Abstract

Background: Atopic dermatitis (AD) is caused by a complex interplay between immune and barrier abnormalities. Murine models of AD are essential for preclinical assessments of new treatments. While many models have been used to simulate AD, their transcriptomic profiles are not fully understood, and a comparison of these models with the human AD transcriptomic fingerprint is lacking.

Objective: We sought to evaluate the transcriptomic profiles of six common murine models and determine how they relate to human AD skin.

Methods: Transcriptomic profiling was performed using microarrays and qRT-PCR on biopsies from NC/Nga, flaky-tail, *Flg*-mutated, ovalbumin-challenged, oxazolone-challenged, and IL-23-injected mice. Gene expression data of AD, psoriasis, and contact dermatitis were obtained from previous patient cohorts. Criteria of fold-change/FCH≥2 and false discovery rate/FDR≤0.05 were used for gene arrays.

Results: IL-23-injected, NC/Nga, and oxazolone-challenged mice show the largest homology with our human meta-analysis derived AD (MADAD) transcriptome (37%, 18%, 17%, respectively). Similar to human AD, robust Th1, Th2, and also Th17 activation are seen in IL-23-injected and NC/Nga mice, with similar, but weaker, inflammation in ovalbumin-challenged mice. Oxazolone-challenged mice show a Th1-centered reaction and flaky-tail mice demonstrate a strong Th17 polarization. *Flg*-mutated mice display FLG down-regulation without

significant inflammation.

Conclusion: No single murine model fully captures all aspects of the AD profile; instead, each model reflects different immune or barrier disease aspects. Overall, among the six murine models, IL-23-injected mice best simulate human AD; still, the translational focus of the investigation should determine which model is most applicable.

Clinical Implications: When testing new drugs for atopic dermatitis, murine models might be used to study barrier or immune features, but human trials are needed to determine effects on actual disease profile.

Capsule Summary: Differences between human atopic dermatitis/AD and murine profiles are significant regardless of the model. While IL-23-injected mice best replicate human AD, the choice of model should be guided by the translational focus of the investigation.

Introduction

Atopic dermatitis (AD) is the most common inflammatory skin disease,[1] caused by an interplay between immune and barrier abnormalities.[2,3] Unlike psoriasis, another common inflammatory skin disease that is largely Th17/IL-23 polarized,[2] AD is characterized by activation of multiple cytokine pathways.[4,5] In addition to immune activation, reduced expression of barrier components (terminal differentiation proteins, tight junctions and lipids) is also characteristic of AD.[6-9] Transcriptomic profiling of AD tissues at baseline and after treatment with broad and specific agents has recently increased our understanding of the disease.[10-12] While these studies highlight a critical role for the Th2 axis in AD,[10,13,14] they also suggest increased Th17/IL-23 and Th22 activation in AD, and particularly in some subtypes (i.e. Asian and intrinsic AD).[4,5,15] Although human testing is needed to elucidate the pathogenic contributions of various cytokines in AD, murine AD models are essential for assessing new drugs at the preclinical level.[16,17]

An ideal murine model should replicate both the epidermal barrier disruption and the cutaneous inflammation of the human disease. While many models have been used to simulate human AD, their transcriptomic profiles and relevance to the AD skin profile are not fully understood, since a direct comparison between frequently used models and human AD is lacking. A number of spontaneous genetically engineered, and inducible “AD-like” models have been described. These include NC/Nga,[16] flaky-tail (*Tmem79*$^{ma/ma}$ *Flg*$^{ft/ft}$),[18-20] *Flg*-mutated (*Flg*$^{ft/ft}$),[21] oxazolone (Oxa)-challenged,[22,23] and ovalbumin (Ova)-challenged mice.[24-27] Furthermore, IL-23-injected mouse model, which has been

traditionally considered to resemble psoriasis,[28,29] and exhibits the largest (25%) transcriptomic homology with human psoriasis fingerprinting among existing "psoriasis-like" models,[30] has also been found to display Th2 activation and simulate "AD-like" skin inflammation.[31] While all murine "AD-like" models (with the exception of *Flg*-mutated mice)[16,19-21,23,25,28] are visibly inflamed, it is difficult to macroscopically differentiate "AD-like" dermatitis in mice from lesions mimicking contact dermatitis (CD) or psoriasis. For example, since flaky-tail mice exhibit Th17-dominated skin inflammation,[32,33] this murine model may more closely simulate a "psoriasis-like" phenotype rather than an "AD-like" fingerprinting.

To evaluate the transcriptomic profiles of common AD models and determine how closely they resemble the intricate cytokine and epidermal abnormalities in AD skin, we profiled five common "AD-like" murine models, as well as the IL-23-injected model, previously considered to best mimic psoriasis. To be able to contrast all polar cytokine responses in humans, the murine profiles were compared with transcriptomic profiles of AD, and two other common inflammatory skin diseases, psoriasis and CD, that share clinical and tissue characteristics with AD.[9,34,35] We found that no single model fully captures all aspects of AD, but surprisingly IL-23-injected mice show the most similar transcriptomic profile to human AD.

Methods

Murine models

Transcriptomic profiling was performed using microarrays and qRT-PCR on biopsies from six models, including NC/Nga, flaky-tail, *Flg*-mutated, Ova-challenged, Oxa-challenged, and IL-23-injected mice. Controls for murine models generally had similar genetic background, comprising the C57BL/6 (Flaky-tail, *Flg*-mutated, Ova and IL-23), NC/Nga without mite infestation (NC/Nga) and BALB/c (Oxa) laboratory strains. The samples of flaky-tail, *Flg*-mutated, Ova-challenged, and NC/Nga mice were harvested at Kyoto University, Kyoto, Japan (**Table 1**). The specimens from Oxa-challenged mice were collected at Leo Pharma A/S, Ballerup, Denmark (**Table 1**). The IL-23-injected mice gene array data were acquired from a previously published cohort (GSE50400),[30] and available RNA samples from these mice were used for qRT-PCR. See Supplementary Methods section in this article's Online Repository (OR) at www.jacionline.org for more details. The Institutional Animal Care and Use Committee of Kyoto University and Leo Pharma A/S approved all experiments.

Representative images of each model are shown in **Fig 1A**. Ear tissues from flaky-tail, *Flg*-mutated, NC/Nga, and Oxa-challenged mice were used, while dorsal skin was harvested from Ova-challenged and IL-23-injected mice. Flaky-tail,[20] NC/Nga,[36] Ova-challenged,[25] and Oxa-challenged models[23] exhibit increased serum IgE levels. *Flg*-mutated mice show normal IgEs,[18] and IgE data are unavailable for IL-23-injected mice (**Table 1)**.[30]

Human cohorts

The AD microarray data was obtained from our meta-analysis derived AD (MADAD) transcriptome,[9] comprised of four AD lesional vs. non-lesional datasets with a total of 97 samples (41 paired lesional/non-lesional samples).

This study also includes a previously published cohort of 25 AD patients (9 females and 16 males; age, 23-73 years [median, 45 years]) with SCORAD scores from 33 to 77 (mean, 56.7; SD, 12.2) and serum eosinophils of 0.6% to 11.8% (median, 4.3%); among AD patients, 14/25 (56%) had extrinsic AD (serum IgE levels, 254-3,000 kU/L; median, 1,292.8 kU/L).[5,11] Ten previously published patients with moderate-to-severe psoriasis were included for comparisons (Psoriasis Area Severity Index, 8.4-59.5; mean, 20.3; SD, 14.5).[5,37] Thirteen previously published patients with allergic CD (n=10 with nickel allergy; n=3 with fragrance allergy) were included.[34] Biopsies from positive patch tests to these allergens were taken at 72 hours from patch test placement. All these subjects were European Americans. Patients' characteristics are summarized in **Table E1**, and the entire list is available in **Table E2**.

Quantitative RT-PCR and gene arrays

RNA was extracted with EZ-PCR Core Reagents (Life Technologies, Grand Island, NY). RNA was reverse transcribed to cDNA using the High Capacity cDNA Reverse Transcription kit (Applied Biosystems, Foster City, CA). TaqMan Low Density Array (TLDA) cards (384 well plates preloaded with TaqMan assays) were used for qRT-PCR. For IFN-γ, IL-13, and IL-17A, which are frequently

undetectable with TLDA, single Taqman qPCR was performed. All primers are listed in **Table E3**. For IL-23-injected mice, PCR analyses were performed using stored samples from a previous report.[30] Expression values (threshold cycle/Ct) were normalized to *Rplp0*.

Affymetrix Mouse Gene arrays 2.1 ST (Affymetrix, Santa Clara, CA) were used for flaky-tail, *Flg*-mutated, Ova-challenged, and NC/Nga mice. Affymetrix Mouse Gene arrays 1.0 ST were used for Oxa-challenged mice, while the previously published IL-23-injected murine transcriptomic data were analyzed with GeneChip Mouse Genome 430 2.0 Array (Affymetrix).

The MADAD transcriptome combined all effect sizes for each probe-set, and identified a set of 595 differentially expressed genes (DEGs; 387 up- and 208 down-regulated) using classical fold change (FCH)≥2 and false discovery rate (FDR)≤0.05 criteria.[9] For the qRT-PCR comparison, we used previously published data obtained from above-mentioned human cohorts. Since non-lesional AD skin is abnormal,[38] we also included a comparison of lesional AD to normal skin.

Bioinformatics and statistical analyses

Murine microarray data were preprocessed in R by the *justRMA* function of the *affy* package and normalized using the *normalize.quantiles.robust* or *normalize.quantiles.use.target* (IL-23 and Oxa models) function of *preprocessCore* package.[39,40]

Changes in expression profiles of each murine model and its controls

were performed using the linear model framework of *limma* package.[41] P-values from moderated t-test were adjusted for multiple testing using Benjamini-Hochberg procedure.

Cross-species-annotation from murine to human ensemble IDs was performed using the *getLDS* function *biomart* package.[42-45]

Linear models were applied to analyze TLDA and qRT-PCR expression data, based on *Rplp0* normalized and negative transformed Ct (-dCt) values. Prior to applying these models to TLDA and qRT-PCR expression data, but after normalization, we replaced non-detected -dCt values with 20% of the minimum dCt for each gene across all samples, while keeping it in the possible range of -40 to 40.

Results

Transcriptomic profiling of "AD-like" murine models

While transcriptomic fingerprinting has been thoroughly performed in AD skin,[4,5,38,44-47] a similar analysis is lacking for "AD-like" murine models. To establish the individual transcriptomic profiles of prominent "AD-like" models and their similarity to human disease, we profiled skin from five common AD-like models[20,21,23,25,36] as well as from the IL-23-injected model, considered to best represent the IL-17/IL-23-centered inflammation in psoriasis,[30] using gene arrays (**Table 1**). Criteria of FCHs≥2 and FDR≤0.05 were used to define DEGs between diseased murine skin and respective controls. The lists of DEGs for each model are listed in **Table E4**.

A Venn diagram, based on unique Human Genome Organisation (HUGO) Gene Nomenclature Committee (HGNC) symbol orthologs and proportional to DEGs, illustrates the overlap between murine models (**Fig. 1B**). Flaky-tail and *Flg*-mutated models are excluded from the diagram since they display the lowest number of DEGs (n=226 and n=47, respectively), despite being among the largest sample sizes (n=5; **Table 1**). Overall, IL-23-injected mice show the highest number of DEGs (n=2753), followed by Oxa-challenged (n=1004), NC/Nga (n=742), and Ova-challenged (n=373) mice. Only 67 DEGs are shared among NC/Nga, Ova-challenged, Oxa-challenged, and IL-23-injected mice, as represented in the center of the Venn diagram (**Fig 1B)**.

Murine models show differential profiles compared to human AD

To compare how well "AD-like", and the IL-23-injected models represent human AD, each murine transcriptomic profile was compared with the meta-analysis derived AD (MADAD),[9] a robust AD transcriptome across four independent cohorts. The murine transcriptomes represent only 37%, 18%, 17%, and 11% of the human AD profile (MADAD), for IL-23-injected, NC/Nga, Oxa-challenged, and Ova-challenged mice, respectively (**Fig 1C**). Only 4% of DEGs in flaky-tail mice and 1% in *Flg*-mutated mice overlap with MADAD. The poor homology between human AD and the murine skin profiles is also illustrated as a heatmap, in **Fig E1,** showing relative expressions of MADAD genes within all murine transcriptomes. **Fig E2** illustrates expression data by sample. Surprisingly, the transcriptome of IL-23-injected mice best represents the up- and down-regulated components of the MADAD followed by NC/Nga, Oxa-challenged and Ova-challenged mice. *Flg*-mutated and flaky-tail profiles are not well reflective of the MADAD increased or decreased elements. The MADAD DEGs with corresponding FCHs and FDRs are shown in **Table E5,** for each model.

Since the choice of cut-offs and hybridization kits can influence intersections between DEGs of various transcriptomes,[48] the MADAD and transcriptomes of six murine models were also compared using ranked gene lists instead of cut-offs, as previously described.[29,30] The 5000 highest up- and down-regulated genes in each mouse transcriptome were identified and ranked according to FCHs, with lowest ranks assigned to the genes with highest regulations. We then analyzed the overlap of MADAD with ranked genes in each

murine model. In **Fig. 1D**, the red and blue lines correspond to the overlap between up- and down-regulated genes, respectively, of murine models and MADAD at any given rank N, where N=1, …, 5000. The light blue line outlines the level of overlap expected by chance (the 95% confidence region of hypergeometric distribution under the null hypothesis), such that any line above it indicates a significant level of overlap and farther distances from it show a higher overlap.[49] For any given rank, IL-23-injected mice represent the highest and most significant overlap with the MADAD, and in decreasing order for Oxa-challenged and NC/Nga mice. The Ova-challenged model has significant overlap with genes up-regulated in human AD, but fails to capture the down-regulated signature of human AD. The transcriptomes of flaky-tail and *Flg*-mutated mice have poor overlap with human AD, consistent with the standard cut-off based approaches (**Fig 1 B-C**).

To associate different mice profiles with relevant biological functions in human AD, an enrichment analysis was also conducted, using KEGG pathways.[50,51] Selected pathways significantly enriched in human AD and in the murine models are shown in **Fig 2A** and **Table E6,** with the black vertical line representing FDR=0.05. The genes represented in each pathway are listed in **Table E7**. The most significantly enriched pathways in the MADAD includes PPAR signaling, cytokine-cytokine receptor interaction, JAK-STAT signaling, T cell receptor signaling, chemokine signaling, cell adhesion molecules, and adipocyte signaling pathways. IL-23-injected mice best simulate the inflammation and lipid pathways in human AD, with enrichments in some pathways also seen

with NC/Nga and Oxa-challenged mice. Ova-challenged mice only share the cytokine-cytokine receptor interaction, PPAR signaling and biosynthesis of unsaturated fatty acids pathways with MADAD. A single lipid pathway (biosynthesis of unsaturated fatty acids) is shared between *Flg*-mutated and flaky-tail mice and the MADAD, although this pathway is not significant for the MADAD. Retinol metabolism, hedgehog signaling and melanogenesis pathways are enriched in flaky-tail mice, but are not enriched in MADAD.

Fig 2B illustrates the top 30 up- and down-regulated MADAD DEGs and their representation in each model (**Table E5**). Again, IL-23-injected mice best represent not only the up- (e.g. CCL18, S100A8, KRT16) but also the down-regulated DEGs (e.g. CLDN8) in the MADAD, while NC/Nga, Ova-challenged, and Oxa-challenged mice mostly capture the up-regulated but not the down-regulated genes in the MADAD. The flaky-tail model only poorly represents key AD genes, and *Flg*-mutated mice entirely lack the top up- and down-regulated human AD genes. The IL-23 model captures some lipid (ELOVL3), tight junction (CLDN8) and water channel (AQP7) deficiencies, previously reported to characterize the barrier defects in AD.[9,44,52,53]

Transcriptomic homology between mice and inflammatory skin diseases

Since the signatures of the six murine models showed limited resemblance to human AD, we expanded our comparison to also include transcriptomic profiles of two other well-characterized polar inflammatory skin diseases, psoriasis and contact dermatitis (CD).[5,11,34,37] We then performed unsupervised clustering with

348 percentages reflecting robustness of each branch in the dendrogram (**Fig 3A**).
349 The resultant dendrogram establishes a tight cluster of inflammatory skin
350 diseases, with clear separation from murine models. *Flg*-mutated and flaky-tail
351 mice cluster together and farther apart from other models. To elucidate the
352 relative distances between individual models and human disease and to identify
353 which murine model is closest to the human diseases, we performed a principal
354 component analysis (PCA) (**Fig. 3B).** The PCA plot shows that murine models
355 are separated from inflammatory skin diseases. IL-23-injected mice are closest to
356 the AD profile (MADAD) on the PC1 axis, followed by CD (to fragrance) and
357 surprisingly only then by psoriasis (**Fig. 3B**). Indeed, a principal variation
358 component analysis (PVCA) also indicates that the organism explains 41.5% of
359 the variations, with disease or mouse model accounting only for 12% (data not
360 shown).
361
362 **qRT-PCR highlights significant differences in polar immune activation**
363 **among murine models**
364 To validate and extend the microarray findings to polar cytokines, qRT-PCR was
365 performed on a wide array of hallmark human AD inflammatory and barrier genes
366 that are often below detection levels in arrays and share murine orthologs. The
367 mRNA expressions were also compared to those obtained in our AD and
368 psoriasis cohorts, and, for selected, available genes also to CD (to nickel and
369 fragrance) populations **(Fig. 4)**.[34] Overall, similar patterns are seen in qRT-PCR
370 and gene arrays. IL-23-injected, NC/Nga, Oxa-challenged and Ova-challenged

mice show large increases in innate, Th2, and Th1 cytokine pathways (IL-1β, IL-13, IFN-γ), as well as increased KRT16 (marking epidermal hyperplasia),[54] and the Oxa-challenged model has the highest activation of the Th2 cytokine, IL-13. Only IL-23-injected and NC/Nga mice reflect all diverse cytokine pathways, including IL-17A activation. The down-regulation of terminal differentiation genes (filaggrin/FLG, loricrin/LOR) that characterizes AD is best captured by *Flg*-mutated and flaky-tail models, and to some extent by IL-23-injected, Ova, and Oxa models but is missing in NC/Nga mice.

Discussion

Over the past decades, many murine "AD-like" models,[20,21,23,25,36] including humanized AD,[55] topical vitamin D analogue application,[56,57] or allergen/staphylococcal enterotoxin B models,[56-58] have been developed as tools for understanding the AD pathogenesis and as preclinical models. The most complete view of the human AD profile is based on transcriptomic profiling of skin lesions.[4,5,9] Key AD features include prominent activation of inflammatory pathways and large defects in epidermal differentiation, tight junctions and lipid profiles.[38,44-46,59,60] Unlike psoriasis that is largely Th17/IL-23-polarized, AD shows more diverse cytokine expression, with Th2, but also Th22 pathway activation,[2] with possible roles also suggested for IL-23/Th17 axis, particularly in specific AD populations, such as Asian AD.[5]

Global transcriptomic profiling of individual murine models is essential for understanding their distinct cytokine and barrier alterations and how well they resemble human AD fingerprinting, as compared with profiles of other common polar inflammatory skin diseases.[29,30] This study is the first to evaluate the fingerprinting of commonly used "AD-like" (and a representative "psoriasis-like") murine models and their relevance to human AD, but also to psoriasis and CD.

A proper model of human AD skin should appropriately represent its two main features, the relevant cytokine networks and the epidermal pathology. However, our data suggest that no single murine model is able to accurately simulate both aspects of AD. Our data separates the models into two clusters. One group includes flaky-tail and *Flg*-mutated mice, which are least reminiscent

of human AD, and particularly of its immune skewing. Flaky-tail mice show a Th17-dominated polarization and *Flg*-mutated mice demonstrate no apparent clinical or tissue inflammation, which is quite different from the human AD profile. The other group, including IL-23-injected, NC/Nga, Oxa-challenged, and Ova-challenged mice, show a broad range of polar immune activation. With the exception of the IL-23-injected model, which simulates some barrier features of human AD, such as reductions in tight junctions (CLDN8), lipids and LOR, other models in this group mostly do not reflect the epidermal abnormalities of AD.

Surprisingly, among all evaluated models, IL-23-injected mice show the largest overlap with human AD skin, which is unexpected since this model has been traditionally used for psoriasis.[61] This model demonstrates remarkable activations of innate immunity, Th1, Th2, and Th17/IL-23 axes, as well as some epidermal alterations. Still, IL-23-injected mice have increased neutrophils and only sparse eosinophils and mast cells,[30,31] that can be found in human AD.[62,63] Furthermore FLG down-regulation, which represents a hallmark of AD, is absent in this model. This model thus replicates the Th2 activation of AD, as well as the Th17/Th22 signature of psoriasis and some AD subtypes. While IgE levels have not been evaluated in our IL-23 model,[30,31] IgE responses take at least several weeks to develop.[25] Perhaps, unlike other models, which have more chronic T-cell activation, and are able to induce IgE responses over time, IL-23 model is a short-term skin inflammation model (profile is created within 7d).

While the NC/Nga model does not reflect the various barrier defects of human AD, including decreases in differentiation, tight junctions, and lipids (i.e

425 FLG, LOR, CLDN8, ELOVL3),[9,38,44-46] it clearly shows the diverse immune
426 polarizations in human AD, including innate, Th1, Th2, and Th17 pathways. Thus,
427 use of NC/Nga mice might be useful to investigate the complex cytokine
428 interactions, but not the barrier aberrations of AD. Ova-challenged mice also
429 replicate activation of inflammatory pathways in AD, although to a lesser extent
430 than IL-23-injected and NC/Nga models.

431 Oxa-challenged mice demonstrate high Th1 and marginal Th2 inductions,
432 with only limited barrier defects (LOR). IL-17A induction is absent in these mice,
433 but a few downstream mediators (S100A8, lipocalin 2/LCN2) are up-regulated.

434 Flaky-tail mice show selective Th17 activation, as previously reported.[32,33]
435 While the Th17 axis is a central driver of psoriasis, some role of this pathway in
436 AD, including induction of the Th2 axis, has recently been suggested.[5,64,65] Thus,
437 while flaky-tail mice replicate some Th17 activation and reductions in FLG and
438 LOR seen in AD, data obtained from these mice should be applied cautiously to
439 human AD as this model lacks Th2 activation, which is the hallmark of the AD
440 immune responses.

441 *Flg*-mutated mice are the only murine model showing significant down-
442 regulation of FLG, similar to reductions observed in human AD.[66-68] However, *Flg*-
443 mutated mice lack both clinical and transcriptomic skin inflammation,[21] and
444 additional barrier abnormalities that are seen in AD, suggesting its limited use as
445 a model to replicate the inflammation and global barrier defects in AD. A
446 summary of clinical and laboratory characteristics of all analyzed models is
447 provided in **Table 2**.

Human inflammatory skin diseases share a number of features, but maintain distinct differences in tissue structure and immune activation. While down-regulation of differentiation genes clearly differentiates AD from the other two inflammatory skin diseases, other immune and epidermal features are shared among the 3 conditions. These characteristics include increased epidermal hyperplasia and activation of Th1, Th17, and Th22 pathways, although, as expected, Th2 polarization is minimal in psoriasis compared to AD.[5]

Our study has several limitations: 1. Only mRNA, but not protein levels were measured, and assessments were limited to a single time-point; 2. We mainly used B6 mice, although BALB/c might be more appropriate in certain cases; 3. We did not perform functional *in-vivo* tests (i.e., transepidermal water loss/TEWL, corneal water content, and pruritus measures).[16,23] The biopsies were taken from different locations and at different ages in mice, possibly affecting gene expression.[69] Last, comparisons with different AD endotypes were not possible here, and should be addressed by future larger cohort studies of various ages, races, etc.

Overall, no single murine model fully captures all immune and barrier aspects of human AD skin, and phenotypical differences between AD and murine models are significant regardless of which model is chosen. Nevertheless, of the models studied, IL-23-injected mice appear to best replicate the human AD profile. IL-23-injected and NC/Nga mice demonstrate a wide array of inflammatory axes, including Th2 activation, and are best suited to assess this AD-centric axis, and how it interacts with other activated cytokines in AD. Oxa-

challenged and Ova-challenged mice, despite showing remarkable inflammation, are not necessarily AD-specific. IL-23-injected, Oxa-, and Ova-challenged models have the advantage that inducing agents can be used on different mouse backgrounds, including existing knockouts of specific genes, to dissect cutaneous inflammation. Flaky-tail mice fail to capture any key features of human AD. *Flg*-mutated mice are best only to represent the *FLG* down-regulation in AD, but not other AD characteristics. Thus, the choice of which murine model to use depends on the translational focus of the investigator, but caution should be exercised when translating murine data to human inflammatory skin diseases.

Figure legends

Figure 1: **A.** Representative pictures of murine models. **B.** Venn diagram of overlapping DEGs for 4 AD models. Flaky-tail and *Flg*-mutated models are excluded due to their small number of DEGs. **C.** Proportion of MADAD DEGs represented in each model.[9] IL-23-injected mice appear separated because these data are from our previous study (GSE50400).[30] **D.** Overlap between top up- (red) and down-regulated (dark blue) genes in each model and MADAD was estimated for rank N=1…5000.[70] The light blue line outlines the overlap expected by chance, such that any line above it indicates significant overlap and distances farther from it show higher overlap.[49]

Figure 2: A. KEGG analysis in the respective MADAD and murine model transcriptomes. The black horizontal line indicates FDR=0.05. **B.** Heatmap of the top 30 up- and down-regulated MADAD DEGs with orthologs in murine models.[9] Corresponding $\log_2$(FCH) are shown. *P<0.05; **P<0.01; ***P<0.001. Coloring (blue: down-regulated; red: up-regulated) appears for absolute $\log_2$(FCH)≥1, with adjusted p-values<0.05.

Figure 3: Genome-wide neighboring analysis of the 8400 genes represented in human-murine orthologs. **A.** Dendrogram applying unsupervised clustering using Pearson's correlation distance and McQuitty agglomeration. Significant clusters have approximately unbiased (AU) p-values ≥ 95%[71] **B.** PCA using $\log_2$(FCH) for

509 the 8400 genes.

Supplementary Legends

Figure E1: Heatmap of the human MADAD genes with orthologs in murine models. The leftmost column represents the direction of dysregulation in MADAD (blue: down-regulated; red: up-regulated) whereas for each murine model, the group-wise Z-score represents the relative expression of MADAD genes in each model.

Figure E2: The murine samples' normalized expression values presented by: **A**) A boxplot of all mouse samples colored by dataset, and **B**) A heatmap of all overlapping mouse genes.

Table E1: Summary of clinical characteristics and demographics of patients (mean ± SE if not specified).

Table E2: Characteristics of studied populations.

Table E3: Primers used for qRT-PCR.

Table E4: DEGs in each murine AD model (models vs. controls).

Table E5: The log2(FCH) values are presented with their corresponding Benjamini adjusted p-value of each murine model contrast, for the MADAD DEGs

ACCEPTED MANUSCRIPT

(cut-off absolute FCH ≥ 2 and FDR ≤ 0.05). The status columns indicate the direction of dysregulation in each murine model (0 = not significant, 1 = significant up-regulation, -1 = significant down-regulation).

Table E6: -log(FDR) values for KEGG pathways in MADAD and murine models (significant pathways > 1.3 corresponding to FDR<0.05)

Table E7: Genes represented in each KEGG pathway
