"IT'S MINIMAL IN USE OF MATERIALS, IT'S SPATIAL, IT'S STRUCTURAL—IT'S EVERYTHING ARCHITECTS SHOULD BE CONCERNING THEMSELVES WITH" - JOHN RONAN

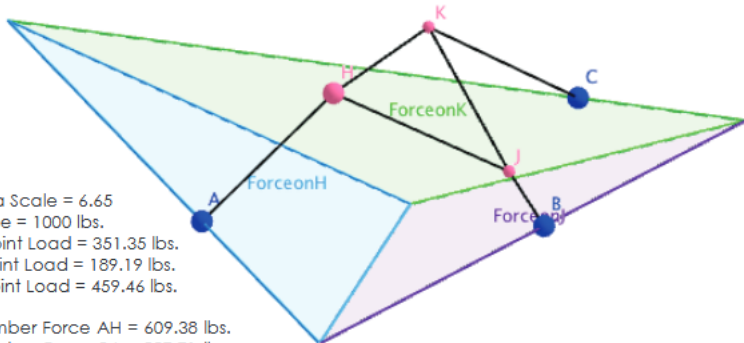

EXPLODED AXON OF FORM

VOUSSOIR CLOUD

This project by IwamotoScott was designed for the SciArc gallery in Los Angeles as a site specific architectural installation. The design itself sought to combine the contrasting construction logics of pure compression shell structures and thin lightweight sheets. The result was an incredibly light system of wood laminate vaults with a porous shell.

Area Scale = 6.65
 Force = 1000 lbs.
 H Point Load = 351.35 lbs.
 J Point Load = 189.19 lbs.
 K Point Load = 459.46 lbs.

Member Force AH = 609.38 lbs.
 Member Force BJ = 557.71 lbs.
 Member Force CK = 358.01 lbs.
 Member Force HJ = 206.95 lbs.
 Member Force HK = 323.20 lbs.
 Member Force KJ = 244.64 lbs.

G E O G E B R A

The architectural form was explored with engineering principles in Geogebra. This three strut exploration was critical in understanging the engineering behind a funicular shell as well as options about design

COMPLETED WOODEN STICK MODEL

11

HANGING CHAIN MODEL 1

HANGING CHAIN MODEL 2

HANGING CHAIN

Chains were cut to length using Geogebra guidelines, attached by pinching the chains. Alluminum round bars were cut proportionately to the forces calculated in that strut using Risa and Robot. These bars were attached using rings

COMPLETED HANGING CHAIN MODEL

FORM FINDING MODEL 1

FORM FOUND

The form was found by taking one funicular shell, replicating and scaling it down four times and, then twisting around an axis. Not only were we inspired by biomimicry, but our shells rotate around an axis as *Ursa Minor* rotates around *Polaris*.

FORM FINDING MODEL 2

DIGITIZATION PROCESS 1

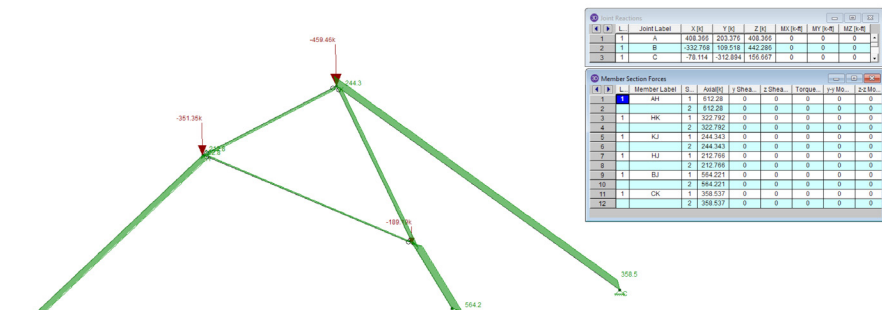

DIGITIZATION PROCESS 2

DIGITIZING

The physical model was digitized twice. The first time, we digitized our hanging chain model. The second time, we digitized our hanging fabric model. The digitizer automatically put our form in Rhino. From Rhino, the model was exported into AutoCad and then to SAP2000.

FALERA
CENTER

ST. REMIGIUS

Our site was located in Parc La Mutta, Switzerland, a Celtic astrological viewing site dating back to the Middle Bronze Age. Polaris is an astrological viewing site for the modern era that honors the Celtic standing stones on site. Physically, our shells keep a low profile on the cherished landscape; no shell is over 30', and our footprint is 6400 ft². Our oculus points to the most important Northern constellation to the Celts, Ursa Minor or "The Lesser Bear".

Polaris not only accommodates the viewing of the night sky, but also daytime and nighttime live music performances. The curvature and placements of the shells work as an amphitheater, and the ground slopes down to work with the shell for natural seating.

Plan view with site context, access points, functional area and main view axis.

DAY & NIGHT SECTIONS

The daytime section (left) shows how soft ambient Northern light links into the space. It also shows how the curvature of the shells accompanied by the gentle sloping of the hills makes a natural performance space. Light from the oculus highlights the performers. The nighttime section (right) shows views to Ursa minor and glimpses to the stars as you progress through the space

JUNE 21ST - NOON

DEC 21ST - NOON

DEC 21ST - SUNSET

LED PLACEMENT

We drew inspiration for our fading shell from James Turrell's Guggenheim instalment. Upon entering the shell, the lights are white and in high contrast to the night sky. As you move further into the space the colors get more rich and compressive untill the final conclusiona at the last shell occulus.

[EXTERIOR NIGHT LIGHTING CONDITION]

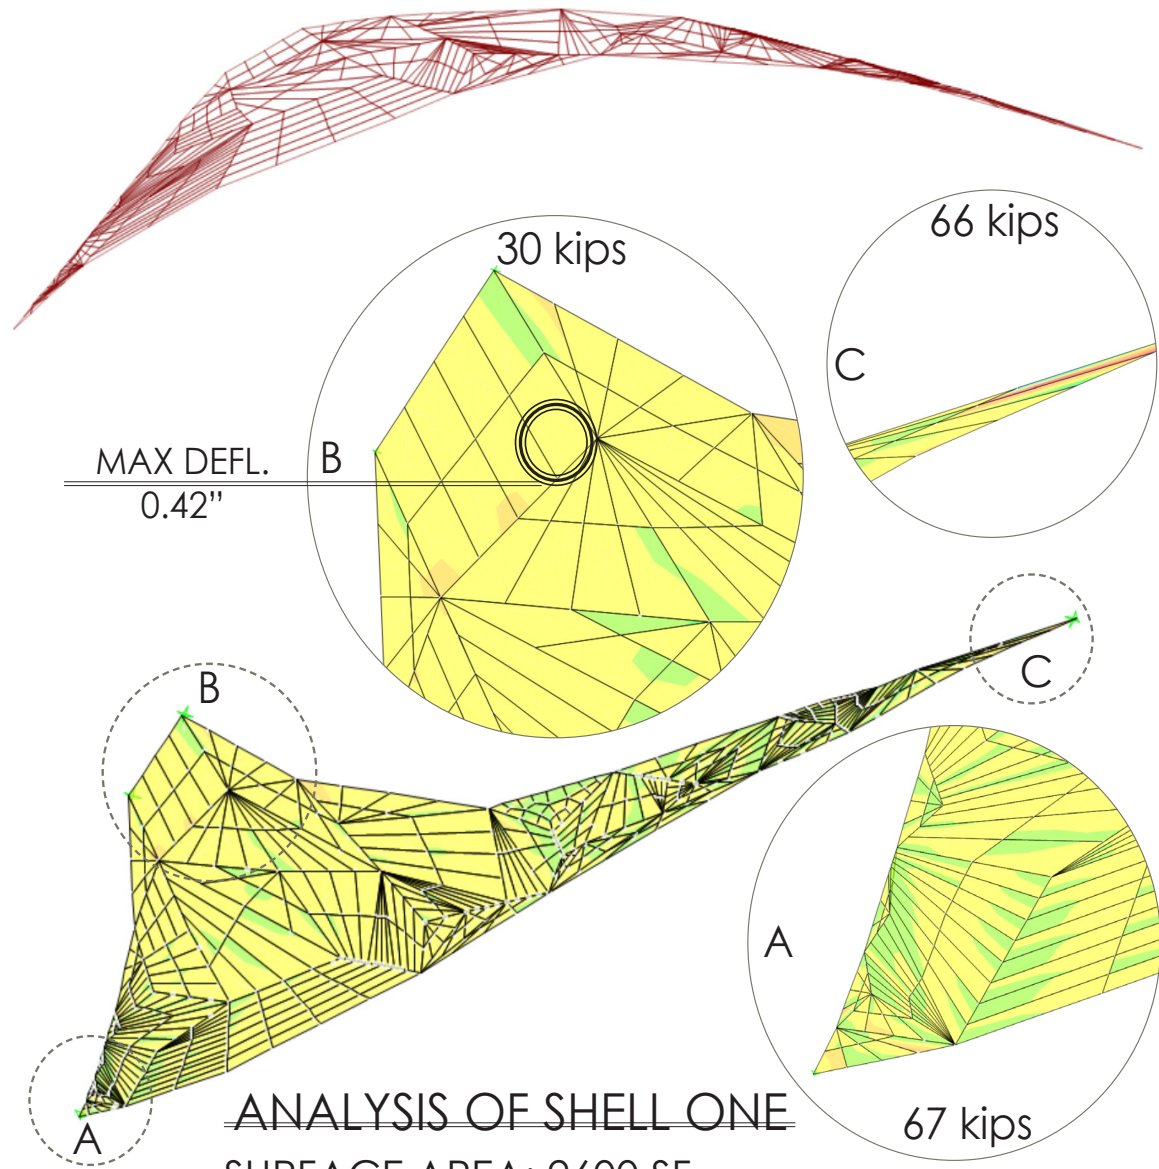

FINAL SHELL

The light placement on the final shell fades into black as it approaches the occulus-- framing the night sky.

INTERIOR NIGHT LIGHTING CONDITION

FOOTING CONCEPT MODEL 2

CONNECTION TO THE GROUND

THRUST CONTAINMENT

Our thrust containment consisted of a poured concrete foundation platform. We had two different thrust containment conditions. We placed a wall underneath the pointiest side that was at risk for buckling (left top.) We also had a gradual fade connection form the shell to the ground (both on right.)

MODEL

A CNC router was used to create the topo out of laminated ply. The final model was made by hanging fabric and applying plaster sheets.

PROCESS

COTTON/NYLON FABRIC

CUT AND SCREWED INTO PLYWOOD
DIPPED IN PAPER -MACHE MIX (ELMERS AND WATER)
DRAPED IN PAPER-MACHE DIPPED PAPER

TARP

CUT TO SIZE AND SCREWED INTO PLYWOOD
LOOSELY DRAPED WITH PAPER-MACHE PAPER

PROGRESS

- COTTON/NYLON FABRIC WAS TOO ELASTIC
- FORM WAS ALTERED BY WEIGHT OF PAPER-MACHE
- FORM WAS INTACT, BUT SAGGED TOO MUCH

- TARP WAS TOO STIFF OF A MATERIAL
- LEARNED FROM FAILURE: PROPER PAPER-MACHE TECHNIQUE

MATERIAL: CLOSE-KNIT LINEN
 HARDENING PROCESS: PAPER MÂCHÉ

FORMWORK PROCESS 1

FORMWORK PROCESS 2

FORMWORK PROCESS 3

FORMWORK PROCESS 4

We chose to begin our formwork with paper-mache hardened fabric hanging from a 6' x 4' plywood board marked with a grid. Once the fabric hardened, we flipped it around--what once was in pure tension became pure compression. We measured incremental distances from the plywood to the shell and cut 2x1's to the correct size. We then placed these 2x's on the grid in their proper place. To prevent puncturing, between the plywood 2x's and the paper-mache shell we put cardboard pads to disperse the point load. We attached cardboard lips on the edge to create a clean edge condition. For water-proofing we covered the paper-mache fabric in tin-foil.

FORMWORK PROCESS 5

FORMWORK PROCESS 6

FORMWORK PROCESS 7

FORMWORK PROCESS 8

CONCRETE POUR PROCESS 1

CONCRETE POUR PROCESS 2

P O U R I N G

We mixed a low-slump concrete and poured it on top of the formwork. The slow slump allowed us to keep the shell thin and to control edge conditions

FORMWORK REMOVAL PROCESS 1

FORMWORK REMOVAL PROCESS 2

R E M O V A L

After a week, we removed the formwork by pouring water between the tinfoil covered paper-mache and the cured concrete. We removed the plywood 2x's with a drill.

DAY & PLASTER

Once everything was removed we plastered the interior underbelly of the shell and the tippy-tops of our footing. this allows light to bounce into the interior of the shell during the day and night.

NIGHT & LED

We attached led lights to the perimeter of our shell. After experierenting with colors we thought teal looked best.

CONCRETE

5" thick shell
4 ksi

STEEL

ASTM A185 WELDED WIRE
(6X6 W5.0XW5.0)

$F_y = 65$ ksi

$F_u = 75$ ksi

MATERIAL PROPERTIES

From the Deflection Diagram, it becomes evident that the largest deflection occurs at the longest span, or the biggest shell, at 0.70". The deflection at the middle of the span progressively decreases as the shell size decreases.

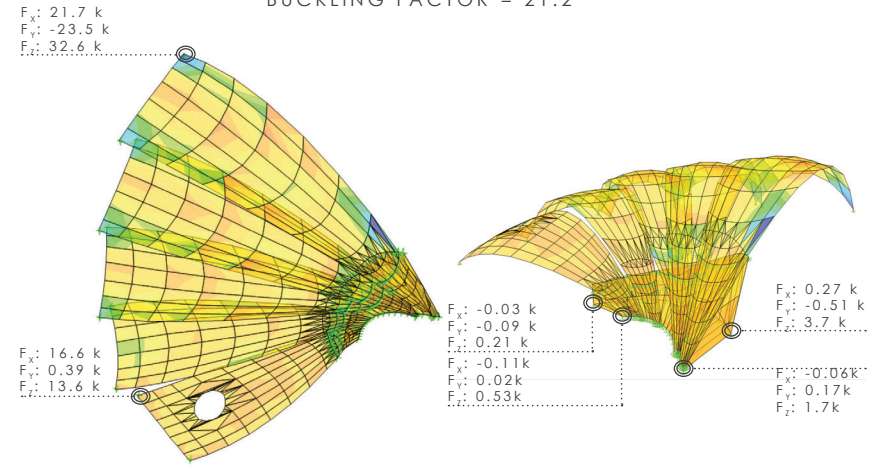

From the Stress Diagram, it becomes evident that the whole structure is mostly in compression (yellow and orange sections). There are some areas in tension (green and blue sections), which are located in the supports.

The reactions indicate that the largest reaction takes place in the support of the longest-spanning shell. The reaction occurs at the steeper (i.e. more vertical) section of the shell. The reactions at the wall (bottom right image) are minimal, considering that the section has a continuous connection to the ground.

SELF-WEIGHT ONLY
LINEAR ANALYSIS

SELF-WEIGHT ONLY
LINEAR ANALYSIS
BUCKLING FACTOR = 21.2

REACTIONS
(MAX AND MIN F.)

In order to understand the condition of the shell when unbalanced live loads are present, a strip of live load is applied at the middle of the span, where the largest deflection occurs. This unbalanced live load condition can be representative of snow loads that occurs in Switzerland.

From the analysis, it becomes evident that the deflection increases on average, about 100%.

When non-linear concrete and non-linear steel analysis was ran, the deflection came out to be 5 times the value of the linear analysis. After messing around with the different properties in SAP, the conclusion was that concrete went nonlinear under only under its self-weight and had high deflections. This is a problem since the analysis was not supposed converge nonlinearly, so the model needs to have even more meshes to have a more precise values in the nonlinear range from the interaction of the concrete and steel. When running linear concrete and non-linear steel, the results were a lot closer to the expected values from running a nonlinear analysis.

UNBALANCED LIVE LOAD (N-S) + SW

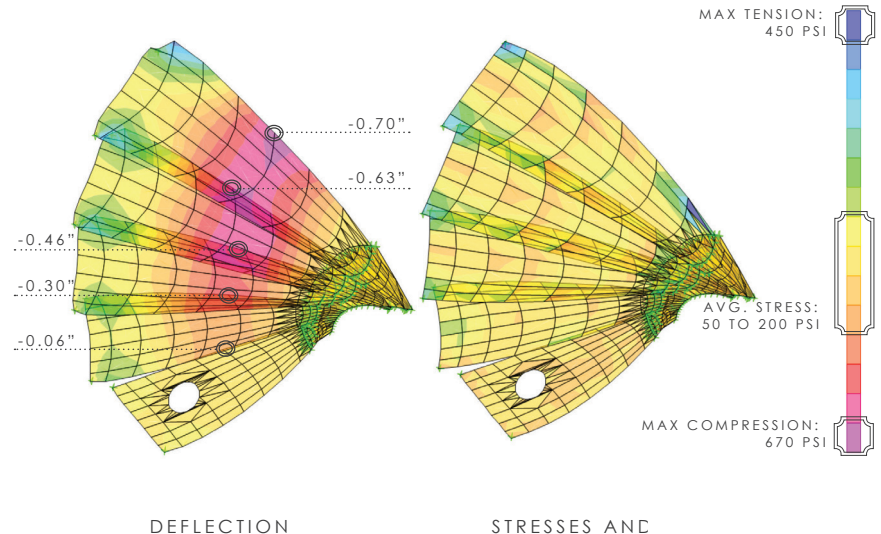

LINEAR ANALYSIS
LIVE LOAD OF 50 PSF

58

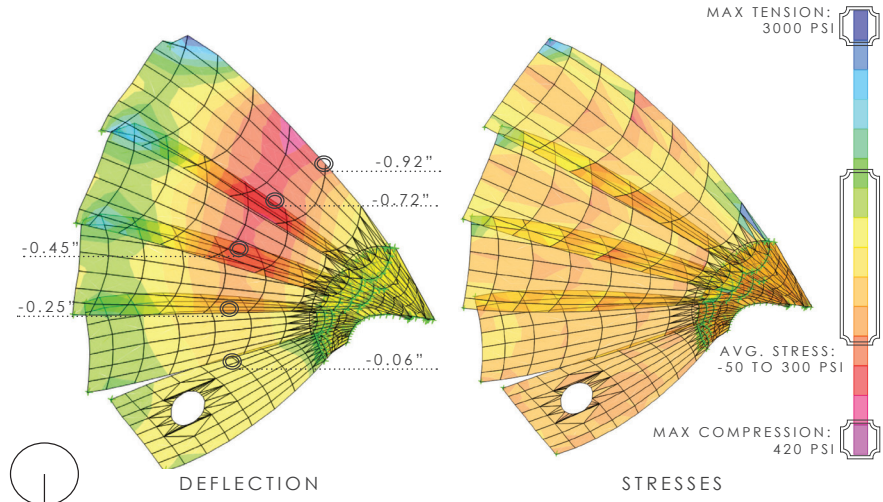

SELF-WEIGHT ONLY

LINEAR CONCRETE
NON-LINEAR STEEL

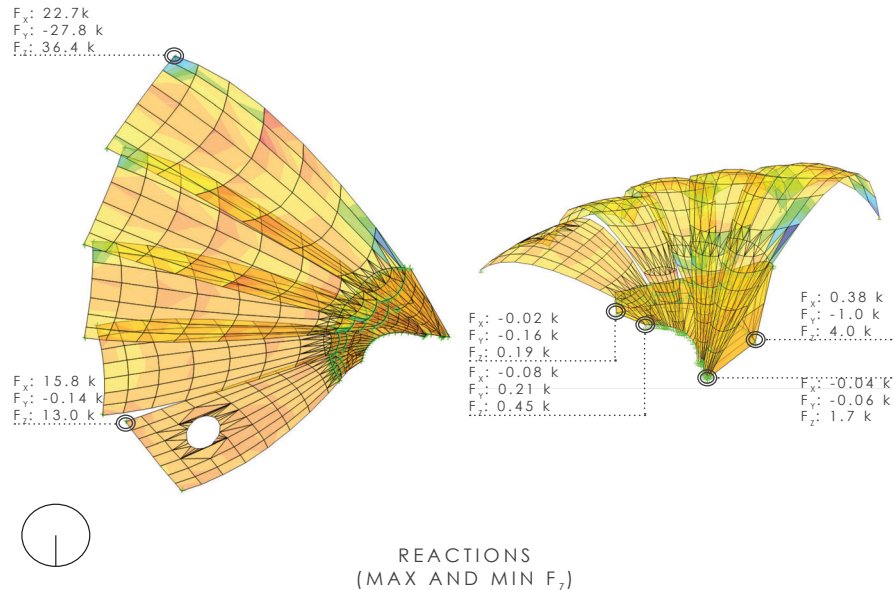

In terms of the lateral analysis, when a lateral load is applied from the north to south direction, the deflections, stresses, and thrusts increases by about 10% from self-weight only. This shows that the structure will perform reasonably well under 20% self-weight lateral load since the structure is a thin shell membrane.

LATERAL ANALYSIS LINEAR ANALYSIS

LATERAL ANALYSIS LINEAR ANALYSIS

In the non-linear push to fail analysis, there was a 1500 PSF live load applied at a strip on the shell. From the buckling analysis, the dead load was amplified by a factor of 21 to get the live loadings on the strip. Looking at the results, there was major increases in the deflected values at the strips where the point load is applied. The conclusion is that the structure failed due to high deflection and would have trouble with serviceability.

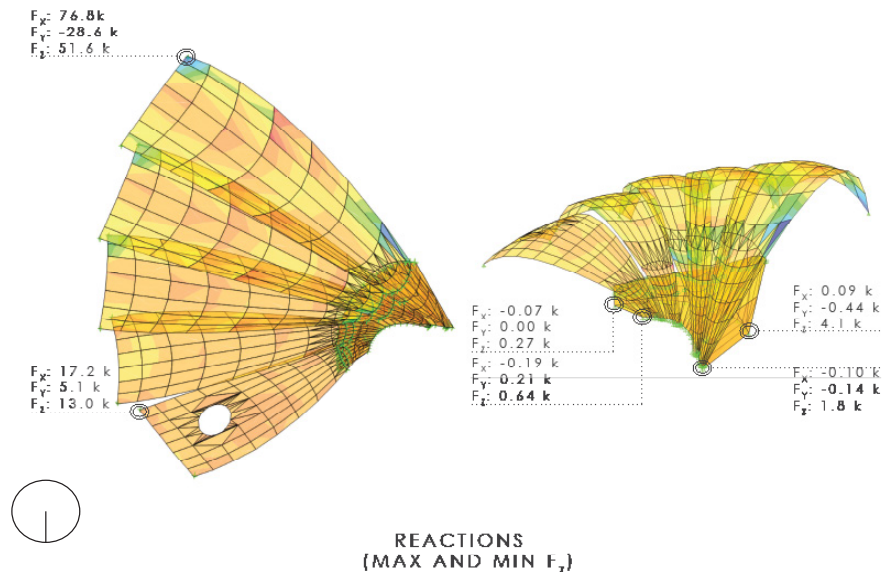

PUSH TO FAIL (N-S)

NON-LINEAR ANALYSIS
LOAD OF 1500 PSF

60

PUSH TO FAIL (N-S)

FINAL WORDS

Overall, we felt that the simple repetition and rotation, about an axis, of our original shell created an elegant form of cascading shells. We feel that we accomplished the main goal of our design, which was to design a funicular structure that didn't distract or overshadow the church in any way and to pay homage to the Celtic astrological traditions of the site. In terms of constructing the physical shell we felt that the hanging fabric approach that we used was one of the more efficient ideas in terms of actual formwork needed however, one change that we would make to add to the structural stability of the shell would be to cast the concrete foundation into the ground rather than complicate things with a separate footing detail. All in all we are happy with the results of our project and believe that while there are things we would change, as a group we are content with the way in which we accomplished our design goals and in how we balanced aesthetic and structure.
