account of its excellent solubility and purity.

It is manufactured in Australia under strictest hygienic conditions.

^{*} Nestlé Research Laboratory.
